Case 2: A 25-year-old female presented with a painless growth in relation to mandibular anterior teeth region for 4 months. Patient was suffering from polycystic ovarian syndrome and had underwent a surgery for breast fibroid. Upon clinical examination, a pale pink pedunculated gingival growth was present in the labial aspect of 31 and 41 involving the marginal and attached gingival. The growth was soft in consistency, measuring about 0.8cm x 0.8 cm in the greatest dimension. There was no bleeding or tenderness present. A provisional diagnosis of traumatic fibroma was given based upon these clinical findings. The entire growth was surgically excised and the biopsy specimen was sent for processing and histopathological evaluation.

Histopathological Findings: The Hematoxylin and eosin stained section of the specimen revealed a parakeratinized stratified squamous epithelium proliferating into the underlying delicately collagenous connective tissue stroma. Diffusely arranged vacuolated cells resembling xanthoma cells were noticed in the connective tissue papillae as well as deep inside the stroma. Minimal amount of lymphocytes arranged diffusely were also evident in the minimally vascular stroma.

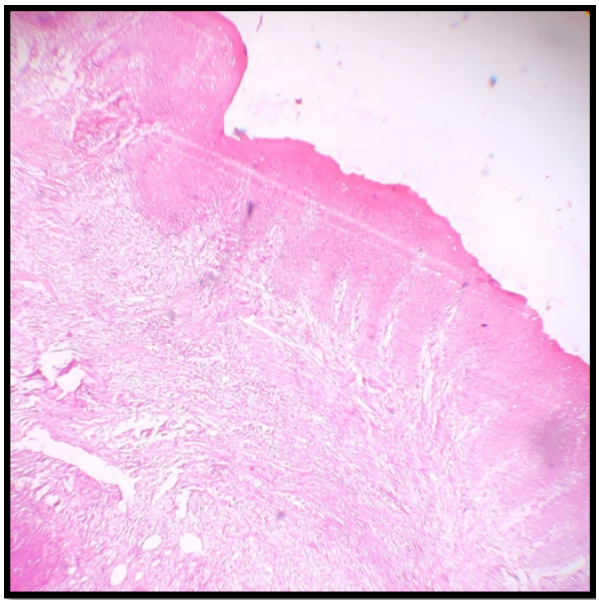

Figure 3 (4x view): The photomicrograph of H & E stained section showinga parakeratinized stratified squamous epithelium proliferating into the underlying delicately collagenous connective tissue stroma.

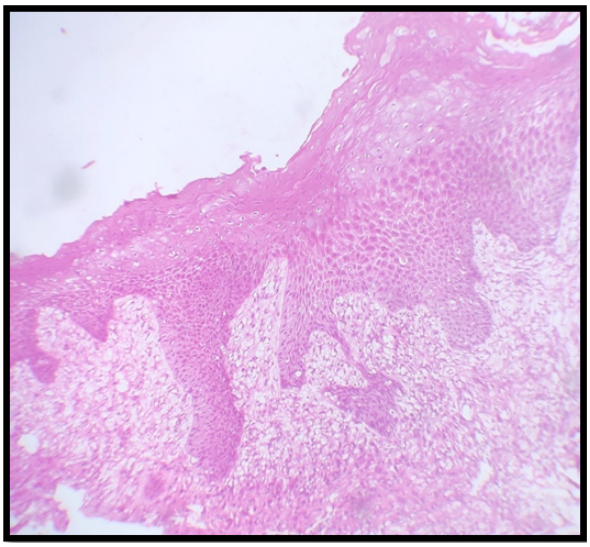

Figure 4 (10x view): Thephotomicrograph of H & E stained section showingdiffuse arrangement of xanthoma cells in the connective tissue papillae and deep inside the stroma.

Based upon these findings, a final diagnosis of Oral Verruciform Xanthoma was made.

Discussion

OVX is an extremely rare lesion with the frequency of occurrence ranging from 0.025-0.5% (9)during the 5^{th}-7^{th} decades of life and mostly diagnosed clinically as Papilloma. The extraoral lesion are even rarer and mostly involve the anogenital areas or and skin in correlation with other chronic skin diseases like epidermal nevi, discoid lupus erythmatosus, epidermolysis bullosa and Congenital Hemidysplasia with Ichthyosiform erythroderma and Limb Defects (CHILD) syndrome.[10]

The exact pathogenesis of verruciform xanthoma still remains unknown. According to one theory it is believed that a local irritant in the form of trauma or inflammation may give rise to degeneration in the epithelium which further leads to formation of lipids in turn scavenged by macrophages. Viral or fungal infections may also act as a local irritant and play a role in its etiology. However, this does not explain the prevalence of OVX in other parts of oral cavity excrept the masticatory mucosa. According to some authors the changes in epithelium occur secondary because of the presence of foamy cells or it is just an illusion because of the pushing effect of the macrophages upwards. Hence, the exact etiopathogenesis still remains questionable.[11-13]

The varied clinical presentation of verruciform xanthoma and its extremely rare occurrence in the oral cavity makes it very difficult to be diagnosed clinically. It presents as a symptomless and painless solitary mass which is usually well demarcated and can display a plaque like, verrucous, sessile or polyploid appearance. The colour of the lesion may also vary from white, pink or red. The most common site of involvement is gingiva and there is a higher predilection in males. Verrucous lesions like verrucous leukoplakia, verrucous carcinoma, squamous papilloma, verruca vulgaris, condyloma acuminatum and squamous cell carcinoma should be considered and ruled out in the differential diagnosis of Verruciform xanthoma.[14,15]

Histopathologically, the hallmark of verruciform xanthoma is the presence of foamy cells or xanthoma cells filling up the connective tissue papillae in between the epithelial rete pegs. The overlying epithelium is mostly hyperkeratotic and proliferates into the underlying stroma in the form of verrucous or papillary projections. The histopathology of OVX is pathognomonic and the final diagnosis relies upon it and it should never be avoided.

The treatment of choice for such lesions is complete surgical excision and follow up. No malignant transformation has been reported till date and the recurrence rate is extremely low.[12]

Conclusion

OVX is an extremely rare disease with an unknown cause and nature and its pathogenesis still remains questionable. The cases presented in this paper signify the importance of histopathology in such rare cases which are and can often be misdiagnosed based solely upon their clinical presentation. A thorough clinical and histopathological examination becomes mandatory and inevitable for the proper diagnosis and treatment of such cases.

3D Printing, Innovative Approach in Dentistry

Utkalika Das[1], Gatha Mohanty[2], Rinkee Mohanty[3], Rashmita Nayak[4]

[1]Clinical Tutor, [2]Senior Lecturer, [3]Professor & Head, [4]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In dentistry use of latest technology and smart devices have made the life of a dental practitioner easier. Researchers are innovating new technologies in dentistry every other day. One of the latest innovations is three-dimensional (3D) printing which makes the treatment planning and execution faster and with precision. Three-dimensional printing is used along with a wide array of various materials. 3D printing is used in Periodontal research as well and 3D printed guides are used for esthetic correction of gingiva. This review highlights on the various 3D printing techniques available for use in dentistry.

Keywords: *Three-dimensional (3D) printing; esthetic correction; Periodontal research.*

Introduction

Over the years there is an increased development of3D printing for dental application. Be it planning of proper treatment or the treatment itself, it has simplified the procedures. Digital OPG (orthopantomogram), RVG, CBCT, Digital impression machine and CAD/CAM.3D printing is mainly applied in Oral surgery, Periodontics and Endodontics. This techniqueis an approach that builds object on a layer at a time, and then simultaneous addition of multiple layers to form an object. Powder or a liquid resin is used that slowly builds an image on layer by layer basis. A thin layer of liquid resin is dispensed by 3D machine and then a computer-controlled UV laser is used toharden each layer in cross sectional pattern. The soft resin that is left is then cleaned properly by a chemical bath at the end.

3D printing in Regenerative Dentistry in Periodontics: Abranch of regenerative medicine that focuses on regeneration of tissues i.e. oral and dental is known as Regenerative dentistry.[1] This branch uses tissue engineering concepts where a triad consisting of signalling molecule, cells and scaffold along with sufficient blood supply helps in forming new bone, cementum and PDL.[2] Guided tissue regeneration procedure remains unpredictable in a periodontal defect due to the open nature of wound, exposure to bacterial biofilm and close proximity to a avascular tooth surface.[3] To solve the dilemma,three dimensional(3D) multiphasic scaffolds and bioactive molecules are combined along with drugs. Besides gene and cell delivery is also used that enables a spatio-material control of periodontal wound healing.[4]

A computer aided design and computer-aided manufacturing (CAD/CAM) software uses a jet binder that is projected at a powder bed.[5] The solvent and powder bind together,forming a silica type solid. This process is repeated by adding a new layer of powder that can build the layer wise scaffold. Multiphasic scaffolds are used in tissue engineering because of the complex structure of soft and hard tissue interfaces of periodontal complex.[6]

Different Technologies of 3D printers

These are various principles on which 3D printers work. The technologies are as follows:

Direct light processing (DLP) technique: DLP work with photopolymers that solidifies and cures the

resin. Each volex dataset is made up of voxels with dimensions as small as 16×16×15µmm in the X,Y and Z direction.[7] This process offers quick photo-typing capabilities with exceptional quality,good accuracy and nice surface finish.

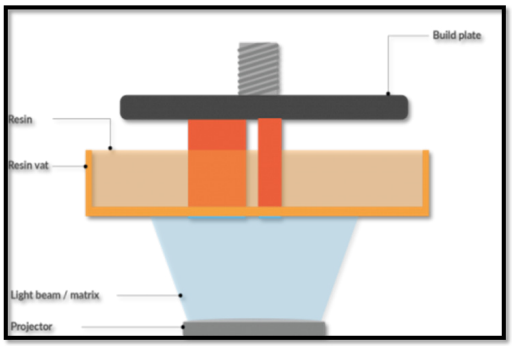

Figure 1. Direct Light Processing (DLP)

Fused deposition modelling (FDM)Technique:S. Scott Crump introduced it in 1980s and then it was in commercial use in 1990 by **Stratasys**. Most of the existing FDM machine use thermoplastic materials. Two materials are used that includesa) Modelling material, which constitutes the finished piece, b)Gel like support material acting as a scaffold.

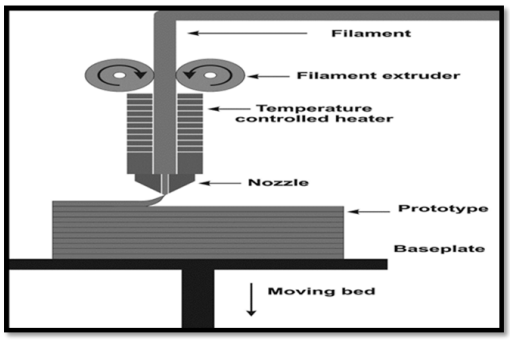

Figure 2. FDM technique

Stereolithography (SLA): This is a manufacturing process which use additive method and where ultraviolet (UV)laser helps focuson to a photopolymer resin vat. A laser light beam is used for tracing the first silica of an object on the liquid surface,causing hardening of a very thin layer. Silica is then traced and hardenedpreceded by lowering of platform. The process is repeated till the complete object is printed.

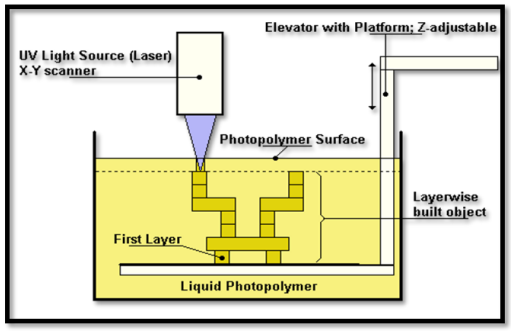

Figure 3. Stereolithography

Inkjet powder printing: Otherwise known as 'binder jetting' and "drop- on- powder". This techniqueselectively bonds powdered material together in different layers and in succession. Gypsum plaster and starch fill the powder bed and the liquid "blinder" activates the plaster. Dyes (for color printing)are also used as binders. Additives are used to adjust surface tension, viscosity and boiling point for matching printhead specification.

Figure 4. Inkjet 3d printer

Selective Laser Sintering (SLS): Heat is used for bonding powdered materials together.A powder is laid down and thereby many objects are produced. Laser is used selectively to fuse some fines particles together. Non bonded powder granules are used in the process of printing which support the object while it is being constructed. "Direct metal laser sintering"is the technique where SLS directly produces a metal object.[8]

Figure 5. SLS 3D Printer

Material used in 3D printers

Materials used in periodontal regeneration are:

(a) Polymers and Hydrogels: Synthetic polymers are materials that are commonly used in biomedical application. Pre-epolymerized cell-laden methacrylated gelatine hydrogels are nowadays used for bioprinting successfully.

(b) Ceramic: Calcium phosphate mineral, such as hydroxyapatite are used these days to make "Ceramic scaffolds".Cells canpopulate the scaffold surface very fast, thereby helping in promotionof cell proliferation and differentiation and establishment of cell tocell interactions.

(c) Composite materials: Polymer-polymer mixture,copolymer, or polymer-ceramic mixtures are printable composite materials.

(d) Polycaprolactone: The choice of material in multi-phasic scaffolds for periodontal regeneration are polycaprolactone. This being a hydrolytically biodegradable polyster can be manufactured in various porosities and requisite shapes.

Future Application: Three-dimensional printing is use in manufacturing of implants. Specifically tailored to patient's jaw maximizes the success of implants. This technique has the advantage that allowssafe and secured placement of implants in areas where a normal dental implant cannot be placed securely.

Conclusion

Considered a promising technological innovation for regenerative Periodontology in dentistry, 3D printers have received commercial awareness and but more trials should be done using this technology to have a widespread application in dentistry. More recently 4D printing has also been introduced where the printed part can change its function as well as shape with time in response to changes in light,water, temperature and electricity.

Teeth in the Line of Mandibular Fracture

Smrutirekha Marndi[1], Sthitaprajna Lenka[2], Suchismita Ghadai[1], Reshmin Begum[1], Barsa Ray[1]

[1]Intern, [2]Professor, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Facial fractures are very common fractures now in these days. Both maxilla and mandible are affected in this case. Male are more affected than female. This may happen due to road accident, fall, fights or during any sport events. Mandible is the most common site of accident although it is the heaviest and strongest facial bone. Injury to the teeth present in the line of fracture may involve many factors like avulsion, mobility, non-vitality,root fracture etc. involving periodontium. It has always been a disputed among the surgeons; whether to extract the tooth or not present in the line of fracture. Some advice to extract the tooth to avoid complication, where some advice to retain the tooth believing in benefit of the patient. This article aims to give an idea about whether the teeth in line of fracture should be retain or remove.

Keywords: *Angle of mandible, fracture line, complication, infection of teeth.*

Introduction

Mandible is the strongest bone in maxillofacial region and is more prone to trauma or accident. It is very common to locate teeth in the line of fracture. The shape and dislocation of fracture depend on the volume of force, soft tissue connection, bone thickness, route of muscle tug and susceptible zones that signify feeble anatomic structures.[1] Such type of fractures are present with pain, hematoma, irrationality of occlusion., edema, dislocation and mobility of fractured particles, facial irregularity and trouble in phonation.[1] About 56-69% of fractures of the mandible involve areas with teeth and there is about 27-30% of chances of fracture in angle of mandible.[2] The management of an angle of fracture is frequently difficult when the mandibular third molar is present in the site. The management of teeth present in line of fracture had changed in past few years. There are no any exact plans or procedures for the management of the teeth present in the line of fracture. Some clinicians' advice to remove the teeth present in line of fracture whereas some advice to keep the non-infected tooth in the site. In past it was believed that; teeth that are present in the line of fracture should be remove immediately to avoid any further complications. They suggested that the affected teeth should be extract immediately to reduce further complications like osteomyelitis. Even vital or non-affected teeth was also removed to avoid get fractured or to get infected. And after that many other studies suggested that the teeth present in the line of fracture can be protected by giving medications properly.[2] But now in recent studies it has resulted that the non-infected teeth that are present in the line of fracture can be conserved.[3]

Proper management of the noninfected teeth in the site of fracture may favor the treatment in some cases. Various authors have given different reviews on this study. According to Halazonetics (1968) revealed double as several fractures occurring at angle of mandible in dentate patients as in those that were edentulous. Oikarinen and Malmstrom (1969) revealed that the area of angle of mandible is included in 17.4% of 1284 cases of maxilla-facial trauma in their research. But none of them; neither Halazonetics or Oikarinen and Malmstorm made detailed orientation to the presence or absence of mandibular third molar teeth in the line of fracture. According to Rowe and Killley (1970) revealed that maximum fractured mandible cases are happen due to

Corresponding Author:
Dr. Sthitaprajna Lenka
Reader, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail:sthitaprajnalenka@gmail.com

sports injury and road accident. Young adults are more likely to be injured in this case. According to Weiss (1965) revealed that the condylar, angle and mental areas were more prone to fracture. Another author Reitzelet al. (1978) did an experiment on the mandible of monkeys and related the forces required to fracture the angle area when the third molar was not erupted with those that create fracture when the teeth was erupted. So, they demonstrated that the presence of an unerupted teeth weakens the region of angle of mandible.[4-8]

Injury to the teeth in fracture line may complicate the fracture even more if it involves the periodontium. In such cases many complications may occur like avulsion, root fracture, non-vitality, mobility etc. These all may create complications during the time of healing or may create delay in healing. The purpose of this study was to evaluate the recent opinions on the treatment of teeth present in the line of mandibular fracture.[9]

Discussion

According to anatomy & location of fractured tooth; It is divided in to 4 types "Anatomic location of fracture, Degree of dislocation of fracture(Hairline; without dislocation, minimal; dislocation within 1-2mm; gross; dislocation within more than 2mm), location of apical foramen and lateral periodontium of fractured tooth the fractured line divided into(including oblique and apical fibers entirely, including three-quarters of the oblique fibers, involving apical fibers entirely, including apical 1/3rd of oblique fibers in both side)".[1]Mandible is the common and major site of fracture area. It is very common to observe teeth in fracture site. Some authors revealed that the presence of teeth can be one of the determinant features of fracture area. Constant extraction of teeth in the fracture line of mandible has no scientific basis and has different drawbacks.[10]

All patients should be observed and radiographs should be taken within 12 hours of the fracture and dislocation. After studying the radiographs in antero-posterior and oblique-lateral assessments of jaw then mark the fracture line of tooth then decide whether the tooth should be extracted or retained. According to line of angle of fracture in mandible, the fracture is "symphysis, para-symphysis, body, and angle and excepted fracture of condyle. In the angle fracture line if the teeth are associated with periodontitis and caries then it should be removed and the remaining teeth should be retained.[3]Sometimes these retained teeth get infected then those teeth should be extracted otherwise it may cause osteomyelitis and non-union. The treatment of angle fracture without presence of teeth is stable internal fixation.While operating maxillofacial trauma patients, there are some important rules to follow for the treatment of bone particles.[11] These rules are accurate structural discount, of bone particles, saving the occlusal plane, and by using the right fixation technique which will clutch the bone properly in useful position while maintaining occlusion until the end of operation and also stoppage of infection. Because the teeth present in fracture line also put effect on that area. So, the surgeon should carefully observe the patient and plan the treatment planning accordingly. In mandible, the angle of mandible area is thin so it may reduce the surface area between bone particles and may confound the mobility of bone particles. So, there are some rules and regulations whether the teeth should be extracted or not depending upon patient condition.[12] Suggestions for extraction of teeth are: teeth having vertical root fracture, teeth having highly mobile condition, teeth associated with periapical pathological condition, carious or fractured teeth that can't be saved by restoration, teeth having chances of acute pericoronitis, teeth having fracture near toCemento-enamel junction, wisdom teeth, roots having oblique/horizontal fracture. Reasons of not extraction of teeth are: teeth that are necessary for structural discount, teeth that role as occlusal stopper, patient having cardiac diseases, blood dyscrasias, patient who are diabetic, having renal diseases, females during lactation period and during pregnancy, teeth involving acute gingival/ peri coronal inflammation, teeth involving maxillary sinus, teeth that are related to maxillary sinus, teeth involving malignant tumours.[4, 13-15]

Fractures in mandible are more common in males than female. It may often occur 96% in male and only 4% in female.[1] According to Mariana Schaffer, "dependingupon anatomical site in mandible for fracture area are; about 10% in symphysis area, 27% in angle region,11% in body, 52% in Para symphysis area. Depending upon age and gender, the fracture line are; in age group of 15-20yrs affected male are 33%, while female are only 6%, in age group of 21-30yrs, affected male are 25% and female are 7%, in the age group of 31-40yrs, affected male are 13% and female are 5%, in 41-50yrs of age, affected male are 7% and female are only 4%. Depending upon fracture location affected area in mandible area are; in condyle 34%, in angle of mandible 17%, in Para symphysis 16%, in body of mandible 13%,

in symphysis 10%, in alveolar process 5%, in ramus of mandible 1%, in coronoid process its 0.6%, and at the end, in base of mandible its 0.3%.''[4, 16,17]

Complications

There are also many complications present in the line of fracture of mandible. It may be linked to the trauma of mandible or associated to interruption in joining the fractured mandible that rise the possibility of complications, but neural complications or any other complications like airway cooperation may make it predictable. If there is bilateral fracture of body of mandible, Para symphyseal or condylar fractures, there may be chances of airway obstructions. Other complications like infection, non-union or malunion, ankylosis are the main complications which may create problems in opening of mouth. Psychological consequences of facial trauma are such that the chances of post-traumatic anxiety condition areat rise in this situation. Other complications like inflammation, edema, ecchymoses and hematomas, emphysema, bleeding from mouth, flap dehiscence, sensory disorders are seen in early-stage of complications. In late-stage perforation of the mucoperiosteum, maxillary sinusitis, mandibular fractures, failed osseointegration, bony defects, periapical implant lesion, mental fatigue, fracture of plate, necrosis of bone, osteoporotic changes, nerve damage, displaced teeth & foreign bodies, gingival and periodontal problems, facial widening and sequestration of bone can happen.[17]

Conclusion

This study states that the proper rigid fixation system and the use of proper antibiotics have decreased the chances of inflammation in the site of mandibular fracture. The involved teeth may be frequently of great worth in relocation of fractured sections and can be used as support for prosthetic settlement. Hence, extraction of those teeth may create supplementary trauma and complicate the fracture and might prevent the chances of rigid fixation. Therefore a 1-yr of revisit in addition clinical and radiological assessment of the teeth present in the line of fracture is recommended. Unnecessary endodontic treatment can be avoided. Tooth buds present in the line of fracture should not be removed or substituted in exact place regardless of the grade of dislocation. Also, the tooth buds in initial stage of calcification and those included in broadly evacuated fracture sites sustained progress and erupted. In case of inflammation, its elimination can be measured, subsequently the existence of contamination is a prognostic factor of irregularity or impaction. Completely erupted teeth related to mandibular fracture should not be removed on a prevention basis to decrease the chances of inflammation on fracture area. Undamaged teeth in fracture line should not be extracted if they don't show any occurrence of excessive mobility or any infection. The decision of extraction of teeth must be decided on the basis of clinical condition. Though proper use of medications, extraction of non-symptomatic teeth is not required. Regular check-up and 1 year of radiological and clinical observation are recommended.

Juvenile Periodontitis: An Overview

Jogadipali Patra

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In this article, Juvenile Periodontis, which is known as an uncommon condition that is characterized by severe loss of attachment and destruction of the alveolar bone that becomes clinically significant during adolescence. It is also known as Aggressive Periodontitis. Juvenile Periodontitis is ramified as Localized juvenile or aggressive Periodontitis (LAP) and Generalized juvenile or aggressive Periodontitis (GAP). It is currently accepted that a combination of immunologic, bacteriologic factors and also hereditary factors which plays a significant role in the etiology of this disease. Hence it can be controlled by maintaining a good oral hygiene, in early stages.

Keywords: *Periodontitis, Localized aggressive Periodontitis, Generalized aggressive Periodontitis.*

Introduction

Generally, periodontitis is known as a severe gum infection that gives damage to the soft tissues and destroys the supporting bone of the teeth. It can lead to loosening of the tooth or loss of tooth. There are numerous types of Periodontitis, among them, the most common are, chronic periodontitis, aggressive periodontitis, necrotizing periodontal disease. Juvenile periodontitis is also known as early onset periodontitis or aggressive periodontitis as it progresses rapidly while ordinary Periodontitis has a slower rate of progression. It is defined as the destruction of supporting tissues of the teeth which becomes clinically significant during the adolescence or early adulthood.[1-3] This disease is classified in localized and generalized form as localized aggressive periodontitis (LAP) and generalized aggressive periodontitis (GAP). As the disease aggravates, the affected teeth increasingly becomes mobile with labial movement leading to spacings of the incisors. Bleeding of the periodontal pocket is also evident. It is evident that the diagnostic features of this disease are characteristic, but some variations are seen in clinical presentation and patterns of destruction in patients. A regular dental check-up along with comprehensive management can improve the treatment process leading to reduced chance of progression of the disease. Generally, there is some differentiation found to have a typical racial and sex predilection; where the blacks and Male teenagers have a higher risk of occurrence rather than the whites and females.[4,5]

Localized Aggressive Periodontitis (LAP): According to Gottlieb, Localized juvenile Periodontitis is defined as a chronic, degenerative, non-inflammatory disease of periodontal tissues, which he referred to as "diffuse atrophy of alveolar bone". It tends to occur among the members of same family. It affects both the sexes.It affects mainly the mesial and distal surface of first permanent molars and Incisors.. Actinobacillus actinomyecetemcomitans bacteria plays a dominant role in progression of this disease.[6] Other microorganisms like *P.gingivalis, E.corrodens, Capnocytophaga, Spirochetes, Bacillus*, etc are also found on the diseased site. Increased level of A.a are found in active sites and lower in healthy sites. These assembles leuko-aggressive properties, bone resorbing factors, collagenase and other immunosuppressive factors that helps in host tissue invasion and evasion defences gives rise to destruction of periodontal tissues.[7] Incidence of A.a found more in younger persons rather than the older one. But as per seen, younger patients experienced more damage in tissues during a short span of time. As per many cultural studies it is found that A. actinomycetecomitans permeates and grows vigorously within the periodontal soft tissues. So the therapy should be done by the total elimination of A. actinomycetecomitans from the supragingival and subgingival plaque, supragingival microflora and periodontal soft tissues. [8-10]

Generalized Aggressive Periodontitis (GAP): Anciently, it is known as Generalized Juvenile Periodontitis and Rapidly progressive Periodontitis. It is

characterized by generalized interproximal attachment loss involving at least three permanent teeth other than first molars and Incisors.[11] Delineated by a more widespread pattern of periodontal destruction. It is associated with a variety of diseases of other systems. Generalized Aggressive Periodontitis is classified into Destructive stage and Non-destructive stage. Bacterias responsible for this disease are Porphyromonas gingivalis, A.a, Bacteroides forsythis. In this case it shows poor serum antibody responses to infecting agents. Subgingival tissues evidents presence of gram negative rods and exhibits suppressed neutrophil chemotaxis. GAP usually affects the individual below 30 years of age.[12] The destruction often appears episodically and it shows severely inflamed and ulcerated tissues leading to a fiery red appearance. Suppuration, attachment or bone loss usually occurs. Some patients may exhibit mental depression, weight loss, general malaise in this disease.[13] GAP patients having a smoking habit are more likely to experience more destruction of tissues in comparison to those who do not smoke or maintaining a good oral hygiene.[14-16]

Treatment: Early detection is enormously important for prevention of attachment loss and bone loss. Depending on severity of the tissue loss extraction of the involved tooth is recommended. Antibiotics can be prescribed like; Tetracycline is a drug of choice (one gram a day) as it produces a crevicular fluid concentration which is 20-10 times that of blood.[8] Other drugs like Tetracycline with Metronidazole, Doxycycline can also be administered systemically. Periodontal therapy; closed curettage and surgical curettage involving scaling and root planning, plaque control protocols, debridement with or without flap using Iodine and hydrogen peroxide solution can be preformed by the clinician. Some chemical plaque control agents like chlorhexidine (0.12%), and povidone iodine(1%) can be prescribed by the clinician for further plaque control as an adjunct to patient's mechanical plaque control majors.[14] Amine fluoride and stannous fluoride mouth rinses and toothpastes as an adjunct mechanical oral hygiene procedures in GAP affected patients are found to be more effective in controlling supragingival plaque accumulation.[15] Bone grafts and root resecting process or hemi sectioning are also done if necessary.

Discussion

Periodontitis is common but fairly preventable. The cause is usually poor maintenance of oral hygiene. It's a risk factor for heart and lung diseases. If the disease is left untreated it progresses to Periodontitis. However in Juvenile Periodontitis, gingiva appears to be normal in early stages. Gingival inflammation is seen in those patients having poor or bad oral hygiene with obvious plaque and calculus. In some major cases it is seen that juvenile periodontitis, however one is left with major clinical impression, that the amount of destruction of periodontal tissues do not commensurate with the local irritants, which can be found.[16,17] The bone loss pattern in this disease is generally designated as an arch shaped pattern of bone loss that extending from the distal surface of the second bicuspid to the mesial surface of the second molar. In the posterior region the bone loss occurs bilaterally and the left and right sides are generally mirror images of each other.[18, 19]

Emergence Profile in Esthetic Implant Restorations: Surgical and Prosthetic Perspective

Gunjan Srivastava[1], Subrat Kumar Padhiary[2], Tusar Kanti Nayak[3]

[1]Professor, Department of Prosthodontics, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Professor, Department of Orthodontics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The main objective in esthetic implant restoration from surgical perspective are maintenance of harmonious gingival architecture and preserving the alveolar crest contour. This review article discusses the importance of various phases of successful implant treatment. Starting fromaccurate diagnosis, assessment of risk factors, assessment of soft and hard tissues for attaining an emergence profile which provides natural appearance to implant prostheses.

Keywords: *Emergence profile, esthetics, implant prosthesis.*

Introduction

Fulfilling the esthetic demands of a patient in implant dentistry is the most difficult task to achieve. While accurate diagnosis, assessment of risk factors, surrounding soft and hard tissue are essential for obtaining the esthetic goals, the emergence profile of the definitive prosthesis plays the key role in providing a natural looking crown.(1)Excellent emergence profile provides a smooth transition from the circular form of implant platform to the natural appearance of the prosthesis at the gingival level. The main objective in esthetic implant restoration from surgical perspective are maintenance of harmonious gingival architecture and preserving the alveolar crest contour. (2)The underlying bone, the soft tissue and the superstructure all affect the esthetic outcome. Therefore, it is recommended that clinician move from one level to the next. Before or at implant placement the bone contour is altered according to the existing requirements related to function and esthetic. Soft tissue management is done with grafting comprising of various techniques and of reshaping of gingival tissues with appropriate gingival former (healing cap) and provisional restorations.(3) Lastly, the prosthesis is fabricated meeting the esthetic demands of the patient.

The factors on which the development of perfect emergence profile depends can be broadly sub- divided into different phases-

1. **Presurgical phase:** Height of Lip line on smiling, Gingival biotype, Shape of the missing and adjacent teeth, Alveolar bone height in relation to adjacent tooth, Height and thickness of hard and soft tissues in edentulous space,
2. **Surgical phase:** Deficient Soft tissue and hard tissue, Implant position in three dimensions
3. **Prosthetic phase:** Gingival former of proper size and length, Provisional restoration, Selection of abutment

Presurgical Phase:

(a) Height of lip line on smiling

- **Low lip line** – It displays only the incisal half of maxillary teeth. Esthetic risk is reduced as lips hide the suboptimal esthetic outcomes.
- **Medium lip line-**It displays most of the anterior maxillary teeth and very little gingival

Corresponding Author:

Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: gunjansrivastava@soa.ac.in

structures. In these cases, esthetic risk is increased and is associated with shape of teeth and appearance of gingival embrasures.

- **High lip line:** It displays total maxillary anterior teeth along with substantial part of gingival tissues. Esthetic risk is significantly increased due to gingival show. Any short comings will be easily noticed.

(b) Gingival biotype

- **Thick gingival biotype:** Low-risk when replacing single missing teeth. Gingival tissue comprises of thick broad band of attached gingivaty pically resistant to recession. Thickened gingiva brilliantly masks the metallic show of implants. This biotype favors the long-term stability of esthetic peri-implant soft tissue.
- **Thin gingival biotype:** Associated with excellent esthetic single tooth restorations if adjacent tooth has sufficient bone crest heights. Thin and friable nature of soft tissue is conducive to formation of interproximal papillae but increased risk of gingival recession.[4,5]

(c) Shape of the missing and adjacent teeth: Esthetic outcome is strongly influenced by the final architecture of gingiva.The shape of missing and adjacent teeth can profoundly influence the generation of interdental papilla. The risk can be reduced by presence of square teethshape. Triangular tooth shapes present greaterrisk for developing the interdental papilla and risk of developing black triangles areanticipated.

(d) Alveolar bone height in relation to adjacent tooth: For single missing teeth, the support for interproximal dental papilla is related to the height of bone crestson adjacent teeth. Where local infections have resulted in vertical bone loss around adjacent teeth, the risk of compromised esthetic outcome is greatly increased.

(e) Height and thickness of hard and soft tissues in edentulous space: The risk of compromised esthetic outcome increases with the deficiency in the height andthickness of soft and hard tissue in edentulous space. In clinical scenario, patients present with missing bone wall orreduced height and thickness of bone due to various reasons of tooth loss e.g. congenitally missing tooth or avulsed tooth with facial bone wall fracture. In such cases, deeper implant placementis undertaken to harness increased ridge width. Deeper implant placement is detrimentalto esthetics as proportion of restorations (long crown) and emergence profile arenegatively influenced. In such situations, site enhancement through horizontal boneaugmentation or soft tissue grafting is recommended.

Surgical Phase:

Deficient soft tissue and hard tissue: Thin soft tissue graft can be used for improving the width and contour of the soft tissues. These grafts are harvested in the premolar area of the palate and can be sutured to the periosteum of the mucoperiosteal flap to avoid displacement of the graft during wound closure. Guided Bone Regeneration (GBR) procedureuses barrier membranes with or without bone grafts and/or bone substitutes. Osseous regeneration by GBR depends on the migration of pluripotential and osteogenic cells. It could be done through Simultaneous approach i.e. GBR at the time of implant placement e.g. minor ridge defect. Staged approach-GBR before the placement of implant to increase ridge thickness and improve the ridge morphology.

Advances in manufacturing bone substitutes and increases in knowledge about guided tissue regeneration procedures have made bone-grafting techniques more predictable

I. Grafting Materials

- ***Autogenous bonegraft*** is a piece of tissue harvested from same person from one area to another. Commonintraoral sitesinclude mandibular symphysis, maxillary tuberosity, ramus, torior exostoses. In case of larger defects, iliac crest or tibial plateau can be used for harvesting the bone.
- ***Allografts*** tissue obtained from a person of similar species. Advantages of allograft bone are preventing another donor site and lessened surgicaltime e.g. mineralized or demineralized freeze-dried bone allograft.
- ***Xenografts*** are acquired from a genetically different species. Commonly used xenografts are natural hydroxyapatite (HA) and deorganified bovine bone. These are inert osteoconductive filler material, which provide a scaffold for new bone formation.

- ***Alloplasts*** are synthetically obtained graft material which includes calcium carbonate, bioactive glass polymers, including synthetic hydroxyapatite and tricalcium phosphate (TCP). They enhance bone tissue repair and increase bone growth. (6)

II. Barrier Membranes: Barrier membrane provide some advantage in grafting technique like they provide adhesion oftissue without mobility, block in-growth of soft tissue, easy to manipulate and help in maintaining space. They could be Non-Resorbable Membranes and Resorbable Membranes.(6,7)

Non-Resorbable Membranes:

- Disadvantages with usage of non-resorbable membranes include wound dehiscence due to incomplete coverage of the defect, wound infection subsequent to exposure of e-PTFE membranes and need for a second stage surgical procedure to remove the membrane. Thisinvolves increased costs and discomfort for the patient

- Expanded Polytetrafluoroethylene- The e-PTFE membrane acts as a mechanical barrier. Fibroblasts and other connective-tissue cells are prohibited from entering the defect site so that the apparently slower migrating cells with osteogenic potential grow in abundance in the defect.

- High-Density Polytetrafluoroethylene- a common problem with highly porous e-PTFE membrane is migration of microorganisms. To resolve this problem, a high-density PTFE membrane (d-PTFE) with a pore size of less than 0.3 micron was introduced.

- Titanium Mesh- The space to be regenerated is preserved without collapsing with the use of titanium mesh. It can be bent to desired shape as it is highly flexible.

- Titanium-reinforced PTFE-It provides stability in large, non-space maintaining osseous defects as the inserted titanium framework allows the membrane to be molded to fit a variety of defects without rebounding.

Resorbable Membrane: The advantages of resorbable membranes includeno need for membrane removal and decreased patient discomfort.

1. Polymeric Membranes- Polymeric membranes are valuable as they prevent loss of alveolar bone in extraction sockets thus avoid alveolar ridge defect.
2. Collagen Membranes

Several advantages of collagen materials to be usedas a barrier membrane are hemostasis, chemotaxis for periodontal ligament fibroblasts and gingival fibroblasts, weak immunogenicity, easy manipulation and adaption, a direct effect on bone formation and ability for augmenting tissue thickness. This makes collagen material an ideal choice for a bioresorbable GTR or GBR barrier. Disadvantage collagen and synthetic polyester membranes lack space-maintaining ability. These membranes are often used with tenting or supporting materials (different bone grafts or bone fillers) to prevent space collapse.(6,7)

Correct implant position in 3 dimensions: The correct positioning of implant in 3 dimensions critically influences the emergence profile of anterior esthetic restoration.

- **Mesiodistal position:** Improper mesiodistal positioning of implants results inreduction in height of thealveolar crest which in turn reduces the height of interproximal papilla.This will lead toformationoflonger contact area in the final restoration resulting in poor emergence profile.

- **Faciolingual position:** Placement of an implant in too facially results in soft tissue recession asmalpositionedimplant reduces the thickness of the facial bone wall. Another prosthetic implicationcouldbe implant angulation error making the rehabilitation procedure difficult.

- **Apicocoronally position:** Placement of implant in a much apical direction leads to bone saucerization resulting in significant bone loss and gradual soft tissue recession.(2)

Prosthetic Phase: Following the placement of implant,several parametersdetermine theprosthetic phase, starting with the gingival former and the temporary restoration, which form the initial gingival collar,followed by the abutment selection and finally, the shape and color of the crown.

(a) Gingival Former: The circular profile of most gingival former is different from nearly triangular profile of the cervical portion of the tooth to be

reconstructed. Therefore, some shape adjustments need to be done to create a natural esthetic emergence profile. The gingival former is anatomically shaped for esthetic soft tissue healing.

(b) Provisional restorations: Provisional restorations are required to shape, prepare, and stabilize the peri-implant tissues before the definitive restoration. They also aid in providing an esthetic evaluation before the finalization of the treatment. The shape and contour of provisional restoration can be easily adjusted chairside to establish the desired emergence profile.[8] This can be done by adding or subtracting temporary material in one to three conditioning steps.[9,10,11]

The peri -implant soft tissuesaround a provisional restoration matures and stabilizes in initial three to twelve months after insertion [12,13].Therefore, it is recommended that the provisional restoration remains in situ for a period of three months.

When the desired shape and emergence profile are achieved, the position of the peri-implant tissue must be accurately transferred to the master cast for fabrication of final restoration.

Customized impression coping: It matches the emergence profile obtained from the provisional restoration. An extraoral impression of the provisional crown is used to transfer the desired emergence profile to the impression coping. The customized impression coping supports the mucosa during impression taking and enables the dental technician to fabricate the optimal shape of the final crown.[14]

The shape of the definitive abutments and the definitive restoration will be identical tothat of the provisional restoration, thereby maintaining the exact soft-tissue architecture, optimizing esthetics, and minimizing gingival discrepancies

(c) Selection of abutment: The selection of an abutment in a particular case depends on several factors, most important is the angulation and spatial position of implant.[15]

I. Straight Abutment: The straight abutment is the most frequently used abutment. It can be used for Single,multipleor full arch restorations It can be used for both cementor screw retained restorations.

In cases where large amount of modification is necessary this abutment is contraindicated.

II. Angulated Abutment: These are the abutments used when the implants are placed in different angulation as compared to adjacent tooth. In order to compensate the angulation desired for the prosthesis, these angled abutments are used It allows for correction of angulation and positional discrepancy. This abutment is available in 15 to 35° angulations.

III. Custom Abutment: Patient specific contours of custom abutment sculpt the peri implant tissue during the healing phase. Final restorations that adhere precisely to patient's gingival contour provide ideal emergence profile. Customized abutments are fabricated in the dental laboratory after an implant level impression is made. The size, shape and material depend on the clinical application. These custom abutments help in smooth and atraumatic transition during delivery of definitive prosthesis.

Conclusion

Esthetics plays a significant role in implant placement but is critical for implants placed in the anterior esthetic zone. An anterior implant restoration must show high esthetic quality because they are most visible while smiling and talking. To provide natural effect to anterior crown emergence profile plays the most crucial role. [16]

Oral Manifestations of Hematologic Disorders

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

It is well known that oral mucosal symptoms and signs are seen in the beginning of haematologic disorders and therefore the patient reports to the dentist first before visiting any general physician or haematologist. Hence it is imperative that the general dentist or the oral physician must be aware of these oral changes so that there is prompt referral to the specialist ensuring a fast diagnosis and early intervention thereby reducing the morbidity and mortality which may be associated with such diseases, especially leukaemia. In this overview of common oral changes encountered in the haematologic disorders is discussed in brief, including all the important facts about the disease.

Keywords: *Anaemia, leukemia, haemostatic defects, oral manifestations.*

Introduction

Haematologic disorders include a number of diseases, disorders with haemoglobin, erythrocytes, leukocytes, thrombocytes, coagulation factors, etc. All kinds of anaemia be it for deficiency of iron or vitamins or due to defects in erythropoiesis or blood loss, can lead to typical oro-facial manifestations in patients regularly visiting the dental clinic.[1]Patients having a bleeding tendency or a coagulopathy also comes with tell-tale oral signs which arouse suspicion regarding their medical status. Leukocytic diseases range from infections to haemotologic malignancy like leukemia, hence a proper diagnosis from the oral manifestations can help save lives. This paper describes the multitude of oral features in few of the important haematologic diseases.

Plummer – Vinson syndrome: Some patients may complain of burning sensation of tongue and oral mucosa. Tongue appears smooth or bald due to atrophy of papillae on the dorsum associated with erythema and fissuring is some cases. Angular cheilitis, thinning of vermilion border of lips, thin atropic oral mucosa with leukoplakia are present. Patient may also complain of dysphagia and on physical examination, spoon shaped nails (koilonychia), Esophageal stricture seen on barium swallow are suggestive features of Plummer–Vinson syndrome which consists of iron deficiency anemia, dysphagia, glossitis and koilonychia.[2] Since PlummerVinson syndrome produce dysphagia, caused by fibrosis of esophagus in post cricoid region and glossitis due to atrophy of epithelium, carcinoma may develop from dorsum of tongue and post cricoid region of esophagus, so it is a premalignant condition.

Pernicious anemia

Some patients may present with complains, of glossodynia, glossopyrosis and on examination of tongue, it appears beefy red in colour either generalized or in patches scattered over the dorsum and lateral borders. Atropy of papillae of the tongue result in smooth or bald tongue called as Hunter's glossitis or Moeller's glossitis. [3]Small, shallow ulcers resembling aphthous ulcers are present on tongue and buccal mucosa with persistent or recurring stomatitis, intolerance to dentures associated with pallor, fatigue, numbness or tingling sensation of extremities, incoordination and loss of vibratory sensation, shortness of breath, loss of weight, yellow tinged skin and sclerae in severe cases are suggestive features of pernicious anemia. It is a macrocytic anemic caused due to intrinsic factor deficiency leading to impaired absorption of vitamin B12. Achlorhydria associated with atrophy of gastric mucosa with a reduction in parietal cells is the pathognomonic feature of pernicious anemia.

Sickle cell anemia: In some patient, delayed eruption and hypoplasia of dentition associated with pallor oral mucosa and increased incidence of osteomyelitis due to hypovascularity of bone marrow are present. Intra-oral radiographs reveal large irregular marrow spaces

with coarse and reduced trabeculation seen as horizontal rows creating a ladder like effect between the roots of teeth, with normal lamina dura and periodontal ligament space. Radiopaque areas are seen representing past thrombi or infarcts. [4] Sickle cell crisis due to decreased oxygenation on exertion, infection or pregnancy is a common finding. They may have pain in joints and limbs, fatigue, cardiomegaly with an additional feature of packing of erythrocytes in peripheral vessels resulting in tissue anoxia. These features are suggestive of sickle cell anemia which is a hereditary type of chronic hemolytic anemia caused due to valine substitution for glutamic acid in sixth position of beta chain of hemoglobin.

Thalassemia: Some patients may present with unusual prominence of premaxilla, flaring of maxillary anterior, retracted upper lip, anterior open bite with painless enlargement of maxilla and mandible due to bone marrow hyperplasia as a result of extramedullary hematopoiesis referred to as "chip munk facies".[5] In some cases teeth discoloration due to excess iron deposition as an indicator of hemochromatosis associated with delayed pneumatization of maxillary sinus are present. Prominent malar bone, mongoloid face, slanting eyes, saddle nose deformity, protruding zygoma, prominent frontal and parietal bones are suggestive features of thalassemia. Intra – oral radiographs reveal salt and pepper appearance due to enlarged marrow spaces, coarse trabeculation, rarefaction of alveolar bone, thinning of lamina dura, shortened root are characteristic features of thalassemia which is a genetic disease caused by diminished synthesis of alpha or beta globin chain of hemoglobin.

PorphyriaSome patients may have red discolouration of teeth on exposure to ultra violet light and red coloured urine associated with atrophic cheilitis, advanced localized periodontal diseases with photo sensitization. Red or brown discoloration of both deciduous and permanent teeth is referred to as erythrodontia due to deposition of porphyrins which has an affinity for calcium phosphate, hence deposited in dentin during tooth development. [1] This is suggestive of Porphyria which is an in born metabolic disorder of pyrrole metabolism characterized by excessive formation of porphyrins in serum and in urine. If the disorder is localized to bone marrow, it is called erythropoietic porphyria and if liver is the site of excessive porphyrin production, hepatic porphyria develops.

Polycythemia: The patient will have an enlarged tongue with reddish color and slightest provocation causes bleeding. This sign of red tongue associated with bleeding in the form of petechiae, ecchymosis, hematoma is a clinical sign of polycythemia.Polycythemia is a condition in which there is abnormal increase in the number of red blood cells.[2,6]

Agranulocytosis: The patient has got multiple localized necrotizing ulcers in the tip of the tongue. Similar ulcers can be seen in buccal mucosa, gingiva and tonsils. The lesions appear as boggy, necrotic ulcers covered by gray or grayish black membrane. This clinical sign suggests that the patient is having agranulocytosis.[6] Agranulocytosis is a condition in which there is absence of granulocytes in WBC. Since the granulocytes are absent, local infection predominates and cause necrotic ulcer.

Leukemia: The patient has rapid gingival enlargement with bleeding. The tip of the gingiva will be purple in colour and mild ulcerations will be seen. This will be associated with petchiae, ecchymosis of skin. This clinical sign is suggestive that the patient is suffering from Leukemia.[7] Leukemia is a neoplastic proliferation of leucoplastic tissue characterized by increased number of immature erythrocytes in the circulating blood and tissues.Leukemic cell infiltration in gingiva is responsible for gingival enlargement. The rupture of minute blood vessels because of Leukemic cell circulation is responsible for bleeding.

Purpura: Patient will have bluish red dots in the oral mucosa, purpuric spots, small red patches, petechiae and ecchymosis in the oral mucosa. This will be associated with skin changes in the form of purpuric spot, petechiae and ecchymosis. The oral sign is suggestive that the patient is having purpura.Purpura is a clinical sign in which extravasation of blood occurs and manifests in the form of purpuric spots, petechial ecchymosis and is associated with bleeding from various orifices of the body.[6,8] This may be due to platelet disorders or vascular disorders. Thrombocytopathy, Thrombocytopenic, Thrombocythemia purpuras are varieties.

Hemophilia: Prolonged bleeding from oral tissue, due to injury or surgical procedures is a sign of Hemophilia. Even if there is prolonged bleeding after extraction of tooth, it will be due to hemophilia. As we know that Hemophilia is a blood disease, hereditary in nature, the defect is being carried by X-Chromosome and is transmitted as sex – linked mendelian recessive trait.

[8]Hemophilia occurs only in males, but it is transmitted from females. This is a coagulation defect in which there is deficiency of clotting factor VIII anti hemophilic globulin.

Conclusion

Many patients having anaemia or with bleeding/ clotting disorders who report to the general dentist or the oral physician have oral manifestations and even facial features pertaining to that disease. The features may be non-specific but they serve as an indicator of an underlying disease which could cause bleeding or issues in healing and could lead to cumbersome complications. Hence treating such patients requires a thorough investigative work up and referral to a haematologist before any dental treatment is initiated.

Stem Cells in Maxillofacial Surgery

Bhawani Patra[1], Stithaprajna Lenka[2], Karishma Rathor[3]

[1]Intern, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Cells with one-off self-renewal and potency are called stem cells. Stem cells can be converted into suitable cells with sufficient biochemical signals. Tissue regeneration involves delivery to wounded organs of different types of cells or cell products for tissue and organ reconstruction. Stem cells have strategies for the recovery and treatment of damaged tissues. In this article we are reviewing use of stem cells in maxillofacial surgery.

Keywords: *Stem Cell, Tissue, Engineering, Organs, Bone Marrow, Regeneration, Scaffolds.*

Introduction

Stem cells are cells that can differentiate into other cell types and can also split through self-renewal in order to produce more of the same stem cell types. For stem cells with medical significance in dentistry. Oral facial tissues have been identified as an origin and therapeutic target.[1,2] The stem cells are of following types:

1. **Embryonic Stem Cells:** Multipotential differentiation is possible, but clinical viability is limited due to medical problems. Embryonic cell lines are formed by the inner cell mass of embryo. The germ layers namely ectoderm, endoderm, and mesoderm are formed but the differentiation of the embryonic stem cells.
2. **Adult Stem Cells:** These stem cells are multipotent. They are obtained from different tissues such as umbilical cord, brain tissue, liver, bone marrow, amniotic fluid, pancreas, dental pulp, cornea, adipose tissue.
3. **Pluripotent Stem Cells:** It is a recent concept that uses suitable vectors to transfer 3-4genes found in stem cells to donor cells. They have the same characteristics as embryonic stem cells.

Stem cells origins are: Bone marrow, adipose tissue, oral and maxillofacial stem cells. Oral tissues are a stem cell origin. Tissue structuring in dentistry has shown promising results of oral tissue or organs being regenerated. The properties of stem cells are self-renewal and potency in regenerative dental usage many organs can be used. For tissue engineering dead cells are not used only alive cells are used as the materials. Tissue engineering contains the use of scaffold for the production of new productive tissue for a clinicaluse. [3,4]

Parameters in tissue engineering includes: - cell source, scaffold, bioreactor. It also leads to engineered tissues, that could allow us to research in vitro human physiology. The 3D extra-cellular matrix cells in the body grow by other cells surrounding to it. Scaffolds are things that are used tocause good cellular communication, in order to convey to the development of new functional tissues for medical purposes. They mimic the native tissue's extracellular matrix.[5]

It includes the possibility of creating and implanting tissues and organs in the laboratory when the body is able to repair itself. This uses cells, biomaterials, and molecules to repair structures in the body that due to disease and trauma do not function properly. In addition to regenerative medicine, tissue engineering can be to construct scaffolds in the human body. These scaffolds are used to sustain organs or organ systems that may have been damaged after injury or illness. Bone regeneration

Corresponding Author:
Dr. Stithaprajna Lenka

is the most relevant and demanding approach to tissue engineering in regenerative medicine.[6]

Dental Stem Cells and Transfer Factors: During the in vivo implantation of endodontically treated real-size, the injection of appropriate fibroblast growth factor and/or vascular endothelial growth factor (bFGF and/or VEGF) resulted in the Introduction of recellularized and revascularized connective tissue into the root canals native dentinal walls. Newly shaped dental tissue appeared thick with the extra-cellular matrix of the body surrounded by disconnected cells. Blood vessels filled with Erythrocyte were present with cell lining of endothelial tissue. In endodontically treated in vivo root canals, though in an ectopic fashion, the current chemotaxis-based approach has effective re-cellularization and re-vascularization effects. Cell homing dental pulp regeneration, can speed up medical translation rather than cell delivery.[7]

Sources of stem cells

Bone marrow stem cells (BMSCS): Sternum or iliac crest production. Hematopoietic stem cells and mesenchymal stem cells have both properties. The mesenchymal cells form as many of oral oro-maxillofacial structures as possible. The benefit of bone marrow is that there is plenty of stem cells and is possible to distinguish a wide variety of cells. Isolation done under general anaesthesia.

Adipose derived stem cells (ADSCs): It is obtained from the lipectomy or aspirate liposuction. A group of pluripotent mesenchymal stem cells with differentiation of multilineage. Useful and accessible to people.[8]

Oro-maxillofacialregion stem cells:

1. **Dentalpulpstemcells (DPSC):** represent a form of adult cell colony with the powerful ability to distinguish between self-renewal and multilineage differentiation.
2. **Dentalpulpofhumanexfoliateddeciduousteeth (SHED):** contains multipotent stem cells from human exfoliated deciduous teeth.
3. **Stemcellsofapicalpapilla (SCAP):** at the edge tips of tooth roots of the tooth.
4. **Dentalfollicleprogenitorcells (DFPC):** A loose ectomesenchyme based connective tissue sac covering the enamel organ and the dental papilla.
5. **Bonemarrow-derivedstemcells (BMDC):** They have the ability to found after trauma in several tissues.

Advantges of Dental Stem Cells:

1. Have high plasticity.
2. For longer period it can be cryopreserved.
3. It showed good interactions with factors of scaffolding and development.
4. Transplantations induce pathogen and immunosuppression, so the best alternative is autologous stem cell.

Stemcelltherapyuses:

- **Repair of dental tissue:** Dental stem cells are known to have opportunities for regeneration of tissue. These include the cell uses for dentin, periodontal ligament and dental pulp to repair damaged tooth tissues. Use of dental stem cells as cell sources to help restore non-dentinal tissues including bone and nerves.
- **Periodontalregeneration:** After implantation into the periodontal defect, BMSCs may develop the alveolar bone, periodontal ligament, and *in vivo* cementum.
- **Dentalpulpregeneration inimmaturetooth:** In the process of immunocompromised mice tubular dentin formation, human pulp stem cells with scaffold (hydroxyapatite/tricalcium) are found.

Toothregeneration: Latest development of this field. Regenerative treatments would be better suited instead of dental implants can be used as an alternative method. Epithelial mesenchymal interactions are important in the production of the tooth. Inductive morphogenesis, stem cells, scaffolds are three key elements that include tooth regeneration.

- **Craniofacial defect regeneration:** Regeneration of craniofacial defects due to cyst enucleation, wound resection and injury. Autologous stem cells and iliac crest bone graft are collected from gluteal area. Autologous fibrin keeps cells in place by cryoprecipitation. It is possible to develop articular condyles mesenchymal stem cells and biomimetic scaffold bioreactor condyles. Salivary gland regeneration is done through two approaches [3] Collagen gel-borne myoblast/progenitor cells are implanted to ensure muscle regeneration into the hemi glossectomized tongue.

- **Soft tissue reconstruction:** Reconstruction of soft tissue is performed in the oromaxillofacial region. Graft and flap transfer are repair techniques. Also used for reconstruction are adipose cells derived from human MSCs.
- **Cancer Treatment (stem cell transplantation):** Bone marrow cells are totally damaged or destroyed by killing cancer cells while undergoing high dose chemotherapy and radiation. Body can no longer produce the blood cells. Stem cells are replaced by transplants of stem cells by encouraging bone marrow to produce healthy cells that are killed by high dose cancer treatment.[9-11]

Conclusion

Traditionally it will be focus more on healing on recipients being able to use their own cells for disease treatment. The first role in dentistry is therapy for stem cell. With regenerative medicine, regenerative dentistry will have to be together. On the other hand, firstly they can be used medically, if not it could cause dangerous response. Maximum time follow up of the patient is needed to read the regenerated Cells for life. Finally, most treatments seek to improve tissue regeneration, and stem cell technology has opened a new road to regenerative medicine. A huge variety of defects are now being treated by the help of regenerative medicine. The future innovation should be able to "mimic nature" or "work with nature" to improve things and innovations such as nanotechnology in order to improve this area.

Oral Manifestations of Cardiac, Respiratory and Renal Diseases

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Many systemic diseases have their manifestations in the oral cavity which sometimes aids in the diagnosis of the systemic disease. It is imperative that, dentists or oral physicians ought to be aware of the different systemic diseases, the drugs that are given for their treatment and also the drug interactions in the patients with the said disease. Cardiac, respiratory and cardiac diseases are very common and many patients with such diseases report to the dentist with dental ailments. This overview aims at increasing the awareness regarding the cardiac, respiratory and renal diseases which have known oral manifestations.

Keywords: *Cardiac disease,oral manifestations, systemic disease.*

Introduction

Using the oral changes as diagnostic indicators for the detecting different cardiac, respiratory and renal diseases is uncommon as they have few and non-specific oral lesions which may not be pathognomonic.[1] However, few specific signs and symptoms specifically indicate the organ system which is diseased and ensue further investigations, leading to the eventual diagnosis of the disease.[2] An overview of the oral mucosal features seen in the cardiac, respiratory and renal diseases is discussed highlighting the not so common features of these important diseases, to educate the budding dentists and oral physicians regarding the same.

Cardiovascular diseases

Congenital heart disease: Cyanosis is bluish discoloration of the mucosa or skin due to increased amount of carboxyhemoglobin in the circulating blood. Patients will have bluish discoloration of gingiva and in other parts of oral mucosa. This discoloration is generalized, persistent and is called as cyanosis and people who are having this discoloration may have 'Congenital Heart Disease–**Fallot's Tetraology'**. In Fallot's Tetralogy, these is congenital defect in which pure blood with oxy hemoglobin and impure blood with carboxy hemoglobin are mixed. Thus, oral mucosal cyanosis is a sign of congenital heart disease.[3]

Sturge weber syndrome: Angiomatous lesion, reddish in colour, persistent, strictly unilateral, involving the area supplied by trigeminal nerve, is a sign of 'Sturge Weber Syndrome'. This will be associated with calcification of meanings and this result in fits.In general practice, complaint of fits is a common complaint and if the patient show Sturge - Weber syndrome, the general practitioner, in the absence of other disease, can diagnose, that fits are due to congenital vascular lesion, Sturge - Weber syndrome. Thus Sturge - Weber syndrome aids to diagnose the cause of fits in general practice. [4]

Hypertension: Bleeding gums is a sign that indicates certain local and systemic diseases. But if a patient has sudden bleeding from the oral tissue, associated with headache and giddiness, that bleeding suggests that it will be due to hypertension. If an abnormal sudden bleeding occurs, it indicates that the patient has got severe increase of blood pressure.

Myocardial infarction: Heart attack is dangerous and in early stage, sometimes it is difficult to diagnose. It a patent suddenly develops acute pain in the left lower jaw, in the region of premolar and molar, the severe pain is referred to the upper part of the neck, shoulder and left side of the chest, this originated pain on the left side of the chest and left lower jaw pain is suggestive of 'Myocardial Infarction', due to coronary thrombosis.[5]

During Coronary thrombosis, pain develops from the heart and transmitted through the Vagus nerve to

brachial plexus and from brachial plexus to cervical plexus and from cervical plexus to the left lower jaw, through greater auricular nerve or through a nerve called cutaneous coli. Thus, even the most dangerous disease of coronary thrombosis can be diagnosed by observing the oral manifestation of left lower jaw pain in molar & premolar region.[6]Similarly, pain from angina pectoris is also referred to left lower jaw. In angina pectoris, the patient will have pain only on exertion.

Hereditary Hemorrhagic Telengectasia: Some patients may present with numerous angiomatous or spider like telangiectatic, blood filled channels on the oral mucous membrane, lips, tongue, gingiva, buccal mucosa and palate. The early sign of the disease is bleeding from oral cavity and epistaxis. Skin lesions are common in face, neck, chest and in the nail beds. The presence of bleeding from oral cavity, epistaxis and telangiectatic lesions in both oral mucous membrane and skin are suggestive features of hereditary hemorrhagic telangiectasia.[7]

Diseases of the respiratory system

Lung abscess: Halitosis is bad breath from the oral cavity and it can occur in many diseases. It can also occur in respiratory diseases like lung abscess and chronic pulmonary tuberculosis. Thus, halitosis will help to diagnose lung abscess and pulmonary tuberculosis of respiratory system. The most serve halitosis occurs in maxillary sinusitis.[7,8]

Tuberculosis: Oral ulcer with elliptical or irregular shape associated with severe pain, with undermined margin is 'Tuberculous Ulcer'. Sometimes ulceration in the gingiva with desquamation and erythema with pain may be 'Tuberculosis Gingivitis'.Tuberculous gingivitis and tuberculous ulcer in the oral cavity may suggest that the patient will have pulmonary tuberculosis. [8] These lesions help to diagnose pulmonary tuberculosis of respiratory system, in many occasions, the pulmonary tuberculosis may not be associated with oral lesions and oral lesions may be independent in its genesis.

Renal diseases

Renal failure: Sudden appearance of diffused superficial ulceration of lip and mucosa covering white membranous patch associated with burning sensation and pain and if the patient gives history of kidney disease this ulceration is uremic stomatitis and suggests that the patient is suffering from Uremia due to chronic renal failure. The lesion in the mouth is called 'Uremic Stomatitis'.

In uremia, the end products of protein, amino acids and urea, when circulate in the blood stream, it reaches the mouth and acts as an allergen and allergic reaction sets. As a result, uremic stomatitis develops. Thus, uremic stomatitis in oral cavity helps to diagnose uremia of kidney disease.[9]

Brown colored soft growth arises from the bone and appears in oral cavity with radiographic findings of loss of lamina dura and alveolar bone as we find in primary hyperparathyrodisim, helps to diagnose secondary hyperparathyroidism due to kidney disease. In chronic renal disease, the kidney is damaged and more calcium is eliminated through urine because of failure of reabsorption of calcium and as calcium is eliminated in the urine, there is hypocalcemia in blood, which stimulates parathyroid to become hyperplastic and produce more parathormone to remove calcium and maintain calcium level. This is secondary hyperparathyroidism.[10]

Conclusion

An overview of the frequent as well as the unusual oro-facial features of the cardiovascular, respiratory as well as renal diseases is presented with a pragmatic outlook regarding the importance of history taking and clinical examination in patients visiting the dental clinic.

Current Trends in Enamel Regeneration: A Review

Utkalika Das[1], Gatha Mohanty[2], Debashruti Naik[3], Rashmita Nayak[4]

[1]Clinical Tutor, [2]Senior Lecturer, Department of Periodontics and Oral Implantology, [3]Post Graduate Trainee, Department of Public Health Dentistry, [4]Professor, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), [3]Clinician, Bhubaneswar, Odisha, India

Abstract

Dental Enamel forms the outermost covering of teeth. Being the hardest mineralized tissue of human body, it is subjected to many challenges such as demineralization and remineralization to maintain an integrity within the oral environment. It is also prone to wear, decay and damage. However, it cannot regenerate as its origin is from the cells lost after a tooth is erupted. Restoration of lost enamel is possible by use of conventional treatment that uses synthetics, however it is impossible to mimic the natural prototype. Clear understanding and recent advances in material science has paved a way in formation of synthetic enamel. Isolation of post natal stem cells and understanding the interactions of proteins and their genetic products has led to development of materials that are smart that can be useful in cell and growth factor delivery. This article highlights the recent trends in bio-mimetic synthesis and strategies that's are cell based and make enamel regeneration possible and the various obstacles that needs to be overcome before it is available to dental practitioners.

Keywords: *Regeneration, Enamel, Tissue Engineering.*

Introduction

The mature enamel has no proteinand it is the hardest, can tolerate cracks as well as resistant to abrasion.[1,2] During the process of enamel biomineralization, mineral replacement usually precedes the assembly of the protein matrix. Amelogenin, a hydrophobic and dominant protein has the ability to form nanospheres which can influence the crystal habit and crystallite packing.[3] Enamel has no collagen and therefore do notremodel. This is in contrast to the mesenchyme-controlled biomineralization of bone where collagen and remodels are used. Dentin is flexible and softer. It can absorb energy, and has ability to resist fracture. It is less mineralized than enamel.

Dentinal matrix is mainly composed of type I collagen and non-collagenous matrix proteins. Dentin gets deposited throughout the life span of a teeth. Globules appear in the immature dentin which fuse during the maturation of the tissue.[4] Similarly, in response to stimulation by recombinant BMPs, dental pulp cells can differentiate into dentin-forming odontoblasts.[5]

Fabrication of Synthetic Enamel: Studies by Cao Y et.al 2014 proposed methodologies for regeneration of enamel that included hydroxyapatite micro structures. Similarly, Fletcher J et al.[6] suggested a hydrothermal method that uses the control release of calcium from Ca-EDTA, transformation of octa-calcium phosphate rod to hydroxyapatite nanorod hydrothermally. They also used hydrogen paste that contained hydrogen peroxide. The conditions required to carry out this technique were not suitable i.e. high temperature, very low acidity and high pressure. So recent research aims to use supersaturated solution and enamel derived protein amelogenin in a condition which is more comfortable for clinical application. Chen et al. fabricated fluorapatite nanorod resembling enamel prism like structure by use of a super saturated chemical solution. The advances of nano technology produced a nano rod which have similar characteristics as natural enamel like structure. It consists of hydroxyapatite that is produced by a solid-state conversion process using organic phosphate surfactant and gelatine.[7]

e-mail: gatha.mohanty@gmail.com

Enamel tissue engineering: Enamel organ epithelial cells manipulation is an advancement that attempts to replace the enamel using tissue engineering. The enamel forming capacity of subcultures Enamel organ epithelial cells was examined by Hondaet al.[8] They transplanted cell on to a biodegradable scaffold in vivo. They further isolated fresh dental pulp cells from pigs during the bud stage of crown formation and plated it on the top of the scaffold. The subcultured EOE cell present was then seeded directly on the pulp cell. They could observe various phenomenon related to amelogenesis process after 4 weeks of transplantation. They also detected amelogenin immune reactivity in tall columnar epithelial cells found on surface of enamel or dentin which suggested that the newly engineered enamel has well developed ameloblast. However, disadvantages in this technique was that the EOE cells disappear after tooth eruption. So, there was a need to find an alternative source for ameloblast.

Cells from Bone Marrow: Hu B et al. at 2006 carried out a study where they could generate a tooth crown by culturing bone marrow cells with single cells suspension of dental epithelium.[9]

Oral Keratinocytes: These keratinocytes can be derived from buccalmucosa, grown in culture and sub-cultivated as well. Masaki J.et al. at 2010, proposed that non dental epithelial cells can be a new source of cells in the process of enamel tissue engineering.[8]

ERM: ERM is a direct lineage from Hertwig´s epithelial root sheath. The epithelial cells derived from Hertwig´s epithelial root sheath has the potential to differentiate into ameloblast and produced enamel dentin complex in combination with non cultured dental pulp cells which are found in core of dental pulp.[10]

Epithelial cells from the skin: Liu Y et al.reported that skin epithelial cells are substitute for ameloblasts and has the potential to convert ameloblasts under effective induction. However further studies are needed to prove that older post natal skin epithelial cells have the capacity to proliferate and differentiate unlike one day old post natal cells which can regenerate tooth germ like structure.[11]

Human embryonic stem cells: Li-Wei et al.observed that human embryonic stem cells have the potential to regenerate ameloblasts like the human ameloblast lineage cells.[12]

Conclusion

Complexities are involved to get a part of tooth regenerated. It is further challenging to treat a tooth with pulp inflammation. The challenge is to induce mineralization along with use of advanced biological systems and therapeutic agents thereby controlling the inflammation. Suitable carriers are necessary for treatment of diseased tooth parts. These carriers should be biocompatible, and have mechanical properties compatible for application in dentistry.Synthetic or natural 3D scaffolds composites along with bioactive materials seeded with specific dental tissue stem cells could be aninnovative approach that fulfil the requirements.

Bioactive Restorative Materials

Upasana Mohapatra[1], Susant Mohanty[2], Sonu Acharya[3], Bismay Singh[4], Debarchita Sarangi[5]

[1]Tutor, Department of Pediatric and Preventive Dentistry, [2]Professor & Head, Department of Pediatric and Preventive Dentistry, [3]Professor, Department of Pediatric and Preventive Dentistry, [4]Senior Lecturer, Department of Pediatric and Preventive Dentistry, [5]Senior Lecturer, Department of Prosthodontics & Crown & Bridge, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Bioactive restorative materials are the latest and the newest subjects of extensive studies and research in dentistry. It is not synonymous with biocompatible restorative materials. In the older times, research on biocompatibility was very much on the high, but in the recent times, research on bioactivity of restorative materials is on the rise. The interaction between dental pulp and these materials, its regeneration and healing are the major areas of interest.

Keywords: *Bioactive, Dentine, Interface, Restorative.*

Introduction

Bioactive material is the one that carries any property of interacting with the tissues in the surrounding areas and has some effects on them.[1] Unlike the biocompatible materials, which were inert towards the tissues, the bioactive materials interact with the dental tissues.[2] They usually stimulate certain biochemical and biophysical reactions, thereby instigating certain biological responses, leading to the production of the apatite layer, which allows the integration of the material to the surrounding tissues.[2] According to Hench, in 1969, "a bioactive material is the one that elicits specific biological response at the interface of the material which results in the formation of the bond between the tissues and the material."[3] These materials are also being successfully used as direct pulp capping agents.[4]

Classification of bioactive materials: According to the classification given in 1944, they are divided into 2 classes:[5]

Corresponding Author:
Dr. Upasana Mohapatra
Tutor, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, India
e-mail: upasanamohapatra.um@gmail.com

1. Osteoproductive materials: These materials exhibit both intracellular and extracellular activities. Here, the bioactive surface is colonized by osteogenic stem cells. E.g. 45S5 Bioglass.[2]
2. Osteoconductive materials: These materials only exhibit extracellular activities. They only render the interface biocompatible, so that the bone cells could migrate through it. E.g. synthetic Hydroxyapatite (HA).[2]

Bioactive materials and their antibacterial functions: For the bioactive material to also function as an antibacterial agent, the metal-based bioactive materials are superior to non-metal-based ones. The metal-based antibacterial, like silver or zinc, are an excellent option as an antibiotic. This is mostly because of the fact that the chemical properties of the metal ion interfere with bacterial growth. The development of resistance is also reduced with these materials because of their properties of unique binding, coordination and redox potentials. They have been noted to be active and effective against *Streptococcus mutans* and against biofilm formation too. The only hindrances for their development in full swing is the systemic toxicity they could pose and the less therapeutic indices.[6]

Bioactive materials in dental practice

Mineral trioxide aggregate: It was first developed by Torabinejad in 1993, as an option for surgical

root repair. But, because of its biocompatibility and potential bioactivity, more extensive studies are being conducted on it.[2] it is a mixture of 3 powders – Portland cement (75%), bismuth oxide (20%) and gypsum (5%).[7] It also contains trace quantities of SiO_2, CaO, MgO, K_2SO_4, Na_2SO_4. Portland cement, which is the main ingredient, contains a mixture of dicalcium silicate, tricalcium silicate, tricalcium aluminate, and tetracalcium aluminoferrite. It is used in a slurry form by mixing the powder with water and it subsequently sets and hardens at the concerned site. The bioactive properties of this material is seen as minimal toxicity to the tissues, minimal pulpal irritation, minimal periapical inflammation, non-mutagenic property, adherence to the tissues, and growth, increased production of alkaline phosphatase, osteocalcin, interleukin-6 and 8, its attachment to the periodontal ligament, cementum growth and formation of dentinal bridge.[8-20]Sarkar et al, in a study significant in regards to MTA, showed that, when the MTA is placed in a root canals and it gradually dissolute, hydroxyapatite crystals nucleate and grow. Hence, the microscopic space is filled up between MTA and the dentinal wall.[21]Jessie et al, in their study showed a proinflammatory and pro-wound healing environment is stimulated by MTA, which runs concurrently with the response of acute inflammation. The cellular and the tissue reactions at the interface leads to a chemical bond with the dentine and due to a diffusion-controlled reaction at the interface. These reactions of MTA offer excellent seal at the interface, and renders the material biocompatible and bioactive.[2]

Bioaggregate: It is the result of the recent developments in the field of nanotechnology of biocompatible ceramics. It is the first material of its kind. It is an aqua-based cement, containing biocompatible nano-ceramic particles.[22] It has shown better results than MTA in terms of sealing at the interface[23]and biocompatibility[24,25]It is composed of calcium silicate, calcium hydroxide and calcium phosphate.[26]its antimicrobial action is also very significant along with significant osteogenic induction and regenerationof periodontal tissues.[24,27-29.] it also shows better adhesion to the dental tissues,and stimulates migration and attachment of pulpal tissue.[30]

Bioactive pulp-capping agents: Bio Aggregate also acts as an excellent direct pulp capping agent as it stimulates the differentiation of odontoblasts and the mineralization, even better than MTA.[31]

Biodentine: It is quick-setting cement, introduced by Septodont in 2011. It was first introduced as a dentine replacement material, which was expected to be used as a coronal restorative material.[2] It contains synthetic tricalcium silicate, dicalcium silicate, calcium carbonate and zirconium dioxide (for radio-opacity).[32]It can easily be used as a restorative material owing to its setting time, which is approximately 12 minutes. This is the disadvantage with MTA (setting time is 3-4 hrs), because of which it cannot be used as a restorative material.[32, 33]

Endosequence root repair material: It was first developed by Brasseler USA along with Endosequence Root Repair Putty. This too uses the technology involving biocompatible ceramics.[2]the properties of this material, i.e., being hydrophilic, insoluble, not containing aluminium and an alkaline pH (12.8)[34] makes it an easier option to operate with. Its setting and hardening are enhanced by the presence of moisture.

Bioactive root canal sealers: They provide a complete seal at the interface between the material (sealer) and the tooth (i.e., dentine). These materials are highly biocompatible. Their high alkalinity (high pH) renders the material antibacterial.[35] Hence, this material gives a chance for successful obturation.

Bioactive Liners: Over the years, many studies have been conducted on the capabilities of the pulp capping agents in formation of a dentinal bridge and inducing pulpal inflammation.[1] MTA acts as a better pulp capping agent than calcium hydroxide, as described by Hilton in a review in 2009.[36] But, because of its long setting time of MTA (3-4 hrs), it poses a difficulty in it being used as a pulp capping agent. So, along with it, a fast setting material (like resin modified glass ionomer liner, a temporary restoration, or Biodentine which has a setting time of 12 minutes)[32,33]has to be used over it.[1] A light-cure calcium silicate liner could be placed, which is to be covered with a permanent restoration. These materials exhibit release of calcium ions and formation of a dentinal bridge.[37,38,39]

Bioactive restorative materials: These materials allow the formation of a precipitate of calcium phosphate at the interface of the restoration and the dentine. These mechanisms provide is a better seal at the interface.[40] They are also claimed to show Biointeractivity, i.e., stimulate the release of calcium phosphate and fluoride ions, thereby preventing demineralization of the tooth. [41] Some examples are Cention N, Activa BioActive.

Bioactive luting agents: The latest in the trend is the Xera Cem. It is in fact the combination of calcium aluminate and glass ionomer cements. The glass ionomer portion contributes the properties of chemical adhesion to the tooth structure, early acidic pH for a short period, flowability and its faster setting time. The other portion of the cement (calcium aluminate) contributes towards good strength, stability, the seal at the interface long retention, biocompatibility and its bioactivity, no dissolution and attaining an alkaline pH.[2]

Summary

The potential of the dental pulp for healing and regeneration allows the researchers for expanding their studies and search for materials which could be used with an advantage of interacting with the dental tissues. The biocompatibility, bioactivity and the biointeractivity of the materials allow them to induce cell proliferation and differentiation, migration of bone cells and creation of a proper seal at the interface of the material and the dentine. These newer approaches provide better understanding and implementation of the bioactive materials.

Abstract

Forensic antilogy or forensic dentistry is the proper handling, interpretation and examination of dental evidence, which has to be offered before the court. Age and description of the person to whom the teeth belong can be accessed using dental history records including radiographs, antemortem and after death photographs and DNA. Person identification is the stronghold of civilization and the identification of unknown individual always been supreme importance to the society. Dental records consist of documents related to the history of present illness, clinical examination, diagnosis, treatment done and the prognosis.

Keywords: *Forensic Odontology; Dental records; Forensics; Medico legal; Antemortem.*

Introduction

Forensic odontology can be defined as a branch of dentistry which deals with the examinationand proper handling of dental evidence and with proper analysis and portrayingof dental findings in the interest of dentist. Forensic odontology is application of the art and science of dentistry to resolve cases pertaining to the law.[1]The word forensic is derived from the Latinword, forensic means public. The word science can be defined as systematized knowledge involving the acknowledgment and formulation of a problem, the collection of data through inspection and testing, and the formulation and testing of hypotheses. Forensic science refers to areas of endeavour that can be used in anadministrative setting and accepted by the court and the general methodical association to analyse the results.[2]

Role of dentists: The forensic dentistry team is headed by a chief with few members. The team which is involved in the process of recognition can be divided into on- site team and away team.

Corresponding Author:
Dr. Stithaprajna Lenka
Professor, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: stithaprajnalenka@gmail.com

On-site Team (antemortem subsection): The collection of antemortem data is done by on – site team, usually this team is housed in the site of the happening. Informing the investigation team are first to be done. A prepared hand out should be given to the members of the team. Communication systems with telephones, fax machines, etc. should be established. All dental records which includescharts, radiographs, models and photographs of the affected should be collected from dentists, hospital and other means of sources. The format of the antemortem should be recorded as it is. These two teams should be involved about their collected information. All the records should be filed alphabetically.[3, 4]

Away team (post-mortem dental examination subsection): Members belonging to this team should be prepared to leave to distant places on getting information. They should be immunized against various diseases such as hepatitis B and typhoid. The data collected by two teams should be collected and examined and at least two or three teams should be involved in this operation and properly examined. Extra – and intraoral radiographs, photographs should be taken. Dental charts must be filled accurately. While taking radiographs obligatoryprotection should be taken to avoid revealing the people working in the area. The post-mortem forms are divided into various categories according to sex, age and types of dental treatments. When some parts of body are recovered, the forms can be kept under "unsexed" category. A first copy is organized with all post-mortem records by numbers.[3, 4]

Comparison ways: Comparison of ante- and post mortem records may be done byphysical method or by using computers. Use of computers reduces tiresome and time-consuminglabour-intensive sorting of records.

Commonly used computer programs: The FBI-NCIC program developed by US army institute of dental research. Tooth pictures – match pictures, developed by class – I Inc: Indent exe developed by McGivney J; MUPIS system developed by Dr Bell; Win ID developed by McGivney J.[6]

Computers greatly help to show records with greatest probability of containing a positive evidence, after checking all ante- and post-mortem records. When utilizing computers, it, is necessary to transcribe the data from dental records to the computer code form.The identification from dental data is the result of human thought process and computers can only aid to certain extent. Whenever possible dental identification should be matched with data from radiographs, fingerprints or physical features to provide a "positive identification".[7]

Because of reasons listed below some of the remains can't be identified through dental evidence.[8,9]

Inadequate or absence of antemortem data: This problem is due to failure to maintain dental records by dentists, inadequate records provided by the dentists or failure to obtain name, address of the dentist who has treated the patient and patients who have not undergone any dental treatment.

Missing persons are foreign nationals: Either embassy of the foreign victims or forensic dentists in their country may be contacted through international organisation for forensic odontostomatology.

Poor or inadequate post-mortem data: This may be due to incomplete recovery of the remains or damage to the remains beyond recognition.

Incorrect data in the records: Incorrect data may be entered in ante or post-mortem data. This should be reduced by repeated cross- checking of records by various members of the team and taking precautions to avoid possible mistakes during data entry into the computer.

Bite marks in flesh: The term bite mark is used to describe a mark made by the teeth or teeth in amalgamation to other body parts. Bite marks can be found in food particles or parts of the body. The bite marks in flesh with which the dentist who is trained in forensic dentistry should be concerned which is more frequently found on the victim's body. A bite mark could be self-inflicted, either intentionally or involuntarily, for example by hand hard-pressed on victim's mouth to strangle a cry.Bite mark of the accused person can be achieved by details of the individual tooth features seen in the mark and those which is observed on the accused. Useful features like tooth displacement, adjacent tooth deformities, tooth rotation in a certain angle can be examined to get to the results. Dental replicas as models can be made and seen if it accurately gets compared to the site of action or scaled paper prints of the bites. Finally, it could be demonstrated in the court showing these replicas on the photos superimposing as the bite marks. These superimposed pictures could be in various prints, it could be black and white, and if it needs proper details as of in complex cases then it could be colour prints.[10-12]

Examination and interpretation

Definite bite mark: Tooth pressure mark by biting edges of the tooth. Redness, slight inflammation and tongue pressure.

Amorous bite mark: Made by gradually increasing pressure. Involves tongue pressure on the site against palatal rugae.

Moderately aggressive bite mark: quick and moderate force.

Aggressive bite mark: Tissues are hampered and slight bleeding. exact tooth could not be revealed as the site has tissues distorted.

Very aggressive bite mark: Tissues being has been torn. The sites involved could be ears, nose and nipples.

Role of saliva: Saliva is often found in the sites of crime together with bite marks and lip prints where the mouth may be involved. Serologicaland cellular results is of enormous use in identifying of the accused. Use of saliva in exposure of drug abuse and drunk drivers is commonly found.Saliva is usually deposited in bite marks found in many homicides, attack and other criminal cases. Since many struggles are faced in bite marks analysis, due toflexible and distortable nature ofskin and lack of good inklingmedium, an important focus in this examination is the saliva deposited during the biting.

Method of detection and analysis of dried saliva stains: Enzymes like alkaline phosphatase, starch and amylase are commonly used. for the recognitionof the age of saliva and quality of deposit,salts like nitrate and thiocyanate have also been usedquartz arch tube, ultraviolet light, lasers, and argon ion laser

Fluorescent spectroscopy: The classical technique used is known as double swab technique is done where a wet cotton is laid on the saliva stain to collect the saliva and then a dry cotton is used.

Sex fortitude can be done by two ways:

- F bodies in males and Barr bodies in females arethe recognition of sex chromatin.
- Sex hormones level determination based on noticeable quantities and ratios of testosterone and 17B – oestradiol by RIA.[13]

Conclusion

Abig amount of data in the field of BBI provided by teeth and jaws, age estimation of solitary minors, sexual abuse, child abuse, sexual abuse,domestic violence,sexual abuse, and. missing and unknown person. Oral health professionals and forensic odontologist can encourage forensic odontology for the purpose of hampering human rights violation through the function of best practice in human recognition.

Tunnelling: A Stable Approach to Manage Mandibular Molars with Advanced Furcation Involvement

Gatha Mohanty[1], Rinkee Mohanty[2], Saurav Panda[3], Anurag Satpathy[4]

[1]Senior Lecturer, [2]Professor & Head, [3]Reader, [4]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Khandagiri Square, Bhubaneswar, Odisha, India

Abstract

One of the challenging problems faced by general dental practitioner is treatment and management of teeth with furcation involvement. In advanced furcation involvement cases when other treatment options are precluded for financial or other reasons, tunnel preparation procedure remains the preferable option to extraction. Specially in the posterior teeth gaining access for oral hygiene procedures is difficult and thereby this technique could be considered as an alternate and successful treatment modality. This case report presents the management of a grade IV furcation with a tunnelling approach.

Keywords: *Tunnel preparation, Grade IV furcation, Mandibular molar, Inter-radiclular brush, Ostectomy.*

Introduction

Management of Deep furcation defect remains a common clinical dilemma for dental practitioners. A variety of treatment modalities have been suggested for the same. Meticulous plaque control and combined periodontal treatment can tackle this challenge optimistically rather than the routine choice of extractions[1,2].

Deep furcation defects can be treated by simple procedures such as scaling and root planning, occlusal adjustments, and gingivoplasty procedures[3,4]. And by more radical approaches such as root amputation or tooth hemisection[1]. Tooth hemisection and root amputation provide good access for plaque control, however these procedures also require endodontic treatment and prosthetic restoration. These additional treatments might be potential risks for future complications[5].

For through and through defects, tunnel preparation is another technique (1) the widening of bi-furcation and trifurcation areas of roots specially the mandibular molars which has a short root trunk, a wide separation angle and long divergence between mesial and distal root can be sometimes be associated with root caries thereby leading to poor prognosis. However this procedure gives access to radicular cleaning post surgically. In a maxillary molar, also tunnel can be prepared in mesio-buccal and disto-buccal roots[6]. We present a case of management of a grade IV furcation with a tunnelling approach.

Case Report: A 40-year-old male patient reported the outpatient department of Institute of Dental Sciences with a complaint of food lodgement and pain in right mandibular first molar region along with intermittent sensitivity. On clinical examination there was moderate tenderness to lateral percussion in relation to tooth #46 with periodontal pocket around furcation area (Figure 1). OPG radiograph revealed severe bone loss in the furcation area in relation to 46 (Figure 2A).The bone support in distal and mesial aspect was relatively intact with no peri-apical radiolucency. Exploration with a Naber's probe revealed a through-and-through furcation involvement (Figure 2B).

Scaling and root planing were completed and patient was recalled for re-evaluation after 4 weeks. A surgical

approach to convert the furcation communication to a tunnel was envisaged. Routine haematological investigations were found to be normal and surgery was scheduled. Periodontalsurgery was performed under local anaesthesia. On intra-operative examination,severe bone loss and through-and-through furcation communication was seen with tooth #46.

Buccal and lingual flaps were raised and the granulation tissue in the defect was removed (Figure 2C). Root surfaces were scaled and planed, the furcationarea was widened by round burs (Figure 2D) at the entrance and then by bone files to create space for postsurgical inter-radicular plaque control (Figure 3A). The mucoperiosteal flaps were then apically positioned and sutured (Figure 3 B, C). After the removal of the dressing, the patient was instructed to maintain the tunnel area plaque-free with interdentalbrushes (Figure 3D).

Patient was asked to follow a postsurgical schedule included rinsing with a 0.12% chlorhexidine digluconate solution for 4–6 weeks[7]. Dailyrinses with 0.025% sodium fluoride solution and the use of a fluoride dentifrice applied directly by the “interradicular”brushes was also recommended, as such treated areas aremore prone for caries. Patient followed regular 3–6 monthsmaintenance visits for a period of 3 year[8].

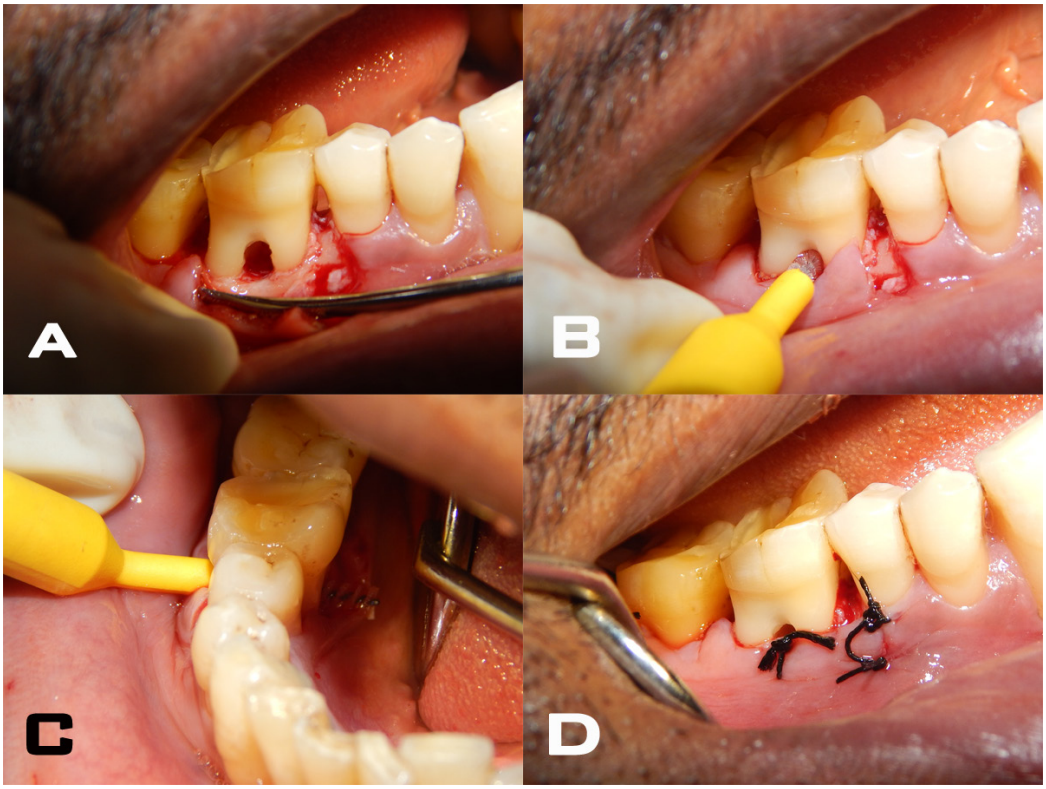

Figure 3. A. Tunnel preparation B & C Interradicular brush check D Flap closure

Discussion

Although regeneration is the best expected treatment outcome for teeth with involved furcations, sometimes alternative method such as obliteration and resections are needed. In any case, elimination of the furcation is the goal of treatment for teeth with advancedfurcation involvement so that the plaque retentive areas are converted to areas that can be cleaned by the patient easily.

Advanced grade III andgrade IV furcation involvement of especially a mandibularmolar can be treated alternately by "tunnel preparation"[9]. However few important factors need to be considered before attempting such procedures such as bone level around roots, angulation of the tooth in the arch[10]. Tilted molars should not be taken into consideration, divergence of the roots. Fused roots are poor candidates while short, conical roots are less favourable.

A major advantage of tunnel preparation is thatit does not require a subsequent endodontic intervention or a fixed prosthetics[11]. Also, on teeth with reduced bone support, this treatment will not lead to significantly increased mobility such as is commonly observed after resection of one or more roots whereas root resections and tooth hemisections are usually associated with time consuming and expensive endodontic and prosthodontic treatment[12]. However, a tunnel preparation procedure does not exclude the possibility of hemisection or root resectionat a later date if indicated.

Sometimes access difficulties arise and those can be managed by widening of the furcation and interradicular surgical dressing placement during initial healing and early introduction of inter-radicular brush.Hamp et al[1] reported a good prognosis with tunnel treatment of class III furcations. Hellden et al[13] further reported that teeth also remained caries free after treatment.

Conclusion

Conversion of a narrow Grade IV furcation communication via a tunneling approach to a self-maintainable area is a stable and preferred treatment option.

Social Networking in Dentistry: A Review

Ipsita Mahapatra[1], Ramesh Nagarajappa[2], Dharmashree Satyarup[3], Sharmistha Mohanty[1]

[1]Post Graduate Trainee, [2]Professor & Head, [3]Professor, [1]Post Graduate Trainee, Department of Public Health, Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

With the expanding rage for internet-based life, medicinal services are likewise not abandoned. Now a days web-based life has turned into a most common marketing strategy for dental specialists particularly for sharing data and drawing in new patients. So, internet-based life has turned into a route for business, including health professionals to communicate with patients. In the way of blogs, tweets, wikis, and social networks, communication has shifted from one-to-one to one-to-many. Be that as it may, there are a few difficulties in deciding the suitable content for web-based social networking. This article will investigate the utilization of web advances for dental education and discuss about the potential limitations of their usage.

Keywords: *Social media, Dentistry, Technology, Web2.0.*

Introduction

In today's era of computers and internet, anybody can find information through internet, however can likewise make data accessible in it. Social media can be defined as a new way of communication that uses the internet to link people from all over the world whether by using computers or smartphones that allow people to share opinions, experiences, and perspectives with each other.[1-3] Social media incorporates social networking sites, for example, Facebook, LinkedIn and Twitter. Additionally, including YouTube, blogs, customer reviews and wikis.[4] With the simplicity of internet access, the quantity of social media clients in India stood at 326.1 million in 2018. Facebook is the largest social network in India, with around 281 million users in 2018, LinkedIn has around 42 million clients and Twitter has 23.2 million active users being the second greatest base in Asia-Pacific after Japan.[5]

Social media or web2.0 has brought a revolution in spreading dental education by providing not only a means for socialization but also progressively used for learning purposes. Students can gain access to data through sources like DVDs containing many reading material and sites with intelligent video instructional exercises. There are four key points of interest in the web-based communities for learning: 1) it empowers joint effort amidst various clients, 2) it enables clients in creating personalized content through various sources of media, 3) allows users in publishing their individual works, and 4) it creates ways for approaching new areas of research.[6]

In relation to health, social media is used in the form of blogging, social networking sites and participation in online care groups. Today, technology has gained so much popularity that the term 'Health 2.0' has been cited in numerous articles and is related to "patient empowerment" which makes interaction between patients and patients and health care providers possible.[7] Regarding dentistry, web-based social networking can be utilized to share arrangements and advancements, share news and updates. Besides that, it is also used in organizing, sharing information through a blog, and providing customer service or monitoring reviews. An efficient method to publicize a dental practice is definitely, social networking. Professional contacts can be maintained which will help to acquire guidance and research support. Dental professionals are using social media as a marketing strategy for their dental office and are gaining attention and appreciation. Social media

has emerged as a medium for promoting oral health and education but one should be cautious in whatever they choose to put on such media such that it builds up people's confidence and influence them on the call for visiting the dentists consistently but not promoting self-medication and becoming dentists themselves. Indeed, even after all these advantages, social media is a challenging task and it has got its issue as well. This article will reflect on the utilization of social media in dentistry while emphasizing on several prospects and hurdles that exist.

WEB 2.0 Technology: With the invention of world wide web in 1989, access to information changed significantly. Web 1.0 was the first stage of the internet which was static and denoted the "read only era". Web 2.0 is characterized as the internet applications which enable sharing and collaboration opportunities to individuals and conveys what needs to be the web. It is a user-generated content that incorporates social media such as Twitter and Facebook, YouTube for video sharing and blogs and wikis, as interactive websites. By using simulated experiences and role playing via avatars, Second Life creates a virtual environment which enhances learning and communication (Figure 1).[8]

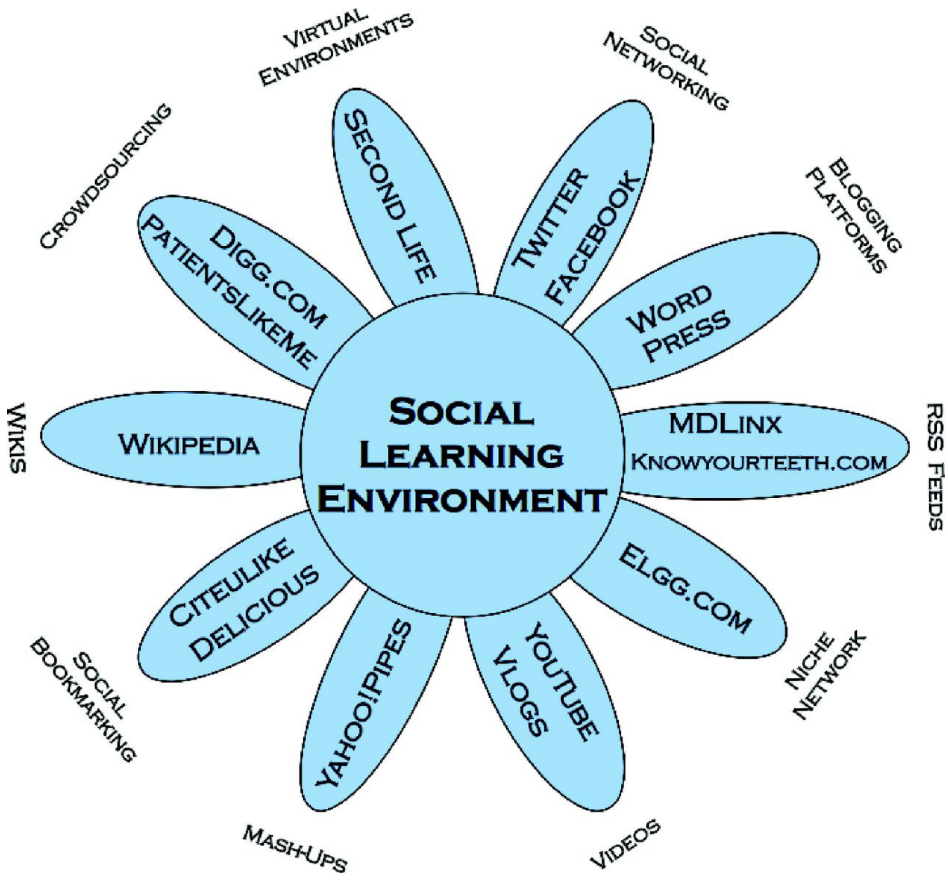

Figure 1. Social Learning Environment

Unlike web1.0, Web 2.0 websites empower clients to create, share, collaborate and communicate their work with others, without the need of any web design or publishing skills.

Facebook: As a social networking website, Facebook has become a platform where more than 750 million people share photographs, videos, remarks and communicate with one another. It offers sending private messages. Additionally, it encourages subscribers to create groups and invite others. Dentists can post their individual works and create a platform for discussion by other experts. They can also create a page to showcase their dental clinic, the treatments available, post pictures of before and after treatment of a patient and also do live video treatments including a tooth cleaning or whitening procedure. This ability of facebook has transferred

it into a consistent network for use in different fields including educational purposes as well as a good marketing strategy. As indicated by study, utilization of social media routinely for sites like facebook and twitter is 85%.[9] Facebook applications are utilized by dental students for preparing objective structured clinical examinations (OSCEs).[9]

Twitter: In 2006, Twitter was established as a social networking site, where subscribers send "tweets," short messages of close to 140 characters, to their followers. Twitter has emerged as a microblogging site which enables health communication between the public and health professionals by the means of tweets. Twitter has recently been used for research and Public Health Surveillance on the basis of tweets regarding dental pain.[10] The inclusion of Twitter led to briefer yet substantive communications for medical students who can have discussion with patients, peers, and other health care professionals.[11] Twitter is used by dental and medical professionals to boost their presentations by posting real-time comments from the audience during a medical conference.

Wiki: A wiki is a knowledge-based website on which users collaboratively modify content and structure legitimately from the web browser. Wikipedia or the free online encyclopedia, is an example of a wiki. The accuracy of Wikipedia has always been a stress over many years, which thwarts the utilization of this website as a reference for, say, a peer-reviewed publication.[8] It was found in an investigation that Wikipedia had generally indistinguishable number of errors as Britannica, which is a conventional encyclopedia.[12] Wikis provide a platform for students to collaboratively create, discuss, edit articles on explicit subjects. Wikis help in spreading dental education by encouraging group and consistent review and also initiates the probability of occasionally expanding the content and activities, significant in a learning procedure. Curricular change in medical and dental education looks for more noteworthy fuse of the essential and clinical sciences. A Media Wiki was incorporated into a medical school by Philips et al. Based on a given diagnosis, students were approached to work in little gatherings to create a patient case. Based on their wiki contributions weekly inputs were given. This collective way to deal with learning helped them during their preclinical years by correlating anatomy to clinical diagnosis.[8]

Blogs: Blogs have become an informational website or web journal, available on the World Wide Web which comprises of discrete, often informal diary-style text entries (posts). Posts (perceptions, opinions, photographs, videos, and so forth., often with links to other sites) are usually displayed in reverse chronological order, so that the latest post shows up first, at the highest point of the web page. Dental blogs have been quite popular these days and they focus in creating awareness about various oral health issues and new treatment procedures. New dentists blog, Mouth healthy, Oral health foundation are some of them. Here, viewers can discuss the topic in depth and learn from each other.

Vlogs: These are video blogs or video recordings which have the comparable detriment of credibility and validity. Being an informative and interesting platform, it can also be used for educational purposes. Inevitably it impacts discussion among peers and helps them in learning from each other.

Youtube: Established in 1997, Youtube is a media where individuals upload and share videos. Dental professionals can post videos and tutorials regarding dental treatments, spread oral health awareness and campaign against tobacco use and its evil impacts. For instance, a channel on YouTube was operated by a Dental college student, Linh Phan, where she posted vlogs which provide viewers with her viewpoint on dental school life. [8,13] She likewise posted tutorials on creating interim restorations. Her channel also has posts on commentaries about the questions posted from the dental students around the world, the offered possible alternatives, or their appreciation of her efforts.[8,13]

Second Life: Second life is a virtual world created by a 3D environment utilized for social, creative, business and educational purposes. It acts as a means of distant education. Scenarios are created by dental educators by allowing students to interact with apprehensive, angry, or special needs "virtual" patients in an attractive, pretended environment.[8] Eventually, it gives students multiple scopes for diagnosis, treatment plan, caries risk assessment, conducting counselling for tobacco cessation, and so forth which will help to overcome their nervousness and improve their certainty before treating genuine patients.

RSS Feed: RSS signifies "rich site summary" or "really simple syndication". RSS channel is a list of notifications or up-to-date information that a website delivers to its users. It helps in accessing information

from favoured websites in in an advantageous and efficient way. The Dental section of MDLinx and, for patients, knowyourteeth.com from the Academy of General Dentistry are some examples of RSS feeds for dental professionals.[14,15]

Elgg: Being an open source social networking platform, Elgg is intended to associate learners and enable them to share resources. Structured essentially for educational applications which consolidates: blogs, social networking, wikis, filesharing, and so on. Subscribers can create and join the dental groups, have full access control, can import content and publish it to blog. In addition to this, they can also add various oral health presentations, documents or webpages and tag these pages. Elgg has turned into a fundamental stage for learning and joint efforts.

Mashups: Mashup is a combination of two or more data sources integrated into one source. It utilizes the RSS technology to allow students in creating "mashups" by merging and remixing information sources, like content, web applications and mixed media, at times for purposes, usually not planned by the original creators.[8,16] One such social networking platform which depends on RSS abilities is Yahoo! Pipes. Medical data sources and visual aids can be combined creatively by employing Mashup to enhance learning.[17]

Social Bookmarking: Social bookmarking can be used to store, sort out, search, and manage "bookmarks" of web pages. Users use a social bookmarking site, where they can save links to web pages that they like or want to share.[18] Scholastic papers in social bookmaking sites are enjoyable. For instance, suppose a dental professor or student finds a website to bookmark, he or she can right-click the site to add it to his or her account and then can "tag" it with a few relevant keywords (teeth whitening, cosmetic dental clinic, best cosmetic dentist). Graphics can also be used to make it more interesting. The list can be viewed by the public, so the individual can direct other peers to it. These sites additionally demonstrate who else bookmarked the site. Another tap demonstrates the bookmark accumulations of others interested in the similar site.[19] Through Social bookmarking academic collaboration is fostered by rearranging the distribution and sharing of reference lists, bibliographies, and different resources among educators and students.[8]

Crowdsourcing and Apomediation: Howe in 2006 gave the term Crowdsourcing, from the words "crowd" and "outsourcing", in which a large group collaborate to find a solution to a problem.[20] Yahoo Answers and Digg are websites which enables individuals to post their inquiries and get the appropriate responses namelessly. By crowdsourcing, problems are presented to public and open call for solutions is then made. The individual who contributes the solution is remunerated with a prize, money, or acknowledgement.[21] In case of Apomediation, the information is "apomediated" by peers is compared with that which is "intermediated" by specialists for the sake of layman. The site PatientsLikeMe is an example, in which patient's share their health information and opinions.[8]

Challenges in using Social Media: With all the rewards of social media, there are as yet numerous issues which should be dealt with. Medical research has analysed the potential challenges of social media in use of dental education. Considerations regarding management of legal and ethical issues is very essential. The HIPAA (Health Insurance Portability and Accountability Act) first used in the United States, is a security law which guarantees personal protection of health-related information about a person. Posting of patients' photos or some other recognizable data is an infringement of protection as indicated by this law. Other than this, another territory of concern is "content related". Posting of amateurish substance can be troublesome towards dental practice. There might be absence of value and unwavering quality and reliability of health information whenever posted by obscure sources. There are some glances where patient starts their own self-medication regime.

Different inquiries come into mind when we examine about the utilization of social media in health industry. Inquiries to consider: Are the dental students realizing how to actively set their privacy settings while using social media? Do they know about the possible disclosure of information they post? Do they know about the probable privacy status changes of the social media platform they use?

Conclusion

With the innovation of social media, the world has turned into a global village. This review article highlights on how social media has made dental health education reach a widespread audience as well as has made a way for dentists to boost their professional influence. Further research should be done regarding the lawful and moral

issues of using social media in dental practices. Dental educators should consider the rapid growth of social media usage and explore it as a platform for oral health education and promotion.

Immediate vs Delayed Implant Placement: A Review

Karishma Rathor[1], Sthitaprajna Lenka[2], Dharmashree Satyrup[3], Neelima Katti[4], Rucha Varu[5]

[1]Tutor, Department of Public Health Dentistry, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [4]Assistant Professor, Department of Periodontics, S.C.B Medical College, Cuttack, Odisha, [5]Private Consultant, Mumbai, Maharashtra, India

Abstract

In the era of new world dental implants replaces the removable partial dental and fixed partial denture. Dental implant can replace the single tooth to multiple tooth, after implant placement successful osseointegration is one of the important factors. Osseointegration is the process binding of bone with the implant surface. In this review article we discuss the two-implant placement technique and they are depending on time duration after the extraction of implant. Immediate implants are placed immediately after the tooth extraction with and without use bone graft. Delayed implants are placed after 3-4 months after the extraction of tooth. So, the main aim of the review paper was the predictability of success of immediate implant over delayed implant.

Keywords: *Dental Implants; Osseointegration; Bone graft; Immediate; Delayed.*

Introduction

In the year 1965, the first dental implant was placed by Sir Branemark the implant is composed of endosteal metal placed inpatient. The main benefit of immediate implant placement after extraction of tooth was to prevent second surgery, prevent bone loss due to extraction. The main benefit of the immediate implant was patient needn't wait for 4-6 months for wound heal and after that delayed implant placement. The various clinical trials found that after the implant placement in extraction socket with and without the use of bone graft have less bone loss after 6 months as compare to delayed implant placement. [1,2]

Other important advantage was chances of bone damage was less because of initial site preparation was not required, only the apical preparation was done with all the drill bit to extend the length to achieve the primary stability. In delayed implant, the flap was raised the bone is exposed and after that initial pilot drill was used followed by till the last drill till the site was ready for the implant placement, then after 6 months second stage surgery was performed. Bone remodeling around the implant was quicker because they are periodontic cells are present in the extraction socket, so they help in the faster new bone formation around the implant. [2-5]

Table 1. Classification based on time of implant placement as mature, recent, delayed or immediate

Author / Year	Classification	Implant placement
Hämmerle et al. (2004)	Type I	In fresh extraction sockets
	Type II	After soft tissue coverage (4- 8 weeks)
	Type III	Radiographic bone fill (12-16 weeks)
	Type IV	Healed socket (>16 weeks)
Esposito et al. (2006)	Immediate	In fresh extraction sockets
	Immediate-delayed	< 8 weeks post extraction
	Delayed	> 8 weeks post extraction

Healing after implant placement: Healing after the extraction undergoes both hard and soft tissues changes; they are dependent on each other. Loss of gingival contour and architecture of bone immediately after the extraction socket, subsequent changes include the maturation of the wound which induces the formation and calcification of the bony material.[6,7]

During the first stage clot formation, which consist of red coagulum, fibrin, inflammatory cells after 4-5 days coagulum is replaced by granulation tissue over a in

Corresponding Author:
Dr. Sthitaprajna Lenka
Professor, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail:sthitaprajnalenka@gmail.com

second stage. After 2-week period, the granulation tissue contracts and is replaced by connective tissue in third stage. Calcification ofosteoid at the base and periphery of the socket commences in fourth stage.[8-10]

This formation of bony trabeculae continues for about 6 weeks and is followed by the fifth stage, in which there is complete epithelial closure of the socket.[11]

Once the tooth has been extracted the alveolar bone underwent coupling mechanism leads to new bone formation with loss of vertical height and reduced gingival tissue especially if it is of a thin biotype. [12-16]

Macroscopically level, the healing pattern will change both hard and soft tissue. In various study bone loss was seen in buccolingual dimension, it led to 3-4 mm of bone loss over period of 6-12 month though most of the reduction takes place in the first 4 months. In area of molar more resorption was seen as compare to single rooted tooth.[17,18]

Other factors can cause further bone resorption areinjury to the alveolus, pathology caused by any infective process, such as periodontal and endodontic abscesses, cysts, and tumors, Systemic conditions which may induce further bone loss include genetic factor, diabetes, smoking, and medication use.[19]

Classical protocol for implant placement: After 8-12 months of extraction the edentulous site was healed and this was the waiting period was thought to be essential for socket ossification and bone maturation. After all radiographic examination implant was placed in the desired site in bone and cover with soft tissue, after 4-6 months patient recalled for second stage surgery. 4-6 months are needed to osteointegration of implant with bone.If the surgeon follows all the guide lines the time total time period from initial implant to loading of implant was one year. [20-22]

Discussion

Several studies have been undertaken to prove the reliability and success of immediate implant placement. Healing in post extraction sites is characterized by bone regeneration within the socket and external dimensional changes due to bone resorption and bone modelling. The extraction socket wound heals by the following stages namely osteophyllic, osteoconductive and osteoadaptive phases. Indication for immediate implant areminimal bone loss around the dental, loss of tooth due to periapical infection, The tooth which cannot be saved by the endodontic therapy, pts with chronic periodontal problems. Contraindications are pus exudates at the time of exodotia, Periapical presence of granulation tissue, no adequate bone at apical to the extraction socket.[23-26]

In study done by Becker et al done immediate implant case in 24 patients and they found that 93.3% of 5-year success rate and non-significant amount of crestal bone loss when they were augmented with barrier membranes. [27]

Misch and Judy, 2000 done a study on delayed implant placements they found out that after extraction in some case there are chance of buccal or facial cortical plate is lost during extraction it leads to reduced bone height and thickness for implant placement after the socket heals thereby bone height and width are reduced forcing the operator to compromise with the size and width of the delayed implant to be placement. Studies have revealed that crestal bone loss is evident in both delayed and immediate implant placements. But in case of immediate implant placement the crestal bone loss was found to be less.[28-30]

Conclusion

Immediate implant placement following tooth extraction has been found to be viable and predictable solution to tooth loss. Patients can now avail the immediate implant placement after extraction of the teeth in the socket immediately without any need to wait for few months for the socket to heal and the bone to be formed. This leads to quicker loading of the implants and restoring the lost teeth. One more advantage of immediate implant over delayed is the crestal bone loss was found to be minimal. Hence immediate placement of implant is better when compared to the delayed implant placement.

Oral Manifestations of Gastro-Intestinal Diseases and Nutritional Deficiency

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

It is an established fact that the oral cavity is the diagnostic indicator to many gastro-intestinal diseases and nutritional deficiencies. Among the most frequently encountered gastro-intestinal diseases are inflammatory diseases like Crohns disease and chronic ulcerative colitis, gastro-intestinal reflux disease and dental erosion. Nutritional diseases manifest as pale, depapillated bald tongue, diffuse erythema in the oral mucosa and oral bleeding. This paper presents an overview to the different manifestations of nutritional deficiencies and gastro-intestinal diseases.

Keywords: *Stomatitis, Glossitis, Perimolysis, Ulcerative Colitis.*

Introduction

When a patient report to a physician for any disease, irrespective of the systemic disease, the oral cavity and tongue is examined first and serves as a diagnostic aid for detection of nutritional deficiency and gastro-intestinal diseases. Starting from stomatitis, dental erosion from hyperacidity, melanosis, ulcers and polyps to hyperkeratosis in the oral mucosa, a plethora of clinical manifestations are observed. [1] The present paper describes these conditions briefly on the basis of their oral features.

Gastric disturbances: Patient may have white coating, which is easily scrapable in the dorsum of the tongue. If it occurs suddenly, associated with bad taste, it is due to acute temperature of the body. The fever may be due to several causes. The white coating suggests that the patient has gastric and gastro intestinal problems.[2]

Hyperacidity in the stomach: The patient will have destruction of tooth in the cervical one third of labial and buccal surfaces. This is called 'erosion". The erosion may be due to acidity in the gingival fluid or regurgitation of acids due to hyperacidity of stomach. Thus, the presence of erosion in the teeth suggests that the patient is having hyperacidity in the stomach. [3,4]

Jaundice: The patient may have green discoloration of teeth either in deciduous or permanent teeth. This suggests that the patient had jaundice or liver disease, bilirubin and biliverdin are formed and they circulate in the blood. These are coloring agents and are pigments. When they circulate in the blood, they reach in the pulp & deposit in the pulp of the tooth from there it enters into dentinal tubules.[4] Thus green colour of tooth is suggestive of liver disease or jaundice.

Peutz–Jegher's syndrome: The patient will have small, spotted, brown or brownish black pigments in the circum oral region. This is melanin pigment. This suggests that it is related to 'Intestinal Polyposis', in a disease called "Peutz–Jeger's" Syndrome. In this syndrome, there is intestinal polyposis, colic pain, and bleeding from rectum. The exact mechanism, why pigmentation occurs in polyposis is not known, but the clinical sign of circumoral pigmentation suggests diagnosing the intestinal disease called Peutz–Jeger's syndrome.[3]

Crohn's disease: The patient may develop, inside the mouth, small granulomatous growth or nodules with fissuring which appear as mucosal indurated polypoid tags in the shape of cobblestone. [5]Sometimes ulceration may also be associated. This clinical sign is suggestive that the patient is having 'crohn's disease. Linear apthous ulceration with hyperplastic borders, indurated fissures on the midline of lower lip, angular cheilitis and glossitis due to malabsorption and symptoms of nutritional deficiency are present. Granulomatous changes of minor salivary gland duct with increased incidence of mucocele.

[6] Oral lesions vary in duration and severity with periods of quiescence or exacerbations. In crohn's disease, the patient will have abdominal pain due to inflammation of intestinal mucosa and colon. This will be associated with rectal bleeding. These symptoms will occur in a number of intestinal diseases, but if it is associated with characteristic mucosal growth, it is due to Crohn's disease. Thus, granulomatous growth of mucosal tags in the oral cavity is a diagnostic point to diagnose Crohn's disease, which is a chronic granulomatous inflammatory disease of bowel affecting ileocaecal region.[7]

Ulcerative colitis: Patient may develop ulceration in the lip commonly or in other parts of the mucosa. The ulceration is diffuse, chronic with broad based papillary projection are red or pink in color and associated with purulent material and the ulcer will have some superficial necrosis. This is called 'Pyostomatitis Vegetans' and this suggests that the patient is having 'ulcerative colitis. [8]Hemorrhagic ulcers of oral mucosa and skin which starts as bullae in one to three days and ruptures to form ulcers, which are discrete and irregular shaped. Gingival bleeding due to malabsorption of vitamin k, vitamin B12 and folic acid. Minute miliary abscess and pustules on an erythematous base which rupture leading to erosions. In ulcerative colitis the patient will have ulcers of colon and bleeding from the rectum. It is an autoimmune disease.[9]

The reason why ulcerative colitis causes pyostomatitis vegetans not known but the pyostomatitis vegetans will heal only when ulcerative colitis is treated.

Coeliac disease: In some patients, recurrent apthous ulceration of oral mucosa, dental hypoplasia associated with sore tongue are present and if these oral findings are associated with steatorrhoea, abdominal discomfort, weight loss and symptoms of nutritional deficiency, then the condition may be diagnosed as Coeliac disease. Coeliac disease is a malabsorptive disorder of small intestine due to immunological reaction to gluten resulting in mucosal damage.[10,11]

Liver disorders: Bleeding tendency following minor injury, gingival bleeding andpost extraction haemorrhage are seen in some cases. In these patients there may be deficiency of coagulation factors II (Prothrombin), V, VII, IX, X which requires normal hepatic function and adequate supply of vitamin K for its synthesis and maturation. Increased bleeding tendency associated with elevation of prothrombin time are suggestive features of liver disorders in which normal lobular architecture is destroyed due to cirrhosis or hepatotoxic drugs.[8,9] Sialdenosis in liver cirrhosis due to alcohol or malnutrition is the common oral finding and is a reversible condition which regresses and disappears during recovery. [11]

Nutritional deficiency disorders

Vitamin A: Non-scrapable whitish Grey patch, which is not attributable to any other diagnosable condition particularly in elderly people, is a clinical sign of vitamin A deficiency. White patch can occur in oral cavity in many conditions like leukoplakia, lichen planus etc. but if the lesion is not specific to any disease, this white patch is to be thought as Vitamin A deficiency.[12] Vitamin A is necessary to maintain the integrity of epithelium and it helps for normal proliferation and exfoliation of epithelial cells. If there is reduction, the epithelial cells fail to exfoliate and the epithelial cells are retained and form keratin. This keratin in the oral mucosa, with logging of water molecules, is responsible for white patch of keratinisation, in the absence of any other specific diseases responsible for white lesion.[13]

Vitamin B complex: Atrophic glossitis and angular cheilitis is a clinical sign of vitamin-B complex deficiency.Vitamin B complex consists of thiamine, riboflavin, niacin, pyridoxine, pantothenic acid, biotin, folic and vitamin B12. Though different Vitamins have different manifestations, the common changes for vitamin B-complex are Atrophic glossitis and Angular stomatitis.

Vitamin C: The gingiva is enlarged, bright red in colour, smooth and shiny surface, boggy in nature with mild ulceration and bleeding. The colour changes to violaceous red. The enlarged gingiva may cover the clinical crown. This condition is called as "Scorbutic Gingivitis". This clinical sign of oral cavity is suggestive of Vitamin C deficiency. Vitamin C is essential for many metabolic activities, but the one important thing is that it is necessary for maintenance of the intercellular ground substance. Since the intercellular ground substance of blood vessels are damaged, there will be bleeding.[13]

Vitamin D: Clinically a localized area with deficient enamel with destruction and brown color discoloration, is a clinical sign that the patient has "Rickets".Vitamin D deficiency produces Rickets in young age. Vitamin D is essential for calcium and if it is not absorbed fully because of Vitamin D deficiency, calcification of tooth and bone is affected. When tooth

is developing, the enamel is laid down layer by layer. During the development of tooth, if calcium is deficient in a particular period, the enamel developing at that time is affected with improper calcification. Hence the defect occurs, change in the tooth could be a marker to diagnose Rickets.[9-12]

Vitamin K: Bleeding gums is one of the clinical signs that indicates many diseases, and one such diseases is vitamin K deficiency.Vitamin k plays an important role in synthesis of prothrombin in liver. Prothrombin plays an important role in coagulation. Vitamin k is responsible for prothrombin synthesis when vitamin K is deficient prothrombin is deficient in the liver and even if there is a mild injury, it causes bleeding which takes long time for coagulation.[12]

Protein deficiency: If the child has a bright reddened tongue with loss of papillae, bilateral angular cheilosis, fissuring of the lips, loss of circumoral pigmentation and the mouth is dry, dental caries free and easily traumatized with the epithelium readily becoming detached from the underlying tissue, leaving a raw bleeding surface, then these oral signs are indicative that the patient is suffering from "Kwashiorkor', a combined protein–energy deficiency in children.

Proteins contribute to cell and intercellular materials and are important in the formation of hormones, enzymes, plasma proteins antibodies and numerous other physiologically active substances.The presence of macroglossia in a patient may be suggestive of 'Amyloidosis'. The tongue is enlarged due to deposition of amyloid. It may also be deposited in gingival tissues.[13]

Conclusion

An alert oral physician/ dentist with adequate knowledge regarding the different systemic diseases can diagnose gastro-intestinal diseases and nutritional deficiencies.

Submandibular Osteoma-Bony growth in the Lower Border of Body of Mandible: A Case Report

Rajat Panigrahi[1], Abhishek Ranjan Pati[1], Sanat Kumar Bhuyan[2], Satya Ranjan Misra[3], Smita R. Priyadarshini[1], Basanta Kumar Choudhury[4]

[1]Reader, [2]Professor, [3]Professor & Head, [4]Senior Lecturer, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha India

Abstract

Osteoma is a benign slow growing tumour which commonly occurs in craniofacial bones. These tumoursoccur mainly due to proliferation of cancellous bone. It can be of peripheral, central or extra-skeletal type. In peripheral type which is described in this case report arises from the periosteom and is a very rare occurrence in the mandible. Osteomas are usually asymptomatic and can interfere with the aesthetics if they continue to grow to a larger size. These lesions are mostly discovered during routine clinical or in radiographs. Here we discuss a single large peripheral osteoma which arise from the right lower border of the mandibular body in a 50 yr old woman. This lesion caused a deformity of the facial region. Radiographic examination including IOPA, OPG and lateral oblique revealed a solitary radiopaque bony neoplasm. Incisional biopsy of the lesion confirmed the diagnosis to be an osteoma.

Keywords: *Peripheral Osteoma, Mandible, Benign Bony Neoplasm.*

Introduction

Osteoma is a benign osteogenic lesion manifesting from compact or cancellous bone. These can be classified into three types according to their origin. a) Central osteoma originates from endosteum b) peripheral from periosteum c) extra skeletal osteoma develops from the soft tissue. Peripheral osteoma is a rare lesion seen mostly in younger age group and both the genders are equally affected. This lesion mostly affects the frontal bone, mandible and maxillary sinuses are affected in orofacial region.[1]

In mandible dense peripheral osteoma is very common rather than cancellous osteoma.[6] The pathogenesis of osteoma is still to be confirmed but they are often referred to as developmental anomaly, tumor or reactive lesions triggered by trauma, muscular origin or infection.[7] Various etiopathogenic hypothesis have been proposed for osteoma formation which includes that lesion is caused by congenital anomalies or by neoplastic proliferation caused by chronic inflammation.[8]

We report here an unusual case of peripheral osteoma present in the lower border of the body of mandible with extra oral growth

Case report: A female patient,50 year,gave chief complaint of swelling in the right lower jaw. The history revealed that the patient discovered a slow growing swelling on right lower side of face since 5 years with no history of trauma, toothache, pain or discharge from the swelling. The past medical, surgical, dental, personal and family history was non-contributory

On extra oral examination a single unilateral swelling was present in the right side of the lower border of the body of mandible. The swelling measured 2cm x 1cm in diameter. The shape of the swelling was roughly ovoid with smooth surface and no changes in the overlying skin. The swelling extended 2cm from the lower border of the mandible. There were no secondary changes associated with the growth. (Figure 1)

Corresponding Author:
Dr. Rajat Panigrahi

e-mail: emaildrrajat@gmail.com

The inspector findings of site, size and shape were confirmed. On palpation the swelling bony hard in consistency with smooth diffused edges. The swelling did not yield to pressure. The swelling was not attached to the overlying skin. The swelling was not movable below the skin suggesting that it is attached to the underlying mandibular bone.

On intra oral examination there was no evidence of any bony growth or swelling in the buccal or lingual aspect of right side of mandible. Root stumps are present in relation to 45 46 47 48. No other mucosal changes were associated on the buccal or lingual aspect in corresponding to the extra oral growth. (Figure 2)

Co-relating all the history and clinical features a provisional diagnosis of benign bony neoplasm was given & differential diagnosis of central haemangioma, bony exostosis, osteoid osteoma, osteoblastoma and osteoma was considered.

Intra oral periapical radiograph taken with increased vertical angulation revealed a single well defined radiopacity present in the lower border of mandible in relation to 36 37 regions (FIGURE 3). Lateral oblique mandible revealed a radiopaque lesion present in the lower margin of the body of mandible. The lesion was attached to the cortical bone ofinferior border of the body of mandible (FIGURE 4). The panoramic radiograph revealed a single well circumscribed radiopaque mass present below the lower margin of the mandibular canal (Figure 5).

Incisional biopsy of the lesion was to be done under local anaesthesia and the specimen collected was sent for histopathological review and diagnosis. The report presented normal appearing dense compact bone with features suggestive of osteoma with missing haversian systems (Figure 6).

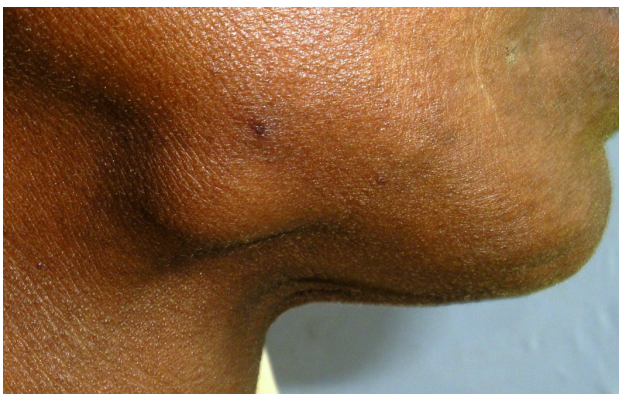

Figure 1: Extra oral manifestation of osteoma

Figure 2: Intra oral picture showing normal overlying mucosa.

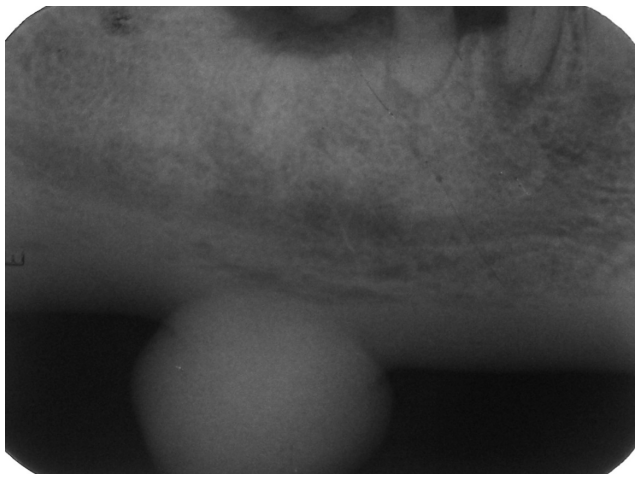

Figure 3: Intra Oral Periapical Radiograph revealing radiopaque lesion in the lower border of mandible.

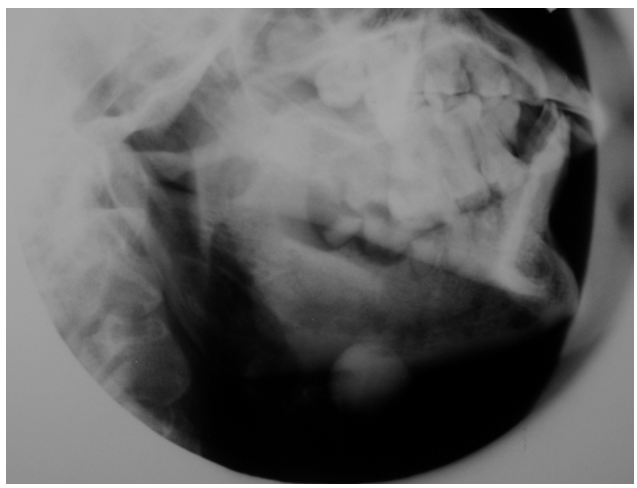

Figure 4. Lateral Oblique shows the lesion being present in the lower border of body of mandible.

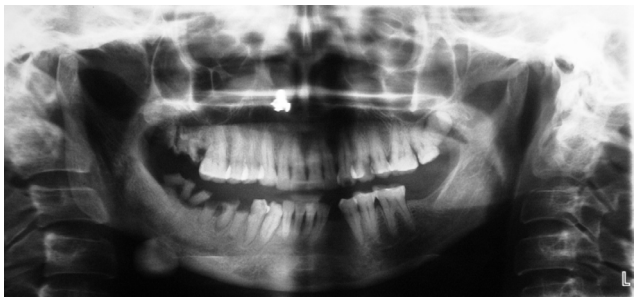

Figure 5. Oral Panoramic Radiograph showing the radiopaque lesion in the right-side body of mandible.

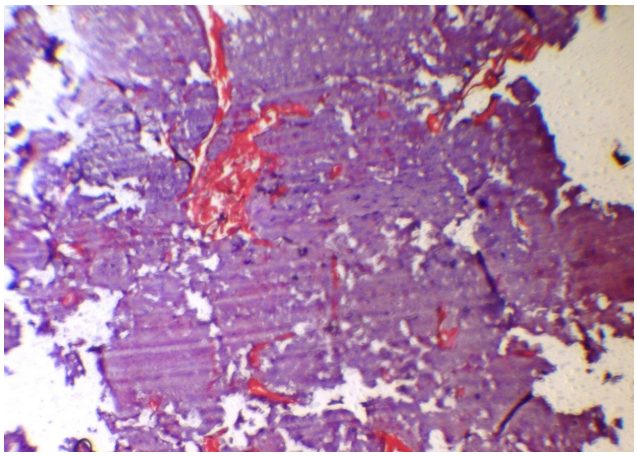

Figure 6. Photomicrograph shows normal appearing dense compact bone with features suggestive of osteoma with missing haversian systems. Mass of irregular osteoid tissues that lie in a highly vascular stroma of connective tissue containing osteoblastic cells. It consists of irregular lacelike osteoid and calcified matrix lined by plump osteoblasts and osteoclasts with a well-vascularized but bland stroma. Densely packed atypical bony trabeculae with decreased vascularity and stroma.

Discussion

The peripheral osteomas are very rareumors. According to Schneider et al, Kaplan et al, Woldenberg et al(2005), Jonan et al(2005), Cincik et al(2005) and Larrea / Oyarbide et al the region affected frequently is mandible. But in the maxillofacial region peripheral osteoma is most commonly reported in frontal bone followed by mandible and maxilla as reported by Sayan et al.According to Bodner et al peripheral osteoma mostly occurs in paranasal sinus. They are observed that they are very uncommon to be found in mandible. On analysing the reported cases of osteomas of mandible in literature it is widely agreed that the most affected region is the body of mandible.

Radiographically, osteomas show a well circumscribed densely sclerotic radiopaque mass. Peripheral osteomas should be separated from several pathologic conditions such as bony exostosis, osteoblastoma, osteoid osteoma and complex odontoma. The most important clinical feature differentiating bony exostosis and osteoma is that bony excrescences that usually stops growing after the individual crosses the puberty period. Osteoblastomas and osteoid osteomas are painful and fast growingtumors as compared to peripheral osteomas. Reappearance of peripheral osteoma after surgical removal is very rare and the diagnosticians should look for new osteomas or other signs of Gardner syndrome, which was also considered in this case, as the OPG revealed many mixed radiopaque and radiolucent areas which were present on both sides of mandible. Histologically, osteomas consists of dense compact bone with no haversian system.

Conclusion

Osteomas are the type of tumors that grows very slow. Once completely removed there is no evidence of recurrence. In the Orofacial region tumors like osteoma frequently occurs in the mandible. Conventional radiographic analysis provides adequate information for diagnosis. Recently due to availability of CT scan it has become the choice for accurate diagnostic evaluation. This has truly enhanced the surgical planning for tumor resection. The choice of treatment of the lesion is complete surgical removal.

Oral Health Promotion Through Schools

Upasana Dhar[1], Ramesh Nagarajappa[2], Dharmashree Satyarup[3], Marlin Jena[1], Abhilash Mohapatra[4]

[1]Post Graduate Trainee, [2]Professor and Head, [3]Professor, Department of Public Health Dentistry, [5]Professor, Department of Prosthodontics Crown Bridge and Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A combined education, promotion, and preventive program in the school would enormously diminish the predominance of prevalent oral diseases like dental caries and gingivitis seen in children and young adolescents. Comprehensive school programs also would preclude the loss of study time due to pain and apprehension before and after treatment. Need of the hour is to develop the best projects for promoting oral wellbeing in schools with emphasis on school-based facilities. The essential objective of school oral health promotion programs centers around the 3 M's-manpower, money, material, in addition to the amount of classroom time it will take from conventional classroom education.

Keywords: *Health education, oral hygiene, oral health, school children, school health programs.*

Introduction

Healthy teeth, gums, soft tissues inside mouth cavity, muscles mastication, tongue, lips, associated glands of oral cavity will be a necessary part of oral health.[1]A healthy mouth is indispensable for an overall development of an individual,so that they can eat, communicate, and socialize without experiencing diseases, discomfort, or embarrassment.

Dental caries is found to be predominant early childhood oral health issues along with gingivitis, trauma, malocclusion, asthma, diabetes, and obesity. Early diagnosis always prevents oral health issues at the earliest. In India, the prevalence of dental caries was 32.6% and 42.2% at 12 and 15 respectively, gingivitis was 84.37%, and malocclusion was 60%.[2] In Odisha, the prevalence of dental caries was 64.3% for school children.[3]The prevalence of other oral diseases such as dental erosion and enamel defects is increasing. As per the data in Odisha, there is a very little knowledge regarding the causes and prevention of oral diseases in children, their parents, and teachers.[4]

According to the accessible information it is significant for us to concentrate on oral health problems from the early age. The Ottawa Charter for Health Promotion[1] outlined five health promotion action are as build healthy public policy, create supportive environments, strengthen community action, develop personal skills and reorient health services.

Oral Health Promotion needs in Schools: Mouth diseases will cause discomfort and tooth loss, this has a negative effect on appearance, personal satisfaction, food intake and, eventually the growth and complete development of children. Tooth caries and gingiva diseases are among the most common diseases conditions in current scenario, predominantly influencing school children. Many children have encountered mouth trauma, a considerable part who are younger than 5 years.[4] Tobacco containing stuffs are advertised directly at children and adolescents, which leads to augmented risk of oral cancers in later life.[5]Oral disease is perhaps the costliest diets and lifestyle related illnesses, and the expense of neglect is additionally high in terms of its financial, social and personal impacts.[6] Many risk behaviors start from the school age years that have heavy influence on children's development and wellbeing.

Dental Caries Prevention: Dental caries is the most prevalent chronic disease condition, which leads to suffering of a child with severe pain, and if left untreated, the diseases may prompt further exaggerated conditions including sepsis. Dental caries can be prevented through fluorides, pit and fissure sealants, diet and nutrition.

Fluoride: Fluoride is the foundation of preventing dental caries. School water fluoridation program positively influenced oral health of children and adolescents. However, it has some major drawbacks that it will not be beneficial for the children until they begin school, school ought to have independent water supply, installation and maintenance cost of equipment is high, training should be given to the workers who will operate, monitor, and maintain the fluoridation unit.

The school-based fluoride mouth rinse program is an important tool to reduce dental caries among children. In 1970, the North Carolina Dental Society conducted an examination for school and community fluoridation, the outcomes were 34% reduction in decayed, missing, and filled permanent teeth among children who had 8 years' experience for taking fluoridated water at school for drinking purpose, and furthermore 86% decrease in dental cavities following 4 years of sealant use on permanent teeth.[7] Fluoride mouth rinse prevents dental caries when used consistently in a school based program and are recommended for children >6 years of age. Weekly mouth rinsing (0.2% sodium fluoride (900 ppm F) for weekly use or 0.05% sodium fluoride (225 ppm F) for daily use) under the supervision of school teachers is accomplished for good outcomes. Dietary fluoride intake in the form of tablets should be administered in school settings. Dietary fluoride supplements when administered from birth to age 13 or 16 years provides caries reductions of 60% to 65%.[7] Fluoride tablet program can also be implemented in which one tablet is given to each student, that they chew and swishes the tablet in the mouth for a minute and then swallow.

Pit and Fissure Sealants: The Pit and Fissure sealants are efficient and safe means of preventing dental caries in newly erupted permanent teeth. For children at high risk for tooth decay, those with ailments related with high rates of cavities, in those who have experienced nursing bottle caries, and who already have initial caries in a permanent molar tooth, this treatment is useful. School based sealant programs will help in reaching to all strata of youngsters and in a mass. Long term assessment studies on school health program have reported reduced decayed, missing and filled surfaces (DMFS), which demonstrated that dental sealants, when used in combination with fluoride mouth rinse, were especially effective in lowering the prevalence of dental caries.[8]The surgeons general's report on oral health indicates that sealants can reduce decay in school children by more than 70%.[9]

Nutrition: Healthy food habits are significant lifestyle habits that should be inculcated at the earliest age and in health promoting schools program it should be included.[10] Ministry of Education takes care of school nourishment services by taking the help of public or private sectors, which is important for schools, teachers, and student.[11],[12] Parents of children should consistently attempt to give them a balanced diet. Sugar consumption in food should be tallied. The nutritional survey (1995)of British preschool children demonstrated that the consumption of non-milk extrinsic sugars (NMES) was essentially higher (19%) than the recommended 10% level. The main sources of NMES in British children are the soft drinks and confectionery. [13] Mid-Day meal Program of Government of India, it provides hot cooked meal to students of Government schools in 7 north eastern districts.

Prevention of Periodontal Disease: Gingivitis is the most widely recognized oral disease. While the disease is to a great extent reversible in nature, it can develop in vulnerable hosts into periodontitis, which is characterized by irreversible loss of periodontal attachment.[14]

Toothbrushing: For students to pick up brushing technique appropriately it is smarter to execute a classroom brushing program. This program will develop a standard toothbrushing habit, which will eventually provide topical application of fluoride through toothpaste to the teeth to decrease the chance of tooth cavities in children. 'The Bright Smiles, the Bright Future' is an awareness program started by IDA and Colgate in partnership in July 2003, focusing on 45lakhs school children across India. It has been routine to distribute "Colgate paste and brush" free to teachers and school children, shown as an activity of state or local IDA branch for teachers training and advancement of oral health.[13]

Plaque control: The formation of plaque is the major cause of all dental problems. Dental plaque is a biofilm or mass of bacteria that develops on the

tooth surface inside the mouth. 'Learning about your oral health' is an extensive program developed by 'American Dental Association' (ADA) and their experts in coordination with the 1971 ADA House of Delegates and is presently accessible to schools' frameworks all through the United States of America. This program is created with a fundamental aim of developing adequate dexterity and knowledge about dental plaque among school children. [13].

Health Education: Health education empowers students to acquire knowledge regarding healthy lifestyle with the goal that they can be advantageous for themselves and the general public on larger scale. Redmond and colleagues examined a school dental health education program among 12-year-old English children in 1999, which included three exercises and discussion in each half yearly period by dental assistants with the support of parents/guardians. The knowledge of dental disease and in oral hygiene improved after this interventions, as well as an increase in the reported duration of tooth brushing.[15] The definitive aim of health education is to enable them to acquire knowledge and to develop critical skills, and thereby to adopt behaviors that will support their future health, by improving their levels of autonomy and responsibility. 'Blanket' referral is a program that can be implemented in India, where they are provided with a referral card that they take to their parents and then to the dentist, who sign the cards upon completion of examination, treatment, or both.

Malocclusion: When there is a discrepancy in the jaw and tooth size (the jaw is too small or the teeth are too large for the jaw to accommodate them in proper alignment) Kumar et al, found in his study that an incredible and dire requirement for orthodontic treatment, oral hygiene aspects must be contemplated. Preventive programs and early treatment of caries are as yet the best method of reducing high prevalence of malocclusion traits, particularly crowding.[16]

Preventive Dentistry in sports: These days, there is an increase in the death due to accidental injuries or sports injuries. The head, neck and mouth region are prone to get affected in sports injuries, playground injuries and road traffic accidents, injuries like avulsion, fracture also occur. As this may affect a child psychology in the growing period it is essential to make them aware regarding the prevention and treatment of such cases. As schools are the major public institution where these mishaps happen, making teachers and students aware, helps society as a whole.

Masochistic Habits: Any repetitive action being done automatically is called habit.[17] Stimulation of mouth with tongue, finger or nails is a source of relief in passion and anxiety in children.[18] Mostly the oral habits found in children are digit sucking, cheek/nails/lip/pencil biting, mouth breathing, tongue thrusting, bruxism. The resulting impact of an oral habit is dependent on the onset, duration, and nature of the habit.[19]

Tobacco avoidance and cessation: Disuse of tobacco is the number one preventable cause of disease and death. Schools that effectively advance tobacco free living make a strong statement that tobacco use is not acceptable. Tobacco free school area support the message students receive in the classrooms, creating no conflict between what is educated and what is experienced in the rest of the school environment. Dental specialist should be appointed through government for school health programs to give lectures regarding oral health, oral hygiene, plaque control, oral and dental diseases,topical fluoride application,oral cancer or smoke and smokeless tobacco habits and hazards counseling. For class promotion both physical and oral health fitness should be made compulsory. In 1980s WHO began a program,"Health Promoting Schools"wherein oral health education are included in primary schools curriculum.[16,17] In 2010-2011, Archdiocesan Board of Education in a rural and coastal areas of Goa implemented a revised school health promotion program in four schools, while another, nine rural schools were also brought under its wing through the Manthan project.[22]

Conclusion

For maintaining a healthy lifestyle, it is important to have knowledge regarding oral health and habits from childhood, for this purpose school dental health programs are one part of total dental public health programs and should be associated to different projects of prevention and education beyond what many would consider possible. Programs main objective is to take care of oral health of school children as they are the most significant casualties of dental diseases, thus promoting oral health of the community. WHO and UNESCO are launching new activity "Making Every School a Health Promoting School" in collaboration with their UN entities and civil society association through the development and promotion of Global standards for

Health Promoting Schools. The program will serve over 2.3 billion school age children, and will contribute to the WHO's 13th General Programme of Work target of achieving "1 billion lives made healthier" by 2023.

Central Odontogenic Fibroma Coexisting with Inflammatory Odontogenic Cyst: The Second Case Report

Swagatika Panda[1], Saswati Sidharatha[2], Neeta Mohanty[3]

[1]Professor, [2]Former Post Graduate Student, [3]Professor & Head, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

This report has described a case of central odontogenic fibroma coexisting with inflammatory odontogenic cyst for the second time in the literature. The case describes a 48-year-old female presented with swelling and intermittent pain in the upper left posterior teeth region. Mobile maxillary left second premolarwas found to be associated with a well-defined unilocular radiolucency and root resorption. Histopathology showed collagenous connective tissue and odontogenic epithelial cells arranged in the form of nests and cords. Along with the conventional features of central odontogenic fibroma an inflammatory cyst was also found. Therefore, the case of central odontogenic fibroma coexisting with inflammatory odontogenic cyst shall be discussed in this report highlighting the possible aetiopathogenesis and prognosis of such lesions.

Keywords: *Odontogenic fibroma, Central Odontogenic fibroma.*

Introduction

Central odontogenic fibroma is a benign fibroblastic neoplasm characterised by nests and islands of odontogenic epithelial cells interspersed in highly cellular fibrocollagenous connective tissue.[1] The odontogenic epithelial cells are usually inactive. Odontogenic cyst may be divided into inflammatory and developmental odontogenic cyst. Presence of inflammatory cells and source of the cysts make any odontogenic cyst as inflammatory. Although central odontogenic fibroma and inflammatory odontogenic cyst individually have been reported several times in the literature coexistence of these two entities has been reported by.[2] This case shall be the second such case to report.

Case Report: A 48-year-old woman visited us with a chief complain of intermittent pain and loose tooth in the upper left side of the jaw. IOPA revealed presence of a unilocular radiolucency measuring 3x2 cm extending from the root zone of left maxillary first premolar to left maxillary second premolar approximating the maxillary sinus (Figure 1). Root resorption in relation to 25 was seen (Figure 2). Both 24 and 25 were extracted under local anesthesia and the lesion was excised. Upon macroscopic evaluations the two formalin fixed tissues, white in colour and rubbery in consistency were received.

The haematoxylin and eosin stained sections showed two bits. One bit showed stratified squamous epithelial lining proliferating as arcading pattern into the connective tissue wall (Figure 3). Connective tissue wall is diffusely infiltrated with dense collection of chronic inflammatory cells.

Another bit showed (Figure 4) an unencapsulated lesion comprising of bundles of collagenous connective tissue many of which were arranged in parallel bundles. Rests of odontogenic epithelial cells were arranged in the form of nests and cords and are seen throughout the lesional tissue. Focal dense collection of chronic inflammatory cells was seen in the tissue.

Fig 1: Radiographic Findings–Unilocular radiolucency in relation to the root apex of 24 and 25. Root resorption in relation to 25 seen.

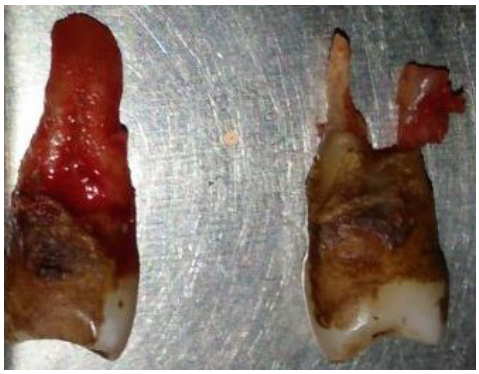

Fig 2: Extracted teeth with resorbed roots

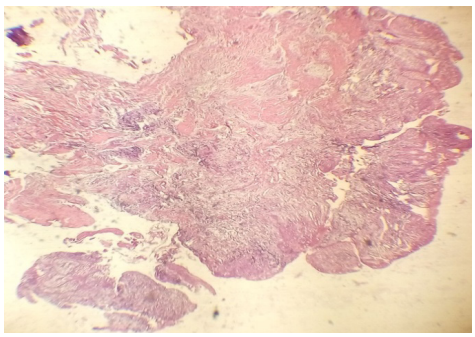

Fig 3: Hematoxylin eosin stain section of tissue is showing arcading pattern of epithelial lining supported by inflamed connective tissue wall (4X view)

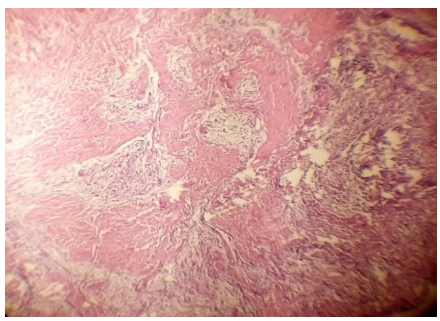

Fig 4: Haematoxylin eosin stain section of tissue is showing nests of odontogenic epithelial cells (10x view)

Discussion

Central odontogenic fibroma is an unusual odontogenic neoplasm simulating endodontic lesions and other odontogenic neoplasms.[3,4]. Wisley has suggested a group of clinical, radiological and histopathological criteria to diagnose odontogenic firbroma.[5] Clinical criteria include a gnathic location, persistent growth which results in painless cortical expansion. Radiological features include large multilocular radiolucent lesions occasionally associated with impacted/unerupted teeth. Histopathological features include presence of nests of inactive odontogenic epithelial cells in a mature cellular fibrocollagenous tissue. Wisley's criteria also includes that the lesion responds to surgical enucleation and having no tendency for malignant transformation. Further Gardener has classified COF into three groups. First being the hyperplastic dental follicle second is the Simple type COF having nests of odontogenic epithelium in collagenous connective tissue stroma.[6] Third variant is WHO type having nests of odontogenic epithelium along with dysplastic dentine or cementum like calcifications. The observation of extremely dense collagen stroma with variable amount of odontogenic epithelial nests, numerous dystrophic calcifications and central location has confirmed the WHO type of COF. The presence of diffusely arranged dense chronic inflammatory cells in the connective tissue wall supported by a cystic epithelium in another bit has suggested the cystic nature of the tissue. Consistent with the previous report the diagnosis of COF coexisting with inflammatory odontogenic cyst was given. COF is considered to be an aggressive neoplasm.[2]

The primary hypothesis to explain this coexistence may explain the possibility of a collision tumour. However, cyst and tumour occurring synchronously is an ill-explained concept. Therefore, the second hypothesis may suggest that the cyst must have been the primary lesion that stimulated COF development. The presence of an inflammatory infiltrate in the cyst may provide growth factors which induce the proliferation of odontogenic epithelial cells and consequently form COF. This suggests the presence of a cyst prior to COF. The third hypothesis may assume that COF growing excessively may undergo cystic degeneration at few areas leading to occurrence of inflamed odontogenic cyst. However, the small size of the lesion may preclude this possibility.

The five cases of tumour recurrences described in the literature appear to have no common features that

would allow the definition of an aggressive pattern of the predilection of recurrence. However preoperative histological diagnostic error and inadequate surgical technique have been the two most common factors for the possible cause of recurrence. Prognosis of all such coexisting lesions needs to be explored through follow up of such patients.

Variable number of mast cells, myofibroblasts and Langerhans's cells are found in histopathology of COF.[7] Numerous stellate plump pleomorphic fibroblasts are also reported by Gunhan.[8]. Several times COF has been also reported to coexist with central giant cell granuloma like component.[9,10] The coexistence of COF with inflamed odontogenic cyst is reported for the second time. The unilocular radiolucency and root resorption of present case contradicts the previously reported case by Ibarguren et al.[2]

Immunohistochemistry with vimentin, S100, smooth muscle actin and c kit may be done to evaluate connective tissue. Similarly, immunohistochemistry with antibodies like AE1/AE2 can be done to see odontogenic epithelium.

Management of Anterior Ridge Defect: A Case Report

Abhijita Mohapatra[1], Abhilash Mohapatra[1]

[1]Professor Department of Prosthodontics, Crown Bridge and implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Loss of teeth is the most devastating situation of patient in dentistry. Loss of teeth leads to resorption of alveolar bone which is an inevitable outcome. This resorption is further magnified in case of trauma. Anterior ridge defects present in a patient is a challenging task to treat, particularly from an aesthetic point of view. Following case report shows replacement of missing maxillary incisors with modified technique. Esthetics, function, phonetics and oral hygiene maintenance are all considered during prosthesis planning.

Keywords: *Siebert classification, Anterior ridge defect.*

Introduction

Anterior tooth loss leads to resorption of alveolar bone. In trauma and congenital defect, the resorption is more. For this type of case requires rehabilitation of tooth loss as well as closure of the soft tissue defect in order to achieveesthetics requirement of patient. The ridge defect with anterior tooth loss often deals with reduction of height and width of alveolar bone[1]. Residual ridge deficiency has been reported in 91% of the cases after extraction.[2]

Seibert in 1983 gave a classification for ridge defects: Class I–Buccolingual loss of tissues with normal ridge height; Class II–apicocoronal loss of tissue with normal ridge width. Class III–combination of bone loss in terms of height and width.[3] These defects may be restored in principle by two method–surgically during the preprosthetic phase or nonsurgical procedure using fixed and/or removable prosthesis[4]. There are different treatment modalities for nonsurgical proceduresare removable partial denture (RPD), cast partial denture (CPD), fixed partial denture (FPD) with gingival ceramics, or an Andrew's bridge. Surgical correction of these defects followed by fixed prosthesis seems to be most tempting treatment choice. However, local and systemic conditions of patient don't always allow surgical correction. Removable partial denture cannot be used when adjacent abutments are periodontally compromised. Fixed removable prosthesis i.e Andrews Bridge is not followed in this case because of cost factors and technique sensitive process. So, a modified conventional fixed prosthesis was planned in consideration with patients demands.

Case Report: A 35-years-male patient reported to the hospital complaining of missing upper right central incisor. A complete medical and dental history was obtained. History revealed that he had met with a road traffic accident 10 years back. On intraoral examination there was loss residual ridge both horizontally as well as vertically in upper right central incisor. It was a Class III type anterior ridge defect according to Seibert [3].

Treatment Option: There are different treatment modalities for anterior ridge defect Siebert class III.

1. Cast partial denture / Removable partial denture.
2. Conventional fixed partial denture.
3. Implant supported FPD.
4. Fixed-removable partial denture.

The patient was not comfortable with removable partial denture as he had to remove and replace the denture. He was also not willing for surgical procedure

Siksha 'O' Anusandhana (Deemed to be University),
Bhubaneswar, Odisha
e-mail: abhijitamohapatra@soa.ac.in

like bone grafting and implant placement. Since it was a three-sided defect, aconventional fixed partial denture designedwas modified as per patient's needs.

Treatment Course:

I. Maxillary left central incisor and maxillary right lateral incisors was chosen in this case as abutments to support the fixed prosthesis after radiological evaluation. Diagnostic impression made with alginate (Zelgan Plus DENSPLY) cast poured using Dental stone Type III (Zermack Elite Rock Dye Stone Type 4). A diagnostic wax up was doneand tried in the patient's mouth for aesthetics and phonetics. (Figure 1)

II. Teeth preparation done in relation to 22 and 12 to receive full metal crowns. (Fig 2) Master impression made using putty wash technique with polyvinylsiloxane (EXPRESS XT LIGHT BODY QUICK RFL) and casts were poured in die stone (Zermack Elite Rock Dye Stone Type 4). Temporary restorationwas fabricated using tooth coloured self-cure acrylic resin (DPI Cold cure) by indirect technique and luted with temporary cement (FREEGENOL TEMPORARY PACK; GC Corp., Tokyo, Japan).

III. Die sectioning done and Wax pattern was made with inlay wax (GC INLAY WAX MEDIUM) for both the abutment teeth with extending into the soft tissue defects. The entire wax pattern assembly was casted with induction casting machine (BEGO FORNAX T CENTRIFUGAL CASTING MACHINE).

IV. Metal try in was done considering with mechanical structural biological and esthetic factors. Fig 2

V. Shade selection was done (VITA CLASSIC SHADE GUIDE) followed by ceramic firing on the copings and gingival ceramics on metal plate extensions. The fixed partial denture with metal plate extension was finished and polished. Figure 3

VI. The provisional restoration was removed and modified fixed partial denture was cemented with resin modified glass ionomer cement (Fuji CEM; GC America, Alsip, USA) on the prepared teeth.

VII. Postoperative instruction was given and review done to assess the prognosis of the treatment. Figure 4

Figure 1. Preoperative

Figure 2. Metal Try in

Figure 3. Finished and polished denture

Figure 4. Post-operative image

Discussion

According to the literatures, usually anterior tooth loss is accompanied by ridge defects and only 9% of the patients did not have ridge defects[5]. The most common defects i.e Class III defects (56% of cases) followed by horizontal ridge defects Class I (33% of the cases).

The famous dictum by Devan is, "Our objective was the perpetual preservation of what remains, than meticulous reconstruction of what was lost." Devan MM. Basic principles of impression making.[7]. In our case, the patient desired a fixed prosthesis for rehabilitation. A conventional CPD and Andrews Bridge was not acceptable to the patient since it was removable prosthesis. Implant placement procedure would have required block graft placement for which the patient was unwilling. Hence, within the constrain option, a modified fixed prosthesis designing was planned in advantageous with completely fixed prosthesis.

Conclusion

The success of prosthetic rehabilitation depends upon various factors like, careful selection ofcases, accurate treatment plan, and careful implementation of a treatment procedure. But the of choice of treatment will be compromised according to patient's needs and financial consideration. In the present case report, modified technique was planned, which successfully replaces the missing teeth along with complete closure of the defect.

Oral Manifestations of Endocrine and Metabolic Diseases

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The human body functions with commands from the brain via the central nervous system and the endocrine system. The endocrine glands secrete the metabolically active hormones which have their effects on the body, bringing about growth, immunity, health and coping with stress are to name a few. As with other diseases, any dysfunction with endocrine system or metabolism affects the oral cavity with a myriad of manifestations, some of which are non-specific while others are pathognomonic. An overview of the common oral manifestations of endocrine and metabolic disorders is presented to enlighten the dentist regarding the various endocrine and metabolic diseases which can bring about oral changes.

Keywords: *Endocrine disorders, metabolic disturbances, oral manifestations.*

Introduction

Amongst the most organ systems of the human body, the endocrine system is considered the most important, as it controls the entire body through its various ductless glands secreting hormones for normal functions. The brain exerts its control on the different systems through the hormones which are secreted in minute quantities from these endocrine glands, yet are so effective that the entire body gets affected. Amongst the most common endocrine disorders is Diabetes mellitus which has classic oral manifestations. Other endocrine diseases, though devoid of any specific oral mucosal changes can pose a challenge during stressful dental treatment and lead to complications, like in hyperthyroidism.[1]. Apart from awareness among the general dental practitioners regarding the oral changes, this article aims at cautioning them regarding the adverse effects during dental treatment.

Hyperpituitarism: What a patient shows macrodontia and macroglossia with increased height with enlargement of facial structures, this suggest that patient is suffering from gigantism, due to hyperpituitarism. If hyperpituitarism occurs in young age, during development of bone and teeth, the over activity of pituitary hormones causes 'gigantism' and in oral cavity, macrodontia, macrognathia and macroglossia occurs. When a patient has got macroglossia, macrognathia, macrochelia and large nose with large face in adult life after epiphyseal end is closed, this suggests that the patient is having 'Acromegaly'. Overactivity of pituitary gland after the epiphyseal end is closed causes acromegaly in which the organs are all enlarged.[2,3]

Hypopituitarism: When the patient shows small sized teeth with delayed eruption and small sized tongue, associated with stunted growth and affected facial height, these oral changes suggest that the patient is suffering from hypopituitarism.[4]

Hyperthyroidism: Usually in children and young adults there will be early eruption of teeth and tremors of tongue. If these changes are found, these are diagnostic points to suggest that the patient is having hyperthyroidism. In hyperthyoidism, or the grave's disease, over activity of thyroid hormone causes early eruption of teeth and tremors of tongue in the mouth.[5]

Hypothyroidism: When a patient shows macroglossia and slightly thick skin and has dull, lethargic look with slow speech as an idiotic nature, these findings suggests that the patient is suffering from myxoedema and this is due to under activity of thyroid gland. Myxomatous tissue is laid down in the tongue causing macroglossia.

Hyperparathyroidism: Brownish colored growth, soft in consistency originating from the bone and extending to the oral cavity associated with multiple cystic cavities of the jaw due to osteoclastic activity, bone pain and pathologic fracture with loss of lamina dura in

radiograph are suggestive of hyperparathyroidism. I n hyperparathyroidism caused by hyperplasia or neoplasia of parathyroid there is more secretion of parathormone which acts on bone, remove the calcium and raise the blood calcium level. Removal of calcium causes cavitation's of bone containing fibrous and vascular tissues which perforates the bone and appears in the oral cavity as 'Brown Tumor'.[6] Loss of calcium in the bone causes bone pain and pathological fracture. Lamina dura is a radiographic term used to describe radiopacity of alveolar bone proper.Removal of calcium from the alveolar bone proper is responsible for loss of lamina dura.

Hypoparathyroidism: Sometimes patients will have teeth with enamel hypoplasia which are affected with horizontal pitting, deficient enamel and this is due to calcium deficiency at the time of calcification of that particular period and this may suggest that the patient has Tetany. [6]

Pseudohypoparathyroidism: Some patients may exhibit small tooth crown covered by thin layer of enamel with hypoplastic pitting. Radiographic examination reveals short roots with blunted apices, large pulp chamber occluded by calcific deposits associated with partial anodontia, delayed eruption. Tetany, convulsions, muscle cramps, laryngeal spasm, small stature with premature closure of epiphysis, ectopic ossification and calcification of soft tissues are suggestive features of pseudohypoparathyroidism, which is a hereditable metabolic disease characterized by excessive production of endogenous parathormone, but a lack of response by target tissues namely bone and kidney. [7] Tetany is a condition caused by hypocalcemia and this occurs due to 'hypoparathyroidism'. When parathyroid secretion, mainly paratharmone is low, calcium level is decreased causing hypocalcemia and hypocalcification of enamel and dentin.[8]

Addison's disease: Pigmentation of oral mucosa in the form of bluish black color in gingiva, palate, tongue, lips develop within short duration in certain patients suffering from "Addison's disease" due to hypoadrenalism. Melanocyte stimulating hormone produced in anterior part of the pituitary gland is responsible for melanin production in the body. Melanin stimulating hormone is controlled by cortisol, secreted by adrenal gland. When adrenal gland is diseased due to autoimmune destruction, tuberculosis, amyloidoisis and neoplasia, cortisol level is decreased. When cortisol level is decreased, Melanocyte stimulating hormone increases and is responsible for overproduction of melanin which deposits as pigmentation in mouth.[9]

Puberty, pregnancy and menopause: Estrogen and androgen are the two sex hormones in females and they play an important role in development and growth of sexual organs and also play an important role in target tissues in the cellular metabolism. Gingival tissue is a target organ for estrogen and any alteration of estrogen and androgen levels, the functions of cellular growth is altered.[2]In females, these hormonal disturbances occur during puberty, pregnancy and menopausal period. During puberty, the hormonal imbalance affects the gingival and the gingiva gets inflamed and bleeding will develop. So, bleeding gums in the absence of any others condition in a girl of puberty period is a diagnostic point of attaining puberty.During pregnancy these hormonal imbalance causes inflammation of gingiva. Gingiva will be enlarged, reddish and there will be bleeding gums. Sometimes due to overactivity of estrogens, there will be proliferation of cells, forming a growth. This growth is called pregnancy gingivitis. During menopause, hormonal disturbances cause inflammation of gingiva and bleeding gums, but most characteristic finding is desquamation of epithelial cells.

Erythematous gingiva with desquamation of epithelium associated with bleeding gums is the diagnostic sign of menopause period of a lady.

Diabetes Mellitus: Generalized gingival inflammation and enlargement with alveolar resorption, mobility of tooth associated with multiple abscess in gingiva which are recurrent in nature are the oral signs suggestive of diabetes mellitus. In diabetes mellitus, there is a failure of peripheral utilization of sugar in cells resulting in hyperglycemia, glycosuria, polyurea, polydypsia and polyphagia. When the sugar content is more in gingival and periodontal tissues, the oral bacteria acts and produces sepsis and destruction resulting in mobility of tooth and multiple abscess.[10]

Mucopolysaccharidosis: Sometimes the patient appears with open mouth, enlarged tongue, protuberant thick lips with long upper lip and on examining the oral cavity, gingival and alveolar process hypertrophy with wide and flattened palate are present. Dental findings include peg shaped or small sized teeth with widely spaced dentition and delayed eruption of teeth. These patients physically appear with short stature, scaphocephalic

skull, short broad neck, narrow shoulders, bilateral corneal clouding, puffy eyelids, depressed nasal bridge, protuberant abdomen, lumbar kyphosis, claw hand with knock–knee. Radiographic examination reveals broadened and narrow mandible, prominent gonion, increased distance between the rami and hyperplastic dental follicles due to mucopolysaccharide accumulation causing localized bone destruction. General examination reveals hepato splenomegaly and death due to cardiac failure and pneumonia results.[2,8] These features are suggestive of Hurler's syndrome which is a genetically determined metabolic disorder of mucopolysaccharides or glycosaminoglycans due to alpha–L iduronidase enzyme deficiency, resulting in excess accumulation of mucopolysaccharides in tissues and urine.

Hypophosphatasia: In some patients, premature exfoliation of teeth occurs and on radiographic examination large pulp chambers, due to deficient odontogenesis and deficient cementum production is noticed. On biochemical evaluation alkaline phosphatase enzyme level in bone is reduced. This enzyme is present in bone, liver and intestine and is necessary for conversion of organic to inorganic phosphate which is essential for normal bone mineralization. Increased phosphoethanolamine secretion in urine which is substrate of alkaline phosphatase is the characteristic finding in hypophosphatasia which is a genetically determined metabolic bone disease caused by deficiency of alkaline phosphatase enzyme.[2]

Conclusion

Although all endocrine and metabolic disorders are not commonly encountered in the general dental practice, except probably diabetes mellitus, awareness about these conditions can avoid many unnecessary complications.

Article on Healing of Wounds in the Oral Cavity

Anisha Anukampa[1], Swati Patnaik[2]

[1]Intern, [2]Assistant Professor, Institute of Dental Sciences, Odisha,
Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Wound healing mechanism is a primary healing process which has relatively little interaction and has no classification about the healing process of the oral cavity. The mechanism of healing includes sequence of biological processes, where the tissues show identical pattern with reduced scar. Saliva in the mouth forms a warm humid suitable and favourable condition for the healing process in a normal healthy person and an immunocompromised person adding the factors affecting wound healing process. Better understanding about the healing would provide information for identifying the issues which will end up in impoverished wound healing in the oral cavity.

Keywords: *Wound Healing, Inflammation, Granulation Tissue, Immunocompromised, Maw.*

Introduction

Oral wound occurring fortuitously or may be infected by the dentist for certain processes like extraction,different biopsy method, major and minor surgery and oral ulcers like diseases. A living tissue replaces the damaged and destroyed tissue in a healing process to restore normal healthy function. Within the tissues there occur a complex, dynamic biological processes that lead to their renewal and repair. This process is described by four phases that overlapand synchronize with one other resulting in tissue repair and closure. The four phases of oral wound repairinclude haemostasis,inflammation, proliferation and remodelling.[1]

Classification of healing of wounds in the oral cavity include local and systematic factors. An immuno compromised individual follows a high risk of delayed and complicated wound healing process. Besides these there lies some method that can enhance the process of wound repair in the oral cavity.

The following discussion of wound healing involves the normal healing of wound and healing in immuno compromised patient. A complex process where the tissue sunder the skin undergo self-healing after the injury is the wound healing process. Normal healing process includes four phases such as haemostasis, inflammation, proliferation and remodelling. The above mentioned four phases must occur in a specific manner maintaining their required function, duration with optimal density.[2]

Haemostasis phase: In this phase, after the injuryimmediately the platelets come in contact with the collagen which results in activation, aggregation and thrombin produces the fibrin mesh which provides strength to the platelet clump and forms a stable mesh. The growth factors and pro-inflammatory cytokines are released by the clot and surrounding the affected area. Chemotaxis occurs when the bleeding gets controlled that enhances the inflammatory phase.[3]

Inflammatory phase: Sequential infiltration of neutrophils, macrophages and lymphocytes is the characteristics of this phase. Proteases and reactive oxygen species (ROS) are synthesized by the neutrophil that kill the bacteria andthe debris are removed. Macrophages clean the apoptotic cells that include the neutrophils are cleaned by the macrophages and tissue regeneration is stimulated by a phenotypic changeover.[4] This phase takes place for 4-6 days along with edema, erythema, heat and pain.

Proliferative phase: In this phase, the main attention is given on filling and covering of the wound by inducing epithelial proliferation and migration over the provisional matrix within the wound. The fibroblasts and endothelial cells are the most prominent cells in the reparative dermis that support the capillary growth, collagen formation and granulation tissue.

The fibroblasts also produce glycosaminoglycan and proteoglycan in the wound bed which are the major components of extracellular matrix. Wound contraction is facilitated by myofibroblasts that are present at wound site. This phase lasts for 4-24 days.[3]

Remodelling phase: After robust proliferation and extracellular matrix synthesis, wound healing enters the final phase of remodelling. In this phase, regression of many newly formed capillaries takes place, as a result the vascular density of the wound returns to the normal state. The newly formed tissue gains strength and flexibility slowly. The collagen fibers undergo reorganization, tissue remodelling and mature leading to an overall increase in tensile strength. This phase varies greatly from wound to wound.

Oral cavity wound healing process with specific characteristics

Healing of palate: This takes place in the presence of the healthy bonesunderlying it and formation of the scarring tissues[5]. Decreased specifications about the immunity mediators,lesser blood vessels,cell multiplication from the bone marrow increases, re-epithelisation takes place rapidly and rapid proliferation of the fibroblast occurs due to early onset of this phase. Inflammatory phase is absent in the fatal wound healing.[6,7]

Periodontal healing: Extracted tooth socket healing follows the pattern similar to the healingprocessbut this depends on the location of the wound and the variation in the of bone loss, adjacent teeth location, protocol of the treatment followed, smoking behaviour and membranesand bone alternatives used.[8, 9]

A huge number of polymorphonuclear leucocytes are found between the residual epithelial cells and crevicular surface in approximately 2hrs after a scaling and root planning. Enlargement of the blood vessels, oedema and necrosis is seen in the lateral wall of the periodontal pocket. Keratinocytes migration and inflammatory cell infiltration is seen after 24hrs. entire pocket epithelization in 2 days. New epithelial attachment in next 4-5 days is seen and completes epithelial healing in 1-2 weeks.[10]In case of curettage a blood clot is formed in the pocket wall, large number of PML and rapid proliferation of granulation tissue takes place. Complete epithelisation occurs in next 2-7 days.[11]

In case of surgery clot is formed as an initial response which is replaced by granulation tissue followed by new connective tissue cell in 24hrs. capillaries migrate to the granulation tissue and connect the gingival tissue. complete epithelisation takes place within 1 month.[12]Interdental papilla degradation forming of back triangle are noticed after periodontal surgeries. Inflammation can be avoided by maintaining a good oral hygiene and minimizing the retraction.[8]

Healing of Dental pulp: Apical blood supply preservation and survival of the damaged odontoblast layer are the factors on which dental pulp healing relay.[11] Pulp healing is the initial step after which regeneration occurs. The process is linked with the adverse effects of inflammation.

The four steps in the healing of dental pulpby direct pulp capping using calcium hydroxide or bio active extra cellular matrix molecules include: a moderate inflammation, the commitment of adult reserve stem cells, their proliferation and terminal differentiation.[13] Prerequisite for tissue healing is inflammation, after which regeneration is followed. This is also called the pulp repair.

Bone healing: Bone healing takes places by primary or secondary intention. Healing by primary intention occurs in the presence of a healthy blood supply without callus formationand a firm fixation without the bone fragments mobility.[14] The major form of bone healing in maxillo-facial surgerythat takes place by callus formationis the bone healing by secondary intention.[15]

Healing of burns: A compromised healing with marked scarring is exhibited duringburns in the mouth.[1, 5]For the next 48-72 hrs it continues the damage leading to the destruction of the deeper tissuesensuing the initial result due to inflammatory and vascular reactions.[3]

Healing of tongue: Because of generous blood supply lacerations do not become infected and heal well. Primary wound healing occurs rapidly, only if deep lacerations more than 2cm, haemostasis becomes difficult to achieve. For effective function after proper repair early motion is advisable.Saliva plays an important role in the wound healing in the oral cavity. Its intakes a peptide called histadine-1that fight against bacteria and aids in wound healing.[16]

Table 1. Factors affecting wound healing[1]

Factors Affecting Wound Healing	
Local Factors	**Systemic Factors**
• Oxygenation	• Age and gender
• Infection	• Sex hormones
• Foreign body	• Stress
• Venous sufficiency	• Ischemia
	• Diseases: diabetes, keloids, fibrosis, hereditary healing disorders, jaundice, uremia
	• Obesity
	• Medications: glucocorticoid steroids, non-steroidal anti-inflammatory drugs, chemotherapy
	• Alcoholism and smoking
	• Immunocompromised conditions: cancer, radiation therapy, AIDS
	• Nutrition

Wound healing in immunocompromised patients: Immunocompromised patients have an impaired or weakened immune system for which normal response to the infection is affected. This inability to respond normally can be caused by number of illness, drugs and diseases which include diabetes, HIV, malnutrition. An immunosuppressed individual is at considerable risk for a delayed and sometimes complicated cause of wound healing.

Such medical condition can become disadvantageous for the response to the wound healing process. Along with the high blood sugar,occlusion of the peripheral blood circulation is often.Restriction of the cells such as platelets and monocytes from entering the wound which are the major cells responsible for healing are because of the reduced blood flow.Such patients are seen with the persisting wounds and a greater risk of infection for which post-operative care becomes more important.[17]

Enhancing wound healing process: Wound healing process can be promoted by following general measures and some medications.

General method: Wound healing is enhanced by increasing blood flow by applying heat in the affected area. In case of oral wounds habits such as proper and regular brushing and mouth rinse can be helpful where as habits such as smoking, chewing tobacco can be injurious and should be avoided. Salt water rinse can be beneficial in reducing inflammation.

Medications: Certain antibiotics and analgesics are prescribed depending upon the type and severity of the wound to give relieve and avoid infection along with a routine mouthwash. Some oral gels can be applied topically depending on the wound to get relief from swelling, discomfort and pain.

Conclusion

Wound healing in the mouth is anextraordinarily compound biological process that is vulnerable to interruption of a variety of components where a processed healing is followed by a high bacterial and viral liability. The body works in a marvellous way leading to repair and replacement of the destroyed tissue when a conducive healing condition is established.

Minimal Invasive Dentistry

Shraddha Ray

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

MID (Minimal invasive dentistry) can be best cited as preventive and biologic approach of dental treatment for the conservation and rejuvenation of healthy dental tissue and structure. The treatment aspect includes earliest and accurate possible diagnosis of dental caries along with sighting out the possible cause and its progress and accordingly planning out the treatment procedure by stopping its restriction and by recuperation of the affected tooth structure and function by alleviating maximum healing of the tooth[1]. This article highlights on the chemo-mechanical and ART procedure of minimally invasive dental treatment as these procedures benefit and focus on treatment of greater mass hence has greater public health significance because it is preferred for school based and community based dental treatment as it's a procedure evolved from fathoming out the cause and type of dental caries and restricting its progress by advanced diagnosis based on which treatment plan is advocated comprising of minimal arbitration of natural tooth structure by elimination of rotary and conservative instruments, syringes and Local anesthesia[2] and leading to usage of desirable, economic and patient comforting materials and environment for dental treatment.

Keyword: *Minimally invasive techniques, Atraumatic restoration, Chemomechanical treatment, Public health, Chemomechanical gels.*

Introduction

MID can be defined as philosophy of professional care, concerned with occurrence, early detection and earliest possible cure of the diseases on a micro level followed by minimally invasive treatment in order to repair irreversible damage caused by such diseases[1]."

MID can be categorized into 4 main categories[2,3] such as: Early identification and diagnosis of caries, Reduction-to stop the progression of the caries the causative factors need to be identified and eliminated it can be done be recapitulating individuals lifestyle by reduction of intake of snacking pattern, sweet beverages and stoppage of smoking. Remineralization which includes cultivation and restoration of strength and function of tooth structure by using materials such as fluorides, calcium sucrose phosphate, sugar substitute hydroxyapetite etc. Repair is done by conservative method without disrupting the natural tooth structure for removal of caries and promoting life span of the affected tooth.

There are various Minimally Invasive techniques such as[4]

- Mechanical-Atraumatic restorative treatment
- Rotary comprises of high and low speed burs
- Sonic oscillations
- Chemo mechanical-Carisolv, Caridex, Papicari, Carie Care
- Kinetic-Air Abrasion
- Hydrokinetic-Laser
- Ozone Technique–O_3

ATRAUMATIC RESTORATION

It's also called interim therapeutic extraction. The term itself suggests that the procedure is atraumatic and painless resulting in increased patient comfort and acceptance and reduced patient anxiety. This technique was developed in TANZANIA in mid 1980 at university of Dares Salaam[4].

Corresponding Author:
Dr. Shraddha Ray
Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar
e-mail: shraddharay@gmail.com

This technique comprises of eradication of soft, demineralised carious tooth structure without interference with the sound tooth structure by using hand instrument only and eliminating the use of Anesthesia and Electrical and Rotary instruments.

Instruments used in this techniques are:

- Mouth mirror
- Explorers
- Tweezers
- Spoon Excavators
- Hatchet
- Carver

ART is advisable for small occlusal cavity where the clinician has good accessibility and visibility of the cavity for restorations. Restorative material like GIC and Resin bonded composites, GIC is mostly used as it has the properties to prevent[5]-

- Micro leakage
- Secondary caries
- Pulp Irritation

Procedure: Pre organization of work scenario outside the patient mouth is that the correct position and posture of the operator should be checked, the required assistance should be available, the patient position should be checked, the operating light is to be examined, inoperating environment inside patient mouth it is essential to check the Hegemony of saliva. Hygiene and hegemony of cross infection should be maintained and examined.It is mandatory to use gloves and masks and have clean working environment and sterilized instruments forRemoval of caries the soft carious tooth structure is removed by using spoon excavator. The cavity can be expanded by placement of dental hatchet if the cavity is narrow and ultimately cleaned by wet cotton or water syringe[6].

Conditioning and preparation of cavity-Prepared surface is cleaned with dental conditioner-10% polyacrylic acid/ GIC liquid.As per the manufacturer's instructions the material is to be mixed within 20–30 seconds. Material should be smooth, glossy, putty type. By using the filling instrument the restorative material is inserted into cavity. To cover up the pits and fissures sealant is spread over. Excessive material is to be removed with a carver and cavity varnish should be applied uniformly[7].

Chemomechanical Method: The method of removal of caries opened new doors in the field of dental sciences. Various new products like gels, and other working instruments and armaterium were introduced in the field of dental sciences which made treatment procedures more easier, comfortable, less time consuming, painless and eliminated the usage of complex instrument like rotary and conservative instrument as only hand instruments were used. More over this method of treatment could focus on public health aspect rather than restricting it to fewer individuals[8].

Mechanism of Action: In this method the penetrates the demineralised dentine. Dentine has two layers the inner layer and the outer layer, the inner layer is partially demineralised and has capability of Remineralization. While the outer layer is incapable of Remineralization so the gel results in breakdown of degraded collagen and softening of carious dentine[9].

Chemomechanical Gels

- Sodium Hypochlorite based (NaOCL)-cariesolv Cariedex
- Enzyme based-Papacarie

Biosolv

Carie-care gel

Carie Care Gel: Is a gel based formulation. It is basically an enzyme designed for non intervening, non invasive, and non traumatic removal of carious dentine. On application of the gel there is selective softening of carious dentine and expedite removal by gentle excavation. The main component of carie care is endoprotien[10,11].

- This gel has-bactericidal and disinfectant properties.
- Food grade dye for localization, water and salts.
- Eradicates the use of rotary instruments and local anesthesia.
- It has maximum patient comfort.
- It is efficient and easy to use.
- It takes only 2-3 minutes to dissolve and act.
- It has a good consistency so the spillover is avoided.
- It has mild anesthetic effect.

- It has a pleasant aroma.

Cariedex: In 1984 after FDA approved cariedex was marked and was ready to use it consisted of 2 solution. Solution 1-sodium hypochlorite. Solution 2-glycine, amino butyric acid, sodium chloride and sodium hypochlorite.

Cariesolve: The gel Carisolv made it to surface on January 1998. It consisted of 2 syringes. 1st syringe-sodium hypochlorite. 2nd syringe-amino acid like lysine, leucine, glutamic acid, amino butyric acid, sodium chloride, sodium hydroxide with carboxymethyl cellulose.

Table Chart

	Cariedex	Carisolv
Solution-1	1% Naocl	0.5% Naocl
Solution-2	0.1m glutamic acid/ leucine/lycine, 0.1% NaOH	0.1m glyutamic acid/leusine/lysine, NaOH
DYE	-----	Erythrosine
Ph	10.99	10.99
Physical property	Liquid	gel
Volume needed	101-501ml	0.2-1.0ml
Time required	5-16min	5-16min
Stability	1hr	20min

V-Carie Solve: It is a caprice papaya extract gel with vitamin A and vitamin C for chemomechanical removal of dental caries. It has painless carious dentine removal procedure. The use of drilling and rotary instrument is eradicated. It is composed of payaya extract, chloramines and clove oil.

Papacarie: This gel has conservative and biologic approach of caries removal. Working time of papacarieis much lesser as compared to other chemechanical gels. It aids in reduction in bacteria, has antibacterial property following easy and painless excavation. It is composed of papacarie, chloramines and toludine blue. It was developed on 2003 in Brazil[12].

Biosolv: It is composed of pepsine enzyme in phosphoric acid. Phosphoric acts as a dissolvent for the inorganic component. Pepsin breaks down the dentured collagen fibers hence the carious dentine cam be effortlessly removed by specially designed plastic instruments. Biosolv has higher acidic Ph which makes it a aggressive material for removal of carious dentine henceforth more studies are required to know the mechanism of action of biosolv and more experiments are required for its stabilization[13].

Conclusion

Once affected a tooth cannot be brought back to its original state, hence MID is one of the best technique to preserve and perpetuate the remaining natural tooth till the possible extent. MID enhances patient comfort and acceptance reduces patients dental anxiety and eliminates the use of complex conservative instruments thereby making this procedure acceptable and assessable to wider public mass like school dental health resulting in coverage and benefiting to larger mass. This field of dental treatment has come up with lots of advancements and materials for patient care, but still many materials need more examinations and studies to understand the mechanism of its action and make it more assessable and establish its optimum effect.This treatment aspect promotes 'remineralization' which makes it a favorable treatment procedure as complex procedure are avoided especially for small occlusal cavities. The future of tooth remineraliaztion lies in the field of MID, as this procedure focuses on preservation of natural tooth.

A Review Article of Oral Manifestations of Systemic Diseases

Jeeban Krushna Sahu[1], Swati Patnaik[2]

[1]Intern, [2]Assistant Professor, Department of Public Heath Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

At present, multiple diseases have an impact on oral health. Oral manifestation in many systemic diseases may be turned out to be the evidence or sign of such diseases. In some systemic diseases, the oral lesions are concurrently accompanied by other medical symptoms; henceforth it is necessary to evaluate these oral lesions by physicians and dentists**.** Identification of such symptoms may help early diagnosis and treatment. This review article based on the oral manifestation of systemic diseases focuses on blood disorders, autoimmune diseases, and deficiency of essential micronutrients.

Keywords: *Oral Manifestations; Blood Disorders; Autoimmune diseases; Endocrine Disorders; Essential Micronutrients.*

Introduction

It is a clear fact that manifestation of the oral cavity is the 1st pathological conditions of the systemic diseases. It has been observed that many types of oral pathological conditions are associated with different types of systemic diseases like Endocrine disorder, an autoimmune disorder, Blood-related disorder, Neurological disorder, Viral and Bacterial infections. As we know oral mucosa consists of heterogeneous tissue which may be disturbed by the changes in blood cell count, change in neurological and endocrine secretions. The occurrence of these diseases may cause many manifestations in the oral cavity in different forms such as ulcerations, lichen planes, leucoplakia, xerostomia, swelling of the salivary gland, etc. So, in these conditions, it is very difficult to evaluate such pathological conditions only by the dentist. So early diagnosis can be done by both dentists as well as physicians. As a result, these diseases can be diagnosed and treated early[1].

Oral Manifestation of systemic disease: Manifestations associated with specific diseases have been described as follows:

Diabetes: Diabetes mellitus is an endocrine disease in which the blood glucose level increases that are called Hyperglycaemia, which is due to the lack of insulin secretion or insulin resistant. It is of two types: Type I (Insulin-dependent), Type II (non-insulin-dependent). The most common type is type II. Type I is more common in children and type II is more common in adult 9. In such diseases, the patient's oral hygiene maintenance is very poor due to a random change in blood glucose level and as a result causes periodontal diseases, bleeding gum, etc[1,2]. An oral manifestation of diabetes Mellitus is xerostomia, root caries, oral candidiasis, periodontal diseases, and prolonged wound healing and an increase in the frequency of infections following surgery. The xerostomia increases the chances of fungal and bacterial oral infections along with loss of taste sensation. Long term manifestation included some mucosal lesions such as candidiasis, oral ulcer, and stomatitis[3].

Treatment: The manifestations should be controlled only by controlling the blood glucose level, take medication as prescribed by the physicians, eat low sugar food, use alcohol-free mouthwash. To prevent root caries and periodontal disease maintain oral hygiene with twice brushing daily and regular visit to the dentist[4,5].

Crohn's Disease: Crohn's disease is a disorder in which infection of the intestine occurs (most common site is colon) and the etiology factor is unknown. It causes inflammation of the intestine, which can lead to **severe diarrhoea**, tiredness, weight loss, and starvation. Inflammation caused by **Crohn's disease** can affect different areas of the digestive tract in different people. The most common sites of oral lesions in Crohn's diseases are lip, gingiva, vestibular sulci, oral and intestinal mucosal lining. It may cause minor aphthous ulcer, impairment of oral functions, psychological stress, angular cheilitis, persistent submandibular lymphadenopathy, gingivitis, and periodontal diseases. The inflammations spread all over the body mucosa lining which is a severe condition[2,6].

Treatment: For angular cheilitis-topical steroids (1% hydrocortisone), for deep ulcerations-topical analgesic or intra-lesional steroids, for lip fissured-intra-lesional steroid and topical tacrolimus and regular visit to the dentist for check up[7].

HIV Infections: Human immunodeficiency virus is a virus that harms the immune system of the subject's body. HIV destroys more CD4 cells; the body is more prone to get various types of infections. Oral manifestations are the most basic orofacial manifestations of HIV infections. The foremost etiological factor of oral candidiasis is the fungus, Candida Albicans;also additional species of Candida may be involved. Different orofacial lesions associated with HIV infections are Kaposi's sarcoma, candidiasis erythematous, pseudo membranous candidiasis, melatoninhyper pigmentations necrotizing stomatitis and angular cheilitis, leukoplakia, and aphthous ulcer[8,9].

Treatment: There is no such permanent treatment for HIV Patients only for the symptomatic relief some medications are prescribed and regular visit to the dentist. For mild candidiasis chlorhexidine 0.12%, Topical amphotericin B for resistant candidiasis, Clotrimazole 1% cream or Ketoconazole 2%cream are for angular cheilitis. Imidazole and triazole are the medication for anti-fungal[12].

Rheumatoid Arthritis:-Rheumatoidarthritis is an autoimmune disease. It is a systemic disorder, which affects the entire body Joints. It befalls when a person's immune system misinterprets the body's healthy tissues for foreign invaders. As the immune system responds, swelling occurs in the target tissue or organ. Oral findings like ulcerations, gingivitis and salivary gland swelling, symptoms like oral dryness and TMJ disorders[4,10].

Treatment: For Dental caries can be prevented by regular maintains of oral hygiene, topical fluoride applications, use of fluoride contain identifies or toothpaste. The dryness of the mouth can be prevented by xylitol chewing gum (sugar-free) and regular visit to the dentist for check up [11].

Anemia: Anemia is a disorder in that conditions healthy red blood cell count decreases to carry adequate oxygen to the body's tissues. Having **anemia** can make the subjects tired and weak. Mucosal pallor is the most common manifestations of anemia. The other manifestations of anemia are glossitis, gingivitis, disturbed taste sensation, Candida infections, atrophy of filiform papillae[12].

Treatment: For blood loss anemiai.e. iron deficiency anemia $FeSO_4$ 200mg 3*/d is prescribed, for hemolyticanemia avoid oxidative drugs, for sickle cell anemia blood transfusion in crisis. For thalassemia alpha and beta major blood transfusion is required and regular visit to the dentist[13,14].

Leukemia: Leukaemia is a carcinoma of the blood cells. In these conditions, the WBCs count increases up to 50lakhs above. **Leukaemia** can occur due to a problem with blood cell production. It usually attacks the leukocytes or WBCs. The foremost oral complications in leukemia are gingival enlargement, ulceration, a tendency to bleeding, taste alterations, xerostomia, Trismus[6,15].

Treatment: Regular visit to the dentist for check up & For

Gingivitis	Maintain oral hygiene by use soft bristles
Ulcerations	Topical steroids 4times/day Biopsy
Gingival bleeding	Antifibrinolytic mouth wash, use soft bristles
Trismus	Physiatrics
Periodontal infections	Antibiotics, antifungal, antiviral

Deficiency of micronutrients: Micronutrients are essential components needed by the body in small quantities. They include microminerals and Vitamins. Micromineral include at least iron, cobalt, chromium, copper, iodine, manganese, selenium, zinc, fluoride, and molybdenum. The Vitamins include vitamin-A, vitamin-B complex, vitamin-C, vitamin-D. Micronutrient deficiency may cause several orofacial lesions and different diseases. It is widespread among

2 billion people in developing and developed the country. It affects all age groups. The deficiency of these micronutrients causes increased dental caries, affects bone health, decreased bone mineralization. Deficiency of Fluoride causes dental decay and affects the bone health[7]. The most common disorder is malnutrition germination[8].

Treatment-Took all form of green vegetables,fru its,citricfruits,milk,yogurt,cheese,seafood,wheat,meat, low consume sugar food,rice,bean,egg,peanut,fishetc. Taking proper calories of food may maintain the macro and micronutrients of the body. And Drink 3-4litters of water per day also help for maintaining micronutrients percentage and Regular visit to the dentist for check up[16,17].

Conclusion

It is very often that manifestations of oral cavity are associated with the specific systemic diseases. A proper diagnosis of the pathological conditions of the oral cavity through a full review of the patient's past medical history should help to diagnosis the cause early. Hence the dentist has the major role to find out the pathological conditions of the oral cavity and can be treated the same.

Abstract

Diabetes mellitus is a group of disorders characterized by an increased in plasma blood glucose (hyperglycaemia). Globally, the incidence of diabetes is rising approximately 3 new cases in every 10 sec and by 2030 it is expected to affect the population of 552 million people, therefore it is now considered as a new epidemic. Various type of diabetes mellitus affecting different group of people has been seen, most commonly are type 1 and type 2 diabetes. diabetes mellitus has greatly elevated the rate of morbidity and mortality which has become a major burden to the health care system of all over the world. Diabetes mellitus almost affect every system of the body; therefore, a thorough history and physical examination must be done in these patients. It also has many oral manifestations which are often neglected by the patients, clinical practitioners and many health care providers. So, in this article we are going to summarize various oral manifestations due to impaired glycaemic level.

Keywords: *Diabetes mellitus, Mucous, Blood Glucose, Fasting blood sugar, Insulin.*

Introduction

Diabetes mellitus is a non-communicable disease and chronic disease of carbohydrate metabolism which has increasing trend in past two decades all over the world and India has been declare as diabetic capital of the world. Diabetes mellitus is the groups of common metabolic disorder that containsthevariousphenotype of hyperglycaemia. Hyperglycaemia can cause both acute and long-term diseases, but most of the complications are due to chronic hyperglycaemic state as it causes microvascular changes[1]. Three important microvascular complication of diabetes are retinopathy (eye), nephropathy (kidney) and neuropathy (nerves of limbs). Various etiologicalfactor leading to hyperglycaemia are decrease insulin secretion, decrease glucose utilization and increase glucose production[2].

It is seen in various studies, there are certain risk factors which have strong association with diabetes are genetic association, obesity, sedentary life style, certain ethnicities, increase urbanisation and economic development, therefore its incidence is more in developed country than in developing country[3].

Type 1 diabetes (also known as juvenile diabetes) is a chronic T cell-mediated autoimmune disease-causingbeta cells (insulin producing cells) destruction in pancreas leading to complete or near-total insulin deficiency. But typical symptoms of diabetes appear only when beta cell function is lost by 80-90%. It can develop at any age most commonly before 20 years of age and has strong genetic predisposition. many genes are involved but HLA complex polymorphism have 40-50% genetic risk and HLA halotypes DR3 and/ or DR4 are found in most of the individual with type1 diabetes. It contributes 5-10% of all diabetes cases. Risk of developing type 1 diabetes is 40-60% if his/her identical twin has the disease, and 20% in non-identicaltwin.It is generally more common in Caucasians and in countries which are in close proximity to polar regions like Finland. Genetic susceptibility cause immune dysfunction leading to inflammatory infiltration of islets cells-insulitis, hence

beta cell destruction decreasing insulin secretion and certain high levels of glucose may be toxic to remaining beta cell, causing profound insulin deficiency and metabolic sequalae of hyperglycaemialike glycosuria, dehydration, lipolysis, proteolysis(weight loss) and other symptoms of diabetes even resulting in ketoacidosis and death if insulin is not replaced[4].

Type 2 Diabetes mellitus (85-90% of all the diabetes cases) most common chronic diseases characterised by insulin resistance, impaired insulin secretion and increase glucose production and is one of the leading causes of death and disability in the world.Prevalence of type 2 diabetes increase with age, approximately 10% in people >65years, 70% of all diabetes seen after the age >50years. it has strong association with family history of diabetes especially first-degree relatives, overeating andobesityi.e., BMI>30kg/m^2, physical inactivity especially in office going people which always works in front of computer, hypertension, history of gestational diabetes, deranged lipid profile i.e., high LDL, cholesterol and triglycerides, polycystic ovarian syndrome and certain ethnicities (African-American, Latino, native American, Asian American, pacific islander) therefore good assessment mandates good medical history including family history, races, drug history, occupation, etc. obesity particularly intra-abdominal fat / central adipose tissue is now considered as major cause of insulin resistance but primary cause is still remain unclear likely multiple defects in insulin signalling[5]. In early stage insulin resistance cause increase insulin production to maintain normal blood glucose, then ultimately beta cells are unable to meet increased insulin demand and gradually progressing to insulin deficiency therefore, it is called relative insulin deficiency[6].

Gestational diabetes is glucose intolerance develop during pregnancy. In this there is an increase in insulin requirement due to insulin resistance is related to metabolic change of late pregnancy. Other type of diabetesmellitusincludes specific genetic effect, metabolic abnormalities, mitochondrial abnormalities and other host specific impaired glucose tolerance.

Diabetes mellitus has various oral manifestation that impact the oral health for which clinician should be well aware of it, so that early diagnosis and timely referral to oral health providers can be made and this article will be give review of association between the diabetes mellitus and oral health.

Sign and Symptoms: Symptoms of hyperglycaemia are polyuria, polydipsia(thirst),change in weight usually weight loss, fatigue, lethargy, weakness, blurry vision, nausea, headache, hyperphagia (craving for sweet foods), mood change, irritability, difficulty in concentrating, apathy, frequent superficial infection (mucosal, skin infection and slow healing of skin lesion after minor trauma).

Criteria for diagnosis of diabetes mellitus:

- Symptoms of diabetes plus random blood glucose concentration >= 200 mg / dl or
- fasting plasma glucose >= 126mg/dl or
- 2hr plasma glucose >= 200mg/dl during an oral glucose tolerance test or
- HbA1C>= 6.5%. fasting plasma glucose or HbA1C is recommended as screening test for type 2 diabetes mellitus[7]

Oral Manifestations: Oral manifestation of diabetes mellitus is firstly due to polyol pathway that converts glucose into sorbitol byaldosereductase and secondly due to formation of advanced glycosylation end products (AGE) which gets deposited in specific organ and causes various complications. it includes xerostomia, burning sensation of mouth, impaired wound healing, increase chances of infection, secondary infection with candidiasis, parotid salivary gland enlargement, gingivitis and /or periodontitis[8].

1. **Periodontal Disease:** Diabetes and periodontal disease show various synergism therefore, Periodontal complication is now considered as sixth complication of diabetes mellitus. In hyperglycaemic patients there is depleted immune functioning, decrease in white blood cells (decrease in neutrophil activity) which weakens the immune system which leads to various infections including periodontitis. Periodontitis is chronic inflammatory disorder which cause destruction of gingivae and periodontal tissue started with bacterial infection. It is slowly progressing and irreversible tissue destruction. Formation of periodontal Pockets resulting from tissue destruction due to breakdown of collagen fibres of periodontal ligament. As it is painless and asymptomatic during early stages of disease, so early diagnosis is difficult and remain undiagnosed and untreated, leads to further progression of disease, more deepening of pockets,

resorption of alveolar bone resulting in loosening of tooth. Gingival erythema, bleeding, oedema, recession, tooth mobility, tooth drifting, suppuration from pockets and tooth loss are seen in advanced disease and patient usually presented in clinics in this stage. Incidence of periodontitis increases three times in diabetic patients than in normal population, therefore glycaemic control is more important is diabetic people, it will reduce the incidence of periodontal disease and also reduce the disease progression[9].Other risk factors of periodontitis are smoking, immunocompromised condition, malnutrition, osteoporosis, medications that causes drug induced gingival overgrowth example-calcium channel blockers, phenytoin, ciclosporin and local factors like anatomical deficiencies,these risk factors have to be rule out for proper treatment of periodontal disease.therapy includes surgery, antibiotics or both . most common antibiotics used is amoxicillin.amoxicillin 250mg three times a day for 7 days or clindamycin 300mg four times a day for 7 days(for patients who are allergic to penicillin group)[10]

2. **Salivary Gland Dysfunction and Taste Dysfunction:** There are three major salivary glands namely parotid gland, submandibular gland and sublingual gland and many minor glands in oral cavity. Reduced salivary flow rate i.e., hyposalivation and dry mouth i.e., xerostomia is main salivary gland dysfunction seen in diabetes. Damage in salivary gland due to diabetes affect both quality and quantity of saliva, thus altering saliva flow rate, pH, salivary protein concentration leading to glandular deterioration. Prevalence of these dysfunction has seen more in diabetic patient with neurological complication. Because of dry mouth patient has symptoms of polydipsia and polyuria. Xerostomia is also risk factor of periodontal infection and tooth decay. Sialosis is a swelling of parotid gland is also seen in diabetic patient.treatment includes saliva substitute and stimulants, drugs can also prescribed in severe cases as pilocarpine and cevimeline Altered taste sensation in diabetic patient has been reported due to salivary gland dysfunction. There may be elevated threshold for taste sensation. these conditions show poorly controlled glycaemic level in known case of diabetes[11].

3. **Oral Fungal Infections:** In diabetes immune system is weakened which give rise to opportunistic infection like Oral candidiasis caused by a yeast *candida albicans.* High levels of blood sugar also favour growth of these organism. these infections can also occur as aside effect of antibiotics abuse, antihistamines or chemotherapy drugs. It is classified as acute and chronic infection. Acute infection are erythematous and pseudomembranous, also called oral thrush. Symptoms of oral candidiasis are white or yellow patches of bumps on inner cheeks, tongue, tonsils, gums or lips, slight bleeding if bumps are scrapped off, soreness or burning of mouth, dry and cracked skin at the corner of your mouth, difficulty swallowing, a bad taste or loss of taste. Candida infection is more seen in diabetic patients with smokers, dentures, oral steroidsand have poor glycaemic control. Chronic infection i.e., hyperplastic candidiasis also known as candida leucoplakia, seen in immunocompromised patients. Manifestations of candida occur in various forms like median rhomboid glossitis, atrophic glossitis, denture stomatitis and angular cheilitis. Salivary gland dysfunction, immune deficiency and hyper glycemia are contributing factors to this infection. local antifungals can be used as treatment, common antifungals are nystatin, clotrimazole and fluconazole. Use of pastilles, lozenges or troches to provide a local and systemic effects[12].

3. **Bacterial Infections:** Diabetes have impaired immune system and poor metabolism make it more prone to recurrent bacterial infection. Higher glycaemic level also gives it good environment for bacterial growth and favours spread of infection to submandibular space and neck. More commonly seen is streptococcal organism. Treatment includes broad spectrum antibiotics.

4. **Poor Oral Wound Healing:** Delayed wound healing makes treatment in this patient more difficult. It shows poor tissue regeneration, delayed osseous healing, delayed vascularisation, reduced blood flow, reduced in innate immunity, decreased growth factor production and psychological stress.

5. **Oral Mucosal Disease:** It includes lichen planus and recurrent aphthous stomatitis. Oral lichen planus has autoimmunity as a underlying cause, therefore it is mostly seen in type 1 diabetes. Atrophic erosive lesions are more common.treatment plan is to reduce pain erythema, ulceration and sensitivity by topical or systemic steroids and glycaemic control

6. **Neuro-sensory oral disorder:** Oral dysesthesia or burning mouth syndrome is another manifestation of diabetes. It is a chronic painful condition associated with burning sensation of tongue, lips and mucosal regions of mouth. factors affecting are uncontrolled diabetes, hormonal therapy, psychological, neuropathy, dry mouth, candida infection. management are usually symptomatic treatment, medication which are often used are benzodiazepams, tricyclic antidepressants and anticonvulsants has shown effective.

Complication of Diabetes

1. **Hypoglycaemia:** Hypoglycaemia is a condition where glucose level abruptly drop below normal i.e., <70mg/dl. It is especially seen in patients with insulin therapy, also referred as "insulin shock" or "insulin reaction", symptoms will appear within minutes. But patient with oral hypoglycaemic agents, symptoms have slower onset. If left untreated can lead to unconsciousness, coma or death, so it's a emergency condition. Condition decreases the requirement of insulin are-weight loss, disruption of food intake, drinking too much of alcohol increased physical activity, termination of pregnancy, recovery from infection and fever.

Symptoms of hypoglycaemia are shakiness, sweating, increased heart rate, dizziness or light-headedness, hunger, nervousness, change in behaviour or personality, tingling or numbness of lips and tongue, sleepiness, blurred vision, loss of coordination, headache, weakness, trouble concentrating, confusion, paleness, irritability. In severe cases, unable to eat or drink, seizures or convulsions, unconsciousness.

Management-unconscious patient

- Termination of the dental procedure
- Patient should placed into supine position with leg elevated slightly
- The steps of BLS quickly (check airways, breathing, pulse)
- Summoning of medical assistance
- Iv infusion
- Administration of oxygen

Management-conscious patient

- Recognized hypoglycaemia
- Terminate dental procedure
- Position patient comfortably
- Assess and perform BLS, as needed
- Definitive care: administer oral carbohydrates
- Successful: unsuccessful
- Permit patient to recover summon medical assistance
- Discharge patient administer parenteral carbohydrates
- Monitor patient
- Discharge patient
- Unconscious patient
- Terminate dental procedure
- Position patient supine with legs elevated slightly
- Assess and perform BLS, as needed
- Definitive care:
- Summon emergency medical assistance
- Administer carbohydrates
- IV 50% dextrose solution, 1mg glucagon, transmucosal sugar, rectal honey or syrup
- Allow patient to recover and discharge per medical recommendation

2. **Hyperglycaemia:** Hyperglycaemia is not a life-threatening emergency but if left untreated can lead to diabetic ketoacidosis and diabetic coma which are life threatening. It can occur in anytime, abnormally high glucose level due to insufficiency of insulin. Other than diabetes, condition which can lead to hyperglycaemia are pancreatitis, Cushing syndrome, pancreatic carcinoma, adrenal insufficiency. Symptoms of hyperglycaemia include glycosuria (high levels of sugar in the urine), frequent urination, increased thirst, fatigue,blurred vision

Treatment-lifestyle modification can markedly decrease the incidence of hyperglycaemia, like daily exercises and eating healthy and well proportionate diet at right time. People who have random glucose level> 240mg/dl should always check for ketone bodies as they are always prone for diabetic ketoacidosis.there are many oral administered anti hyperglycaemicagents (OHA) and insulin therapy to reduce blood sugar level[13].

3. **Diabetic Ketoacidosis:** It occurs due to imbalance between insulin and blood glucose. When insulin level is too low, large amount of cells undergo breakdown which leads to formation of acidic ketone bodies.these ketone bodies are toxic to body, If left undiagnosed and untreated it can lead to coma and death.

Symptoms-fruity odour breath,dry mouth, high blood glucose levels, high levels of ketones in the urine, frequent urination, shortness of breath, tired feeling, dry andflushed skin, nausea, vomiting and abdominal pain, confusion

Treatment-if is suspected, immediate hospitalization is needed, with immediate glycaemic control with insulin therapy[14].

Conclusion

There is huge impact of altered glycaemic level in every system of the body including oral health. A healthy oral cavity is definitely directly proportional to the good prognosis and various treatment measures associated with diabetic mellitus. It is the major role of the dentist to know the underlying causes of the periodontal diseases, resulting from disturbed glycaemic level in patients. Various surgical and non-surgical therapies, depending upon the grade of infection of the periodontist should be performed to ease the other complication arising from diabetes so early diagnosis and early control of glycaemic level prevents serenity of these manifestation.

Applications of Botulinum Toxin in Dentistry

Reshmin Begum[1], Sthitaprajna Lenka[2], Smrutirekha Marandi[3], Barsa Ray[3], Bhawani Patro[3]

[1]Intern, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The prospect of treatment options in dentistry are broadening rapidly. Application of conservative, minimally invasive and affordable treatment options like use of botulinum toxin are gaining popularity. The toxin is produced by anaerobic bacterium Clostridium botulinum. It can be used as a treatment option for muscle generated dental diseases and used to treat esthetic dental conditions.

Keywords: *Botox, botulinum toxin, BTA.*

Introduction

Botulism term was derived from the Latin word botulus, meaning black sausage. Initially found in rotten sausage, that induced food poisoning. This toxin was discovered by Justinus kerner in 1817. It was the first toxin to be adopted in medicine, approved by the US Food and Drug Administration. Subsequently, while treating a patient with blepharospasm using BTA, Carruthers serendipitously discovered that it reduced the appearance of wrinkles in the glabellar region. Then they found that it was also effective on wrinkles around the eyes and the nasolabial folds[1]. The toxin is used in dentistry for treatment of diseases like parafunctional clenching, extra capsular myogenic temporomandibular disorder, trismus, and the associated headaches.

Structure and Types of Toxin: There are eight serologic types (A, B, C1, D, E, F, And G).Molar mass: 149kg/mol. The serotypes that are harmful to the human system are A, B, E, F, and G. Among which BTA is highly toxic. BTA and BTB are clinically used and their active regions are specific with a desirable effect that can be obtained by controlling the concentration[1].The most commercially available and used BTA products marketed worldwide are BOTOX®; ALLERGAN, Dysport® and for BTB,MYOBLOC®. BOTOX® is more effective than dysport® and MYOBLOC®, thus the doses used during treatment should be chosen cautiously.

Mechanism of Action: BT shows an action of dose dependent weakening of muscle activity, as it is injected into the required muscle. It causes a short term degeneration of nerve supply to the facial muscle by attaching itself with glycoprotein complex and suppresses the discharge of acetylcholine leading with neuromuscular blocking effect. However, it can be re-developed by germination of new proteins. Therefore, blockade is temporary. Thus, treatment with botulinum is actually a palliative approach rather than a curative option[2].

Preparation: Botulinum toxin is reconstituted with preservative-free 0.9% sodium chloride. Therefore, it should be stored in a refrigerator with a temperature of 2-4 degree Celsius and discarded if more than four hours elapse after reconstitution. The preferred syringe is a tuberculin syringe with a 26-30g needle[3]. It is recommended that the reconstitution should be gentle a*s* froth arising out of vigorous shaking can lead to surface denaturation of the toxin[2]. The toxin is dispensed in small vials containing 100 U or 500 U.

Injection Method: The patient position should be perpendicular to the floor; the site of injection must be properly inspected while the patient is forming different face expressions which will help in determining the

Corresponding Author:

e-mail: sthitaprajanalenka@gmail.com

exact area. The areas to be injected should be sterilized with betadine. Before injecting, application of ice is preferable to stop bleeding along with pain. The toxin is infused and some pressure is applied if bleeding is seen at the site. After completing the procedure, patient lies in straight position for some minutes. then the patient is given postoperative instructions which are; avoid lying down for 4h, no strenuous activity to be performed for 24hrs. Pain killers shall be prescribed if pain is present, ice packs can be applied to lessen bleeding and swelling if present. Dosage differs in both females and males which is determined by volume of muscle as the latter has more muscle volume they require more doses to achieve a desirable results. The results are visible within 4-14 days and lasts up to 4-6 months[4].

Clinical Application of Botulinum Toxin in Dentistry: BT is best known for its cosmetic uses. It is acquiring more popularity in the field of dentistry, where it is used for improving dental esthetics of patients as well as used for therapeutic purposes. Botox® has received maximum approvals and is used worldwide.

Cosmetic Uses:

1. **Facial Wrinkles:** The most common treatment done by BT is for wrinkle therapy. Facial wrinkles become more prominent with aging due to pull in the skin by lower facial muscles. It has been also used in the treatment of horizontal forehead lines perioral lines, platysmal bands and crow's feet. The potency of BTA in diminishing of facial wrinkles has been proven in randomized controlled trials. BTA is injected at least 1 centimeters above the orbital rim avoid injecting frontalis to reduce the chances of the brow ptosis. The injection site and the pattern of injections vary depending on the desired brow position. It is preferred to inject lower doses away from the brow so as to avoid the frozen look[2].

1. **Massetar Muscle Hypertrophy:** Masseteric hypertrophy is caused due to parafunctional use of the jaws or clenching. The conventional treatment is partial resection surgery of massetar under general anesthesia which has various complications whereas BT used in such cases has seen to be safer and efficient. Injection sites identified by palpation during clenching receive 12 U of BTA percutaneuosly in the thickest part of the muscle[2].

2. **Gummy Smile:** Excessive visibility of gingival tissues in the maxilla while smiling caused by hyper-functional muscles of the upper lip. The etiological factors can be altered passive eruption of teeth, hyperactive upper lip muscles, dentoalveolar extrusion, and vertical maxillary excess. Several surgical techniques are used for the treatment; however BT injections have gained popularity for the treatment of gummy smile because of less invasive, cost effective and require less time. Muscle are injected close to the nasalis or orbicularis oculi, with some fibers intermeshing the elevator labii superioris, levator labii superioris alaeque nasi, levatorangulioris, and zygomaticus major and minor[5].

3. **Drooping of Corners of Mouth:** It is caused due to hyperactivity of depressor angulioris. The site of infusion is the trajectory of nasolabial fold to the jaw line.

4. **Asymetric Smile:** Facial asymmetries may happen due to over activity of one of the depressor labii inferioris[6]. The muscles responsible for upper asymmetric smile are the lip elevator muscles while the muscles responsible for lower asymmetric smile are depressor labii inferioris and depressor angulioris. The injection site is the muscle fibers of the depressor labii inferioris.

5. **Perioral Rhytidis:** They are also called as smoker lines .the vertical. It is induced by continuous constriction of orbicularis oris which is elevated with certain factors like age. Botox injections or derma fillers are choice of treatment for them.

6. **Sad/Reverse Smile:** This is caused due to ageing as the skin loses its firmness due to decrease in the consistency of collagen and elastic fibers. BT injections have proved its efficacy in the treatment of this condition.

Therapeutic Uses

1. **Temporomandibular Joint Disorders:** Temporomandibular joint disorder is a term used to describe disharmony in the TMJ, masticatory muscles, and its associated structures due to orthopedic and myofacial disorders. These disorders can be treated by application of BTA. BTA is the treatment of choice because surgery is an expensive and invasive treatment option.

2. **Trigeminal Neuralgia:** Also called tic doulourex, is a chronic pain condition that affects the trigeminal

or 5th cranial nerve, one of the most widely distributed nerves in the head. Its management is based on prophylactic pharmacological treatment with anti-epileptics and neurosurgical treatments are recommended which may cause damage to nerve therefore, BT has been found to be efficient treatment for this condition.

3. **Facial Nerve Palsy:** It is neurological condition in which facial nerve (cranial nerve 7) is partially or completely lost. BT has been found to be efficient treatment for this condition.
4. **Bruxism:** Severe clenching and grinding of teeth is termed as bruxism. Commonly, oral appliances are used in this condition. BT has been found to be efficient treatment for this condition whose effect lasts for at least a month.
5. **Chronic Migraine:** Chronic migraine is a disorder which is highly discomforting. BT can be used to treat this condition.

Contraindications: Allergic to any botulinum toxin preparation[8], septicity at injection site[8], Pregnancy and lactation[3] are the various contraindications to Botox therapy.

Adverse Effects: In general, adverse are uncommon and localized. Side effects include neck pain, muscle stiffness, rash, itching, and headache. This can also accompanied by nausea, diarrhea, stomach pain, loss of appetite. The two most common medication related side effects from BT orofacial injections are alterations in salivary consistency and inadvertent weakness of the swallowing, speech, and facial muscles[2]. Some effects may be seen beyond the site of injection "spread of toxin effect". Generalized muscle weakness, diplopia, dysphagia, and breathing difficulties[3].

Conclusion

The innovation of BT in the field of medical science has widened the horizon of dentistry. A dentist can deal and treat various conditions with botulinum as dentists' have a vast knowledge about the head and neck. They can treat problems related to facial and oral cavity using BT injections with proper training. BT has been seen to be more efficient and successful in treatment of many facial and oral musculature dysfunctions. It provides with quick, conservative and painless approach. As it is a minimally invasive technique patients do not undergo through complicated surgeries. BT though, has good safety profile but should be used at recommended doses to avoid the risk of toxicity of toxin. The site of administration also plays an important role in its efficacy. Therefore, BT is a great asset in the field of dentistry.

Current Scenario in Management of Condylar Fracture: Review Literature

Trupti Sahoo[1], Subrat Padhiary[2], Stiti Pragnya[3]

[1]Intern, Institute of Dental Sciences, [2]Professor, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, [3]Post Graduate Student, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The treatment of mandibular fractures has created a large number of conversation and dispute in maxillofacial accidental cases and there are a lot of techniques to treat them. Condylar fracture can be extracapsular or intracapsular, displaced, deviated, displaced or dislocated. The management of condylar fracture can be done by conventional management using closed treatment or surgical management with open approach. Most surgeons look for closed treatment. Yet open reduction of condylar fracture with RIF has become increasingly popular in recent years. The management of mandibular condylar fracture can be considered by the patient's age, the presence of upper and lower jaw fracture, if the condylar fracture is unilateral or bilateral, the stage and movement of the fracture, the dentition status and occlusion of tooth.

Keywords: *Mandibular Condyle, Temporomandibular Joint, Fractures.*

Introduction

Mandibular condylar fractures are commonly found in 20-62% of all the mandibular fractures[1]. The cause for the increase rate of condyle fracture is due to the joining the ramus of mandible with high strength and firmness with condylar head along with low stiffness[2]. Road traffic accidents, falls and interpersonal violenceare the main reasons for condylar fractures[1]. Pain, restricted movement of mandible, muscle contraction, deviated mandible, malocclusion, extreme modifications in the temporomandibular joint, osteonecrosis, facial irregularity and ankylosis, irrespective if the treatment was done or not are the main difficulties in mandibular fractures[3]. Condylar fractures can be treated through one of two method with conservative (closed reduction + immobilization) and /or surgical (open reduction + internal fixation) method[1]. Many surgeons suggested closed reduction due to arising complications of surgical method, like infection, nerve injury, injury to blood vessel, and scar. Currently open treatment has been more commonly used by reducing difficulties such as pain in TMJ, arthritis and restricted mouth opening through precise reduction of fractured fragments with the development of novel surgical tools and various surgical method[4].

Closed Reduction and Functional Therapy: For closed treatment, IMF is completed using arch bar and wire, followed by retaining the fixation of both the jaws for 2-4 weeks. After getting constant union of the fractured area, a wire for IMF is detached. Then standard occlusion is made after fixation using rubber, and after that 2 weeks of soft diet is continued. Physiotherapy that contains exercise of the mandibular movement and exercise of mouth opening is directed[2].

Advantage: It is a comparatively safe. During the treatment no nerves and blood vessels injury happen and also there is no difficulties such as scar and infection in postoperative period.

Disadvantage: Long duration in IMF has drawbacks like periodontal tissue injury and buccal mucosa, poor

e-mail: trupti.sahoo95@gmail.com

oral hygiene, speech disorder, improper nutrition, mouth opening complaint and breathing disorder[4].

Open reduction and internal fixation: Severalmethod of open reduction are there depending on damaged area and degree of fractured bone displacement. Generallythe various method to visualise the fracture are preauricular, postauricular, submandibular, Risdon, combinedand retromandibular approaches[2].

Advantage: In direct approach to the fracture site, the reduction of the fractured fragment has a best anatomical result. It can avoid difficulties like breathing disorder, speech disorder, and dietary difference by shortening IMF period through rigid fixation.

Disadvantage: It is an invasive management, which may cause nerve or vessels damage perioperatively and postoperative problems can be seen including infection[4.]

Literature Review: Ellis and Throckmorton related the vertical measurement of mandibular and facial morphology after open or closed reduction for mandibular fractures of condylar process, in 146 patients. Eighty one cured by closed and sixty five by open techniques. The patients cured by closed approaches established irregularities, categorized by shortening of the facial aspect of injury[5].

In the study of the Santler et al. two hundred thirty four patients with mandibular condylar fractures are treated with open or closed method. Patients treated with surgery were greatly complained of pain at peak opening of the mouth. In patients with severely dislocated condylar fractures, open reduction is only indicated[6].

Marker et al. planned study to record the effects of closed condylar fractures management which showed that closed condylar fractures management is atraumatic, safe, and reliable and in only a few cases can cause malocclusion and distorted function[7]. Rutges et al. conduct a study with closed reduction that comprised of MMF with wires in case of severe occlusal disorders. Elastic MMF has been used to treat mild occlusal disturbanes[8].

Villarreal et al. conduct a retrospective analysis of one hundred four condylar fractures. The functional development achieved through open method was greater than that achieved through closed method. Open reduction improved the occurrence of condylar postoperative defects and mandibular irregularity[9].

Hyde et al., observed 42mm of incisal opening in surgical group while in conservative management group with elastic traction, it was 32mm. According to this, the result of this study was signified the importance of surgical over conservative management[10]. According to Eckelt et al. significant differences were found for the parameters of lateral excursions in the surgical (up to 16mm) against the closed (up to 13mm) groups[11]. Carneiro et al. decided that there were no differences in the protrusive and lateral excursive movement whether condylar fracture was treated by surgical or nonsurgical method[12]. Ellis et al. determined that the patients cured by closed method had larger proportion of malocclusion related to the patients cured by open treatment method in spite of the detail, the early movement of the fractures was more in patients cured by open reduction[13].

Indications for open reduction of mandibular condyle fractures and rigid internal fixation[14-16]

Absolute indication:

1. When there is no synchronization between absolute or relative contraindications then only the patient is given the option of surgery
2. It can also be indicated in patients where the pre-traumatic occlusion cannot be restored by manipulation and closed reduction
3. If RIF is used to deal with other fracture of the face that causes the malocclusion
4. In certain cases for e.g. skeletal flaws, an entirety of periodontal diseases, less than 3 teeth per quadrant indicates that the firmness of occlusion is constrained
5. Shifting into the middle cranial fossa
6. Extracapsular lateral aberration
7. When there is a potentiality for fibrosis in an open fracture
8. Foreign body intrusion

Relative indication:

1. When oral orifice is completely edentulous
2. Periodontal predicaments
3. Condylar fractures which is mutually present in an edentulous patients without the use of splint
4. Unilateral or bilateral fractures in condylar region which splinting is not necessary for medical condition and functional therapy is unlikely

5. Reciprocally present fractures in condylar region with pulverised midfacial fragmentation, prognathy or retrognathy
6. Fracture of one side condylar with unpredictable base
7. Dereliction
8. Seizure irregularities which are unrestrained
9. Patient enduring from state of asthma
10. Psychological understanding
11. Paralysed neurological situation with early documentation of apprehended improvement in the patient
12. Substance misconduct

Contraindications for open reduction of mandibular condyle fractures and rigid internal fixation[14-16]

Absolute contraindications

1. Head of the condylar fracture csn be seen at the ligametous attachment which can of 3 types single fragment, communited or medial pole
2. If a health condition or chronic trauma increases the risk of a prolonged general anaesthetic
3. Perfect occlusion
4. Reduce pain
5. Suitable movement of mandible

Relative contraindications

1. If a simpler approach is just as efficient
2. Neck of the condylar fractures are perceptibility thin and are limited to the region below the condylar head

The determination of this review was to conclude if the literature indicates advantage of open vs closed management for condyle fractures in adult. Another study shows that ORIF improves most method of condylar and/or mandibular mobility (MIO, aerotrain, protrusion, and lack of chin deviation). In addition, it was better to improve reduction of postoperative pain and occlusion to open care patients[17].

In subcondylarregion, two main endoscopic approaches have been established. The procedure first defined by Jacobovicz in 1998 and the one favoured by the senior authors (Y.D., R.S.) includes the use of an endoscope by means of an intraoral incision with or without the use of Transcutaneous screw incision and trocar.[18,19,20] Troulis and Kabanlaterdefined an endoscopic-assisted extraoral approach to fractures in subcondylar region by a mini-Risdon approach through submandibular incision of 1.5cm. They reported an easierorientation with"en face" operating field visualization[21, 22].Schon et al studied the treatment of 17 intraoral or extraoral endoscopic-assistedpatients with mandibular fractures. They decided that the intraoral endoscopic approach was reliable for condylar fractures such as lateral override andthat the extraoral endoscopic approach was dislocated fractures such as medial override fractures was indicated[23]. Meulleret al. distinguished that outdated management of fractures in subcondylar regionwith MMF leads tomalreduction and significant functional and aesthetic sequalae, including facial irregularity, reduced mouth opening, and potential for late temporomandibular joint disturbances. The writers therefore encouraged endoscopic healing of adult condylar neck and subcondylar fractures that reveal dislodgment or dislocation and have adequate proximal bone stock to accept miniplate fixation[24]. Buschang's research in 1999, the highest of growth spurt among teenagers occurs in females (12.2 and 14.3) and correspondingly in males. The rate of growth then decreases incrementally in 1-2 years. [25].

In endoscopic approach, patient should be positioned on the operating field in flat position. Anaesthesia equipment should be away from the patient. The table should be $180^0$for the specialist and assistants to have access to the head.The settlement of camera monitors will allow both the surgeon and assistant to view the operation (Figure 1 & 2) [26].

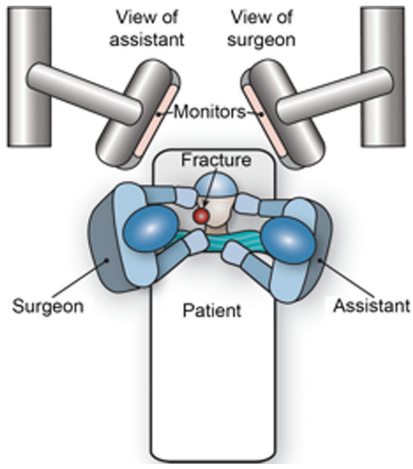

Fig 1: In this view, the camera should be positioned behind the surgeon and the assistant in order to allow both to see comfortably

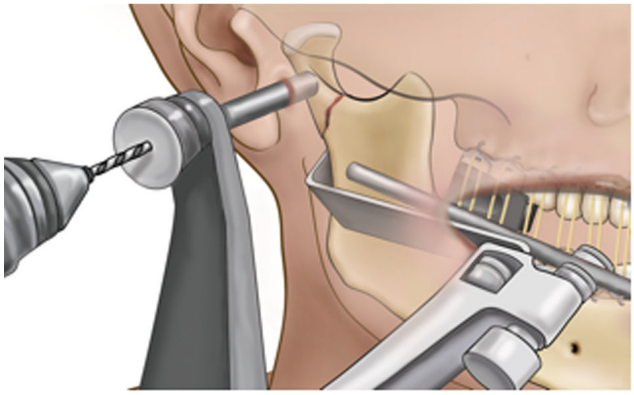

Fig 2: Endoscopic view of a percutaneous incision for direct observation with camera

Discussion

Controversy has historically plagued the management of subcondylarfractures. Years of study resulted in a better understanding of the biomechanics of tempero-mandibular joint and the profit of ORIF in cases of displaced and foreshortened subcondylar fractures. Open reduction problems have resulted in the development of modern surgical method and the implementation of new technologies, which increased the scope of subcondylar fracture for the craniofacial surgeon. [27].

The most common injuries in condyle fractures are seen in mandible and it is around 20%-62%. Surgical versus nonsurgical treatment of fracture remains contentious[28]. Recently, due to the progress, self-assurance and greater involvement of health care professionals with internal rigid fixation techniques, open method in children was widely accepted.

In adults with mandibular fracture, 3 therapy is recommended:

1. MMFphase is followed by physiotherapy
2. Physiotherapy with no Maxillomandibular Fixation time
3. Open Reduction with or without Internal Fixation[3]

It should also be noted that people who research condylar fracture management usually have extensive knowledge of whatever care they receive. Even though the findings of the studies in the literature may support ORIF over closed treatment for many variables of outcomes, specific experts may not have such advantages if their surgical procedures are not good. One must be able to carefullymake ORIF with least complications,if one is to understandthe improved outcomes. For those with little experience, it may be best to use CT and in case of malocclusion, orthognathic surgery can be used in the future

Different technology to improve transoral ORIF has ensured that some of the adverse ORIF related sequelaewere avoided by atransfacialmethod, such as facial damage of nerve. For example, using an endoscope to aid visualisation and right-angle drills and screw drivers has made transoral surgical approaches a reality, reduces the risk of facial nerve injury andeliminates the risk of facial injury.This method has been used in the management of mandibular condyle fracturesbut after a period of progress, the method has not been usuallyestablished[17].

The endoscopic-assited method in transoral are a safe and common methodforcondylar and subcondylar fractures. Patients cured with this approach indicateda higher effect in the mandibular area while it takes time and wants exclusive instruments. So, authors have therefore recommended the use of this procedure for adult subcondylar fractures in specific cases where acceptance and protection is a major concern for patients.[29]. After going through the major literatures on the controversy and our own institutional experience on treatment protocol for condylar fractures, we advocate for the open reduction technique in majority of cases. As we compare between the direct open surgeries with endoscopic technique, the later stays way advanced to the former in patient comfort and residual deformities. But till now very few centres are equipped and experienced in this novel technique and we are not so fortunate on that note. In future, surgeons should go for this endoscopic approach to the fractured condyle and refine the technique and instrumentation for the betterment of the entire fraternity and ultimately the patients.

Role of Medicinal Herbs in Periodontal Therapy

Rinkee Mohanty[1], Gatha Mohanty[2], Rashmita Nayak[3], Anurag Satpathy[3]

[1]Professor & Head, [2]Senior Lecturer, [3]Professor, [3]Professor, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Bhubaneswar, Odisha, India

Abstract

Gingival and periodontal diseases are among the common problems in oral health globally and is seen to be rising more in developing countries. Most of these diseases are caused due to the microbial aggregates in dental plaque. The conventional chemotherapeutic agents have limited success in the complete elimination and prevention of periodontal disease. Rise of incidence in periodontal diseases,increased resistance by pathogenic bacteria and the threat of opportunistic infections, has renewed the search for alternative and complementary treatment strategies over the years. Ayurveda the ancient system of healthcare mentions a large number of herbal plants beneficial in the management of periodontal infections. The nature derivedphyto-chemicals that are isolated from plants are considered to be better alternatives to synthetic chemotherapeutic agents. The herbs and medicinal plants in the medica (Ayurvedic material) have been proven not only to be safe and useful but with very minimal side effects. This paper attempts to study the various herbal medicinal plants that possess antimicrobial, anti-inflammatory, astringent, antiseptic and analgesic properties which can be used efficaciously for the prevention and management of the gingival and periodontal diseases with minimal adverse reactions. Hence an integration of modern oral hygiene practices with the ancient traditional ayurvedic herbs in the various gingival and periodontal diseases can provide safe, affordable and economic treatment options to patients in general and to the low socio-economic group.

Keywords: *Herbs, Ayurveda, Oral Hygiene, Gingival disease, Periodontal disease.*

Introduction

Oral diseases like Dental caries and Periodontal diseases in particular have become a major oral health concern worldwide. The connection between oral diseases and the action of the various microbial species existing in the oral cavity is well established[1]. A rise in the incidence of oral diseases (particularly in developing and underdeveloped countries), increased resistance to commercially available chemotherapeutic agents, opportunistic infections and financial constraints in certain strata of patients has led to the global need for finding alternative treatment and preventive options in the management of dental diseases, that are safer and economical[2,3].

Āyurvedaor the science of life is a 3000-5000-year-old system of Hindu traditional medicine native to the Indian subcontinent which stresses on the use of medicines derived from plantsand treatments. Herbal medicines are drugs of plant origin which are nowadays used to treat several systemic diseases as well as oral diseases to attain or maintain improved overall well being[4]. More than one thousand Indian medicinal plants are used informulations according to Ayurveda or other ethnicity[5].

In the recent years there has been a growing interest in the use of these herbal medicines in the management of periodontal diseases as welldue to their Anti-inflammatory,Antimicrobial, Antioxidant properties[6]. This review is an attempt to gain information and knowledge of the several herbal products that can beused in management and prevention ofperiodontal diseases.

Medicinal Herbs Used in Management of Periodontal Infections: Periodontal diseases have affected mankind since the beginning of mankind, are universal in nature and presently a major health concern all over the world. Dental plaque has been implicated as the primary etiological agent responsible for both gingival and periodontal diseases[7]. Untreated gingival and periodontal diseases cause inflammatory changes of the periodontium with formation of periodontal pockets and loss of attachment which eventually leads to tooth loss. In recent years, periodontal diseases have also been linked to a number of systemic diseases like Cardiovascular diseases, Respiratory diseases, Stroke, Diabetes, Preterm low birth weight babies,Arthritis, Alzheimer disease etc[8].

It is therefore very important to maintain the health of the periodontal tissues by using proper oral hygiene measures to reduce the inflammatory and bacterial load caused by dental plaque. Conventional oral hygiene maintenance procedure includes a combination of Mechanical Plaque Control (Toothbrushing, Interdental cleaning aids, Flossing etc) and/or Chemical Plaque Control (Chemotherapeutic agents in the form of mouth rinses). Ayurveda, the ancient system of medicine defines health as "the equilibrium of the three biological humours (doshas), the seven body tissues (dhatus),proper digestion and a state of pleasure or happiness of the soul, senses and the mind[9]. Various Ayurvedic herbal plants with their immensepotential in the management of dental health have been reviewed in the past. Various procedures in Ayurveda have been mentioned for maintaining the oral hygiene. These include *Dant Dhavani* (Brushing), *Gandoosha* (gargling) or oil pulling, *JivhaLekhana* (Tongue scrapping) and various tissue regeneration therapies.

Brushing or *Dant Dhavani* is chewing of herbal brushes in the form of sticks (called as dantakashta) in the morning and after every meal for prevention of oral diseases. These herb sticks are either "*katu*" (acrid), "*kashaya*" (astringent) or "*tikta*" (bitter) in taste. The method of use is to crush one end,chew it and eat it slowly[10]. Neem stick (*margosa*or *Azadirachtaindica*), fresh stems of *liquorice* (*Glycyrrhiza glabra*), *black catechu* or the *cutch tree*(*Acacia Catechu* Linn.), *Arjuna* tree (*Termmalia arjuna*), *fever nut* (*Caesalipiniabouduc*) and *milkweed plant* (*Calotropis procera*)[11] have proved beneficial in reducing dental plaque when used for brushing. *Gandusha* (gargling) or oil pulling: The swishing of oil in the mouth for oral and systemic health benefits is ancient Ayurveda. As a traditional Indian folk remedy, oil pulling has been used since years to prevent oral malodour, bleeding gums, decay, dryness of throat, cracked lips and for strengthening teeth, gums and the jaws[12,13]. Various oils have been used for oil pulling therapy such as coconut oil,sunflower oil, sesameoil or olive oil[14]. Clinical and microbiological studies have shownoil pulling therapy to be quite effective against plaque induced gingivitis[15,16].

Tissue regeneration therapies: *Amla* (*Phyllanthus emblica*) or the Indian gooseberry is considered as oral health rebuilder. *Amla*in the decoction form is quite effective as a mouth rinse. Healing of connective tissue is seen when one-gramamla is taken internally[17]. Regular use of *Bilberry* and *hawthorn berry* fruits stabilize collagen and strengthens the gum tissue[18].Besides *Liquorice* root has role in cavity prevention, plaque reduction and potent anti-bacterial effect[17].Along with the medicinal herbs mentioned above, there are several other herbal plants and their products which can be used to treat and manage gingival and periodontal diseases.

Traditional medicinal herbs used in Periodontal therapy and their Properties:

Amala (Emblica officinalis): It has well known astringent and antioxidant property to fight tooth decay, and is also effective in thetreatment of a toothache, gingival inflammation[19], apthous stomatitis[20] and mouth ulcers of many types.

Anar/Dalima (Punicagranatum): Pomegranate derivatives when applied topically has been found to be useful inreducing gingival inflammation as well as counts of bacterial and fungal units. Theantibacterial activity could be due to ingredients like ellagitannin,punicalagin found in pomegranates[21,22].

Launga/Clove (Syzygiumaromaticum): The primary component of clove's volatile oils being Eugenol works as an anti-inflammatory agent. Eugenol[23] also contains a variety of flavonoids and is used widely inroot canal treatment, as temporary fillings, dental abscesses, for gum pain, and other gum diseases[24].

Datiwan (Alucitabidentata): Stem is used as a toothbrush and is considered to be good in the treatment of pyorrhoea[25]. Its root juice can be used for the treatment of a toothache also. Leaves are also used.

Gotu kola (Centellaasiatica): Can be used to treat mouth ulcers and heal wounds with promotion of

connective tissue growth. Sastravaha et al[26] in a study impregnatedbiodegradable chips with *Centellaasiatica* and *P. granatum* and established its effecton periodontal disease. They found statistically significant improvements in reduction probing depth, plaque, and clinical attachment level gainat the end of 3 months in the test group when compared to the placebo.

Amra/Mango (Magniferaindica): Mango leaf contains ascorbic and phenolic acids which have knownanti-bacterial properties. They have the potential to fight periodontal pathogens like *Prevotella intermedia* and *Porphyromonas gingivalis*[27].

Neem (Azadirachtaindica): Several studies have documented the anti-bacterial, anti-inflammatory, analgesic, antioxidant, antifungal, antiviral, immunostimulant properties of neem.Chatterjee A et al.[28] have found out the anti-gingival and anti-plaque efficacy of Neem mouth rinse when used as an adjunct to routine periodontal therapy.

Nilgiri (Eucalyptus globulus): Eucalyptus extract shows both anti-cariogenic and anti-plaque property.

Tila/Sesame (Sesamum indicum): It is a rich source of vitamin E, phenolic compounds, and antioxidants. Sesame oilpulling reducedplaque index, gingival index and totalbacterial count of aerobic microbes in chronic gingivitis patients[14].

Triphala: It contains extracts of *Terminaliachebula*, *Terminalia belerica*and *Phyllanthus embelica*. Triphala shows inhibitory action against PMN, MMP-9 and some other collagenases[10]. Itpossesses *anti*-plaque properties and also usedas a gum astringent.

Harita/Turmeric (Curcuma longa linn.): Due to its excellent anti-inflammatory properties, turmericin the form of gel or mouthwash, can be very effective in reducing plaque and gingival inflammation when used as an adjunct to mechanical plaque control[29].

Curry leaf tree (Murrayakoenigiispreng): This green leafy plant known for its aromatic leaves. It forms an important ingredient of the Indian cuisine. It has been reported that 2.65 volatile essential oils such as sesquiterpenes and monoterpenesare found in fresh curry leaves which has broad antimicrobial effects on *S. mutans*, *Streptococcus sanguinis* and also helps to reduce halitosis.

Tea tree oil (melaleuca oil): It has antibiotic properties which is useful in management of chronic gingivitis, bleeding gums and halitosis. It also has the ability to penetrate the gingival tissues thereby making it beneficial for local applicationin inflamed gingival tissues.

Arjuna (Terminalia arjuna): Its active ingredients Arjunolic acid, ethyl gallate, flavone, ellagic acid and gallic acid have antimicrobial properties thus making it suitable in the treatment of multimicrobialperiodontal infections.

Rumi mastagi/mastic gum (Pistacialentiscus): It has antioxidant, anti-inflammatory as well asbactericidal effect. It is highly effective in the elimination of potential periodontal pathogens (*S. oralis*, *P. gingivalis*, *F. nucleatum*, *A. actinomycetemcomitans*, and *P. intermedia respectively*) that are commonly associated with periodontal disease.

Wheat grass: Burgeoning shoots of the *Triticum aestivum*plant, have antioxidant, antibacterial and anti-inflammatory propertiesdue to the presence of antioxidants, Vit-C and zinc. Wheatgrass juice or wheatgrasssupplement prevents gingival and periodontal inflammationby reducing or eliminating the potential periodontopathogens.

Goldenseal: Bererinewhich is an important component in goldenseal is known for its anti-bacterial, anti-viral and anti-fungal property. Goldenseal strengthens the immune system, prevents gingivitis and tightens the gums due to its astringent properties.

Licorice root: It is certified by the ADA as an herb that inhibits plaque accumulation and gum diseases. It has both anti-bacterial and anti-viral properties.

Meswak (Salvadorapersica): Meswak, is derived from Arak tree (*Salvadorapersica*) that grows mostly in Saudi Arabia and several other parts of the Middle East. It is mainly used as a chewing stick instead of the traditional toothbrush to maintain oral hygiene by different cultures in several underdeveloped countries. The Meswak extract has also been incorporated in dentifrices in the recent years because of its antiplaque and antigingiviticeffects.

Berberis vulgaris: It contains Berberine, an alkaloid agent which has highantiplaque and anti-gingivitis properties. Most active alkaloid (isoquinolines group) is extracted from the root and stem of the barberry plant.

Lippiasidoid: The major components of *Lippiasidoides* essential oil possesses potent antimicrobialproperties and is effective against oral pathogens to reduce the accumulation of dental plaqueand severityof gingivitis by reducing the inflammatory load.

Tulsi (Ocimum sanctum): Tulsi has antimicrobial property against a varietyof microbes like *C. albicans*, *Staphylococcus aureus*, *Escherichia coli* due to its phytoconstituents which include eugenol, palmitric acid,vallinin, galic acid, Vitamin A, Vitamin C etc which prevent plaque and calculus and reduce halitosis.It also has astringent and mouth freshening properties.

Myrrh: This ancient herb is known since ages and has a lot of medicinal properties. Hence using myrrh oil as a mouthrinse by adding to warm water is a very effective way to alleviate bacteria and maintain good oral hygiene.

Sage: The herb Sage has antibacterial properties which helps prevent plaque formation, prevents tooth decay and alsohelps to cure oral sores.

Green tea: Epigallo catechin 3 gallate and Epicatechin 3 Gallate are the most predominant catechins found in green tea.

The anticollagenase, antimicrobial, antioxidant, antimutagenic and hemostatic properties of the catechins are found to be of great use in periodontal disease treatment. The green tea catechins affect the red complex periododontopathogens. Sanjeevini et al. (30)in a short term studycould assess the effect of greentea catechins on the red complex organisms using PCR analysis and found Green teato be very effective in reducing the periodontal pathogens when used as a local delivery system as an adjunct to scaling and root planing.

Shiitake mushrooms lentinan: Shiitake mushrooms have a role against bacterial, fungal, viral pathogens. Shiitake is aherb which is very useful and forms the base of several plant extracts like lentinan. Extremely rich in Polysaccharides (beta-glucan) and lentinan, these mushroomshelpin stimulating the immune systemand promotes the innate immunity to combat certain illnesses.

Conclusion

Plaque induced gingivitis and periodontitis are among the most important diseases affecting the oral cavity. Ayurvedic classic literature has given a list of all the naturally available herbs and medicinal plants but it is very important to select the herbs carefully and have a thorough knowledgeof the properties of the herbbefore using it for treatment purpose.

Herbal extracts are being used in periodontal therapyto reduce gingival inflammation,as anti-plaque agents, as antiseptics, antioxidants,antimicrobials, antifungals, antibacterial, antivirals andanalgesics. They are also effective as gum astringents and as mouth freshening agents. The traditional knowledge of Ayurveda and the modern oral hygiene method should be integrated and encouraged to provide safer and more affordable treatment options especially to the lower socioeconomic strata of the society. Further studies and greater research are however required to assess the long-term anti-plaque efficacy, toxicity and interactions of these herbal medications when used for maintenance of oral hygiene.

Osteodystrophy of Jaw: A Review

Namrata Mishra

Post Graduate Trainee, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India

Abstract

Pathologies particularly for jawbones and do not occurs in any bones are linked to odontogenic tissue or dentition. Jaws may anchorage non-odontogenic bony pathologies are not visible in any region of body. From the other bones are different in many wider aspects. It is special due to its progress from chambers moving from embryonal neuroectoderm embryologically. Tooth associated jaw bony lesions are classified in odontogenic tumors and cystic lesions. It includes various lesions such as fibro-osseous lesions, giant cell pathologies, bone tumors may be neoplastic or non-neoplastic and reactive bone disease, some disease are related connective tissue,nutritional deficiency, craniostenosis syndrome.

Keywords: *Classification of Jaws, Connective Tissue Disorders, Craniosynostosis Syndrome.*

Introduction

From the other bones are different in many wider aspects. It is special due to its progress fromchambers moving from embryonal neuroectoderm embryologically. Tooth associated jaw bony lesions are classified in odontogenic tumors and cystic lesions. It includes various lesions such as fibro-osseous lesions, giant cell pathologies, bonetumors may be neoplastic or non-neoplastic and reactive bone disease, some disease are related connective tissue,nutritional deficiency,craniostenosis syndrome.[1]

1. **Connective tissue disorders:** Osteochondrodysplasia and craniosynostosis syndrome:

   Osteogenesis imperfecta, Apert syndrome, Crouzon syndrome, Ehlerdanlos syndrome, Cleidocranial dysplasia, Achondroplasia, Chondroectodermal dysplasia, Marfan syndrome

2. **Metabolic bone disease due to nutritional deficiency/calcium metabolism disorders:** Osteomalacia, Rickets, Scurvy, Renal osteodystrophy, Vitamin d resistant rickets, Hypophosphatasia, Langer cell histiocytes.

3. **Endocrine disorders**: Hyperthyroidism, Hypothyroidism, Hyperparathyroidism, Hypoparathyroidism, Hyper-adrenal Cushing syndrome, Hyper pitutarism-gigantism/acromegaly, Hypopituitarism-dwarfism/Simmonds disease.

4. **Fibroosseous lesion:** Fibrous dysplasia: Mono ostotic Fibrous dysplasia, Polyostotic Fibrous dysplasia, Craniofacial Fibrous dysplasia

   Osseous dysplasia: Periapical osseous dysplasia, Focal osseous dysplasia, Florid osseous dysplasia, Familial gigantiformcementoma

   Ossifying fibroma: Conventional ossifying fibroma, Juvenile trabecular ossifying fibroma, Juvenile psammomatoid ossifying fibroma

   Others: Paget's disease, Cherubism, Massive osteolysis, Infantile cortical hyperostosis, Hyperostosis corticalisgeneralisata, Tricho-dento-osseous syndrome. [2]

Osteogenesis imperfecta: It is also known as brittle bone disease or lobsteindisease. Many infants depict with this disease are still born or die shortly after birth, patient shows bone deformity hyper extensibility and hyper elasticity and joint deformity of joints, extreme fragility and porosity of bones which are prone to fracture, formation of hyperplasticcallus, which resembles osteosarcoma. There is presence of faint blue sclera which is slim,pigmented choroids depicting and producing blue hue. Dentinogenesis imperfecta is the manifestation of osteogenesis imperfecta, there is occurrence of enamel hypoplasia, class 1

malocclusionalong with impacted 1st and 2nd molar is associated, ectopic dentition is also there, appearance of poorly calcified and semi translucent deciduous teeth. It also shows pale dirty pink, half normal size, with globular crowns with short roots along with maxillary hypoplasia.[3]

Marfan syndrome: It is also termed as marfanachard syndrome or arachnodactyly, because of defective gene FBN1 gene, it is also autosomal dominant disorder. Clinical features of this disease are patient depicts tall stature, lateralcurvature of spine (scoliosis), webby finger (arachnodactyly), pigeon chest deformity, funnel chest appearance, Steinburg thumb sign, dolichostenomelia,joint hyper mobility, ocular disturbance like catact retinal detachment,flat cornea, cardiac issues like aortic root expansion. Steinberg thumb sign which highlights after closing the thumb in close fistis considered to be positive if thumb extension is from palm of hand. Patients will be having enlarged frontal sinus with frontal bossing, temporomandibular disorders with enlarged skull height. Oral clinical presentation is bifid uvula, high arched palatal vault, malocclusion, variousodontogenicinfections of maxilla and mandible.[4]

Osteopetrosis: It is coined as marble bone disease or also known as stone bone disease or Alberg Schonberg disease which is an extremely rare inherited abnormality where the bone becomes hard and dense which can lead to osteosclerosis.It has two types of clinical representation fist one is non neoplastic autosomal dominant type and another is neoplastic autosomal recessive type. Non neoplastic form is associated with adult group and neoplastic form is associated with infantile group.[5]Oral manifestation of this disease is delayed tooth eruption,partial absence of teeth,enamel hypoplasia, abnormal dentinogenesis,proneonatal dental caries, mandibular proclination,multiple odontomes,widened lamina dura,abnormalities of periodontal membrane,in case of osteopetrosis, the number of osteoclasts may be decreased,normal or elevated .mostly osteoclast dysfunction enhance the pathogenesis of this disease,lacuna of carbonic anhydrase in the osteoclast is noticeable.[6]Mild osteopetrosis leads to no symptoms and presence of no problems but in case of serious forms it can lead to stunted growth, deformity and elevated risk of fractures. Patients suffer from anaemia, hepatosplenomegaly, recurrent infections, extra medullary haematopoiesis. It can lead to blindness,facial palsy, deafness and due to escalated pressure given on the nerves from the excessive bone formation encircling on the cranial nerve foramina. Differential diagnosis of this disease are hypervitaminosis D, hypoparathyroidism, Paget's disease,diffuse bone metastasis of breast or prostate carcinoma,intoxication with fluoride, lead or beryllium and haematological disorders such as myelofibrosis, leukaemia, sickle cell disease. Corticosteroids are given to treat anaemia and revitalizing bone resorption as well as fractures and osteomyelitis can be treated.[7]

Crouzon syndrome: It is also as craniofacial dysostosis or craniostenosis or Crouzon craniofacial dysostosis. It is a sporadicinheritedcondition which is a mode of craniosynostosis, where there is a previouscombination of fibrous junctions between certain frames of cranium. In case of this disease there is fusion of sutures in a premature case distressing the appropriateprogression of cranium and head and potentially altering the shape and development of skull.Crouzon syndrome is initiated due to alterations of FGFR2 gene usually FGFR2 which is inherited autosomal dominant. It is principally categorised by previous closure of fibrous junctions between certain bones in cranium and distinctive facial anomalies. It shows brachycephaly,eyeballs appear to protrude or bulge forward proptosis, hypertelorism,strabism us,frontal bossing,midface hypoplasia, short upper lipohyperplasia maxilla along with mandibular prognathism, exceedingly arched palate with congested teeth and malocclusion. Crouzon syndrome with (acanthosis nigricans) is a rare genetic abnormality which represents abnormal velvety thickening and hyperpigmentation of dermis,advanced hydrocephalus and thinning or jam of back of adenoidalroute is seen.[8, 9]

Apert syndrome: Apert syndrome is a type of acrocephalosyndactyly. It is characterised by craniosynostosis which affects the proper growth of skull and head. It is categorised by craniosynostosis, prematuretermination of fibrous junctionsamongst certain bones in the skull. It may have widely spaced eyes (hypertelorism), bulging eyes, down slanting palpebral fissures, maxillary hypoplasia and cleft palate .Bilaterally faces are not symmetrical, patients representing flattened nose with low bridge,delayed tooth eruption, malocclusion, open bite, having moderate to severe acne,malformation of tracheal cartilage, upper respiratory tract infections,sleep apnoea and malnutrition. It is triggered by a transmutation in the "fibroblast growth factor receptor 2 gene" which plays a

critical role in skeletal development.[10,11]

Pierre–robin syndrome: "Pierre robin "a French stomatologist,invented this condition in 1923,Pierre robin arrangement was actually elaborated as combination of "micrognathia" which is designated as mandibular hypertrophy and an atypical posterior establishment of the tongue (glossoptosis) which leads to airway obstruction and feeding difficulties .The tiny mandible is known to be due to an essentialinherentanomalies or a deformity problematic where intra uterine development is obstructed or mandibular arranging is altered. In PRS the micrognathia progresses to glossoptosis, which leads to airway obstruction and unable to feed. Mostly, family members of PRS infants have greater chances of cleft lip and palate. Cleft palate is linked with deletions on (2qand 4pand 3p,3q,7q,78q,10p,14q,16p,22q) deletions. Micrognathia is linked with "4p,4q,6qand 11q deletions and 10q and 18q" duplications. Mainly it is clinically diagnosed with"PRS "by using (fluorescence in situ hybridisation) (FISH) and (array comparative genomic hybridisation) (ACGH).Conclusion of this study is 40 percent of (PRS was secluded and 60 percent) were linked up with another syndrome they were "Stickler and Velocardiofacial syndromes". "Stickler syndrome" is linked with mutation in (COL2A1,COL9A1,COL11 A1,COL11A2), whereas "velocardiofacial syndrome"is caused from a microdeletion of chromosomes (22q11.2)." Jakobsen et all"highlights that non syndromic PRS is associated with (SOX9 and KCNJ2)dysfunction, both on chromosomes 17,related to a series of unrelated PRS patients,those who had a balanced translocations between chromosomes 2 and 17.It is associated with stickler syndrome which is an autosomal dominant condition which signifies short mandibular ramus, antegonial notching of mandibular body, myopia and joint problems. Velocardiofacial depicts retrognathic mandible, hypotonia, palatal abnormalities impaired thymus growth and cardiac malformation. Non-surgical management like nasopharyngealtube is used to avoid the site of upper airway obstruction. Tongue Lip Adhesion is used to resolve the problem of gloosoptosis by pulling the base of tongue forward and suturing the lower lip. It can be completed on infants who do not have any lower teeth, as they could connect taste through the reparation.[12,13]

Ehlers danlos syndrome: "Ehlers danlos syndrome "is coined for a group of consisting heritable soft connective abnormalities which depicts generalised joint hypermobility, skin texture disorders and visceral and vascular dysregulations. Type 5 collagen disorders is the cause of a classical variety EDS. Joint hypermobility is relatively maximum found in upto one third of children. It has a clinical presentation such as musculoskeletal and neuropathic pain,joint instability,fatigue, anxiety and cardiovascular disorders.[14]

Cleidocranial dysplasia: It is a very uncommon congenital abnormalities which is of autosomal dominant inherited disorder that progresses the disturbance in the development of the bones of cranium, clavicle and facial skeleton. The most vital representation is clavicular hypoplasia which progresses the ability to approximate the shoulders anteriorly. It also depicts the frontal, parietal, occipital bossing, open fontanelles, pubic symphysis is wide,stature is short, mental retardation, hypertelorism, delayed skeletal maturation,acute gonial angle is short .Dental abnormalities shows multiple supernumerary dentition,retained deciduous teeth, class 3 malocclusion, delayed eruption, high arched palate .This disorder is associated with mutation in (RUNX2 gene)called as CBAFA 1 gene which is present on the tiny arm of chromosome 6p21,responsible for proper functioning of osteoblasts .Also depicts naso-orbiti maxillary hypoplasia depressed nasal bridge,short tapered fingers, seldomly brachial plexus irritation occurs.[15,16]

Achondroplasia: Achondroplasia is the supreme general form of dwarfism in human population. It happens with anoccurrence of 1 in 15-25000 and in 80 percent cases. It is an autosomal dominant genetic disease, shortstature in achondroplasia mainly leads from restriction of limbs with adjacent piece sex aggerated disproportionately, a phenotype called as (Rhizomelia). Large cranium with frontal bossing and hypoplastic mid face is due to growth of cartilage defects at cranium base. Foramen magnum narrowing and spinal stenosis are more common and needs neurosurgical corrections. The dimension of the trunk is comparatively normal but is often deformed by excess lumbar lordosis. Genetic relationship studies placed in the achondroplasia gene on tiny arm of chromosome 4 and mutation analysis identified an arginine to glycine substitution at residue 380 in "fibroblast growth factor receptor 3 "(FGFR3). A severe complication narrowing of the spinal canal due to degenerative deviations of the spinal canal can cause to nerve root compression and requires surgical decompression.[1-3,17]

Chondro-ectodermal-dysplasia: "Ellis van creveld

syndrome " also known as chondroectodermal dysplasia, mesoectodermal dysplasia or chondrodystrophy, which is a rare autosomal recessive congenital disorder .It is characterised by chondrodystrophy, polydactyly, ectodermal dysplasia and congenital cardiac abnormalities .Patients depicts growth failure of the proximal tibial epiphysis and the tibial segment can be disproportionately smaller than femoral segment,or fibula may be smaller than tibia. EVC is happened by a mutation in a non-homologousgene, EVC2, which is positioned close to EVC gene in a head to head configuration. Oral manifestation shows hyperplastic frenula, absence of mucobuccal fold, gingival hypertrophy, hypodontia, dystrophic philtrum and cleft palate. The differential diagnosis of EVC includes Weyers syndrome, Mckusick Kaufman syndrome Jeure syndrome. Treatment should be initiate as early as possible which requires gingivectomy, frenectomy, amputation of extra digits beneath sedation or general anaesthesia.[1-3]

Downs syndrome: Downs syndrome is the furthermost commonly occurring chromosomal disorder in human population. It is the genetic cause of intellectualdisabilities worldwide. This syndrome is caused due to trisomy of the whole or part of chromosomes 21 un all or some cells of body and gradual elevation in expression due to gene dosage of "trisomic genes". It shows mental retardation, short stature, congenital cardiac disorders, gastro-intestinal defects, weak neuro muscular tone, morphologically abnormal features of head, neck and airways, visual and audio-vestibular impairment, hematopoietic abnormalities.[1,18]

Osteoporosis: Osteoporosis is characterised by less bone mass, structuraldegradation and porous bone which are linked with greater risk of rupture, and porous bone are linked with high prone to risk. Loss of bone is related to minimising oestrogen levels escalation. Fracture risk in post-menopausalfemales. Screening and diagnosis use a bone strength. patients having less body mass are more prone to fracture.[12] Use of glucocorticoids and patients suffering from rheumatoid arthritis are more chances of having osteoporosis. Diagnosis is done by the measurement of bone mineral density or by occurrence of a fragile fracture of hip or vertebra or absence of any kind of trauma. It is measured through dual x ray absorptiometry, which depicts a real expression of the bone in exact terms of grams of mineral as g/cm 2 of calcium per square cm of the detected bone.[5-7]

Infantile cortical hyperostosis: Infantile cortical hyperostosis is also termed as" Caffey disease" or" CaffeySilverman disease" is categorised by frequent sequences of subperiosteal development of new bone along 1 or more bones initiating within the initial five months of life. A genome–wider canopy for genetic association in a wide family along with an autosomal dominant type of Caffey disease which depicts a locus on chromosome 17q 21 .Patients having this mutationhad noticed frequent cortical hyper osteosis,joint hyper elasticity, hyperextensibility of dermis,hernia specially in inguinal region also mimics some features of(Ehlerdanlos syndrome) TYPE 3.These results elaborates the spectrum of (COL1A1) related pathologies to add on hyperostoticdisorder. It is a process of inflammation of soft tissue, as well as there is facial asymmetry, severe malocclusion occurs, mandible is predominant site specially angle and ramus region. There is escalation of serum alkaline phosphatase level.[14-18]

Rickets: Rickets is caused due to deficiency of vitamin D and calcium. In rickets patients there is less mineralization at the growing salver, where as osteomalacia there is impairment of mineralization of bone matrix. Child depicts asymptomatic or may having pain, irritability, poorgrowth, pot belly appearance, hypoplastic enamel and dentin, mainly lower extremities deformities and dental abscess, pigeon chest appearance, chances of pathological fracture is there. Serum alkaline phosphatase is escalated in case of hypophosphatemia and hypercalcaemicrickets."25(OH) D "is the best marker of vitamin D.[15-18]

Langerhans cell histiocytes: Langerhans cell histiocytes is a very sporadic clonal pathology categorised by the proliferation of (CD1)a positive unripe dendritic cell, also a disease of monocyte macrophage system. It can occur at any age, but mainly it occurs in between 1 to 4 years of age. It includes tender bony lesions and rashes.fever, loss of appetite, loss of weight, exhaustion, irritability, loosening of gums and teeth (loose teeth syndrome), swelling of jaws. Typical radiographic findings are a self-contained lesion of the skull and a (vertebra plana) Cervical lymph nodes are soft or hard matted groups with lymphoedema, gingival hypertrophy, ulceration in soft palate, hard palate and buccal mucosa. Early development of dentition occurs with LCH infiltration of mandible and maxilla.Treatment depends on the variety of LCH,two drugs regimen are given with "vinblastine"and "prednisolone for an initial rigorous phase for 6 to 12 weeks, followed by conservation

therapy for at least 12 months duration.[16-18]

To Study the Turnaround Time of Cashless Discharge Process

A.P. Pandit[1], Lincymol Abraham[2]

[1]Chief Medical Director, Chellaram Hospital for Diabetes Care & Multispecialty, Bavdhan, [2]Student, Dept of Hospital Admin, SIHS, S.B. Road, Pune

Abstract

The objective of the project is to study and assess the Medclaim Process mapping and discharge process Turnaround Time and look into the problems that arise during the whole discharge process. For Discharge process Analysis real time data was collected from the wards, Pharmacy, Billing Department for intimation, reception of papers at billing, clearance time from pharmacy, intimation time received at billing, bill ready time, final clearance time and physical vacation time.

This study is an explorative, descriptive and explanatory research which was done in a 500 bedded hospital in Pune and sample size was 100. The collection of data was done in data capturing format.

Keyword: *Mediclaim, Discharge Process, Turnaround Time.*

Introduction

The Indian healthcare industry was estimated at USD 40 billion in 2010 is expected to reach USD 280 billion by 2020. Large investments by private sector players are likely to contribute significantly to the development of India's hospital industry, which comprises around 80% of the total market, according to the report 'Indian Hospital Services Market Outlook' by consultancy RNCOS. As per estimates by ratings agency Fitch, the sector is poised to grow to USD 100 billion by the year 2015 and further to USD 275.6 billion by 2020.

Health is a human right. It's accessibility and affordability has to be ensured. The escalating cost of medical treatment is beyond the reach of common man. While well to do segment of the population both in Rural and Urban areas have accessibility and affordability towards medical care, the same cannot be said about the people who belong to the poor segment of the society.

Mogli defines "discharge as the release of a hospitalized patient from the hospital by the admitting physician after providing necessary medical care for a period deemed necessary"[1] Dr.Sakarkar defines "discharge as the release of an admitted patient from the hospital" [2].

Health care has always been a problem area for India, a nation with a large population and larger percentage of this population living in urban slums and in rural area, below the poverty line. The government and people have started exploring various health care financing options to manage problem arising out of increasing cost of care and changing epidemiological pattern of diseases.

The control of government expenditure to manage fiscal deficits in early 1990s has led to severe resource constraints in the health sector. Under this situation, one of the ways for the government to reduce funding and augment the resources in the health sector was to encourage the development of health insurance.[3]

In the light of escalating health care costs, coupled with demand for health care services, lack of easy access of people from low income group to quality health care, health insurance is emerging as an alternative mechanism for financing health care.

Indian health financing scene raises number of challenges, which are:[4]

- Increase in health carecosts.
- High financial burden on poor, eroding theirincomes.
- Need for long term and nursing care for senior citizens, because of increasing nuclear familysystem.
- Increasing burden of new diseases and healthrisks.
- Due to underfunding of government health care, preventive, primary care and public health functions, have beenneglected

In simple terms, health insurance can be defined as a contract where an individual or group purchases in advance, the health coverage by paying a fee called "premium". Health insurance refers to a wide variety of policies. These range from policies that cover the cost of doctors and hospitals, to those that meet a specific need, such as paying for long term care. Even disability insurance, which replaces lost income if you cannot work, because of illness or accident, is considered health insurance, even though it is not specifically for medical expenses.[5]

Health insurance is very well established in many countries, but in India it still remains an untapped market. Less than 15% of India's 1.1 billion people are covered through health insurance. And most of it covers only government employees. At any given point of time, 40 to 50 million people are on medication for major sickness and share of public financing in total health care is just about 1% of GDP[6]. Over 80% of health financing is private financing, much of which is out of pocket payments and not by any pre-payment schemes. Given the health financing and demand scenario, health insurance has a wider scope, in present day situation in India. However, it requires careful and significant efforts to tap Indian health insurance market with proper understanding and training[7].

Over the last 50 years, India has achieved a lot in terms of health insurance. Before independence, the health structure was in dismal condition i.e. high morbidity and high mortality and prevalence of infectious diseases. Since independence, emphasis has been put on primary health care and we made considerable progress in improving the health status of the country. But still, India is way behind many fast developing countries such as China, Vietnam and Sri Lanka in health indicators.

The new economic policy and liberalization process followed by Government of India since 1991 paved the way for privatization of insurance sector in the country. The Insurance Regulatory and Development Authority (IRDA) bill, passed in Indian parliament, is the important beginning of changes having significant implications for the health sector.

In the present competitive world, quality of health care is playing an important role in the modern society. Among various factors affecting the health care system, discharge process is one of the important factors related to patient satisfaction. As the final step in the hospital experience, the discharge process is likely to be well remembered by the patient. Even if everything else went satisfactorily, a slow, frustrating discharge process can result in low patient satisfaction. It is an important area which touches the patients' emotion; influence the image of the hospital and patient satisfaction. Therefore, the demand for effective health services is ever increasing.

Discharge process is defined as the process of activities that involves the patient and the team of individuals from various discipline working together to facilitate the transfer of patient from one environment to another .Soon after completion of treatment, the patient as well as his or her escorts expects to be relieved off immediately. The delay in discharge process leads to dissatisfaction and affects the image of the hospital.

Discharge planning is essential to the concurrent patient care review system conducted as part of the hospital's utilization management effort. If discharge planning is delayed, patient's stay can be unnecessarily extended. Discharge planning is centralized, coordinated effort, to ensure that each patient has a planned program for needed continuing care and follow ups. When it comes to the discharge subject, it's the moment where the patient pays for the services enjoyed in the hospital and the management receives for the same. This we call Billing, which plays a vital role in the discharge process, which involves much of clerical work to be done in the billing office and demands time. But for the satisfaction of the patient, minimizing the time consumption in billing is again an importantfactor.

Therefore this time management study on discharge is undertaken with the aim of giving better services for the patient satisfaction within the minimum time. This can be done only with the help of thorough study of time taken for the whole discharge process beginning from Discharge order time till the patient leaves the Hospital.

Discharge Process: According to Erwin (2001), "Discharge planning–a centralized, coordinated,

multidisciplinary process that ensures the client has a plan for continuing care after leaving the hospital. It prepares the patient and family for transition from the health care setting to another which includes assessing patient needs at discharge, making arrangements and referrals for follow up care and coordinating the various professional and volunteer services. It needs to be initiated on admission to the hospital and then continues as an ongoing process throughout the hospital stay." Good discharge planning involves the patient from the beginning, using his strengths, providing resources to meet his limitations, and is focused in improving outcomes on the patient's life. Driscoll (2000) stated that discharge planning is a process where patients' needs are identified and a plan formed for a smooth transfer from one environment to another. Most modern definitions of discharge planning include the notion of helping patients through transitions from one level of care to another. It is not focused on moving the patients out of the hospital, rather on helping them progress through a number of levels ofcare.

The discharge planning process facilitates successful transitions, such as: from intensive care to intermediate care; a surgical unit to a rehabilitation program or from home care to a hospice unit.

Discharge planning is a process that:

- Begins with early assessment of anticipated patient careneeds
- Includes concern for the patient's total wellbeing.
- Involves patient, family and caregivers in dynamic, interactive communication as planningprocesses.
- Prioritizes collaboration and coordination among all involved health care professionals.
- Results in mutually agreed upon decisions about the most economic and appropriate options for continuingcare
- Is based on thorough, update knowledge of available continuing careresources.

Although the process is complex, the basic concept is a straight forward discharge planning helps patients progress towards optimal health. Unsuccessful discharge can be defined as unplanned readmission within six weeks of discharge.

Factors associated with delayed discharge: Recent researches have tended to highlight contributing factors towards delaying of discharge process. According to Black and Pearson (2002), the three important factors those are likely to cause delay in dischargeprocess:

(i) Individualfactors
(ii) Medicalfactors
(iii) Organizationalfactors.

Individual factors: Individual factors associated with a delay in discharge process are diverse including; personal choice, age, emotional disposition and personal support from family and friends. Recent Australian research (Laughlin & Colwell, 2002) showed that the average length of stay was four times greater for people aged 65 years old and over with dementia compared to all other people. Black and Pearson (2002) conducted a study in Scotland that suggested that 1.3% of patients aged 65 to 69 experienced delays compared with 9.5% of those aged 90 years old andover.

Medical factors: Along with long with individual factors, medical factor also contribute toward delays in the discharge process. In Sweden (Black & Pearson, 2002) a study of people aged 64 years old and over suggested that this group of population was more likely to experience new medical problems requiring treatment after they had already been slated for discharge, thus further exacerbating and complicating their discharge from hospital. The rate of delayed discharge was strongly associated with diagnosis. In terms of broad groups of diagnosis, the rate was highest among those diagnosed with nervous system disorders and circulatory disorders and mental disorders. A Canadian prospective observational cohort study of 130 patients who had undergone an elective thoracic surgical procedure found that the three most frequent medical complications that prevented discharge were persistent air leaks, pulmonary infections and atrial fibrillation. (Anthony & Barr, 2004)

Organizational Factors: Often the patient's clinical condition is not the cause of discharge delays: but rather, organizational management of health care services play a greater role. The literature highlights a small number of studies that suggest, for example, that how a patient is registered influences discharge planning. Whether people are labeled as an emergency or elective admission or if they are a planned short stay admission or a long stay admission, may influence whether or not people are likely to have a delayed discharge. It has been found that people who were admitted to hospital as an emergency admission experienced greater delays than those with elective admissions.

Delayed Discharge: A 'delayed discharge' is a hospital inpatient who has been judged clinically ready for discharge by the responsible clinician in consultation with all agencies involved in planning the patient's discharge and who continues to occupy a bed beyond the ready for discharge date. It is very important that, while the clinician in charge has ultimate responsibility for the decision to discharge, the decision must be made as part of a multi-disciplinary process and focuses on the needs of the individual patient. These patients are clinically ready to move on to a more appropriate care setting either within or out with patient's home.

In this study also it was observed that sometimes patients would wait for the consultant to confirm from them that they were fit to be discharged.

Delayed discharges are defined as delays in discharge from acute hospital of patients whose treatment episode in hospital is finished and who have been assessed as medically fit to leave. This will be after any period of rehabilitation required in hospital has been concluded. Delays related to patient choice are one of the factors affecting delays in discharge from acute hospital care.

Delays related to patient choice occur when the patient or their family or relatives has identified a preferred post-hospital placement that is not immediately available, and the patient remains in hospital awaiting a place in the preferred option.

Intermediate care: The DH published initial guidance on intermediate care in 2001. The guidance set out definitions of intermediate care, service models, responsibilities for provision and charges and planning. The British Geriatric Society defined intermediate care in 2006 as services that met the followingcriteria:

- They are targeted at people who would otherwise face unnecessarily prolonged hospital stays or inappropriate admission to acute inpatient care, long-term residential care or continuing NHS in-patientcare.
- They are provided on the basis of a comprehensive assessment, resulting in a structured individual care plan that involves active therapy, treatment or opportunity forrecovery.
- They have a planned outcome of maximizing independence and typically enabling patients and service users to resume living athome.
- They are time limited, normally no longer than 6 weeks and frequently as little as one to 2 weeks orless.
- They involve cross-professional working, with a single assessment framework, single professional records and sharedprotocols.
- Inclusion of adults of all ages, such as young disabled people managing their transition toadulthood;
- Renewed emphasis on those at risk of admission to residentialcare;
- Inclusion of people with dementia or mental healthneeds;
- Flexibility over the length of the time-limitedperiod;
- Integration with mainstream health and socialcare;
- Timely access to specialist support asneeded;
- Joint commissioning of a wide range of integrated services to fulfill the intermediate care function, including social carere-habilitation;
- Governance of the quality and performance of services.

The guidance is primarily aimed at commissioners but is also of interest to practitioners, providers, service users and their relatives. Further resources for commissioners were published in 2010 as part of a preventative package for older people, which includes intermediate care (DH 2010).

Method

The study was conducted in the wards (surgical, medical, and economic) in a 500 bedded hospital in Pune from 7th May to 7th August 2015.

The research approaches adopted in this study were exploratory, descriptive and explanatory method.

Data collection was done through observation, data capturing format and by interacting with staffs in various departments.

Data collection was done through convenient sampling method and was primary data. The sample size for the study was 100.

Results and Summary

In this study, it was observed that there was a significant delay in the discharge process. The main

reason for the delay is insufficient staff and overload of work on staffs and stacking of files in various departments. Therefore, the hospital could notadhere to the NABH standards of time for dischargeprocess.

Table1: Discharge Process Time in comparison with the NABH standard for discharge Process

Sl No	Steps in discharge procedure	Average observed time taken	NABH Standards	Difference
1	Preparation of discharge summary	108	30	78
2	Pharmacy clearance	69	30	39
3	Preparation of bills	263	30	233
4	Bill Settlement	35	30	5
Total		**475**	**120**	**355**

Conclusion

Time management study will give the managers an idea about the current time taken for the process and can compare it with the NABH standards to implement various steps towards reducing the unnecessary delay in the process. If all the sub processes of the discharge process comply with the time limit specified by the hospital and if the recommendations are implemented, the current discharge time can reduce to 1.5hrs.

Conflict of Interest: None

Ethical Permission: No Ethical issues are involved, as the study was undertaken as a part of Summer Internship of MBA (HHM) student, and there were no human or animal experimentation.

Extinction of the Elixir of Life: Depletion of Groundwater Level In Chennai

R. Sakthivel[1], A. Arun[2], Mark Keith Faraday[2]

[1]Research Scholar, [2]Assistant Professor, School of Hotel and Catering Management, Vels Institute of Science Technology and Advanced Studies (VISTAS), Pallavaram, Chennai

Abstract

Orientation: There has been a growing unease in depletion of ground water in Chennai due to the increase industrial population, creating difficulties in day to day operation of hotels.

Research purpose: To list out the problems with regard to water scarcity faced hotels in and around the areas of Chennai. Exhibit the practices and procedures followed by the hotels in overcome these problems.

Motivation for the study: Currently the city is facing a major water scarcity problem which is due to climatic changes, over consumption of ground water supply, lack of water saving activities etc. Hotel industries being a prime user of groundwater exerts a principal role in depleting the groundwater hereby has the responsibility in rescheduling the water conserve practices.

Research design, approach and method: A qualitative and quantitative study has been done in twenty three hotels located in and around Chennai with a well designed questionnaire as the research tool.

Findings: Presently no well planed practices or policies exist in water management at hotel industries. Still many hotels have not implemented water conservation initiatives to save groundwater. Awareness has to be created among the managements, employees and guest to minimise the water crisis. .

Keywords: *Conservation; Elixir; Hotel Industry; Water.*

Introduction

The elixir, magical or medicinal potionis a clear liquid which is sweet flavoured and can cure all illness of human kind. Of all liquids water is considered the elixir of the earth[1]. Saint poet Tiruvalluvar in his epical work Thirukkural expressed that the world evolves due to the blessing of water, the eternal liquid which makes the earth to live.[2]

Water is essential for living beings without water human being can survive only for a few days. It is essential for cellular homeostasis and life[3]. Our planet earth and the life form on it are inseparable from this simple inorganic compound[4]. The three quarter of this beautiful blue planet is covered with water in which approximately only 1% is fresh-water in rivers, lakes and in ground water.[5]

Ground water is the prime source for drinking, 85% of the rural and 50% of urban water requirements are being satisfied by the ground water. According to United Nations Educational, Scientific and Cultural Organization (2012) India stands first in copious user of ground water[6] and the usage rate is relatively high than their recharge rate. By 2020 water availability per person may even reduce to 48 litres per person per day that is comparatively lesser than the world's standard scale[7].

A survey held during the month of March 2017 in 15 areas of Chennai shows the fall in level of ground water ranges from 0.70 metres to 2.88 metres compared to the previous year.[9] The ground water in Chennai is over exploited if 100 litres seeps into the ground 90-100 litres of water is pumped out.[8]

Corresponding Author:

Beside the domestic users, industrial sectors are the major exploiters of the ground water. Among these industries hotel industry uses a major part of the ground water creating scarcity for water in their location. On an average the hotels at Chennai accommodates around 12000 to 14000 guest per day. The guest in a hotel consumes at least 750 to 900 litres of water for their daily activities, [10] beside the provision of water for the guest daily activities the hotel also consumes water for kitchen, laundry, landscaping etc for an aesthetic service for their guest or consumers.[11].

For the smooth running the hotels uses around 41% of water for the restroom and bathroom uses, 7% for kitchen activities and heating cooling facilities respectively 8% for housekeeping activities and 13% for landscape irrigations[12] The usage proportion of water depends upon the facilities provided or categorization of the property.[13]

The study gives attention to usage proportion of water at departments in hotels and the opinions of employees about the conservation measures followed by the hotel sectors to conserve water followed in the hotel which in turn reduces the ground water depletion.

Material and Method

Hotel industry has been always considered a boon in development of a nation's economy with no great collision on natural environment; beside there exist a grumble of consumption of vast amount of goods and energies especially local water reserves.[14]

A qualitative and quantitative study[15] was conducted to estimate the extent of ground water usage, practice and measures in water conservation at hotel industry. The study is qualitative as it depends more upon the conceptual knowledge of the population selected also quantitative to comprise a required number of population across the selected area.

Pilot Study: A face to face interview was conducted with officials of various hotels at Chennai, A set of questions that includes questions about the usage of water at various departments, preventive water management measures followed at hotel to reduce water usages, social responsibilities in conserving water at hotel industry.

Population and Sampling: The study population covers supervisors, executives and higher authorities from hotel sector. A purposive sampling[16], a method of selection a study population upon specific criteria for the study is adopted to target the selective people including executives and managers of departments, chief engineers, and others well versed in the practices and procedures of water measures in the selected hotels at Chennai.

The study was carried out more ethically with co-operation of the participant and confidential[17, 18] as disclosure of details may create an adverse effect to participants and their employer.

Data Collection: The primary data gathered using the pilot study from the officials at hotel industry are well organized and evaluated, additionally secondary data from internet sources and journals are evaluated together and a well structured questionnaire was prepared as the tool for data collection.[19] A well organized questionnaire with three sections was framed constituting open, closed, dichotomous, multiple choice and scaled question[20] to bring out the water usage proportion in departments of hotel industry, precautionary measures in water conservation the degree of acceptance of the employee and employers attitude towards water management programs.

250 Questionnaires were distributed to the respondents at major departments like Food and Beverage Production, Food and Beverage Service, Accommodation Operation, Front Office, Engineering departments the chief users of water. Questionnaire was also sent by mail to 68 respondents for their convenience. The filled in questionnaire were collected were checked whether completely filled in and validated for transcription. Among the response 239 were considered as valid responds from respondents.

Data Analysis: Validated data from the respondents are coded, entered and analysed with the statistical tool SPSS (21.0). Descriptive, one-way anova test, t-test, correlations analysis was used for the analysis of data.

Results and Discussion

The study was conducted during the month of January to April 2018 in star categorized hotels located in and around the city of Chennai, Tamil Nadu. The targeted population were hoteliers at management levels. Questionnaire were used as a tool for collection of data Table.1 shows the statistic breakup of the valid

and invalid questionnaires used for further studies. It illustrated that survey carried out by sending the questionnaire by mail is easier and the response is also comparatively accurate.

Table. 1 Validation of surveyed questionnaire

Particulars	Total		Invalid for the study		Valid for the study	
	Frequency (N)	Percentage (%)	Frequency (N)	Percentage (%)	Frequency (N)	Percentage (%)
Questionnaire Circulated Personally	250	79	64	25.6	186	74.4
Questionnaire Circulated By mail	68	21	15	22	53	78
Total	318		79		239	

Reliability test: Data from valid questionnaires for the study are coded and uploaded in SPSS statistical tool (20.0) version, and checked for their reliability. The analysis result proves the data are more reliable with Cronbach's Alpha value as 0.794.

Demographic statistics of respondents: The demographic statistic, Table. 2 exhibits a picture about the respondents participated in the study. The sampling was done under purposive selection method as the study needs the respondent to be in or above supervisory level of management, works at least a year in the particular star categorized property.

Table 2. Demographic statistics of respondents

Demographic Statistics			
Demographic Factors		Frequency (N)	Percentage (%)
Gender	Male	163	69
	Female	76	31
Age	Less than 25 Years	84	36
	26-35Years	77	32
	36-45 Years	49	20
	Above 45 Years	29	12
Designation Level in Management	Supervisory Level	71	29
	Middle Level	128	54
	Top Level	40	17
Years of Experience in Surveyed Hotel	1 to 2 years	81	34
	2 Years 1 Month-5 Years	106	45
	Above 5 years	52	21
Hotel's Star Categorization	Three Star	113	48
	Four Star	87	36
	Five Star	39	16

Source of water for hotels in Chennai: The primary data from officials at hotel and secondary data from sources of internet and magazines reveals that only 40% of water requirement of a hotel has been provided by the government bodies of the city the rest has been bought from the private agencies. A hotel need 80 to 147 kilolitres of water for a day's operation, they spend nearly Rs. 800 to Rs. 2400 for 24,000 litres of water buying from these agencies.

Kendall's W test: Water is more essential for daily operations for all activities from cleaning to cooking employees been asked to rank the end use of water at various departments. The data has been analysed for their degree of agreement using Kendall's W test which ranges between 0(disagreement) to 1 (agreement) [21]. The analysis shows the agreement is strong as the Kendall's W coefficient value is (0.767) and significant at (0.00) level.

Table 3 illustrates the ranking position of opinions about water usage in hotel departments. Usage of water at guest rooms has been ranked first among other usages. Beside these usages, water is also wasted while used in cooling or heating systems, R. O plants, leakages due to poor maintenances has been ranked last.

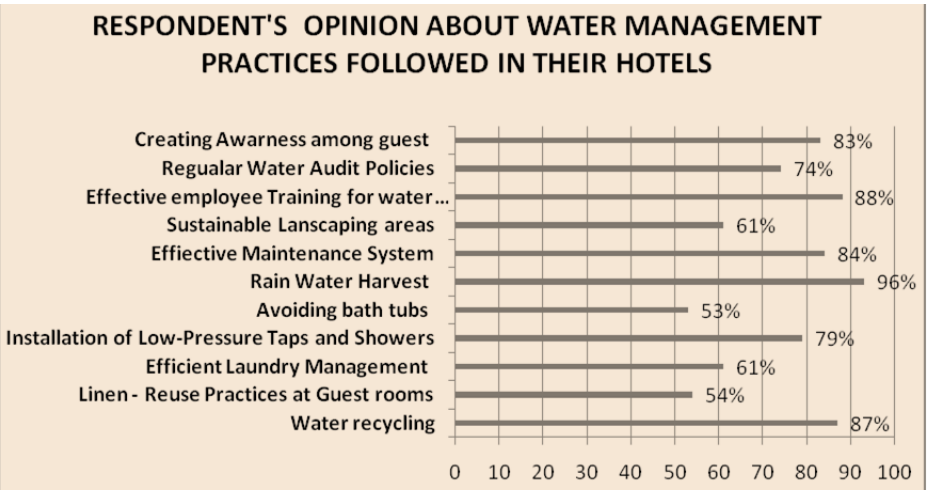

Table 3: Ranks

Particulars	Mean Rank
Landscape	3.35
Public area toilets/ lockers	2.94
Laundry	3.71
Guest rooms	1.98
F & B Production & Service Activities	2.05
Swimming Pool	4.11
Wastage	4.84

Test Statistics: Kendall's Coefficient of Concordance = 0.767 significant at (0.00) level.

Respondent's Opinion about Water Management Practices followed in their Hotels: The questionnaire constitutes a section of questions covering all technical facts and personal responsibilities of employees to observe the opinion about water management and conservation practices in their hotels[22,23]. Figure. 1 illustrates the opinions of employees employed in the surveyed hotels about the practices and procedures in water management and conservation. According to the study (96%) of the respondents feel confident that their hotels have been equipped with rain water harvesting. Around 83–88% of employees are aware that their hotels are creating awareness among the guest with regard to water conservation, hotel posses a well planned maintenance system, Effective water recycling plants and provides effective training for the employees.

Figure 1: Respondent's opinion about water management

Anova-test: Anova is an ideal method of statistical analysis to analyze the significance relation of variances.[24] One-way anova analysis is done among the variables effective water management, star categorization and employee training. The analysis (Table. 4) shows that there exist a significant relationship between the variables Effective water management and Training provided for employees (F = 24.268) and between the variables Effective Water Management and Hotel's Star Categorization (F = 16.784) at a significant value (< 0.5) level.

The analysis concludes that the effectiveness in water management depends upon the grade or

categorization of the hotel and also the efficiency of well trained employees.

Table. 4 One-way Anova test

Variables	Training for employees		Hotel's Star Categorization	
	F-Value	Significance	F-Value	Significance
Effective Water Management	24.268	(<0.5) Level	16.784	(<0.05) Level

One sample *T*-test: Factors that obliterate and deplete the ground water level are analysed using t-test Table.5 shows that these factors are significant and main causers for the ground water pollution and depletion.

Table 5. One Sample T-test

S.No.	Ground Water Depleting Factors	T-Value	Significance Level
1	Employee unawareness and irresponsibility	77.11	(0.00) level
2	Nonexistence of appropriate recycling plants	53.09	(0.03) level
3	Usage of eco-friendly cleaning equipments and agent.	83.71	(0.021) level
4	Effective drainage facilities and garbage clearance	78.03	(0.033) level

Conclusion

The study analyzes the qualitative and quantitative information from the employees of hotel industry elaborates that hotel itself faces more crucial crisis with regard to water needs. Practice and procedures by reduce the wastages of water; enhancement of conservation certainties and personal responsibilities has to be adopted to overcome the groundwater depletion. Possible steps have to be taken by the hoteliers to enhance the ground water level.

Suggestions: Chennai city faces a high water crisis at all seasons; ethically recuperation of ground water has to be considered a prime role by the hoteliers. The study proposes few suggestions by consolidating respondent's opinions for employees and employers at hotel sector. Employees have to be well trained in water management, an effective recycling plant to be installed, Enhance self responsibility among employees, refuse usage of toxic chemical and agents, organized an effective maintenance team, display signs and boards to create awareness among employees and guests, reduce the usage of linens, planning appropriate drought plants and landscape areas, reduce concreting the floors around

Limitation of the Study: The core of the study depends upon the response of the employees at hotels; the busy schedules of the employees, unawareness about the water management practices, employee's loyalty and disclosure of policies are main limitations for the study.

Perception of Hotel Management Students towards Entrepreneurial Motivation Factors

Sai Sukumar B.[1], A. Arun[2], Mark Keith Faraday[2]

[1]Research Scholar, [2]Assistant Professor, School of Hotel and Catering Management, Vels Institute of Science Technology and Advanced Studies (VISTAS), Pallavaram, Chennai

Abstract

Perception of Entrepreneurial prospect from hotel management curriculum, made a vibrant raise in selection of these course as career among the students. The study covers the final year degree and diploma students undergoing hotel management course as the participants. A well administered questionnaire was set and distributed among 193 students from final year in a random. Data collected were analysed using the statistical tool SPSS (21.0). The result concludes that the students undergoing hotel management course are enthusiastic and passionate to turn out to be an entrepreneur. New aspects and training modules are been expected from the students with regard to entrepreneurship in their curriculum.

Keywords: *Entrepreneur, Hotel Management, Perception, Student.*

Introduction

Entrepreneurs are economic boosters; a nation's growth is more dependent upon the entrepreneurship quality among the citizen. According to Business Dictionary an entrepreneur is initiative and risk taker using the opportunities to develop an organisation to accomplish achievements and records[1]. Regardless of international qualms and issues, the hospitality industry maintains its growth in a constructive rate. According to the United Nations World Tourism Organization report (2015) the industry contributes around 10% of world's GDP and more than 6% exports globally.[2] Hospitality industry covers up small to large scale business providing the leisure services or products to national or international consumers. The hospitality product is composition of spare from multiple entrepreneurs. The industry provides manifold opportunities for the young entrepreneurs to develop their own businesses[3].

Changing trends and developing technologies, economically have a close collision and impact on hospitality industry. These changes bring into a positive augmentation in their micro and macro environments providing unlimited openings for the progression of budding entrepreneurs.[4] Hospitality sectors directly or indirectly provides a wide opportunities like bakery, facility planning, multi or speciality restaurants, coffee shops, ticketing and travel operations etc.

An entrepreneurship in hospitality industry is sourced and enhanced by the creative and innovative thinking, as the entrepreneurial way of thinking is more essential to find out new innovative business or to revitalize the active or ongoing business .[5] The businesses in hospitality sector is more dependent on the human work force[6] than other resources, hereby the financial investments for the business may range from zero investment to even million crores.[7]

The entrepreneurial education has become more fundamental and prevalent[8], it benefits the students educating entrepreneurial skills building up confidence and develops self-belief and maturity.[9] Hospitality management courses are entrepreneurial programmes always have a vibrant popularity among the young aspirants[10]. Many intrinsic and extrinsic motivational factors like the curriculum of programme, family supports, faculties, institutions etc. develops a positive and constructive perception among students to turn out himself an entrepreneur.[11]

Among the students the entrepreneurial quality is more based on the interest, intention[12] and the behavioural approach[13] towards entrepreneurship the entrepreneurial qualities of a hospitality management student depend upon the institutions, curriculum, infrastructural facilities, family supports, etc. Educational institution, play a vital to orient and train their students becoming a successful entrepreneur.[14]

Curriculum of hotel management graduation is composite; it invokes and develops boundless perception and entrepreneurial ideas among their graduates. The industrial exposure training formulates a good impact about the industry making them understand the actual industrial scenarios. The syllable for the course is structured in a manner constituting a set of program to develop the basic knowledge and skills of their students and enhance them to succeed in present dynamic and business environment[15]. The lively learning prospect constructs an entrepreneur quality in the student throughout their studies.

Family background and parent's occupation influences and motivates the entrepreneurial perception of the student providing financial and moral supports.[16] Governmental bodies and banking sectors promotes the young emerging entrepreneurs helping out in provision of investment, conduction of training programmes that builds up their entrepreneurial perception.[17]

The present study was to exhibit the perception of hospitality management students towards entrepreneurship also discusses the motivational factors that enhance the actual entrepreneurial perception among the students.

Materials and Method

The study was both the qualitative and quantitative; a well structured questionnaire was framed and used as the research tool. The questionnaire consist of three section first section was designed to collect demographic parameters of students including family and education backgrounds. Second part records the students view becoming an entrepreneur and third section comprises the viewpoint about the motivational factors that enhances the entrepreneurial quality among the students. The entrepreneurial qualities are ranked and the perception about motivational factors enhancing perception were rated with likerts five point scale ranging from 1 as Strongly Disagree to 5 as Strongly Agree.

The sample population were the final year hotel management students at universities in Chennai and Kancheepuram. Printout copies of the questionnaire were distributed in person to the students and in few cases the softcopy was uploaded online (google forms) distributed to more than 250 students. Among the responses 193 were considered qualitative for the study.

Statistical Analysis of Data: Analysis of the data are done with the Statistical software SPSS (21.0). Data were treated or analysed with tests like t–test to find whether there exist significance in student's responses in selection of their business areas relationships between gender, age, and attitude with entrepreneurial perception. Chi-square test to check their business is more oriented to hospitality industry or other businesses after their graduation. Friedman's test was conducted to check the ranking position of the qualities for being a successful entrepreneur. Beside these test percentile calculations were done to find the maximum responses for a perception preferences.

Result and Discussions

The data collected from the students with regard to their entrepreneurial perception were analysed using SPSS–Version 21, data are checked for their reliability thecronbach's Alpha value is (0.726) and significant at (0.00) level. It is understood that the data are around 73% a reliable indication that the questionnaire and the response from the students are good and reliable for the research work.

The demographic factors constituting the gender, age, course, and departmental preferences are listed out in Table 1. From the table it is observed among the respondents (90.1%) are male and (9.9%) are female students. It shows the hotel management courses are more open and preferred by the male students compared to the female students. With regard to age students below 20 years is (54.4%), between 20 to 25years is (41.9%) and there exist no students above 25 years in degree whereas in diploma there exist (3.7%)of total respondents. (56.9%) students were undergoing their diploma and (43.1%) their bachelor degree in catering and hotel management. Finally the student's parental background into hospitality industry shows the majority of the students (89.2%) are not into hospitality sector only a few (10.8%) students are favoured having their parents with their background into hospitality industry.

Table 1: Demographic summary of responses from students

S. No	Demographic Factor		Frequency (N=193)	Percentage
1	Gender	Male	174	90.1%
		Female	19	9.9%
2	Age	Below 20	105	54.4%
		20–25 years	81	41.9%
		Above 25 Years	7	3.7%
3	Course	Bachelor Degree	83	43.1%
		Diploma	110	56.9%
4	Parental Background in Hospitality Industry	Yes	21	10.8%
		No	172	89.2%

Student's Preferences on their Business: The students were questioned about their preferences in sources of their investment for business, form of business, and their preference in selection of business area. Table 2 exhibits the following.

Source of Investment: Students are more aware of procedures and practices with regard to start their department specialized businesses leading percentage of them are interested to work in the hospitality firms of their business interest and learn the basic business strategies. They want to start their business after a few years of experience from their area of interest. With regard to their investments (46.1%) of the students prefer to avail a bank loan, (26.9%) of the students seeks financial help from their parent savings, (19.7%) are interested in applying for government sources and very few students (7.3%) prefer in debts and pledging properties for their investments.

Preference on Business Type: Upon the preference on the types of business, majority of the students (65.8%) are interested in starting their own business and (34.2%) are interested in partnership. With regard to selection of partners for their business students preferred their friend (83.9%) when compared to their relatives or family members.

Preference on Business Area: The hospitality industry had many prime choices of areas for the students to develop their own businesses, whereas the development of business more depends upon their innovative and creative perceptions or ideas. Among the choices restaurants (40.9%) was most preferred and facility agency (4.6%) was least preferred by the students.

Orientation of the students entrepreneurship is more towards the hospitality industry, this is proved by the analysis of data using chi-square test that results with chi–square value 134.306 being significant at (0.00) level.

Preferences in selection of Business area is analysed with one sample t–test resulting as the t–value 24.537 with mean difference 2.275 and significant at (0.00) level. This illustrates that there exist a significant difference in preferences on areas of business between the students.

Table 2. Students Preferences on their Business.

S. No	Particulars		Frequency (N=193)	Percentage
1	Source of Investment	Governmental Sources	38	19.7%
		Bank Loan	89	46.1%
		Pledging (or) Debt	14	7.3%
		Parent's Savings	52	26.9%
2	Preference on Business Type	Sole Proprietorship	127	65.8%
		Partnership	66	34.2%
3	Preference on Business Area	Restaurant	79	40.9%
		Coffee Shop	26	13.5%
		Catering Outlets	29	15.2%
		Bakeries	37	19.1%
		Facility Agency	9	4.6%
		Quick Service Restaurant	13	6.7%

Friedman's Test: Friedman's test was done to analyse the data exhibiting the qualities for being a successful entrepreneur. According to the student's perception the test results are made known in table 3, it shows the ranking position of the entrepreneurial qualities in the view of students. In the mean rank from Friedman's Test it is inferred, among the qualities framing an entrepreneur, students feel that the hardworking quality in an entrepreneur makes him achieves his business goal. Nextly the motivation and innovative thinking.

It is understood the test is more significant at (0.00)

level with the greater chi square value 257.875.

Table 3 Ranking Position of Entrepreneurial qualities

	Mean Rank
Risk taker	3.35
Motivated	2.94
Ambitious	3.71
Innovative thinker	2.98
Resourceful	4.11
Hardworking	2.05

Test Statistics of Friedman's Test

Chi-Square value is 257.875 significant at (0.00) level

Motivation features enhancing Student's Entrepreneurial Quality: The entrepreneurial quality among the students can be enhanced by features like the family support, course curriculum, institution studying, faculties, etc. these motivational factors will always brings into a moral support for the students to develop their creativity and entrepreneurial skills.

The independent t test results with f-value (13.784) significant at (0.00) level shows that the demographic factor gender does not have any influence in the entrepreneurial perception of the students

Table 4 point up self motivation of the students to become a successful entrepreneur. Being known that entrepreneurship is more risky they feel being an entrepreneur is more prestigious and attractive. Students are confident with their future business plan and want to prove themselves as a good entrepreneur than oriented only for profit or money.

Table 4: Student's Self motivation to become an entrepreneur

S.No.	Particulars	Disagree		Neutral		Agree	
		Frequency	Percentage	Frequency	Percentage	Frequency	Percentage
1	Being an entrepreneur is more prestigious	4	2.0%	19	9.8%	170	88.2%
2	The career as an entrepreneur is very attractive	6	4.6%	32	16.5%	155	78.9%
3	My business ideas makes me more confident to become an entrepreneur	7	3.6%	65	33.6%	121	62.8%
4	I understand entrepreneurship is riskier than being salaried	23	11.9%	18	9.3%	152	78.8%
5	Earning money is not the mission of an entrepreneur	45	23.3%	12	6.2	136	70.5%
6	Becoming an entrepreneur gives me the utmost satisfaction	13	6.7%	28	15.5%	152	78.8%

The following table 5 interprets the perception of student's with regard to motivation to enhance and develop their entrepreneurial dream.

Today the younger generation are more vibrant and bold to express their confidence among their family members. They feel more confident that the family will support and stand by them during the inception of new business in all aspects.

The hotel management syllable and curriculum is more practical and training oriented that brings in and develops the entrepreneurial qualities among the students. The students about their support from the curriculum, institution and faculties are more positive anyhow they expect still more positive measure from the institution to motivate their entrepreneurial skills.

Table 5. Perception on family's support, curriculum and institution

S.No	Particulars	Disagree		Neutral		Agree	
		Frequency	Percentage	Frequency	Percentage	Frequency	Percentage
1	My Family allows me to start my own business	17	8.8%	31	16.1%	145	75.1%
2	Family members improves my business ideas	27	13.9%	41	21.2%	125	64.9%
3	Family is ready to support financially	39	20.2%	21	10.8%	133	69.0%
4	Entrepreneurship is a part of my curriculum	21	10.8%	33	17.1%	139	72.1%
5	Success stories of entrepreneurship are discussed in regular academic sessions	54	27.9%	19	9.8%	120	62.3%
6	The curriculum enhances entrepreneurship dream	28	14.5%	31	16.1%	134	69.4%
7	The institution's infrastructure is apt to develop our entrepreneurship skill	42	21.7%	10	5.1%	141	73.2%
8	Institution arranges periodic training/seminar/workshops with entrepreneurial achievers	59	30.5%	21	10.8%	113	58.7%
9	Faculties improves the positive attitude to become an entrepreneur	32	16.5%	29	15.1%	132	68.4%
10	Faculties supports innovative thinking beside curriculum	27	13.9%	41	21.2%	125	64.9%

Pearson's Correlation: The variables motivation strength in student and the factors family support and Institutional supports were correlated using Pearson's correlation analysis, thus Table 6, shows that there exist a significant relation among the motivational strength in student and supports from their family and institution.

Table 6. Pearson's correlation

Particulars		Family	Institutions
Motivation Strength	Pearson Correlation	.339**	.544**
	Sig. (2-tailed)	.000	.000
	N	193	193

**. Correlation is significant at the 0.01 level (2-tailed).

Conclusion

Education instigates an entrepreneurial ability and initiative among the students, Hospitality management studies are considered prime among other entrepreneurial courses. Student's entrepreneurial perception is more positive, being provided with a variety of opportunities to raise their business despite financial investments. The study concludes as the hospitality management students are more positively motivated becoming an entrepreneur. Beside the students also expects more entrepreneurial oriented prospects into their curriculum.

A Study on the Effectiveness of Working Environment in Hyundai Motor India Limited, Chennai

A. Kadhar Lal

Assistant Professor & Research Supervisor, Post Graduate and Research Department of Commerce., The New College (Autonomous), Chennai

Abstract

Work environment in general comprises of the physical location, equipment used organisational climate and the activities of an employee while engaged in the performance of his work. Effectiveness of work environment contributes towards organisational productivity, employee satisfaction and ultimately towards organisational effectiveness. work is an integral part in everyone life. working environment plays a crucial role in enhancing the performances of an individual and the organisation as a whole.

This study titled "Effectiveness of working environment" analyses the impact of positive working environment towards organisation effectiveness. The information needed for the research is gathered from both primary and secondary sources of data. The chapter consists of company profile, Need, Scope, Objectives and Limitation of the study, Research Methodology, Finding, and suggestion. The Research design adopted in this study is Descriptive research. The sample size was based on the application of the formula. The various statistical tools used for the study were Percentage Analysis, interval estimation, chisquare test,weighted average,correlation,Two way Anova. Chart are also used to give pictorial representation of data collected. The interpretation are summarized and suggestion are provided.

Keyword: *(i) Work environment, (ii) Workplace., (iii) Labour scenario, (iv) Work circumstances, (v) Labour Situations, (vi) Employee situation in work.*

Introduction

A positive working environment for employees is the common goal of all good owners and managers. Such an environment encompasses favourable working conditions, good air quality, timely management feedback and an understanding of job goals and priorities.

Work life was conceptualized in terms of need satisfaction from an interaction of workers' need. It was hypothesized that need satisfaction is positively related to organizational identification, job satisfaction, job involvement, job effort, job performance. Job satisfaction is not the same as motivation, although it is clearly linked. Job design aims to enhance job satisfaction and performance, method include job rotation, job enlargement and job enrichment. Other influences on satisfaction include the management style and culture, employee involvement, empowerment and autonomous work groups.

Industry Profile

1. The automotive industry's main tasks during the 10th Five-Year period

(1) China will promote strategic reorganization of the automotive industry and provide support and direction to cooperations between influencial corporations. Powerful corporations will be encouraged and supported to develop further and become bigger and stronger. Distribution of resources will be optimized and a pattern of large automobile corporation groups will be established. A supplementary system of auto parts manufacturing will also be developed to improve competitive ability.

(2) Step by step, China will enhance the independent ability to develop and spread new products,techniques, materials and energy sources actively to encourage the advancement of techniques, accelerate development of the

automotive industry and upgrade automobile products.

(3) High and new technologies will be employed to develop key automobile spare parts, which will gain either a comparative advantages or larger developmental potential. Efforts will be made to enhance the country's ability to develop new products and strengthen the competitive ability to realize the simultaneous development of spare parts with whole vehicles and take part in the international division of labor.

Company Profile: Hyundai Motor India Limited is a wholly owned subsidiary of Hyundai Motor Company, South Korea and is the largest passenger car exporter and the second largest car manufacturer of India. Hyundai Motor India presently markets 54 variants of passenger cars across segments. Hyundai Motor India Ltd, continuing its tradition of being the fastest growing passenger car manufacturer, registered total sales of 559,880 vehicles in the calendar year (CY) 2009, an increase of 14.4 percent over CY 2008. In the domestic market it clocked a growth of 18.1 percent as compared to 2008 with 289,863 units, while overseas sales grew by 10.7 percent, with export of 270,017 units. Hyundai Motor India currently exports cars to more than 110 countries across EU, Africa, Middle East, Latin America and Asia. It has been the number one exporter of passenger car of the country for the sixth year in a row

Hyundai Motor India's fully integrated state-of-the-art manufacturing plant near Chennai boasts of the most advanced production, quality and testing capabilities in the country. In continuation of its commitment to provide the Indian customer with global technology, Hyundai Motor India commissioned its second plant in February 2008 which produces an additional 300,000 units per annum, raising Hyundai Motor India 's total production capacity to 600,000 units per annum

Need for the Study

- Working environment is needed for an organisation in order to find out the area where improvement can be made in the work.
- It helps individual growth as well as fosters the growth of organisation and would be of great help to sustain in a competitive economy.
- The study focuses on the employee relationships at various levels and it also concentrates on the various factors that contributes towards increased motivation.
- It is required in order to remove psychological and social work environment problem which hinders the growth of the employees.

Objectives of the Study

Primary Objective: To study the effectiveness of working environment in "Hyundai Motor India Limited."

Secondary Objective:

- To know the various factors that influence job satisfaction among employees in the organisation.
- To study the attitude of the employees towards training and development program.
- To identify the employee's perception towards the grievance handling procedure adopted in the organisation.
- To study the satisfaction level of employees towards health,welfare and safety measures.

Scope of the Study: Help the organisation to identify growth opportunities of workers to enhance their performance. It provides safe work environment for employee to enjoy working. It enables organisation to easily adopt to change in technology. It shows the satisfaction of the employee with respect to the pay package.

It helps the management to find out the opinion of the employee regarding their work environment. The work potential of the employee which will ultimately lead to necessary training program.

Limitations of the Study:

- Since the time given to the researcher was very limited, it was not possible to meet sufficient number of employee.
- Access to record and files to know about the employee was not possible all the time.
- The respondent may be biased in their respondents.
- Interaction with higher level official was limited since they were highly engaged in their work .
- The data collected from respondents are qualitative in nature.

Review of Literature: An attractive and supportive work environment can be described as an environment that attracts individuals into the health professions,

encourages them to remain in the health workforce and enables them to perform effectively. The purpose of providing attractive work environments is to create incentives for entering the health professions (recruitment) and for remaining in the health workforce (retention). In addition, supportive work environments provide conditions that enable health workers to perform effectively, making best use of their knowledge, skills and competences and the available resources in order to provide high-quality health services. This is the interface of the work environment and quality of care. Working environment can be divided into two components namely physical and behavioral components. The physical environment consists of elements that relate to the office occupiers‟ ability to physically connect with their office environment. The behavioral environment consists of components that relate to how well the office occupiers connect with each other, and the impact the office environment can have on the behavior of the individual. According to Haynes2 (2008), the physical environment with the productivity of its occupants falls into two main categories office layout (openplan verses cellular offices) and office comfort (matching the office environment to the work processes), and the behavioral environment represents the two main components namely interaction and distraction. These components can further be divided in major attributes and operationalised in the form of different independent variables. These variables will be used for analysis of their impact on dependant variable. It is generally understood that the physical design of offices and the environmental conditions at work places are important factors 10 in organizational performance. The empirical research by Stall has also shown that when human needs are considered in office design, employees work more efficiently. One survey conducted by Brill in particular has suggested that improvements in the physical design of office buildings may result in a 5-10 percent increase in productivity and eventually increase performance. Other studies have examined the effect of physical work environment on workers‟ job satisfaction, performance, and health. For example Scott, (2000) reported that working conditions associates with employees‟ job involvement and job satisfaction. Strong et al (1999) in a study observed that social, organizational and physical context serve as the impetus for tasks and activities, and considerably influence workers‟ performance5. Researches on quality of work life have also established the importance of safe and healthy working conditions in determining employees‟ job performance. The influence of working environment, which is mostly composed of physical, social and psychological factors, has been extensively examined in past two decades. In a number of studies, employees‟ motivation, job satisfaction, job involvement, job performance, and health have been found to be markedly influenced by psycho-social environment of work organization. According to Franco performance relies on internal motivation but presence of internal factors such as necessary skills, intellectual capacity and resources to do the job clearly have an impact. As a consequence employers are supposed to provide appropriate working conditions in order to make sure the performance of employees meet the required standards.

Research Methodology

Research: The research is an attempt to study a problem or a situation at any given circumstances and identify various causes or consequences of that particular problem. It tries to solve a complex and complicated problem through use of various tools and techniques.

These tools and techniques try to bring out a logical, accurate and scientific solution to given problem.

Research Design: A research is the arrangement of condition for collection and analysis of date in a manner that aims to combine relevance to the research purpose with economy in procedure. In fact the research design is the conceptual structure within which research is conducted; it constitutes the blue print for the collection, measurement and analysis of date. The research design adopted in the study was descriptive study.

Descriptive Research: Descriptive Research includes survey and fact finding enquiries of different kinds. The major purpose of Descriptive Research is description of the state of affairs, as it exists at present. The main characteristics of this method are that the researcher has no control over the variables, researcher can only repeat what has happened or what is happening.

Size of the Sample: 120

Analysis and Interpretation

Table 1: Table Showing the Age of Respondents

Age	No. of Respondents	Percentage
<25 Years	39	32.5
26-30 Years	47	39.16
31-35 Years	23	19.16
36-40 Years	4	3.33
>40 Years	7	5.85
	120	100

Findings: The above table shows that 32.5% of respondents are in the age group of less than 25 Years, 39.16% of respondents are in the age group of 26-30 Years, 19.16% of respondents are in the age group of 31-35 Years,3.33% of respondents are in the age group of 36-40 Years, and 5.85% of respondents are in the age group of greater than 40 Years.

Inference: It is inferred that majority of respondents are in the age group of 26-30 Years.

Table No. 2: Table Indicating the Gender of Respondents

Gender	No.of Respondents	Percentage
Male	83	69.17
Female	37	30.83
	120	100

Findings: The above table shows that 69.17% respondents are Male, 30.83% of respondents are Female in the organization.

Inference: It is inferred that majority of respondents are Male in the organization.

Table No.3: Table Indicating the Working Period of Respondents

Experiences	No. of Respondents	Percentage
<6 Months	10	8.33
1-4 Years	45	37.5
5-10 Years	32	26.67
10-15 Years	21	17.5
>15 Years	12	10
	120	100

Findings: The above table shows that 8.33% of respondents have got an experience of less than 6 Months, 37.5% of respondents have got an experience of 1-4 Years, 26.67% of respondents have got an experience of 5-10 Years, 17.5% of respondents have got an experience of 10-15 Years, and 10% of respondents have got an experience of greater than 15 Years.

Inference: It is inferred that majority of respondents have got an experience of 1-4 Years working period of employees.

Findings

- It is found that 32.5% of respondents are in the >25 Years, 39.16% of respondents are in the 26-30 Years, 19.16% of respondent are in the 31-35 Years,3.33% of respondent are in the 36-40 Years, and 5.85% of respondent are in the >40 Years.
- It is found that 69.17% of respondents are Male Worker in the organization, 30.83% of respondents are Female Worker in the organization
- It is found that 31.67% of respondents are in the Salary Package, 37.5% of respondents are in the Career Growth, 18.33% of respondent are in the Promotion, 12.5% of respondent are in the Motivation.
- It is found that 84.17% of respondents are Satisified with working hour, 15.83% of respondents are not satisfied with working hour.
- The first preference goes to salary package, second preference goes to Health,Welfare,safety measure, third preference goes to carrier growth, fourth preference goes to Team wok, fifth preference goes to Support from Management, sixth preference goes to Training and development, seventh preference goes to Skill utilization.
- It is found that 44.17% of respondents are Expert Within the organisation, 32.5% of respondents are External consulants, 23.33% of respondent are Immediate superior.
- The first preference goes to Quality in Work to improve upon, second preference goes to Confidence, third preference goes to Morale, fourth preference goes to Knowledge, fifth preference goes to SkillSet.

Suggestion:

- To increases the co-ordination between the departments, by conducting the other activities.
- To provide promotion on the basis of performance and target attained by the employees in their work.

- To get suggestion from the employees during the formation of goal and strategies.
- It is suggested to consider the entire employee in the grievance handling procedure.
- The monetary reward can be provided to the efficient employees in order to increase the level of motivation.
- Periodical group discussion and group interaction between departments must be held to enhance the healthy working environment.
- The management can identify the various flexible work options like constructing intranet and website.
- Promotion of time interval need to be reduced by implementing and creating awareness in performances appraisal system for the employees to improve work efficiency.

Conclusion

- In order to build up organisation strategies and improve the work environment, a well co-ordinated and integrated approach is necessary for designing and implementing the quality of work life program is necessary for development for Human resources.
- The study is conducted to analyse the effectiveness of working environment in Hyundai Motor India Limited.
- This study helps to find that the working environment is effective to some extent and there is no significant change in the environment.
- Working environment is to increases the production and to maintain a healthy relationship between the employer and employee in the organisation.
- After studying the interrelationship among working environment the following conclusion can be made. It includes some factors such as intrinsic motivation, job involvement, job attractive are all responsible for potentially enhancing work life.
- Thus the study reveals that companies should take enough initiatives to improve work environment. Accurate and consistent scales should be developed to measure the above factor and regular monitoring need to be done.

Evaluation of Factors Responsible for Failure of Root Canal Treatment in an Adult Indian Population: A Cross Sectional Study

Anuj Varshney[1], Aditya Shetty[2], Mithra N. Hegde[3], Shishir Shetty[4], Lakshmi Nidhi Rao[5]

[1]Post Graduate Student, [2]Additional Professor, [3]Head of Department, [4]Professor, [5]Sr. Lecturer, Absmids, Nitte University, Deralakatte, Mangalore

Abstract

The root canal treatment failure is a frequentproblem occurring in dentistry. Inadequate chemo mechanicalpreparation, poor obturation, over obturation, persistence of bacteria, instrument separation, missing canal,coronal microleakage are some of the causes responsible for the failure of the root canal treatment. 400 root canal treated teeth with failure were included in this study and were recorded using digital radiography. Under obturation was the predominant factor for the failure of root canal treatment. The larger number of the endodontic failures was found in the timeperiod of within 4-5 years. The maximum average time period causing failure was seen to be 3.85 yearsfor over obturation..

Keywords: *Over obturation, microleakage, persistent periapical infection.*

Introduction

- The main criteria behind the successful outcome of the pulp space therapy is based on the entire removal of the infected pulp tissue and irritants present within the root canal system followed by a hermetic seal.[1]
- The majority of the pulp space therapy failure arises because of the failure of the practitioner to locate all the canals which is mainly due to the presence of extra root or canals indicating variations in root canal morphology.[2]
- The quality of coronal restoration holds a pivotal role in governing theperi-apical condition of the root filled teeth .A perfectly sealed coronal restoration with a poorly filled root canal system may remain successful for a longer period of time, whereas poorly sealed coronal restoration with properly obturated root canal may show failure in a short time.[3]

Corresponding Author:
Prof. Dr. Aditya Shetty
Additional Professor, AB Shetty Memorial Institute of dental Sciences, Deralakatte, Mangalore
e-mail id : shetty_aditya1@yahoo.co.in

- Preoperative periapical radiolucent lesion also determines the success rate of pulp space therapy. Study done by Gulabivala etal, stated that presence of a lesion in the preoperative radiograph could adversely affect the prognosis in comparison with a tooth without a lesion.[4]
- According to European Association of Endodontists, an ideal root canal treatment should be short of the radiographic apical foramina by 0-2 mm with a tapered canal from coronal to apical area without any gap between obturating material and dentinal wall.[5]
- Hence, the purpose of the study was to enumerate the most common factors causing failure of pulp space therapy in the Indian population as the findings of the previous studies varied in the different locations it was done in.

Materials and Method

Source of the Data:

- The present study was conducted in the Department of Conservative Dentistry and Endodontics, A.B. Shetty Memorial Institute of Dental Sciences, Mangalore.

- 400 patients with root canal treatment failure were recorded using digital radiography.

Inclusion Criteria Involved: Pain after root canal treatment, swelling, pain on percussion, parulis.

Exclusion Criteria Involved: Vertical root fracture**,** badly broken down unrestorable teeth.

Procedure: The patients were evaluated under the following experimental groups

- Under obturation (Fig. 1)
- Over obturation (Fig. 2)
- Missed canal (Fig. 3)
- Instrument separation (Fig. 4)
- Perforation (Fig. 5)
- Persistent periapical infection (Fig. 6)
- Absence of full coverage restoration (Fig. 7)

Statistical interpretation of Data: Statistical analysis was performed with SPSS 22.0 software. Descriptive statistics were presented in the form of frequency and percentage. Time period and reasons for failure were compared using chi-square test. p value <0.05 was considered statistically significant.

Study Design: An excel sheet was prepared using the following data:

Following numbers were assigned for each parameter

- Gender : 1= male, 2=female
- Age : 1 = 10-20years, 2 = 20-30 years, 3 = 30-40 years, 4 = 40-50 years

  5 = 50-60 years
- Time period : 1 = 0-1 years, 2 = 1-2 years, 3 = 2-3 years, 4= 3-4 years,

  5 = 4-5years
- Under obturation, over obturation, missing canal, instrument separation, perforation, persistent periapical infection, no crown follow up : 0 = No, 1 = Yes

Endodontically treated teeth with failure

Gender

Age

Tooth type

Anteriors

Premolars

Molars

Under obturation

Over obturation

Missed canal

Instrument separation

Persistent periapical infection

Tooth Receiving Crown During Follow up

Perforation

Time period after Root canal treatment

Findings:

Table 1: Factors responsible for endodontic failure in terms of frequency and percentage

Factors for endodontic failures	No. of patients	Percentage of procedural errors
Under obturation	198	49.5%
Over obturation	27	6.75%
Missed canal	35	8.75%
Instrument separation	69	17.25%
Perforation	6	1.5%
Persistent periapical Infection	13	3.25%
Without full coverage Restoration	147	36.75%

The most contributing factors responsible for endodontic failures were under obturation (49.5%), absence of full coverage restoration (36.75%) whereas the least contributing factors responsible were perforation (1.5%) and persistent periapical infection(3.25%).

Table 2: The association of endodontic failures in different time periods

	Frequency	Percentage
<1yr	41	10.25%
1-2yr	58	14.5%
2-3yr	72	18%
3-4yr	107	26.75%
4-5yr	122	30.5%
Total	400	100.0

The larger number of the root canal treatment failures was found in the time period of 4-5 years (30.75%) and least number of pulp space therapy failures was found in 1year. (10.25 %) of treatment.

Table 3 : The association between the factors of pulp space therapy failure and endodontically treated maxillary teeth .

Maxillary teeth	Under obturation	Over obturation	Missing canal	Instrument separation	Perforation	Persistent periapical infection	Without full coverage restoration
Anterior	22	12	2	4	0	6	11
Premolar	30	4	2	2	0	0	21
Molar	35	8	10	17	2	0	25

Under obturation was the predominant cause behind the failure of pulp space therapy in maxillary anterior, premolar and molar teeth.

Table 4 : The association between the factors of pulp space therapy failure and endodontically treated mandibular teeth.

Mandibular teeth	Under obturation	Over obturation	Missing canal	Instrument separation	Perforation	Persistent periapical infection	Without full coverage restoration
Anterior	12	0	0	2	0	0	7
Premolar	8	1	0	6	0	0	16
Molar	91	2	21	38	4	7	67

Under obturation was the predominant cause behind the failure of pulp space therapy in mandibular anteriors and molars, whereas absence of full coverage restoration was predominantly responsible for failure in mandibular premolars.

Time period and reasons for failure were compared using chi-square test. Significance was only found in cases of under obturation and instrument separation [Table 5 and Table 6].

Table 5: The time lapse between time period and under obturation

			Under obturation		Total
			No	Yes	
Time Period	<1yr	Count	20	21	41
		%	48.8%	51.2%	100.0%
	1-2yr	Count	34	24	58
		%	58.6%	41.4%	100.0%
	2-3yr	Count	34	38	72
		%	47.2%	52.8%	100.0%
	3-4yr	Count	66	41	107
		%	61.7%	38.3%	100.0%
	4-5yr	Count	48	74	122
		%	39.3%	60.7%	100.0%
Total		Count	202	198	400
		%	50.5%	49.5%	100.0%

*p<0.05 Statistically significant

Highest number of failures due to under obturation was seen in time period of 4-5 years.

Table 6 : The time lapse between time period and instrument separation

			Instrument Separation		Total
			No	Yes	
Time Period	<1yr	Count	35	6	41
		%	85.4%	14.6%	100.0%
	1-2yr	Count	46	12	58
		%	79.3%	20.7%	100.0%
	2-3yr	Count	65	7	72
		%	90.3%	9.7%	100.0%
	3-4yr	Count	69	38	107
		%	64.5%	35.5%	100.0%
	4-5yr	Count	116	6	122
		%	95.1%	4.9%	100.0%
Total		Count	331	69	400
		%	82.8%	17.3%	100.0%

*p<0.05 Statistically significant

Highest number of failure due to instrument separation was seen in time period of 3-4 years.

Discussion

Under obturation was the most common factor causing endodontic failure which accounts for 49.5% of the cases. This condition could arise as a result of

incorrect measurement of the working length as well as incomplete debridement of the pulp space.[6] This is in accordance with the study done by Akbar et al.[6] The average time period for under obturation which lead to failure was seen to be 3.6years in the present study.

In this present study endodontic failure occurring due to absence of full coverage restoration (36.75%) was considered to be the second most common factor. This could be because of the following reasons i.e. potential microleakage, or due to excessive occlusal load on the root canal treated teeth or due to the presence of unsealed accessory canals on the floor of the coronal pulp.[7]This finding is in accordance with the study done by Saunders et al.[7]

In the present study absence of full coverage restoration was predominantly responsible for failure in mandibular premolars [Table 4]. This could be due to insufficient crown structure due to which it may have not been able to withstand the occlusal load. This is in support with the study conducted by Sorensen et al.[8] In the present study absence of full coverage restoration lead to failure on an average time period of 3.55years.

In the present study, failure due to instrument separation contributed 17.25% .Instrument separation might have caused treatment failure by getting stuck inside the radicular pulp space thereby, obstructing the adequate chemo mechanical preparation and hence, causing failure .[9] This is in contrast with the results of a clinical investigation done by Crump MC et al on association of separated rotary files to the outcome of pulp space therapy which stated that the separated instrument would most likely not affect the prognosis in the absence of any preoperative infection and peri radicular changes.[10]The average time period for Instrument separation which lead to failure was seen to be 3.37years.

In the present study, missing canals contributed (8.75%) of failures. This could be caused by the practitioner's inefficiency to find these canals because of the complex pulp space morphology.[11] This finding in our study supports the study done by Arnaldo et al,[2]The average time period for missed canal which lead to failure was seen to be 3.54 years**.**

The present study showed majority of the failure in the mandibular molars (42.75%) in comparison to maxillary molars (20%)which could occur due to more intricacies in pulp space anatomy of mandibular molars.[12] This study is in agreement with the study done by Wasti et al, which showed type VI morphology in a minute percentage, as well as the occurrence of three canals with distinct foramina in the mesial roots and the presence of two canals in the distal roots of the mandibular first permanent molar whereas comparatively increased number of type V morphology was observed in distal and palatal roots of the maxillary first molar teeth.[12]

Over obturation was found to be the least contributing factor for endodontic treatment failure (6.75%) which may be due to inadequate length determination, over instrumentation or extrusion of sealer .[13] This findings further confirms study done by Yousuf et al, which reported that molars have the shortest roots as compared to other tooth groups, making them more susceptible to this type of error.[12] In the present study the average time period for over obturation which lead to failure was seen to be 3.85years.

Perforation is an iatrogenic error which could lead to endodontic treatment failure.[18] In the present study, failure due to perforation contributed 1.5 %, most of which were seen mostly in the furcal region mainly during access cavity preparation. Failure could have occurred due to failure of perforation repair material to provide an adequate seal hence forming a pathway for communication between this tissue and microorganisms.[14-16]This is in support with the previous study conducted by Akbar et al.[6]The average time period for perforation which lead to failure was seen to be 3.66years in the present study.

According to the present study,persistent periapical infection contributed to 3.25% of the procedural errors. This could be because of different microorganisms that are self-reliant and unsusceptible to antibacterial treatment which include prevotella, campylobacter, actinomyces, and eubacterium.[17]This is in support with the previous study performed by Gulabivala et al. who found a decrease in the success rate of pulp space therapy between 9–13% with preoperative periapical lesion.[4]In the present study the average time period for persistent peri apical infection which lead to failure was seen to be 2.61years.

Conclusion

From this study we could infer that:

1. Under obturation was the predominant factor seen to be responsible for the failure of root canal treatment.

2. Highest failure was seen in maxillary and mandibular molars
3. The larger number of the endodontic failures was found in the time period of within 4-5 years.
4. The maximum average time period causing failure was seen to be 3.85 years for over obturation

Can Menstrual Cups become an Alternative to Sanitary Napkins? A Critical Analysis among Women in Bangalore City

Aishwarya N.[1], Simran Tharani[2]

[1]Assistant Professor, School of Business Studies and social sciences, CHRIST (Deemed to be University), Bangalore, India, [2]Student, CHRIST (Deemed-to-be) University, Bangalore

Abstract

The topic of menstrual hygiene is always considered as a taboo to speak out in the public and even women hesitate to discuss their feelings or experiences about the same. With the help of revolutionary product called 'Sanitary Napkins', many women were able to understand their menstrual pattern and maintain their personal hygiene effectively. However, there has been number of new products flooding the market that is eco-friendly as well as economical. One such product is 'Menstrual cups' and this research paper primarily tries to understand the consumer awareness and the usage of menstrual cups as an alternative to sanitary napkins among women in Bangalore city. Since sanitary napkins result in generation of ample amount of wastes and possess the risk of health hazards like TSS,UTI and yeast infections; this research focuses on understanding how women are ready for adopting eco-friendly method like menstrual cups. To understand the same, a sample of 138 women respondents were taken for the study from different age groups, educational qualification and income groups and were asked to fill a questionnaire. Their perception on menstrual hygiene, menstrual cup awareness and its usage are recorded, analysed and interpreted with the help of SPSS.

Keywords: *Environmental hazards, Menstruation, Menstrual cup, Personal hygiene, Sanitary napkin.*

Introduction

Menstrual cup is a next generation reusable female hygiene product that has been designed after receiving feedbacks regarding sanitary napkins and tampons from women all across the world. It is a good option for upgradation from sanitary napkins and tampons as it provides ease of traveling,hygiene, safe, cost-effective and fully compatible with one's life style. It allows a normal female to perform duties hassle free during menstruation. It is small in size and funnel shaped which is usually made up of rubber or silicon that is inserted inside a women's vagina to catch and collect the blood fluid during menstruation. It reduces the risk of diseases relating to TSS, UTI,Yeast infections etc. However, menstrual cups have been available for decades, but their use is limited by bulky design and the need for multiple sizes[1].

This research is primarily being undertaken with an objective to understand the consumer awareness and usage of menstrual cups as an alternative to sanitary napkins among women in Bangalore city. From the macro level perspective, it shall help gain an understanding on how women of the modern era of 21st century are open to such kind of method as a replacement to the conventional method of sanitary napkins. Some of the reasons why women choose menstrual cups as an alternative to sanitary napkins in comparison to other method are: its holding capacity; eco-friendly in comparison to tampons;generally recyclable; can be worn for more than twelve hours and no frequent changes are required, which have to be taken care of incase of the other conventional method; less expensive and requires less decomposition time.

This action and reaction attitude study is very much focussed on the women belonging to the Bangalore city in India ranging from school and college going girls to working women class, homemakers and others in the city. At the micro level, it will provide insights about do women still feel period shame in this era, are they still hesitant to talk about sensitive topic like this? Is the menstrual hygiene improving with the usage of unconventional method? Is the risk of TSS and other related diseases reducing with the help of usage of such kind of cost effectiveand eco-friendly method?

The growth of the menstrual cups market is fuelled by factors such as need of eco-friendly, safe, comfortable, clean and cost effective products as an alternative to sanitary napkins or tampons. The global market of menstrual cups was valued around USD 995 million in 2016 and by the end of 2023, it is expected to reach 1.4 billion growing at a CAGR of around 4.6% during the forecast period ranging from 2017-2023. Menstrual cups as of today have become one of the most affordable solutions for feminine hygiene protection. They are reusable and have a lifecycle of more than 2-3 years. Comparing the initial investment in menstrual cups ($15-$75) to the cost of disposable sanitary napkins and tampons, it can actually help in saving hundreds of dollars.Table 1 shows the global and national level players in the market.

Table 1: Global and India level players

Diva International Inc.	She Cup
Lunette	Rustic Art Menstrual Cup
The Keeper	Everteen Menstrual Cup
Inc	iCare soft Menstrual Cup
Vcup	Intimus Menstrual Cup
Mooncup Ltd	
Lady Cup	

There is so much of concern about the environment and health concerns relating to the disposal of tampons and sanitary napkins. Tampons, sanitary napkins or be it a baby's diapers are made of synthetic materials which take years to decompose. The city of Bangalore is already thriving hard to manage it landfills and non-degradable wastes such as sanitary napkins create a menace for the city corporation A women's menstrual life cycle lasts for about 40 years and in their lifetime, this ends up generating ample amount of waste that gets accumulated in landfills and at times washes up the shores of local beaches or sewages in the Indian context. Even in the process of preparation, during the manufacture and bleaching process, there is a possibility of dioxin to be created which has health as well as environmental hazards associated with it[2]. It reveals that most of the women are concerned with price of the product and the environmental impact. The definition of what exactly "green" is debatable. Since women might want to consider the reusable options when using for the 2nd or the 3rd time as completely clean or laundered. It even provides an introspection of whether women will become more open to the idea of green alternatives provided they are aware of the risks associated with conventional menstrual products[3].

The perception about menstruation among young girls in India are always a shameful secret. Majority of the young girls in rural villages are too shy to use sanitary napkins and avoid it because of the cost factor[4]. Girls in the rural India sit separately during menses and majority of them do not even know why menstruation occurs. Few girls got the knowledge about menstruation after its occurrence[5] and also think it as a mechanism to excrete dirty blood from the body[6]

There were also instances found during the previous researches that menstruation negatively affected the girls' experience at school and in the classroom and caused an array of negative emotions. Girls reported leaving school often to change or bathe due to menstrual leaks and as a result missing class lessons. Poor concentration in class attributed to menstrual pain and worry over potential leaks was also mentioned[7].

Research conducted among 158 participants aged between 20 to 50 years with regular menstrual cycle in Gujarat Medical Education and Research Society showed that menstrual cup was preferred for comfort, dryness, and less odour. Further, the results demonstrate that this reusable vaginal device has no significant health risks and is acceptable to many women without the need for fitting or other medical services[8].

The need for menstrual education is the need of the hour. The mothers and teachers agree on the importance of menstrual education for girls yet mothers do not reveal all the necessary facts to their daughters, this may be because of the mother's own lack of knowledge[9]. Young girls should be sensitized about this topic and proper communication has to be given via movies or street plays.

Materials and Method

The objectives of the study include:

1. To study the consumer awareness of menstrual cups among women in India, particularly belonging to the city of Bangalore.
2. To find out how open women are to using alternatives like menstrual cups are which serves as eco-friendly method in comparison to other traditional menstrual products.

This study has been conducted with the help of a structured questionnaire as the primary source of data and secondary sources include the journal and publications on menstrual cups. The predicted sample size is 135 and positively 138 responses were recorded. The sample under study consists of only women ranged from young girls to women till the time they attain their menopause stage (Maximum 45-50 age). Stratified sampling technique has been adopted where girls and women have been stratified as per their age and occupation respectively. The tabular and graphical representation of the data has been done and further analysed with the help of SPSS software.

Results and Discussions

Table 2 shows the demographic factors of the respondents. About 64 per cent of college students in the age group of 18-21 year old girls are the major respondents of this study. They are aware of their menstrual cycle pattern and more than 50 per cent of them maintain their menstrual hygiene really well.The hesitation to talk about periods and related issues is still prevalent among many women (77.50 per cent),no matter how much we as a society touch the age of modernity.Most of the women (72 per cent) have stain related issues with sanitary napkins and are aware of the diseases like UTI, TSS and yeast infection which are related to it (63.80 per cent). About (73.90 per cent) of respondents do show positive signs towards other economical and eco-friendly products like menstrual cups apart from cloth, and sanitary napkin.

Table 2: Demographic factors and awareness of menstrual cups among women

Particulars	Percentage of Responses
Age	
11-17yrs	3.60%
18-21yrs	63.80%
22-30yrs	8%
30yrs and above	24.60%
Occupation	
School Student	2.00%
College Student	65.20%
Working Class Women	15%
Home Maker	14.50%
Others	3.00%
Menstrual cycle awareness	
Yes	90.60%
No	2%
Maybe	7.40%
Period shame feeling	
Yes	77.50%
No	16.70%
Maybe	5.80%
Awareness of diseases related to sanitary pads	
Yes	63.80%
No	21.00%
Maybe	15.20%

Maximum number of women (83.80 per cent) are aware of menstrual cups in Bangalore and are using it on a daily basis.It has been said that the first source of knowing about menstrual cups emerged from social media (50 per cent) and the respondents feel that the social media platform should be usedfor spreading awareness about the same.Easy to use, Eco-friendliness, washable and reusable feature, durability, economical option are considered to be the benefits of using menstrual cups (31.90 per cent). Figure 1 shows the pie chart of women feeling period shame.

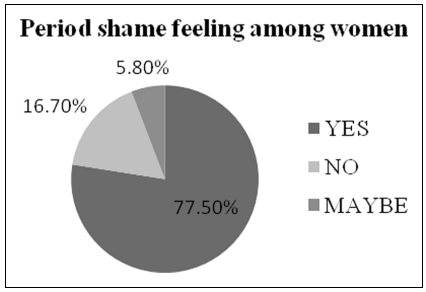

Figure 1: Pie chart showing period shame feeling among women

Women who are new to menstrual cups wants to try the same on trial and error basis and would use it on a daily basis provided they are comfortable with it (48.60 per cent). Since, skin protection is an important factor when one uses personal care products, the respondents feel that consultation with gynaecologist for the usage of menstrual cups is mandatory (57.20%). About (32.30 per cent) women who use menstrual cups regularly are moderately satisfied with it and worry about the insertion pain it causes (50 per cent). This fear of pain also serves as a barrier for using such kind of a product in the long run (25.60 per cent).

Figure 2 shows the bar graph showing barriers to menstrual cups. Table 3 shows the summary of hypotheses test result.Surprisingly good amount of responses was received from women above 30 years and above. This shows that even the elderly do have substantial knowledge about the emergence of new alternatives like menstrual cups. Most of them are concerned with the menstrual hygiene and are open to using alternatives like menstrual cups. Menstrual cups acts as a satisfactory alternative to other menstrual management method and also is a sustainable solution for the city, with moderate cost-savings and much-reduced environmental effects compared to tampons[11].

T-test, correlation and chi-square analysis were the tools used for this study. There is a significant difference between age and awareness of menstrual cups; occupation and awareness of menstrual cups; age and satisfaction level of menstrual cups. There is no significant difference between age and period shame feeling; age and awareness of diseases related to menstruation; and between menstrual hygiene and awareness of menstrual cups.Women in different age groups have different levels of awareness of menstrual cups; out of which women in younger age have more awareness of the same through social media and women online forums. Similarly women with different occupation have different levels of awareness. Homemakers have little knowledge about this product when compared to office-goers. College students have better awareness about the product when compared to rest of the occupations. Irrespective of the age group, women are hesitant to talk about their menstrual cycle and are unaware of the awareness of diseases related to menstruation. This implies the feeling of hesitation, embarrassment and shame that women experience when they talk or are asked about menstruation.In usage and satisfaction level of menstrual cups, women in the age group of above 30 years are satisfied. Even though young girls are aware of the product, they are reluctant to use the same because of the fear of insertion pain.

Table 3 Summary of Hypotheses test results

Hypotheses	Relationship	Empirical Support
H_1	There is a significant difference between age, occupation and awareness of menstrual cups	Supported
H_2	There is a significant difference between age and period shame feeling	Not Supported
H_3	There is a significant difference between age and awareness of diseases related to menstruation	Not Supported
H_4	There is a significant difference between age and Satisfaction level of menstrual cups	Supported
H_5	There is a significant difference between menstrual hygiene and awareness of menstrual cups	Not Supported

The future status as per the opinion of the women undertaken for the study predicts that about 60% of the women in future i.e., 2025 will be completely open to the idea of using menstrual cups as their personal care product and they opt Social media to be the right platform to advertise the product. Hence marketers and women communities have to take steps to spread the awareness and usage of an Eco-friendly product among women.

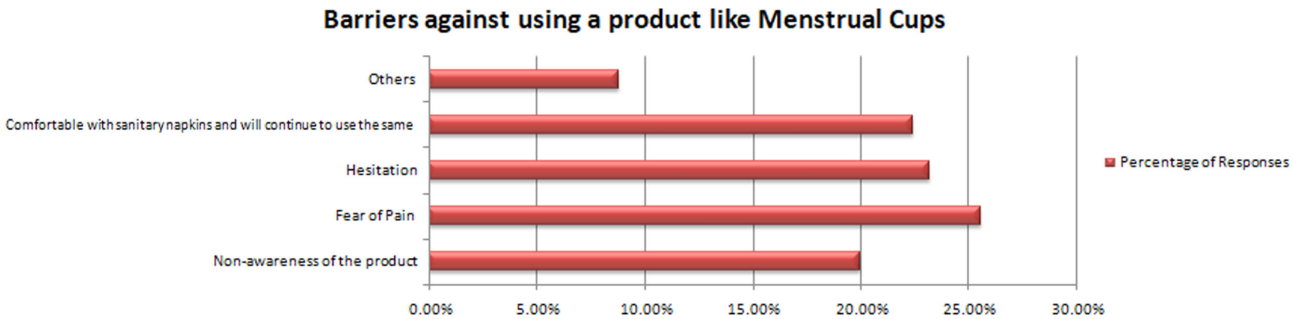

Figure 2: Bar graph showing barriers against using a product like menstrual cups

A woman based research into menstrual cups, its related hygiene and the marketing perspective of a product like menstrual cups and acceptance of the same has been studied in depth. The scope of this research should have further been expanded to include the male opinion and how open they are to addressing a sensitive issue like this.Although, the research has explored most of its objectives, other cities and countries can be

explored for a deeper understanding of a product.Since the scope and document of research is the usage and awareness of menstrual cups, it has not addressed other alternatives like tampons in detail.

Conclusion

Awareness and usage of menstrual cups as an alternative to sanitary napkins has been quiet an extensive research. Long after the emergence of sanitary pads, it did help women in maintaining menstrual hygiene. But it was realised that this accounts for about good percentage of expenditure every month and can get heavy over the pocket of a middle or lower level households. Considering this, even after the removal of GST, it is still not completely the most viable option. It takes years for sanitary napkins to decompose and therefore, it becomes important for the government to introduce other alternatives for women. The focus of the government should be mostly on educating and spreading awareness on eco-friendly menstrual products among the school girls who are the future generation. Separate courses related to menstruation, menstrual hygiene and products; environmental hazards caused by sanitary napkins and its prevention method should be taught well in schools and colleges. The research study initiated a great deal of awareness about menstrual cups as a product to regular users and young girls in the city of Bangalore.

Plasma Cell Gingivitis: An Uncommon Clinical Entity–A Recent Update

Shamimul Hasan[1], Rajat Panigrahi[2]

[1]Professor, Department of Oral Medicine and Radiology, Faculty of Dentistry, Jamia Millia Islamia, New Delhi, [2]Associate Professor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Plasma cell gingivitis is a rare, benign inflammatory condition of uncertain etiology. The exact etiology is not known, although, it is considered as a hypersensitivity reaction to a number of allergens. The lesions appear as well demarcation on the gingival with erythema and edema extendsto the muco-gingival junction. Early and accurate diagnosis entails thorough history taking, hematological and histopathologic examination. The condition is treated according to the underlying allergic component; removal of the cause will cure the lesion.

Keywords: *Allergen, hypersensitivity reaction, Plasma cell gingivitis, Treatment.*

Introduction

Plasma cell gingivitis is very uncommon, benign in natureandinflammatory condition of unknown etiology. It has been referred to as plasmacytosis of the gingiva, idiopathic gingivostomatitis, plasma cell gingivostomatitis, atypical gingivostomatitis and allergic gingivostomatitis.[1] This benign condition was first described in 1952 when Zoon referred to the lesion as "plasma-cell infiltrate" condition involving the glans penis.[2] These conditions have also been reported on the lips, tongue, vulva, conjunctiva, nasal aperture, larynx, and epiglottis.[3]Kerr et al in 1971 reported a case of plasmacytosis of gingiva and found that the most etiological factor responsible for the allergy to be the chewing gum. The tissue became normal upon discontinuation of the use of chewing gum.[4,5]

Review of Literature: Plasma cell gingivitis (PCG) is basically a gingival hypersensitivity reaction with predominant plasma cells in the connectivetissues.[6] There is no known etiology of plasma cell gingivitis. However, it may be considered as lesions of idiopathic etiology due to allergen, and the origin is neoplastic in nature.[7]The immune reaction to some allergic antigen forms the basis of the condition.

Based on causative mechanism, plasma cell gingivitis is categorized as three types: (a) idiopathic lesions, (b) allergen causing (c) neoplastic.[4] This entity is thought to be a B-cell mediated disorder with T-cells augmenting the response.[8]a different form of PCG, known as plasma cell granuloma can occur, manifesting as an enlargement of a specific intra oral region.The term "plasma cell granuloma" specifically by infiltrates of polyclonal plasma cytes on a particular focal region.[9]

Mintin present in the toothpaste and chewing gum,[10] cinnamonaldehyde,[11,12] strong spices (pepper, cardamom)/chilies, chewing of khat,[13,14] and some ingredients of the herbal toothpastes constitutes the possible reported allergens.[15] Clinically, these cases occur almost exclusively in the oral cavity. Angular cheilitis, erythematous gingivitis, and glossitis are the major symptoms, although laryngeal manifestation has also been reported in one case.[16] PCG is characterized by macular lesions that are bright red, velvety, sharply circumscribed, and flat to slightly elevated. Pruritus, burning sensation, or pain occur infrequently and the

Corresponding Author:
Dr. Rajat Panigrahi
Associate Professor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India
e-mail: rajatpanigrahi@gmail.com

lesions are generally asymptomatic.[17,18] Gingiva shows bleeding on the slightest manipulation with loss of stippling. However, there is no loss of attachment.[6,7] Gingival ulceration is rare in plasma cell gingivitis. PCG is a very atypical type of enlargement which presents as painless, diffuse, erythematous, and edematous lesion of the gingiva with a clearly demarcatingand extending up to the mucogingival junction (Figure 1).[19]

Figure 1. Plasma cell gingivitis. Patient reports a change in the tooth paste.

Discussion

The gold standard for finaldiagnosis in the cases of PCG is histopathology which aids in differentiating it from other lesions that clinically resemble localized PCG. Thorough serologic and hematologic testing is mandatory as Plasma Cell Gingivitisresemblesgingival changes in other conditions like leukemia, lichen planus and cicatricial pemphigoid.[20]Histological features of this lesion includes spongiform pustules in the epithelium and a dense infiltrate of normal polyclonal plasma cells in the underlying lamina propria(Figure 2).

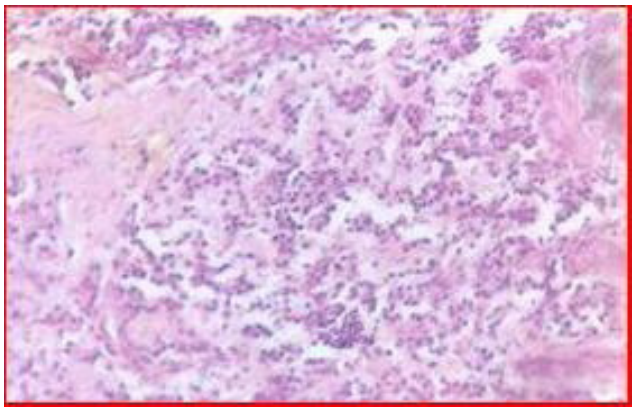

Figure 2. Histopathology showing plasma cells in the connective tissue.

The management of a patient with plasma cell gingivitis should be symptom-based; plaque control and conventional therapies alone will not cure the disease. Identification and elimination of the allergens in an effort to discover the underlying cause. In a patient with an unknown underlying cause allergy testing can be undertaken.[21]

The condition is best managed by identification of the possible allergic agent. This entails a thorough clinical history (patch testing is usually negative). Elimination of the causative agent results in resolution of symptoms.[22-25]

Conclusion

Plasma cell gingivitis is an uncommon entity of obscure etiology. Early diagnosis is necessary as PCG has very much identical pathologic changes often found clinically as in leukemia, HIV infection, discoid lupus erythematosus, atrophic lichen planus, desquamative gingivitis, or cicatricial pemphigoid that must be identified through hematologic and serologic testing.

Effects of Vitamin Deficiencies on Oral Health

Sayantanee Chaudhury

Post Graduate Trainee, Department of Oral and Maxillofacial Pathology and Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The health and functions of skin and mucous membrane epithelia are regulated by vitamins which are organic substances soluble either in fat or water. In economically disadvantaged communities' due to inadequate dietary consumption there is reduced intake or impaired absorption of vitamin and minerals that causes nutritional deficiency diseases. Often the oral cavity shows the early signs and symptoms of systemic diseases, nutritional deficiencies due to rapid epithelial cell turnover in oral mucous membrane. Water-soluble vitamins such as vitamin B2 (riboflavin), B3 (niacin), B6 (pyridoxine), B9 (folic acid), B12 (cobalamin), and C are obtained through dietary or supplement sources as they are not stored in the body in large amount. Fat-soluble vitamins that affect the oral mucosa include vitamins A, D, and K.

Introduction

Water-Soluble Vitamins

Vitamin B1 (thiamine): In tissues thiamine is found as thiamin pyrophosphate (cocarboxylase) which converts carbohydrates to glucose and takes part in intracellular fat and protein metabolism. Vitamin B1 is absorbed from small and large intestines.

Sources: It is found in cereals, grains, beans, nuts, pork and duck.

Deficiency: There is no confirmation that vitamin B1 insufficiency causes any oral manifestation.

Risk Factors: Polished rice, chronic alcoholic patients who do not take food at all, gastrointestinal disease, diabetes mellitus and renal dialysis.

Vitamin B2 (riboflavin): Riboflavin is a component of coenzymes FMN (flavin mononucleotide) and FAD (flavin adenine dinucleotide). These coenzymes exert an important role in regulation of intracellular metabolic oxidation/reduction reactions.It is essential for carbohydrate, fat and protein metabolism. It is absorbed from the intestinal tract**.**

Sources: It is found in dairy products.

Deficiency: Patients with vitamin B2 deficiency have oculo-oro-genital syndromes like conjunctivitis, photophobia, erythematous, scaling patches in genitalia and perianal skin and superficial ulceration. Riboflavin deficiency results in atrophic glossitis in which the filiform papillae become atrophic and the fungiform papillae become mushroom shaped giving a reddened tongue. In severe cases complete atrophy of all the papillae results in glazed, smooth, magenta colored tongue. Other oral manifestations are glossodynia, cheilosis, and angular cheilitis. Riboflavin insufficiency causes ariboflavinosis.The symptoms are cracked lips, swelling of the tongue and burning sensation of the oral cavity, dry mouth.

Risk Factors: Alcoholism, gastrointestinal diseases, malabsorption, diarrhea, deficiency of vitamin B3 zinc.

Vitamin B3 (niacin, nicotinic acid): Nicotinamide adenine dinucleotide and nicotinamide adenine dinucleotide phosphate are the amide derivatives of vitamin B3. They are mainly required to maintain the cell function and metabolism.[1] The main role of niacin is to synthesis cytosine, thymidine which are

thepyridoxine nucleotide. In the other hand oxidation/ reduction reactions are regulated by Niacin. Thus, it helps in metabolism ofamino acid, fattyacid, carbohydrate. Adenine triphosphate (ATP) production is also maintained by vitamin B3.[2]

Sources: Vitamin B3 is found in yeast, red meats, liver, potatoes, pasta, lean pork, salmon, poultry, fish in large amount and milk, eggs contain small amount of Vitamin B3.

Deficiency: Pellagra is a widespread problem resulting from vitamin B3 deficiency.The symptoms pellagra includes mainly diarrhea, inflamed skinand dementia.[3] If the patient remains untreated death may occur. Vitamin B3 deficiency causes malaise, apathy, and weakness, nausea, abdominal pain, and bloody mucoid and watery diarrhea with malabsorption. Initially there is presence of erythema and edema that may cause burning sensation and presence of blisters like acute sunburn. Oral manifestations are bright red glossitis, cheilosis, angular cheilitis, sores in mouth that causes burning sensations in the mouth, erythematous gingiva, mucosal edema and angular cheilosis, mucositis that causes painful ulceration of the mucous membrane, stomatitis, oral pain,appearance of ulcers in the gingiva, the tongue becomes denuded, glossodynia that causes burning sensation in the mouth, inflamed swollen red smooth tongue, dorsum of the tongue becomes dry & smooth, dental caries.[4]

Risk Factors: Chronic alcoholism, gastrointestinal disease, consumption of isoniazid, 5-fluorouracil, sulfapyridine**.**

Patient presents with congenital defects in which tryptophan transport systemis affected in the intestine,kidneys. It results in Hartnup disease in which non polar amino acid absorption is affected**.**

Vitamin B5 (Pantothenic acid): Vitamin B5 plays instrumental role in metabolism of fatty acid, synthesis of cholesterol, and degradation of amino acid. It is a component of coenzyme A.

Sources: Vitamin B5 is found mainly in meats like chicken, beef, liver and also found in corn, broccoli, peanuts, egg, soybeans, cauliflower,tomatoes,lobster,sa lmon and whole grains.

Deficiency: There is no specific evidence that vitamin B5 deficiency causes any specific oral manifestations.

Vitamin B6 (pyridoxine): It is a complex of pyridoxine,pyridoxal and pyridoxamine.Vitamin B6 takes part in decarboxylation of amino acid,protein and fatty acid metabolism.

Sources: Vitamin B6 is found in sunflower seeds, chickpea, salmon,shiitake, organmeats, beef liver, whole grains, fruits other than citrus and starchy vegetables.

Deficiency: It's deficiency results in fatigue, weakness, dizziness associated with anemia, burning paresthesia, depression, confusion, and generalized seizures. Oral manifestations include atrophic glossitis, angular cheilosis, xerostomia–dryness of the mouth, pellagrous stomatitis, and erythematous gingiva.

Risk Factors: Chronic alcoholism, malabsorption, malnutrition, renal failure, renal dialysis, liver disease, advanced age.

Vitamin B7 (biotin, vitamin H): Vitamin B7 helps in synthesis of fatty acid, amino acid catabolism, and gluconeogenesis.

Sources: It is mostly found in soybeans, cooked oats, egg yolks, unpolished rice, almonds, peanuts, walnuts, whole grains.

Deficiency: Vitamin B7 deficiency causes some neurologic diseases such as depression, hallucination, ataxia, and peripheral paresthesia. There is no specific oral manifestation of vitamin B7 deficiency.

Risk Factors: Consumption of raw egg for prolonged period, patients who are dependent on intravenous nutritionlacking biotin supplementation, diabetic patientas well aspatients with biotinidaseinsufficiency**.**

Vitamin B9 (folic acid, folate): Tetrahydrofolate is the active form of vitamin B9 that plays an important role in purines, thymidine, and amino acid synthesis. It helps in DNA repairing, RBC production.

Sources: The significant sources of Folate are green vegetables,beans, citrus fruits, spinach, broccoli, yeast, legumes, lima, kidneybeans, grapes, strawberries, peanuts, walnuts, juices, organ meats, beef liver. There is of deficiency 60% to 90% of folate in cooked food items.

Deficiency: Therefore,mostly affected tissues by folic acid deficiency are those which show cell turnover with high rates. Glossitis, sore tongue, aphthae, atrophy of lingual papillae,

Risk Factors: Under developed socioeconomic status, advanced age, alcoholism, starvation, malabsorption, pregnancy, chronic hemolytic anemia, certain medications like phenytoin, sulfasalazine, metformin, tobacco smoking, bleeding.

Vitamin B12 (cobalamin, cyanocobalamin): Cobalamins consist of a planar group with a central cobalt atom (corrin ring) and right-angles. Vitamin B_{12} was first crystallized ascyanocobalamin, but the main natural cobalamins have deoxyadenosyl-, methyl- and hydroxocobalamin groups attached to the cobalt atom. It is an important cofactor for DNA synthesis.

Source: It is found in milk, cobalamin-fortified cereals, eggs, and meat.

Deficiency: Angular cheilosis, burning mouth, inflamed gingiva, bleeding gum, halitosis, epithelium of the oral mucosa becomes dysplastic, oral paraesthesia, periodontal fibresbecome lose and get detach from the tooth structure, taste sensations become distorted followed by loss of taste sensations, ulceration, ulcerative gingivitis, denuded tongue,glossitis,glossodynia, tongue is "beefy"red, smooth & glossy, delayed wound healing, xerostomia, bone loss, aphthous ulcers.[5]**Causes**: Starvation, insufficient dietary intake, impaired absorption of stomach, vegans.

Risk Factors: person with low dietary intake, Vegans, malabsorption.Pernicious anemia, Gastrectomy, Congenital transcobalamin II deficiency, Nitrous oxide (inactivates B12)

Vitamin C (ascorbic acid, L-ascorbic acid and ascorbate): Vitamin C plays a significant role insynthesis of nor epinephrine, amination of such hormones like peptide hormones, biosynthesis of carnitine, and tyrosine metabolism and collagen formation. It repairs healthy tissue with its antioxidant properties.[6]

Sources: It is present in citrus fruits like lemons, oranges, tomatoes, broccoli, green peppers, and cabbage.

Deficiency: Insufficiency of vitamin C causes various oral symptoms that include scurvy- swollen and bluish or reddish inflamed gingiva, periodontal destruction, increased risk in candidiasis, mucosal petechiae, gingival bleeding, sore burning mouth, soft tissue ulceration, gingival bleedingand malformed teeth, gums become swollen and spongy that bleeds on slide provocation. Presence of superadded infection, loss of connective tissue and alveolar bone that causes loosening of teeth. Severe vitamin C deficiency causes scorbutic gingivitis. Untreated scurvy leads to intracranial hemorrhage followed by death.[7]

Risk Factors: Mainly seen in malegender, person with low dietary intake and tobacco smoking that causes reduction of absorption of vitamin C and increased degradation of vitamin C.

Fat Soluble Vitamins:

Vitamin A (retinol): It plays a significantpart to maintain the integrity of epithelium, vision sensation, immunity, reproductive system. Vitamin A mediates bone modeling and growth and modeling of teeth. It combined with long-chain fatty acids and present as esters in the food and the body.

Absorption mainly takes place in the intestine. It is stored in the liver, kidneys, and adipose tissue. Then it is transported to the plasma and there it bounds to α-globulin, retinol-binding protein (RBP)**.**Vitamin A acts as avitalconstituentthat is required to sustain the maintenance of oral mucous membrane, salivary glands, and teeth.[8]

Source: It present in cod liver oil, sweetpotato, carrot, eggs, whole milk, broccoli, squash,green leafy vegetables fortified cereals, capsicum, mango.

Deficiency: Vitamin A deficiency causes ocular, cutaneous, and mucosal changes. Oral manifestations are keratosis of labial mucosa, xerostomia, hyperkeratosis of oral epithelium, periodontal disease, increased rates of intraoral infection, desquamated oral mucosa, candidiasis, inflamed reddish gingiva, leukoplakia,altered taste sensation, arrested enamel development, enamel developmentbecomes messed up, tooth becomes brittle, degenerating salivary glandand increased risk of dental caries,impaired tooth development in children.

Prolonged deficiency of vitamin A loss of specificity of epithelial basal cell layer leads to formation of stratified squamous epithelium with keratin production followed by keratinizing metaplasia of epithelial cells. Deficiency of retinol causes salivary gland atrophy followed by impaired defense mechanism of the oral cavity against infection.[9]

Risk Factor: Malnutrition, malabsorption, alcoholism, impaired biliary secretion, vegan diet.

Vitamin D (calciferol, cholecalciferol, ergocalciferol): Vitamin D has an important role in calcium and phosphorus homeostasis. In human there is photo activation of 7-dehydrocholesterol to cholecalciferol that produces Vitamin D, then it is converted to 25-hydroxycholecalciferol and further converted to active metabolite by renal 1α-hydroxylase. Absorption of Vitamin D occurs in small intestine.

Source: Sunlight, reference nutrient intake (RNI). It is present in fish liver oils, fatty fish, egg yolks, and fortified milk in limited quantity.

Deficiency: Oral manifestation included loss of periodontal ligament attachment, enamel hypoplasia. During tooth developmental period insufficient supply of vitamin D can cause delayed tooth eruption, loss of lamina dura and cementum. Histologic evidence shows hypocalcified globular dentin with clefts and tubular defects occurring in the region of pulp horn. There is periapical involvement of deciduous or permanent teeth followed by formation of gingival fistula.[4]

Risk Factors: Insufficient sunlight exposure, malnutrition, malabsorption, advancedage, hepatic disease, renal disease.

Vitamin E (tocopherol): Vitamin E is divided into two parts; Tocopherols-commonest is α-tocopherol and Tocotrienoles. It acts as an antioxidant and affects cell proliferation and growth.

Sources: It is present in a wide variety in dietary source.[10]Vegetables and seed oils, soya bean, saffron, sunflower, cereals and nuts.

Deficiency: There is no significant oral manifestation of lack Vitamin E.

Risk Factors: Genetic abnormalities, impaired biliary secretion.

Vitamin K (phylloquinone): Vitamin K has an important role in regulation of the factors II, VII, IX, and X which are the procoagulant factors and the anticoagulant proteins, protein C and protein S. Vitamin K_1-phylloquinone

Vitamin K_2- menaquinone.

Major absorption occurs in the terminal ileum.

Sources: It is found in green leafy vegetables, cauliflower, Brussels sprouts, collard greens, spinach, mustard greens,broccoli,parsley, soybean, canolaand olive.

Deficiency: Increased risk of gingival bleeding, sub mucosal hemorrhage is seen in oral manifestations. In untreated patients' death may occur due to uncontrolled systemic hemorrhage.

Risk Factors: Certain anti-bacterial drugs, cholestaticjaundice**,** Vitamin K antagonists, Oral anticoagulants.

Table 1: Oral Manifestations[11]

Deficient Vitamins	Effect on oral structure
Vitamin A	Decreased epithelial tissue growth, Impaired tooth formation, Enamel hypoplasia.
Vitamin D/ Calcium phosphorus	Lowered plasma calcium, Hypo mineralization Compromised tooth integrity, Delayed eruption pattern Absence of lamina dura, Abnormal alveolar bone patterns.
Vitamin C	Irregular dentin formation, Dental pulpal alterations Bleeding gums, Delayed wound healing, Defective collagen formation.
Vitamin B1 (Thiamine)	Cracked lips, Angular cheilosis
Vitamin B2 & Vitamin B3	Inflammation of the tongue, Angular cheilosis Ulcerative gingivitis
Vitamin B6	Periodontal disease, Anemia Sore tongue Burning sensation in the oral cavity.
Vitamin B12	Angular cheilosis, Halitosis, Bone loss, Hemorrhagic gingivitis Detachment of periodontal fibers Painful ulcers in the mouth

Conclusion

Due to inadequate diet and mal nutrition there is malabsorption and disturbance in utilization of certain important factors that are present in daily food. People who stay in undeveloped poor countries mostly present with vitamin deficiency syndromes. Malnutrition affects the oral mucosa through an altered tissue homeostasisin different ways and advancedoral diseases.

Modifications of Local Anesthesia in Medically Compromised Patients: A Review

Upasana Mohapatra[1], Susant Mohanty[2], Sonu Acharya[3], Bismay Singh[4]

[1]Tutor, Department of Pediatric and Preventive Dentistry Institute of Dental Sciences, [2]Professor & Head, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, [3]Professor, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, [4]Senior Lecturer, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

The association of local anesthesia, the vasoconstrictor used in it and the medical condition of the patient concerned has long been studied, analyzed and modified. With the advancement in medical and dental practices, the number of complications relating the above stated parameters has also increased. This article gives a review of how the conditions of medically compromised patients effect the use of local anesthetic agent and the vasoconstrictors used with them in dental practice.

Keywords: *Local Anesthesia, Complications, Medically-Compromised.*

Introduction

The use of a vasoconstrictor in local anesthesia brings about vasoconstriction of peripheral vasculature locally, which leads to creation of a bloodless operating field and reduced absorption of the local anesthetic agent to the blood stream. This increases the depth and duration of anesthesia, and decreases the systemic and/or harmful effects of anesthetic agent.[1] The most commonly used vasoconstrictors in dental office are Epinephrine and Levonordefrin. Epinephrine is preferred over Nor-Epinephrine because of the fact that, it causes severe and paradoxical bradycardia because of its action on the cardiac β1 receptors, thereby increasing the heart rate.[1] 2% Lignocaine with 1:80,000 Epinephrine is the most commonly used vasoconstrictor in the dental office.[1] by using 1:200,000 or 1:100,000 solution, duration of anesthetic action is maintained sufficiently for most of the minor surgicalprocedures in dentistry.[2] A slow injection of the anesthetic solution, containing vasoconstrictor or not, must be carried out (1ml/minute).[2]

The effects of Epinephrine are vasoconstrictionof peripheral vasculature, increased sinus node conduction rate, increased contractility and irritability of the myocardium, increased conduction rate of AV nodes, bronchodilation, vasodilatation of skeletal muscle. It stimulates the α1 receptors of the smooth muscles of the peripheral vessels, thereby leading to peripheral vasoconstriction, decreased absorption of the local anesthetic agent, local ischemia of the tissues.[2] This ischemia also occurs in the blood vessels (called vasa nervorum) which supply the axons of sensitive nerve fibers of the site anesthetized. The metabolic activities of the nerve cells are reduced, thereby reducing the nerve impulse transmission, leading to increased depth and duration of local anesthesia.[1]

Review of Literature

Cerebrovascular system: The cerebrovascular system is usually depressed by the use of higher doses of local anesthetic agent. This depression is manifested as bradycardia, hypotension, and collapse of cerebrovascular system and might lead to cardiac arrest.[3] The early manifestations of this depression is commonly caused by vasovagal reactions like, giddiness and syncope, mainly when the patient sits in an upright position in the dental chair.

Hypertension: In 1964, American Heart Association and the American Dental association jointly provided a concluding statement that "the typical concentrations of vasoconstrictors contained in local anesthetics are not contraindicated with cardiovascular disease so long as preliminary aspiration is practiced, the agent is injected slowly, and the smallest effective dose is administered".[4] After many studies including different categories of subjects, it has been found that, when the subjects are injected with local anesthesia without vasoconstrictor, their Blood Pressure is noticeably uncontrolled when pain and anxiety are kept under control, than in the patients who are injected local anesthesia with vasoconstrictors prior to dental extraction.[2] The recommended total dosage of Adrenaline should be limited to 0.04mg in patients with cardiac risk.[5,6] This is approximately equal to local anesthetic containing 1:100,000 Adrenaline. Levonordefrin, as a vasoconstrictor shows one-fifth effectiveness as Adrenaline. So, it is used in a concentration of 1:20,000, which has the same clinical risk as 1:100,000 concentration of Adrenaline.

Unstable Angina: Unstable angina is referred to deterioration of symptoms in recent times and decreased response to medical management protocols. Angina de novo is the total number of anginas in 4 weeks' duration or less. Crescendo angina mainly refers to an increase in frequency of angina, duration of the attacks, severity of symptoms, and a decreased response to medical care.[1] Even injecting a quantity of local anesthesia with vasoconstrictor just higher than a safe minimal dose can cause a noticeable increase in cardiac stroke volume and oxygen consumption in healthy individuals who are normotensive. In such patients, preliminary aspiration should be carried out and minimal effective should be administered.[2] And in case of emergency dental treatment, medical consultation is necessary and eliminating pain should be the major concern. Epinephrine dosage should be limited to 1 or 2 cartridges of 1:100,000 (0.018mg-0.036mg) solution.[7]

Stable Angina: Dental anesthesia poses a significantly lesser threat to stable angina patients having a history of myocardial infarction or not than to unstable angina patients or having a history of recent myocardial infarction (within 6 months). The clinical factors in management of such patients are stress and anxiety control and absolute pain control throughout the procedure. For proper stress management, local anesthetic with vasoconstrictor is necessary and the dosage of Epinephrine-containing local anesthesia should be limited to one or two 1.8 ml cartridges.[1] Elective dental procedures are postponed and only emergency dental procedures should be carried out in such patients, i.e., patients suffering from unstable angina, myocardial infarction (within 6 months), or coronary artery bypass graft surgery (within 3 months).[8] In case of after 6 months duration of myocardial infarction, doses of Epinephrine should be stuck to less than 0.036 mg. [9]

Recent coronary artery bypass surgery: Both, local anesthesia administration with vasoconstrictor and routine dental treatment should be post-ponded to 3 months duration after surgery, which is the delicate period for healing, during which notable ischemic changes occur.[3]

Cardiac Dysrhythmia: A physician consultation is required to assess the current status of such patients. Stress management is of utmost significance for patients especially with coronary atherosclerotic heart disease, ischemic heart disease or congestive heart failure.[3] So, local anesthesia containing vasoconstrictor should be administered for pain and anxiety control, but, the safety limit of total dose should not be exceeding two 1.8 ml cartridges per appointment. Periodontal ligament or intraosseous injections should be avoided with local anesthesia containing vasoconstrictor.[10] Elective procedures should be postponed until the disease is well under control.

Refractory arrhythmias: This carries a high risk for immediate cardiac arrest, leading to death and is one of the major reasons for contraindication for use of vasoconstrictor with local anesthesia in dentistry.[1]

Heart failure: Uncontrolled and untreated congestive heart failure has a poor prognosis and a risk of sudden cardiac arrest (leading to death) because of ventricular arrhythmias.[3] But, well-controlled and treated congestive cardiac failure can be treated with arelative safety and limited vasoconstrictor quantity of two 1.8 ml cartridges of Epinephrine-containing local anesthesia. Patients under treatment of Digitalis glycosides, such as Digoxin must be treated with utmost care as interaction of the drug with vasoconstrictor might precipitate dysrhythmias.[3] Patients, who are under the management with long-acting nitrate drugs, such as nitroglycerin, Isordil, or Isorbid, or under a vasodilator such as Minipres may exhibit a reduced efficacy of vasoconstrictor in local anesthesia, thereby reducing the duration of anesthesia.[11]

Cerebrovascular Accident: Dental treatment should be postponed to 6 months after the stroke because a patient with a history of stroke has a higher risk of having another stoke within 6 months from the first stroke. 3 After 6 months, dental procedure can be carried out by using vasoconstrictor-containing local anesthesia when pain control is required. The dosage of vasoconstrictor must be minimized for patients who have a history of stroke associated with cerebrovascular problems. [3]

Pulmonary diseases: The most frequently encountered pulmonary diseases in patients in the dental offices are asthma, tuberculosis and chronic obstructive pulmonary disease (chronic bronchitis and emphysema).

Asthma: In asthmatic patients, stress reduction protocols should be strictly followed, and hence, judicial addition of vasoconstrictor in local anesthesia is also important.[3] But, according to Food And Drug Association warnings, drugs containing sulphites cause allergy in susceptible individuals.[12,13] Usually the severe steroid-dependent asthmatics are allergic to sulphites, which are used in local anesthesia solutions containing vasoconstrictors to prevent the breakdown of the vasoconstrictors. Hence, in these patients' vasoconstrictors should be avoided, which would thus prevent the usage of sulphites.[14,15]

Chronic Obstructive Pulmonary Disease: This is characterized by chronic obstruction of ventilating system of lungs. The two most common forms are bronchitis and emphysema, where patients have decreased respiratory functions. So, the precautions to be carried out in a dental office require the prevention of respiratory depression. If these patients have coronary heart disease/or hypertension, vasoconstrictor in local anesthesia should be regulated according to these associated diseases.[3]

Renal diseases: As the local anesthetics used in dentistry are excreted by kidney, so the dosage should be reduced to safe minimal dose and interval between subsequent injections should be increased. 16 In case of a tumor in the adrenal medulla, called pheochromocytoma, administration of vasoconstrictors should be strictly contraindicated.[15]

Hepatic diseases: Amide local anesthetic agents are metabolized in the liver. So, dosage of these solutions should be avoided or atleast reduced. This might mostly be the case in patients with chronic active hepatitis or in patients carrying the hepatitis antigen. Minimum dosage local anesthesia has to be administered. But, with patients with complete recovery, routine local anesthesia administration can be carried out. The same stands true for more advanced cirrhotic diseases too. Hence, for such patients, local anesthetic doses should be decreased and the interval between following injections should be increased. In such a case, injection of a rapid-onset local anesthetic such as Lidocaine or Mepivacaine, and subsequently an injection with a long-acting local anesthetic like Etidocaine or Bupivacaine would stand as the most preferred option of maintaining the safe dosage, and achieving the desired effects in pain control in patients.[3]

Pancreatic diseases

Diabetes Mellitus: Patients with either Type I or Type II diabetes mellitus, if well-controlled and are well under treatment, can be routinely treated. But, stress management protocols should be strictly followed. Type I diabetes mellitus patients, who are under the treatment of large doses of Insulin show unpredictable shifts between hyperglycemia and hypoglycemia. Hence, the dosage of vasoconstrictor should be minimized to avoid the chance of vasoconstrictor-enhanced hypoglycemia.[17] Because the action of Adrenaline is the exact opposite to the action of Insulin(Adrenaline stimulates neoglucogenesis and hepatic glycogenolysis), which leads to hypoglycemia.[1] For patients with unstable diabetes mellitus, Epinephrine amount maintained in one to three cartridges of local anesthesia (0.018mg to 0.054mg) would be sufficient to rise the chances of ketoacidosis and hyperglycemia.[1]1:100,000 Adrenaline-containing solution should be kept at a minimal dosage.[1]

Thyroid diseases

Hyperthyroidism: Epinephrine use must be refrained from or decreased to one to two cartridges in patients without treatment or with uncontrolled levels of thyroid hormones. Unjudicial use of vasoconstrictor might precipitate hypertension and cardiac dysrhythmias.[3]

Hypothyroidism: Mild to severe hypothyroid patients have central nervous system depression, which might be the cause of exaggerated responses of these patients to local anesthetic agents. For the patients with severe hypotension, dental treatment should be postponed till the condition is under control.

Blood dyscrasias

Sickle cell anemia: Vasoconstrictor-containing anesthesia can be used safely in these patients, if the dose is limited to one to two cartridges, but stress reduction protocols should be strictly maintained.[18]

Methehemoglobinemia: Prilocaine (specifically, among other local anesthetics) might lead to an increase in methemoglobin levels, if specially associated with other drugs having the similar effect[19,20] (interactions like Dapsone, Isordil, Nardil, Septra, Nitroglycerine, etc.)[21]

Conclusion

A critical understanding of the medical condition of the patients is required to avoid any untoward situation. Stress reduction protocols, preliminary aspiration, slow injection and a safe minimal dose can help achieve a smooth running of the dental procedures. A reduced concentration like 1:200,000 exhibits similar effects of vasoconstriction and is recommended for medically compromised patients.[15]

The Periodontium: A Comprehensive Overview

Manisha Khandelwal

Intern, Institute of Dental Sciences, Shiksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The periodontium is the foundation for their dentition. The components of periodontium are–The alveolar mucosa, gingival, cementum, the periodontal ligament and the alveolar bone which serves as the supporting apparatus for teeth in function and in occlusal relationship. The knowledge of the details of the tissue compartments,the cells which are involved and how the cellular products acellinteract will provide a greater understanding of the function of periodontium. Thus, it is important to know about the anatomy and physiology of the healthy periodontium and its relationship to the natural dentition, jaws and oral environment.

Keywords: *Periodontium; Dentition; Oral Environment.*

Introduction

The **primary dentition** is composed of 20 teeth with 10 in each arch. There are five teeth in each quadrant composed of two incisors(central and lateral),one canine, and two molars. These teeth are referred to as letters A, B, C, D, E. The primary tooth begin to erupt at six months of age. The **permanent dentition** is composed of 32 teeth which is sixteen in each arch. These are eight teeth in each quadrant, composed of two incisors (central and lateral), onecanine, two premolars and three molars. These teeth are referred to as 1(central incisor) to 8 (3rd molar wisdom tooth).The permanent teeth begin to erupt and replace the primary teeth at 6 years of age. The permanent teeth complete eruption by approximately 13 years of age with the exception of 3rd molar.[1]

Periodontium of the primary dentition: The word periodontium comes from Greek term peri which means around and odons which means tooth. Literal meaning is that which is around tooth. It has been found that periodontium of primary dentition differs from that of permanent dentition in several aspects. The gingiva in primary dentition appears to be more reddish vascular and flabby and lacks stippling as compared to permanent dentition. The periodontal ligament in primary dentition are wider and have less dense fibers. The alveolar bone in primary dentition has less trabeculae and calcification, more marrow spaces and greater blood supply and lymphatic drainage. The periodontium of primary dentition resorbs more easily because it contains more sialoprotein and osteoprotein which facilitates the binding of osteoclast.[2]

Oral mucosa contains following three zones:

- The gingiva and covering of hard palate termed as masticatory mucosa
- The orsum of the tongue,covered by specialized mucosa
- The oral mucous membrane lining the remainder of oral mucosa.

Gingiva: Gingiva is the part of oral mucosa that covers the alveolar process of the jaws and surrounds neck of the teeth.Anatomically, gingiva is divided into: marginal gingiva

- Attached gingiva
- Interdental gingival

How is the child's gingiva different from that of an adult?

- Marginal-also known as–unattached gingival, it is the terminal edge or border of gingival that surrounds the teeth in collar like fashion.
- marginal gingival of child has rolled edges in primary dentition
- In children, it is flaccid and retractable due to immature connective tissue and gingival fibers and increased vascularization.

- Attached-it is continuous with the marginal gingiva. It is firm,resilient,an tightly bound to underlying periosteum of alveolar bone.
- Width-Primary Dentition-Greatest in incisor region, decreases in cuspids and increases again in primary molar region.
- Permanent dentition-Greatest in incisor region and less posteriorly with least in premolar region.
- Interdental-It occupies the gingival embrasure which is the interproximal space beneath the area of the tooth contact.
- It is pyramidal or col shaped
- Because the contact point isbroad, flat and low the papillae are shorter and rounder than those in permanent teeth.
- HISTOLOGIC FEATURE-In child connective tissue of gingiva contains less abundant collagen fibers than adult.
- COLOUR-The gingival colour of the young child may be more reddish due to increased vascularity and thinner epithelium.

Physiologic changes in gingiva associated with tooth epithelium: Pre eruption bulge-It is present over the crown of the tooth which is about to erupt. It may be slightly blanched. Formation of gingival margin-As the crown penetrates oral mucosa, marginal gingival a sulcus develops. Usuallyedematous, rounded and slightly reddened. Normal prominence of gingival margin-prominence of gingival margin especially over maxillary anterior is normal till the teeth is fully erupted.[3]

Periodontal ligament: It is specialized fibrous connective tissue that surrounds and attaches roots of teeth to alveolar bone. It is also known as periodontal membrane.it is continuous with connective tissue of gingival and it communicates with marrow spaces through vascular channels in the bone.

Principle fibers of PDL: The most important element of periodontal ligament are principle fibers which are collagenous and are arranged in bundles which follows a wavy course when viewed in longitudinal section. The principle fibers are arranged in 6 groups that develops sequentially in developing root: Transseptal fibers; alveolar crest fibers; horizontal fibres; oblique fibers; apical fibers; interradicularfibers.[2, 4]

Cementum: Cementum is calcified avascular mesenchymal tissue that forms the outer covering of the anatomical root. It is of 2 types: cellular and acellular.

- **Acellular:** It is the first cementum formed which covers approximately the cervical third and half of the root and it does not contain cells. It is formed before the tooth reaches occlusal plane.
- **Cellular:** It is formed after the tooth reaches the occlusal plane and is more irregular and contains cells in individual spaces that communicates with each other. Cellular cementum is less calcified than acellular cementum and are separated by other fibres that are arrange either parallel to root surface or at random.5 -7

Alveolar bone: It is portion of maxilla and mandible that forms and supports the tooth socket. It forms when the tooth erupts to provide the osseous attachment to the forming periodontal ligament, it disappears gradually after the tooth is lost.

It contains 2/3 inorganic matter and 1/3 organic matrix.

Inorganic Matter: It is principally composed of minerals, calcium and phosphate along with hydroxyl,carbonate,citrate and trace amounts of other ions such as sodium, magnesium, and fluoride.

Oraganic Matter: It mainly consists of collagen type I (90%) with small amount of non-collagenous protein such as osteocalcin, osteonectin bone morphogenic protein, phosphoprotein and proteoglycans.[4]

Table 1. Differences between primary and permanent periodontium

Primary	Permanent
Gingiva is generally absent in a healthy child, similarly,recession is in frequent.	Gingivitis is common in adults
Alveolar atrophy is rare	Alveolar atrophy occurs
Cementum is very thin and of primary type. Secondary cementum is characteristically absent.	Secondary cementum is present.
Roots have enlarged apical foramen. Thus, the abundant blood supply demonstrates a more typical inflammatory response.	Foramens are restricted. Thus, reduced blood supply favors a calcific scarring.
Incidence of reparativedentin formation beneath carious lesion is more extensive and irregular	Reparative dentin formation is less.

Primary	Permanent
Localization of infection and inflammation is poorer in pulp.	Infection and inflammation in pulp is localized.
Pulp nerve fibers pass to the odontoblastic area.	Pulp nerve fibers terminate mainly among the odontoblasts.

Conclusion

The periodontium of primary dentition differs a lot from that of the permanent dentition. The periodontium of primary dentition play a more significant role for doing the dental treatments. Periodontium of primary dentition should be preserved while doing the clinical treatments However, dental education should do more to reinforce altruistic motive in students to develop commitment to improve future of the oral health environment.

Obstructive Sleep Apnoea: An Overview

Prateek Kumar Sundaray[1], Sthitaprajna Lenka[2], Karishma Rathor[3], M. Krishna Kumari[4], Alok Mahapatra[1]

[1]Intern, Institute of Dental Sciences, [2]Professor, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, [3]Tutor, Department of Public Health Dentisry, Institute of Dental Sciences, [4]Post Graduate Trainee, Department of Prosthodontics Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Obstructive sleep apnoea is a frequent disarray define by constant chapter of nocturnal respiratory arrest due to failure of upper airway. OSA element syndrome, being extreme daytime vacation is combined among symbolic cardiovascular dysphoria & fatality. Contrasting analysis benefits are today applicable as a practical administration of this disorder. "Subsequently more than three decades from its first purpose Continuous positive airway pressure (CPAP) do still perceive as the gold accepted therapy".Nasal CPAP is deeply compelling that developing quality of life & contracting the clinical importance of sleep apnoea.

Keywords: *Continuous positive airway pressure, Obstructive sleep apnoea, Oral Appliances, Uvulopalatopharyngoplasty, Polysomnography, Upper airway.*

Introduction

Obstructive sleep apnoea is a sleep disorder. It causes breathing to stop and start frequently while breathing the muscles in the pharynx keep the airway open. Commonly these muscles relax slightly during sleep. However, if they relax in excess it may cause airway to get blocked & the individual wakes up due to shortage of oxygen in the lungs. The patient tries to breathein consciously to re-saturate the blood with oxygen so that he will fall back into sleep. In a worldwide study It is estimated at 3% to 7% in men and 2% to 5% in women. Its symptoms such as too much of day time somnolence and is associated with a significant cardiovascular morbidity and mortality. It is defined as repeated episodes of obstructive apnoea and hypopnea during sleep, together with daytime sleepiness or altered cardiopulmonary function.[1] Particular segment of the people has been diagnosed because of lack of cognizance of sleep apnoea diagnosis with the physician.[1,2]

Definitions: Sleep apnoea upper & lower airway obstructive patients mainly complains of lethargy and fatigue in daylight and also during sleep. Upper-airway resistance syndrome is marked due to rise in response to increased upper-airway resistance with no sign of an elevated apnoea or hypopnea index. Heavy snoring is founded in Patients with the upper-airway resistance syndrome.[3,4]

Pathogenesis: Restriction or obstruction may occur in upper airway that includes velopharynx, oropharynx, or hypopharynx. This kind of situation are triggered by the crucial neuromuscular tone,upper airway muscle syndrome & the pattern of sleep. These episodes are generally most flashy during rapid eye movement(REM) sleep because of the hypotonia of the muscles present in the upper airway which is a peculiar of stage 1 sleep.[4] The Upper-airway patency during sleep is decided by the soft-tissue and the skeletal muscles surrounding the upper airway. The upper airway narrowing is triggered in obese patients who have significant amount of adipose tissue in the neck, which causes the narrowing of airway. It has been reported that MRI has shown fatty

Corresponding Author:
Dr. Sthitaprajna Lenka

e-mail: sthitaprajnalenka@gmail.com

infiltration inside the pharyngeal tissue of patients with sleep apnoea.Patients with tonsillar hypertrophy skeletal deformities plays a major role in upper airway closure at the time of sleep.[6]

Pathophysiologic consequences: The major possibility hazards of Sleep apnoea are cardiovascular disorders (E.g. Pulmonary hypertension,myocardial infection,congestive cardiac failure & sudden stroke. Various author suggest that there is a significant combination of sleep apnoea with morbidity & modality. Drowsiness, dullness, irritabilityand personality distortion have been associating to nocturnal desaturation and chronic sleep deprivation caused by sleep fragmentation. Sleep fragmentation may be the most important predictor of daytime sleepiness.[7]

Diagnosis: Several other condition can cause daytime sleepiness but can usually be excluded by a careful history given below.

Lack of Sleep: Deficient time in bed, Extraneous sleep disruption (like Babies & children), Shift work, excessive caffeine intake, Physical illness (like different types of pain), Sleep disruption, sleep apnoea/hypopnoea syndrome, periodic limb movement disorder(recurrent limb movements during non-REM sleep,frequent, nocturnal awakenings).[8]

Sleepiness with relatively normal sleep: Narcolepsy, Idiopathic hypersomnolence, Neurological lesions(like hypothalamic or upper brain stem infarcts or tumours), Drugs, Psychological/psychiatric, Bleakness.[9]

Narcolepsy is a rare cause of sleepiness,occurring in 0.05% of the population. Idiopathic hypersomnolence occurs in younger individuals & is signalize by long nocturnal sleeps.

Sleep studies: A full night of polysomnography, organized by a technologist in a sleep laboratory, has usually been noticedas the gold standard for analysing sleep apnoea. Thepolysomnogram is a comprising study used to scroll many physiologic variables in order to diagnose a wide spectrum of pulmonary and non-pulmonary disorders of sleep. Portable, unattended monitoring systems that can be used outside the hospital promise a more cost-effective alternative to the standard diagnostic nocturnal polysomnography. [10]

Treatment: The highly effective treatment for sleep apnoea is CPAP. It is a device which is consist of a mask and the patient has to keep that mask in the mouth and the nose region and the device slowly push the air into the upper airway to keep it patterned during the hours of sleep. Alternate self-management for sleep apnoea is describe below. Self-care like Aerobic Exercises 1 hour for 7 days improves the cardiovascular health and the patency of upper airway. Supportive care like CPAP & airway management (clearing a blocked airway of food,foreign objects,fluid & other obstructions.[11]

Oral appliances: Specific studies have exposed that oral appliances are suitable for positive airway pressure for some sleep apnoea patients. An ample variation of appliances are available, differing both in construction and in the manner in which they alter the oral cavity. The appliances are worn only during sleep and are generally well tolerated. Not all patients have a clinically meaningful response to oral appliances, which are currently regarded as second-line therapy. Patients with mild sleep apnoea who do not tolerate therapy with positive airway pressure are good candidates for a trial of an oral appliance. Close collaboration between the physician and the dental consultant is necessary to ensure optimal patient selection and to avoid any mutation of dental occlusion or temporomandibular-joint discomfort.[2, 4]

Surgical treatment

Tracheostomy: Tracheostomy bypass the UA & is the most adequate surgical procedure for treatment of OSA. It is basically 100% effective. Unfortunately,tracheostomy is a deform method & decreases the patient's quality of life.[9]

Palatal Surgery: In 50 percentile of patient uvulopalatopharyngoplasty, is remedial. Preoperative radiographic studies are not adequatelypredicted success of a surgery.[9]

Maxillofacial Surgery: A diversity treatment modalities has been implemented to intensify and to improve the sleeping pattern of the patient. The method are palatopharyngoplasty. Example: Pierre robin syndrome patient where the patient has lack of growth of genioglossal muscle and also the mandible. In these patients palatopharyngoplasty may not be a good option, distract osteogenesis is the ideal treatment option in these patients.[9]

Long-Term Management: All patients with OSA should have ongoing, long-term administration for

their chronic ataxia. Those on chronic therapy (PAP, OA, positional therapy) should have regular, ongoing follow-up to monitor attachment to healing, side effects, progress of medical difficulty linked to OSA, and advance resolution of symptoms. Those with destruction of OSA (weight loss, surgery) should be monitored for continued risk factor modification and to look for return of symptoms.[12]

Various treatment modalities are available for smooth management of obstructive sleep apnoea. CAPA is a gold standard device in-controlling symptoms & increasing the quality of life of the patient suffering from apnoea & reducing clinical complications in these patients. Surgical treatment of sleep apnoea is controversial. According to authors mandibular or maxillary advancement with the help of distraction osteogenesis is giving better results in sleep apnoea patients. All the patient with obesity should be encouragedto change their lifestyle in order to lose weight & bariatric surgery can be examined BMI over 40. Maxillomandibular surgery is excessively applicable & can be recommended to patient with craniofacial abnormalities. Tonsillectomy and adenoidectomy are effective in children and in adults with enlarged tonsils. Uvulopalatopharyngoplasty is a well-entrenched procedure to be considered as a second-line option when PAP has failed.[12]

Conclusion

Sleep disordered breathing is progressively presence accepted in the surgical population. This morbidity modifies the anesthetic care of afflicted patients. It is accordingly essential for the anesthesiologist to demonstrate a firm forgiving of the patients at risk and the pathogenesis of this disorder. This will enable the anesthesiologist to maintain specific care in the perioperative period.

Unilobed Lipoma in the Floor of Mouth: A Rare Case Report

Rajat Panigrahi[1], Sanat Kumar Bhuyan[2], Abhishek Ranjan Pati[1], Smita R. Priyadarshini[1], Basanta Kumar Choudhury[3]

[1]Reader, [2]Professor, [3]Senior Lecturer, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha India

Abstract

Lipomas are comparatively uncommon mesenchymaltumours which are benign and originates from adipose cells. Oral lipoma can occur anywhere in the body but commonly develop intraorally in lip,tongue, palate,buccal mucosa, vestibule, and below the tongue and salivary glands. Their progressive growth cause hindrance with speech and mastication due to the tumour's dimension. Here in thispublication we discuss a case of lipoma in a 28-year-old female patient underneath the anterior one–third of tongue with no pain but interfering with speech and phonation for 2 years.The patient was completely asymptomatic with a large swelling in floor of the mouth and complained of difficulty in speech and eating.

Keywords: *Soft Tissue Tumour, Sublingual, Mandible.*

Introduction

Case report: A female patient of 29 years reported of large swelling in the right side below the tongue, measuring approximately 3x3.5 cm in size. The swellinggradually started as a small one and within two years it increased to achieve the present dimension with no signs of inflammation, pain and of mucosa colour. The chief complaint was difficulty in eating and phonation. The intraoral swelling is soft in consistency, even surface, mobile, and fluctuant, which could not be compressed and non-reducible, non-tender on palpation.

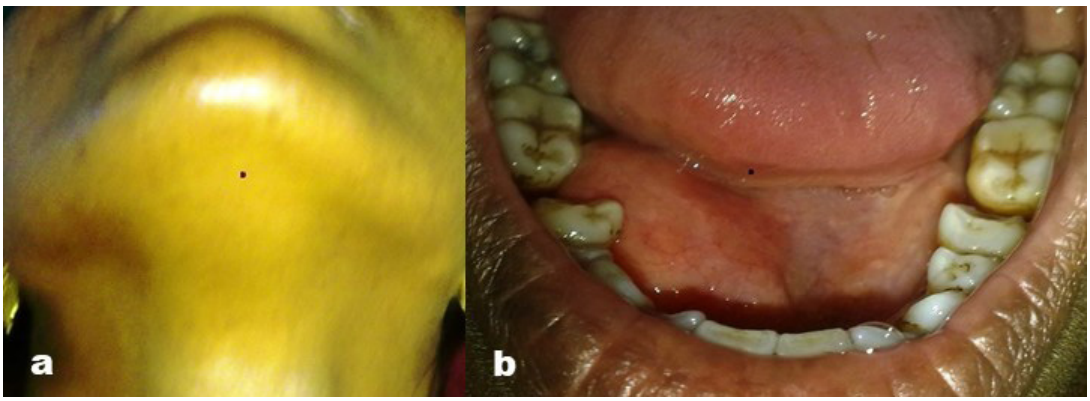

Figure 1a. Extraoral view showing a diffused swelling in the right submandibular region. 1bIntraoral view shows a diffused swelling present in the right side of the Floor of the mouth

Occlusal radiograph revealed radiopaque structures present resemblingsalivary stones or any calcified mass. USG of the lymph nodes and gland revealed presence of echogenic mass approximately measuring 2cm × 3cm in diameter. MRI revealed a characteristic radiographic form; it shows a hyperintense mass rangingfrom 83 to 143 Hounsfield units with well-definedmargins MRI of

the right paramedian floor of the mouth showed well encapsulated lesion in (26x23x16mm) with T1W/T2W hyperintense lesion with total attenuation in fat saturated image.

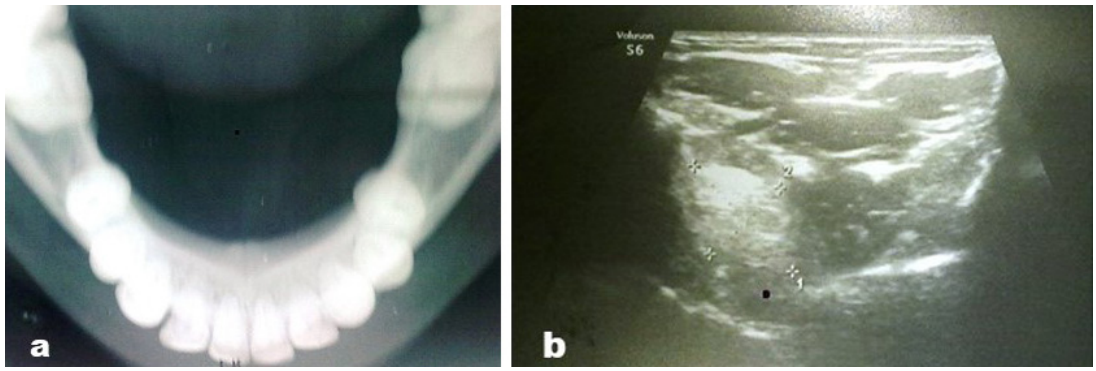

Figure 2a. Occlusal Radiograph; 1b. USG shows an echogenic mass present in the right submandibular region

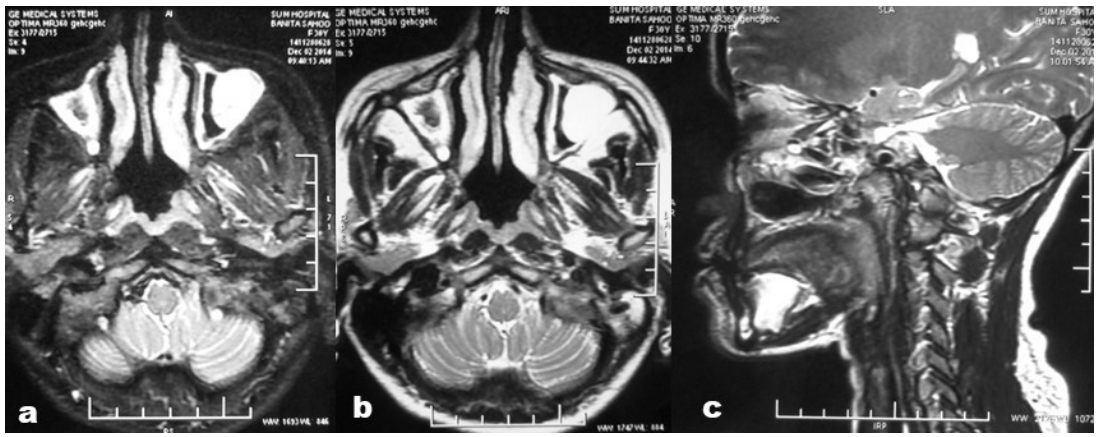

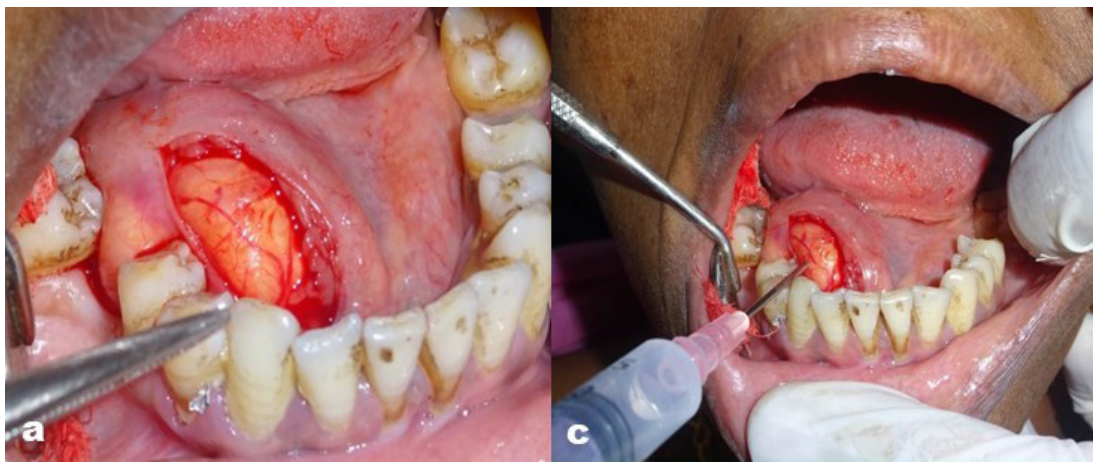

Figure 3a.T1 Axial view in MRI shows an hyper intense mass in the right submandibular region; 3b. T2 Axial view in MRI shows an hyper intense mass in the right submandibular region; 3c. T2 saggital view in MRI shows an hyper intense mass in the right submandibular region

Local anaesthesia is used to excise the lesion surgically. A longitudinal cut was made in the floor of the mouth in the mucosa overlying the tumor,on giving a blunt dissection the lesion popped out from surrounding tissues. The resected mass was yellowish in colour and soft in consistency. Mucosal layers were closed using absorbable sutures.

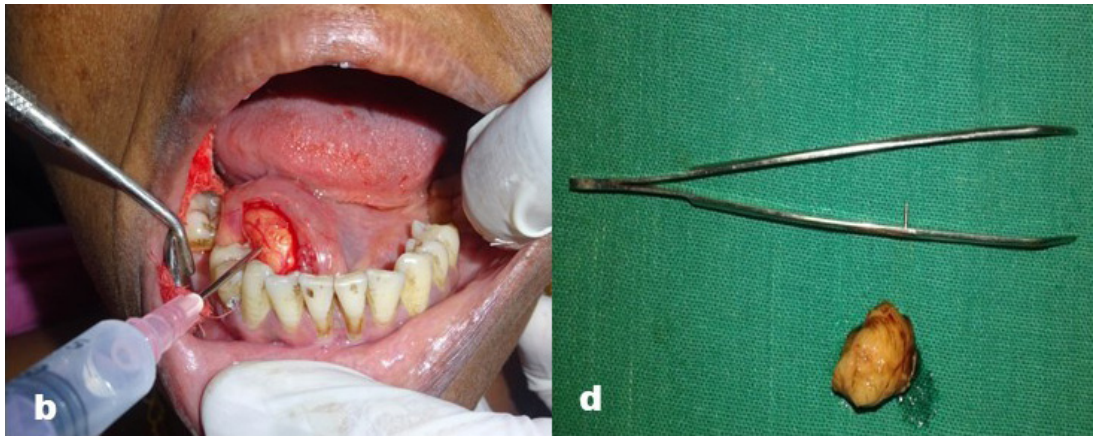

Figure 4a Intra operative picture shows the mass beneath the mucosa after the incision; 4b. FNAC of the lesion shows negative, 4c. The intraoperative picture shows that the mass is attached to the underlying structure; 4d, shows the tumour mass after excision

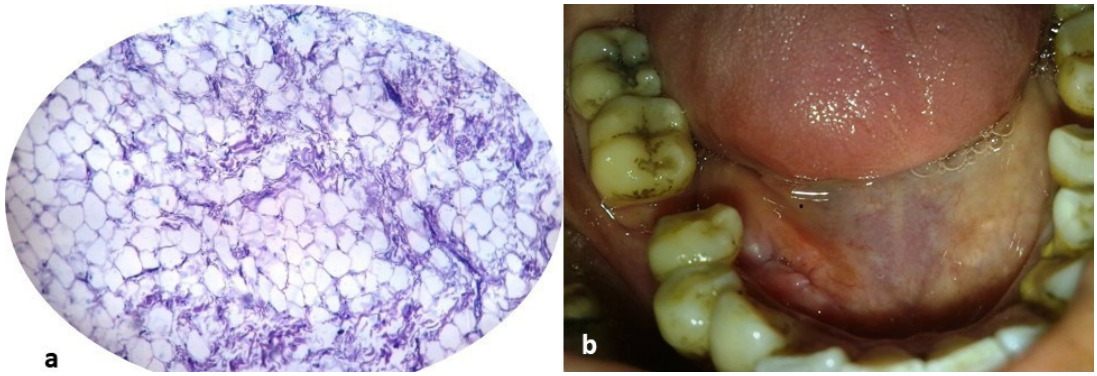

Figure 5a H & E x 100 Photomicrograph of the excised lesion showing mature adipocytes separated by fibrous septae; 5b. (FOLLOW UP) healed lesion after one month.

Histopathological inspection disclosed the occurrence of keratinized stratified squamous epithelium with mature lipocytes and demonstrating a thinstroma, sectioning of the excised tissue revealed mature adiposities and of fat tissue lobules,not connectedto the surface epithelium by fibrous connective tissue stroma. Lobular arrangement of tumour cells was seen. These lobules were detached from each other by fibro vascular connective tissue septa.

Discussion

Lipomas are neoplasms of mature adipose tissue which is benign in nature, seen in head and neck region(1 to 4%)[1]. Thepeak incidence is fifth or sixth decade of life, anduncommonin children[2]. The tumors may be encapsulated. Most lipomas develop in the subcutaneous tissues,uncommon in oral cavity [3]. Some studies showed a female preponderance [4]. Although benign in nature, their continuousexpansioninterfereswith speech and mastication[5].Lipomas are slow growing, well-circumscribed, painless soft tissuetumors, sometimes located superficially or deeply, with a malignant counterpart called liposarcoma. most frequentlyseen in buccal mucosa, labial structure, tongue, palate, buccalsulcus and floor of the mouth.According to Furlong et al over a period of 20 years showedonly 125 cases of oral lipomas, which shows the infrequency of these oral tumours[6]. ROUX first described it in 1848 as "yellow epulis"[7].

There are two pathogenic mechanisms describing the pathophysiology of lipoma i.e. HYERTROPHY and METAPLASIA theory. According to the former theory etiological factors are obesity and indefinite growth of adipose tissue that contributes for the development of lipoma but the major drawback being that the lipoma developing in non-existant adipose tissue location, couldn't be satisfactorily explained with hypertrophy theory. These lipomatous cells are not used up in periods of starvation unlike other fat cells.[8]

According to "metaplasiatheory" as fat cells can also be derived from mutant connective tissue cells anywhere in the body, so their development occurs due to differentiation of in situ mesenchymal cells into lipoblast.In fewcases, trauma and long-standing irritation may also be a factor in the development of lipoma[9]. Lipomas arise from multipotential cells which stay dormant until adolescence when they differentiate into adipose cells under the influence of hormones. [10]. As in the present case, patient gave no history of trauma and may be presenting as neoplasm. Chromosomal disturbance viz. translocation of t (3; 12) (q 127; q 13) and I (3; 12) (q28; q14), diabetes mellitus,increase in cholesterol level are the etiological factors. [11]

Rare cases of intraosseous lipomas in body of mandible and ramus have been elaborated by Oringer and Johnson respectively.[12]

Lipomas develop as slow developing,sessile, round to ovoid sub mucosal nodules. The size varies from 0.2- 1.5 cm in diameter, tumors as huge as 50 mm have been reported in buccal mucosa.[13] Histopathologically the tomor can be divided asclassic lipoma, fibro lipoma, angiolipomas, spindle cell lipoma and pleomorphic, myxoid, sialolipoma, and intramuscular lipomas [14]. Intramuscular or infiltrating lipoma originatewithin skeletalmuscle bundles and infiltratesalong the intramuscular septa. They may mimic liposarcoma but due to the absence of cellular pleomorphism, nuclear hyperchromatism and low mitotic activity, they are differentiated.[15]

Surgical excision or lipectomy and liposuction are the two treatment modalities. Recurrence is brought down by wide surgical excision simultaneously by conservation of adjoining structures. Lipomas that are well encapsulated, come out easily with no recurrence or damage to the surrounding structures. It is advisable to remove them with a little extension of the adjacentan atomical structure to avoid recurrence and conserving surrounding structures[16].

Conclusion

This above case of lipoma presented at a very unusual site, that is, on the floor of the mouth and demonstrates the heterogeneity in presentation. Intraoral lipomas are seen only during routine dental examination which causes pain very rarely, resulting in late treatment. The patient usually worried about theaesthetics or discomfort. It is mandatory for a clinician to diagnose intraoral lipomas. latest diagnostic method should be used to rule out any other tumor and treatment should be done accordingly.

Herbal Toothpaste: A Comprehensive Overview

Baibhabi Sahu[1], Rinkee Mohanty[2]

[1]Intern, Institute of Dental Sciences, [2]Professor and Head, Department of Periodontics and Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dental caries is the microbial infectious disease. In recent years it is the most comment health problem in the world. Toothpaste is a paste or gel dentifrices used with a tooth brush to promote oral hygiene. Tooth paste cleans the teeth protects them against tooth decay and keeps them looking healthy and attractive to look at also ensuring fresh breath. Brushing the teeth is only effective if using toothpaste as well.

Keywords: *Toothpaste, Gel Dentrifices, Oral Hygiene, Brushing, Plaque, Calculus.*

Introduction

Dental caries is the microbial infectious disease. In recent years it is the most comment health problem in the world.[1,2] It is a chronic disease which destroy the tooth tissue and affect chewing and aesthetic appearance plaque, calculate and fermentable carbohydrate are the source of caries development plaque forms continuously on tooth surface.[3] In in all age groups and it will be removed by brushing with a tooth brush with tooth paste. There are many herbal available in market and herbal toothpaste is also one of the products. Toothpaste is the common product in our family and we hardly care to know about the product which we are using. Herbal toothpaste is having advantages over commercial products. This study also contains about the advantages and disadvantages of herbal toothpaste.[4]

Importance of toothpaste: Brushing with toothpaste is important for several reasons. First and fore most a tooth paste and a correct brushing action to work to remove plaque, a sticky harmful film of bacteria that grows on the teeth that causes cavities, gum disease and eventual tooth loss if not controlled second tooth paste contains fluoride which makes entire tooth structure more resistant to decay and promotes remineralisation, aids in repairing early decay before the damage can even be seen. Third special ingredients in tooth paste help to remove stains overtimes fourth, toothpaste help freshen breath and leave the mouth with a clear feeling.[5]

Composition of toothpaste:

Detergent:

- Amount weight 1 to 2%
- Material: Sodium laurylsulfate, sodium mono glychride sulphate.
- It decreases the surface tension and acts as a surface-active substance and removes the debris with its foaming action.

Binder:

- Amount weight =3%
- Material- carrageenan
- Binding agents are hydrophilic colloids which are used to stabilize dentifrice formulations by preventing the separation of the solid and liquid phases.

Colorants:

- Amount weight = 1 to 2%
- Material-Food colorants
- It provides dentifrice with pleasing colours.

Flavouring agent:

- Amount weight = 1 to 2%

Corresponding Author:
Dr. Rinkee Mohanty
Professor and Head, Department of Periodontics and Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: rinkeemohanty@soa.ac.in

- Material-peppermint, spearmint and winter green and sweeteners such as saccharine.
- It gives flavour.

Fluoride:

- Amount weight = 0 to 2%
- Material-Sodium fluoride, Sodium mono fluorite phosphate.
- Fluoride presents dental carries.

Tartar control agent:

- Amount weight = 0 to 1%
- Material-Tetra sodium pyro phosphate.
- Tartar control agent stabilizes the amount of calcium in saliva and interferes with the crystalline structure of calculus.

Desensitizing agents:

- Amount weight = 0 to 5%
- Material-Potassium nitrate, potassium chloride
- Desensitizing agents promotes occlusion of dental tubules.

Abrasive:

- Amount weight = 20 to 55%
- Material-calcium carbonate, brushite, silica.
- Abrasives are added to clean the teeth and to remove stains and polish the surface.

Humectant:

- Amount weight = 20 to 35%
- Material-Glycerine, sorbitol, paraffin oil
- Humectants act as a moisturizing agent and provide a smooth creamy texture to the dentifrice

Water:

- Amount weight = 15 to 25%
- Material-Deionized water
- Water acts as a solvent and dissolves ingredients allowing them to be mixed.

Types of toothpaste: There are variety types of toothpaste: toothpaste for children, herbal toothpaste, whitening toothpaste, fresh breath toothpaste, anti-plaque toothpaste

Toothpaste for children: These kinds of toothpaste are specially created for children. They have pleasant flavours and come in attractive colours. These toothpastes contain no sugar and have low concentration of fluoride to prevent causes fluorosis.

Herbal toothpaste: Herbal toothpastes are made from natural ingredients and some are certified as organic. Now a day many consumers have started using natural toothpaste in order to avoid synthetic and artificial flavours which are commonly found in natural toothpaste. They don't contain any artificial flavours or chemicals. It is good choice for people who allergic to mint or to sodium lauryl sulphate, a foaming agent that is included in most commercial toothpaste brands.

Whitening toothpaste: These toothpastes contain special ingredient such as hydrogen peroxide for teeth bleaching and whitening. The peroxides deliver oxygen radicals to enamel. According to American Dental Association (ADA) because it acts as a bleaching agent, hydrogen peroxide actually changes the colour of the enamel on the surface of the teeth by cleaning the extrinsic stains that discolour the outside of the tooth. Tooth whitening toothpaste have higher abrasive value than normal toothpaste to remove food and other stains.

Fresh breath toothpaste: These are most popular toothpaste in the market. They contain enhanced flavouring agent with antibacterial agent to help fight against halitosis.

Anti-plaque toothpaste: Anti-plaque agent reduces plaque growth. This can have a positive effect in reducing plaque growth on teeth, reducing gingivitis and potentially reducing caries.

Composition of herbal toothpaste

Herbs used in herbal toothpaste

Turmeric: A daily intake of turmeric about half a teaspoon reduces the growth of false DNA patter.

Aloe Vera: Aloe Vera may be effective in the treatment of gum wounds.

Peppermint: Pepper-mint is used in flavouring agent.

Mint leaf: Mint is used for dental care because of its genocidal and freshening properties.

Small cardamom: It helps to produce smoky flavour. It disinfects the oral cavity the germs and drives away bad breath.

Clove: Cloves are also said to be a natural anthelmintic. The essential oil is used in aroma therapy.

Lemon peel: Contains high amount of vitamin C

Orange peel: Contains high amount of vitamin C

Banana peel: Vitamin A and B rich in banana has anti-oxidant

Pumpkin peel: Pumpkin is found having zinc content that is really good for skin.

Mango peel: It has been recommended as a drug in preventing dental plaques.

Papaya peel: Papaya has antibiotic, antifungal, anti-microbial, anti-inflammatory.

Jack fruit seed: Jack fruit seed contains vitamin A, C, B. The seeds contain minerals like calcium, zinc and phosphorus that strengthen the teeth.

One herbal toothpaste brand and it's advantage and disadvantage. Vicco is must trusted and original herbal product. It has all the ingredients which help us in avoiding tooth disease. It refreshes the breath, cleans the teeth and prevents the gum disease. It made from herbal stem and flower not the artificial ingredient. It also contains vajradanti which actual means diamond teeth. It also does not use any sugar

Advantage: No bodies wants that their body of full of chemicals. So, we must go for natural alternatives available in the market. At least it saves our tooth from decay. There are many advantages of herbal toothpaste Commercial toothpaste contains sodium Lauryl toothpaste which can cause irritation and inflammation while doing the brush. But in case of herbal toothpaste there is no chemical ingredient. Natural oral care products are effective in removing bacteria and keep the mouth healthy. Peppermint and spearmint oils are present in herbal toothpaste which helps in destroying the bacteria

Disadvantages: Safest products of herbal toothpaste that which is certified as organic otherwise they may also endanger our tooth. It should not contain cinnamon and any artificial chemicals.

Discussion

A study carried out by Ozgu Ilkcan Karadagluoglu at al in February 2019 showed that herbal toothpastes exhibit statistically significant antibacterial activity against s.mutans than their initial form after the addition of essential oil.[6] Another study carried out by Mullaly BH, James JA. Culter W A, in 1995 showed that herbal based toothpaste was effective as the conventionally formulated toothpaste in the control of plaque and gingivitis.[7] A study carried out by Fabiana Ozaki showed that both herbal and commercial toothpaste were effective in reducing plaque and gingivitis in subjects with established gingivitis.[8] A study carried out by Sudhir Rama Verma, Husam Sherif, Ahemed Serafi, Salim Abu Fanas, Vijay Desai, Eiyas Abuhijleh in February 2018 showed that Brushing with Meswak-based toothpaste gave a significant drop in plaque score when compared with TTO-based paste.[9] A study carried out by Mohan Kumar KP, Priya NK, Madhushankari G S showed that herbal toothpastes have similar antibacterial effect as conventional toothpaste. Toothpaste with multiple herbal ingredient is more efficient than the toothpastes with fewer herbal ingredients in an anticariogenic property.[10] A study done by Banani R et al showed that herbal toothpaste successfully whitens the teeth, kill germs, imparts freshness feel inside mouth.[11]

Conclusion

As brushing is a very basic phenomenon of our life and at least we should take care of such a small phenomenon. We can do it by not using any chemical toothpaste but to go for herbal toothpastes which are certified and free from artificial dyes and all. By keeping small things in our mind, we can change our life and keep ourselves and our family healthy.

Application of CAD-CAM in Oral and Maxillofacial Surgery: A Literature Review

Pratikshya Kothai[1], Santosh Kumar Subudhi[2], Subrat Padhiary[2], Sthitaprajna Lenka[2], Kalyan Sundar Pal[3], Basant Kumar Choudhury[4]

[1]Post Graduate Trainee, [2]Professor, [3]Post Graduate Trainee, Department of Oral & Maxillofacial Surgery, [4]Senior Lecturer, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to Be University), Bhubaneswar, Odisha, India

Abstract

CAD/CAM means computer aided design and computer aided manufacturing. It is the technology concerned with the use of digital computers to perform certain function in design and manufacturing. CAD can be defined as the use of computer system to create, modify, analyze or optimize an engineering design. CAD/CAM used for designing as well as controlling the manufacturing process. Reconstruction the craniofacial structure is difficult due to its complex anatomical structure, presence of vital structure adjacent to the affected part, chances of high infection. For any craniofacial reconstruction autograft is the gold standard. But use autografts have limitation such as large defect, chances of infection, additional surgeries, highly qualified team, donor site morbidity etc. But the CAD/CAM system focuses on 3D modeling which gives the surgeons the ability for precise preoperative planning and perform virtual resection of the defect and design the patient specific implants.

Keywords: *CAD-CAM, Craniomaxillofacial, Reconstructive Surgery, Prosthesis.*

Introduction

This technology first used in craniomaxillofacial surgery in 1980's. At that time an anatomical model with all features is prepared from the slices of CT scan. In that decade 3 to 6 mm slices of CT scan, which used to produce physical model of face and head by this technology had multiple limitation which overcame by means of Selective Laser Sintering (SLS) and Stereolithography (SLA) and 3D printing technology now a days.[1-4]

Other progresses in this field at that time were:[5,6]

1. Higher image quality with good resolution and 1 mm thick slices of CT scan.
2. Cone beam computed tomography which produce finer detail as well as it reduces the patient exposure to the radiation.
3. Use of software for analysis of radiographic images.
4. Introduction newer biomaterials for this technology.
5. Higher processor speed of the computer chip along with higher storage space, high RAM for better processing and use of graphics card. All these advancement in computer technology produces real life visualization of the problem and rapid processing.
6. Algorithms software which creates 3D images from the 2D slices of CT scan were introduced in 1990's which further enhances the visualization of the defect for the surgeons.

Applied aspect: In maxillofacial prosthesis: Till 1990s, multiplestudies took place for CAD/CAM for its application in fabrication of different prosthesis of external maxillofacial region, where CAD-CAM used for digital capturing of the anatomical detail and designing the prosthesis digitally and its manufacturing. Primarily

e-mail: paulsaaheb@gmail.com

laser scanning, wax milling and other computer programs are used for designing and prosthesis fabrication. Its use proved to be promising but not adopted in day to day practice completely till now.[7,8]

Planning and placement of implants: Different programming like Surgicase, Anaplastology Module, Materialize NV helps in Maxillofacial prosthesis fabrication by simulated surgery, determine the suitable place for placement of implant by detecting presence of important structures, volume of the bone, and density of the bone. Therefore proper size of the implant and suitable site for placement of implant can be planned and a customized dill guide also design as per planned. The software also helps in mirroring of anatomical situation for proper prosthesis placement.[9,8]

Capturing implant locations and surrounding surfaces: For the design of an implant-based prosthesis the implant locations, the internal tissues and the surrounding external surfaces. Data must be captured from mobile anatomy, including complex textures and incoherent surfaces (like hair), and the sharp edged detail of the abutments. CT, MRI and CBCT help to collect data of the internal and external geometries which is an important step for planning the implant position and also helps to evaluate the position of the implant post-operatively. Photogrammetry scanning has role incapturing anatomical surface and can be used easily in clinical setup. It has 'multi-camera set-up' whichhelps to record the data without moving around thepatient within second.[10-13] However, its application is limited. The prerequisite for maxillofacial prosthesis fabrication by means surface scanning technologiesare:

1. Speed with accuracy
2. Repeatability
3. Colour and surface texture capturing capability
4. Determination of the contour, surface detail and shape of an object
5. Should not be affected by environmental condition

Prosthesis 'body' design and manufacture[14,15]: CAD/CAM technology had been promoted to design and fabricate prosthesis but in clinical practice these techniques is not adopted completely. This also translated successfully into workshops focusing on the use of digital design in Maxillofacial Prosthetics. Similar techniques have been used in other patient-specific applications, such as custom implant and surgical guide design, as described earlier in the literature review. Two set of computed tomography been used. The preoperative one used for planning purpose and for evaluation of the implant placement site. And postoperative one to determine the exact location of the placed implant. This has been considered as the first attempt at considering the retention components in the digital design of a prosthesis. Incorporation of retentive mechanism on prosthesis surface is challenging also be important for retention of the prosthesis which improve the property and also improve clinical result.

In Surgery: Recently CAD-CAM used in planning for different surgical procedure ranging from trauma management to reconstructive surgery. Increased used of the CAD-CAM helps surgical team to visualize and treatment planning preoperatively.[16]

Orthognathic procedures: Modern 3D virtual planning for orthodontic surgery has critical advantages compared to conventional treatment planning.[17]

Trauma: CAD-CAM used in management of traumatic injuries of facial skeleton like comminuted mandibular fracture and fracture involving all third of the face. 3D visualization of fracture offacial skeleton helps in proper reduction of fractured bone segments. CAD/CAM used in production of occlusal splints for bettermanagement of facial asymmetry, functionality and aesthetics. Areas which are avulsed or necrosed replaced by customized prothesis. Along with this, use of CAD-CAM act as cutting guides with improvement in accuracy and reduced error during shaping and harvesting autologous graft.[18-20]

Temperomandibular Joint (TMJ) Reconstruction

Reconstruction of TMJ done in two steps:

1. First step is Gap arthroplasty and
2. In second stage implant designing and fabrication done with the help of post- operative CT scan.

But in CAD-CAM this prosthesis can fabricate pre-operatively in a single stage with the help of simulation of TMJ gap arthroplasty, 3D planning. TMJ functionality, occlusion also checked virtually before insertion which provide better functional outcome of the surgery and less post-operative complication.

Mandibular Atrophy: CAD-CAM can also beused in management of defect of atrophic mandibular alveolar crest where other procedure had failed. Different graft

also planned for virtually and executed for reconstruction of the atrophic mandible.[21]

Planning for onco-surgery: Extend of lesion along with safe margin for resection of the lesion is critical for successful management of any carcinoma. Previously it was difficult to access the proper anatomy precise margin for resection and requirement of graft size for the defect created by the resection of the lesion and they decided intra-operatively in trial and error method. Thus, these procedures require precision, surgical skill and huge intra-operative time and suboptimal reconstruction.[22]

Whereas CAD-CAM offers pre-operative planning by surgical team for reconstruction of complex facial structure, helps to determine the actual resection margin of the lesion, planning for the graft and helps in co-ordination between oncologic and reconstructive team. Overall this technology reduces the time of surgery, post-operative complication and recurrence of the lesion.[23]

Pros of CAD-CAM in this Field[24-26]:

- More accurate diagnosis which helps in planning for better treatment/surgery.
- Anatomic structures are visualized directly.
- Act as guide for surgery.
- Practice of the surgery can be done virtually which helps in later stage.
- Helps in incision design and helps to determine the margin for resection.
- Assessment for placement of graft
- Contouring of plates used in reconstruction purpose
- Fabrication of custom prostheses, distraction devices, fixation device
- Reduced surgery time, anesthesia,as well as exposure of the wound
- Result is more predictable
- Better communication between colleague
- Can be used for patient's education purpose

Discussion

This technology has potentiality in consistent aesthetical and functional outcome in advance reconstruction. This is suitable for application in cases with varying complexity because of it helps to visualize and manipulate the complex 3D structure of the maxillofacial bony structure. This helps to perform reconstructive and critical surgical work more precisely in trauma, in prosthesis fabrication, in orthognathic surgery and in oncological procedure too.Use of CAD-CAM in different steps of the reconstruction also reduce error and helps in intra-operative decision-making with expedition of the surgical phase.[3] With passing years this cad-cam procedure, which gaining acceptance in different field of medical science make diagnosis better and become an innovative solution for reconstruction of complex maxillofacial structure.[24]

Conclusion

Reconstruction the craniofacial structure is difficult due to its complex anatomical structure, presence of vital structure adjacent to the affected part, chances of high infection. For any craniofacial reconstruction autograft is the gold standard. But use autografts have limitation such as large defect, chances of infection, additional surgeries, highly qualified team, donor site morbidity etc. But the CAD/CAM system focuses on 3D modeling which gives the surgeons the ability for precise preoperative planning and perform virtual resection of the defect and design the patient specific implants.

Complication of Dental Procedures During Pregnancy

Akankhya Mishra[1], Sthitaprajna Lenka[2], Karishma Rathor[3]

[1]Intern, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Pregnancy is stated as the series of embryo and fetal escalation and progress in uterus. It is a delicate condition which creates a cycle of changes for the adaptation in fetal progression. The squall of hormones which is stimulated in pregnancy causes physical changes in a mother's body and oral cavity is no exemption. Throughout this stage some of dental treatments are prohibited due to different complications. This study is the consideration of various adaptation and adjustments during treatment of pregnant woman.

Keywords: *Pregnancy, Dental, Treatments, Complication, Contraindicated.*

Introduction

Pregnancy is related with various physiological and endocrinal changes in the body and special and common changes in the body. Special and common changes seen during this period which includes gingivitis, pyogenic granuloma, and dental caries increased susceptibility to odontogenic infections, ptyalism, enamel erosions, tooth mobility and xerostomia[1]. One of the lead changes is an increase in the level of estrogen and progesterone[2].

Dental care: The Trimester Approach: Health care providers refer to three segments of pregnancy, called trimester. The first trimester is from week 1 to week 12. In this period treatment maybe narrowed because of vomiting at the time of sunrise. Only emergency treatment should be indicated during this time. Routine preventive procedures including oral prophylaxis can be performed during this phase. Elective dental treatment must be contraindicated during first trimester due to organogenesis procedures of fetus. The fetus is particularly vulnerable during this period.

Corresponding Author:
Dr. Sthitaprajna Lenka
Professor, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: sthitaprajanalenka@gmail.com

The second trimester is from week 13 to week 28. This is the safest period to induce any essential dental treatment. Pregnant women should be advised to discuss with their prenatal care providers about the employ of sedatives and medication. The fetus further developed and pregnant woman is more comfortable. *The third trimester is from week 13 to week 28. In this period expert assessment is needed. Treatment should be avoided because of enhanced physical uncomfort.*[3]

There are two types of hypotension seen in pregnant women. In the first type of hypotension, postural hypotension is seen in pregnant woman in the period of first trimester; this normally happened when she wakes up in the early hour during sun up but doesn't reappear at day time. The exact reason of this condition is unknown. The other one is called as supine hypotensive syndrome of pregnancy, happened during third trimester if the woman continues in supine position greater than 3-7mins. Signs and symptoms of syncope become more prominent in this period of time, and after that the women faints. The inferior vena cava is compressed by the flaccid, graviduterus so that the venous return from the lower limbs reduced. When the position of the patient changes to lateral side or to standing position, then the inferior vena cava is not compressed by the weight of gravid uterus, therefore the probability of syncope eliminated.[4]

Gingivitis is the most common obstacle seen in a pregnant woman, which is supposed to be seen in the time period of second trimester. Localized gingival hyperplasia, which is also called as pregnancy tumor, is

also occurred in pregnant woman. It must be postponed after delivery, if surgical procedure is advisable. Dental procedures and treatment in any form is hazardous to both doctor and the pregnant patient. For example, while prescribing medications and during medicinal interactionin the period of pregnancy results in various complications which includes symptoms such as pain, fear, anxiety because of the physical and psychological stature of the pregnant patient. The treatment and management of odontogenic infection must be carried out urgently because, this odontogenic infection leads to fever which plays the active role in miscarriage.[2]

It is advisable to do necessary supra gingival scaling and root planning. The prevention of plaques formation during pregnancy especially in the 1st trimesters is indicated for mother and fetus. Other than dental plaque management, no definite dental treatment should be carried out during the period of 1st trimester in pregnancy as it can be perilous to the fetus.[2] Even though pregnant patients are not immunologically compromised, but sometimes immune system of a pregnant woman becomes concealed, hence forth there is a reduction in cell mediated immunity and natural killer cell activity. Odontogenic infections must be treated and managed with at most care during any time of pregnancy because odontogenic infection has the ability to convert into deep space infection assertively which results in cancelation of oro-pharyngeal airway. There should be drainage of abscess and pulp offensive of extracted tooth should be removed to reduce the infection. Patient status and treatment procedure should be informed to the obstetrician. Patient with severe dental pain should be treated and managed as the same method. Use of Analgesics for a long time except the precised treatment is prohibited. It is not essential for the patient to wait for the entire treatment procedures till the delivery[1]

Maternal periodontal disease is a risk factor of preeclampsia hypothesized. Women with severe periodontal disease are at high risk of preeclampsia in the period of pregnancy. Preeclampsia is a hypertensive pregnancy disorder that causes severe maternal and fetal morbidity and death. 5% pregnant women are affected by it.[1]

General Consideration: Treatment ought to be meant for controlling of disease while keeping a healthy and good oral hygiene and inhibit the possible problems which could be seen during pregnancy or in post partum time period. Patients who have been marked for any pregnancy related complications and problems by the obstetrician must be consulted before any dental treatment. For example: hypertension induced by pregnancy, gestational diabetes, risk of repeated abortion or past history of premature delivery. If blood pressure is greater than 140/90 mmHG simultaneously, which is usually induced by fear and pain, patient must notify the obstetrician.[1]

Pregnant patients with diabetes suffer numerous problems due to sever periodontal diseases compared to pregnant patients not having diabetes. The two chief enhancing factors for periodontal disease are diabetes and endocrinal changes, so that it changes and affects the maternal and fetal outcomes.[3] A supple,remote, hyperplastic growth is seen which induced by pregnancy is also called as pregnancy epulis or pregnancy granuloma. 5% pregnant patients are affected by this disease. Clinically most affected area is the anterior region of upper jaw. It is normally seen in second trimester and it develops vastly. It is normally reduced in size after labor and diminished completely. Surgical produres may be indicated often, which is usually postponed after labor.[3]

Positioning of patient on dental chair: The dental chair positioning of pregnant woman is necessarily considered, specially in the period of 3rd trimester because the uterus comes directly over to the inferior vena cava, femoral vessels and aorta due to the expansion with growing fetus and placenta. If the patient remains in supine position for long during a procedure, the weight of the gravid uterus might implicates sufficient pressure which decreases the blood circulation by these three main vessels. After that the blood pressure decreases which leads to syncope or almost syncopal situations. This condition is called as supine hypotension. This situation can prevented by adequate dental chair positioning of pregnant patient on her left side and elevating the head rest of dental chair, so that the main vessels would not be compressed.

Radiography: Embryos and fetuses are more sensitive to radiographs compared to adults due to most embryonic cells are not comparatively differentiating and faster. Prenatal radiation exposure can cause fatal condition or certain developmental anomalies, based on the phase of development and growth of the fetus during the radiation exposure. The most susceptible period of organ formation of a fetus is between the 18th and 45th days of gestation period. The threat to the developing

fetus is directly proportioned and attached to the increasing in irradiation. The irradiation exposure rate of a fetus should be less than 10 rads. If it goes above 10 rads, it will be considered as dangerous and risky, which leads to mutation, mental illness and retardation and anomalies of eye, although radiation exposure to the uterus is minimum during any routine dental checkups and diagnostic radiographs, dentists and obstetrician often suggests to avoid radiographs in the period of pregnancy. In case of the diseases, which needs to be diagnosed and treated immediately, then radiographs are only indicated seeing the status of the and condition of that disease.

Table 1. Medications

Drugs that are indicated and drugs that are prohibited during the period of pregnancy	
Drugs, those are indicated during pregnancy	Drugs, those are prohibited during the period of pregnancy
ANTIBIOTICS Penicillin, cephalosporins, tetracyclins, doxycyclines, Amoxicillin, clindamycin, erythromycin (estolate form)	
Erythromycin (except Estolate form)	
ANALGESICS acetaminophen, aspirin, diflunisal, etodolac	
Acetaminophen with codeine	
In small doses	

The major concern during prescribing medicines to a pregnant patient is based on the affecting possibilities on the fetus. Aspirin and ibuprofen are prohibited to use in the period of pregnancy.

Antibiotics: The penicillins, together with amoxicillin and the cephalosporin, are usually harmless for use in the period of pregnancy. For those patients who are allergic to penicillin, in that case erythromycin can be the substitute but the estolate form is prohibited because of its potential to cause cholestatic hepatitis in the time of pregnancy. Another two drugs are prohibited for causing discoloration of fetal dentition are tetracycline and doxycycline, as well as the threat of reducing or slowing the bone growth. Metronidazole should not be given to the pregnant woman because of its mutagenic properties towards bacteria and micro-organisms.

Analgesics: Most widely used analgesic drugs are acetaminophen, measured safe in the period of pregnancy. In case of severe pain, acetaminophen along with oxycodone is advisable as compared to acetaminophen with codein as codein leads to various birth defects and anomalies. Aspirin and ibuprofen are prohibited in the period of pregnancy. Aspirin in higher dose in the period of pregnancy leads to certain raise in duration of pregnancy and labor as well as hampers with associated function and increasing the bleeding time, it should be taken towards the end period of pregnancy. It is risky to the mother for antetartum and postpartum hemorrhage. Aspirin is also responsible for cleft lip and palate. Ibuprofen uses stem cells from enhancing the drugs in the development of al anomalies, deleterious changes and neonatal circulation. Aspirin and ibuoprofen prohibiting the prostaglandin synthesis and can lead to limitation of fetus ductus anterious which causes pulmonary hypertension and rising in fetal death therefore they are prohibited to use during 3rd trimester.

Sedative Agents: Barbiturates, prescribed to pregnant women, happen to cross the placenta and can affect the fetus. Developmental disorders have been seen during pregnancy or infants going to be born to, in cases of chronic barbiturate users. Dizapam has been responsible for birth disorders including cleft lip and palate, which is also referred as category D drugs and prohibited to use in the period of pregnancy. It is not yet been decided to use nitrous oxide as sedative agent during the period of pregnancy. It is prohibited during the 1st critical trimester and less used in 2nd and 3rd trimester because nitrous oxide leads to deactivation of vitamin B12 synthesis, which causes birth disorders. Therefore, it is prohibited in the period of pregnancy because 1st trimester is the most sensible period and the brain is progressively developing till 2nd and 3rd trimester even into the period of childhood.

Table 2. Drug teratogens

Drug Teratogens	
Alcohol	Cranio-facial abnormalities, fetal alcoholic syndrome
Tobacco	Brain damage, cleft lip and palate
Cocaine	Placental abruption, conginitive delay
Thalidomide	Malformation of extremities of new born
Methyl mercury	Brain damage, micro cephaly
ACE inhibitors	Cranio-facial abnormalities
Tetracycline	Maternal toxicity and discoloration of tooth
Phenytoin	Hypoplastic nails, typical facies
Warfarin	Facial chondro dysplasia and dismorphism
Barbiturates	Facial cleft lip and palate deformity

Table 3. Categories of drugs

Category	Evidence
A	Controlled human studies indicate no apparent risk to the fetus. The possibility of risk to the fetus is remote.
B	Animal studies do not indicate fetal risk. Fetal controlled human studies have failed to demonstrate at risk.
C	Animal studies show an adverse effect on the fetus but there are no controlled studies in humans. The benefits from the use of such drugs may be acceptable.
D	Evidence of human risk, but in certain circumstances, the use of such a drug may be acceptable in pregnant woman despite potential risk.
X	Risk of use in pregnant woman clearly outweighs possible benefits.

Conclusion

Dental health which is also called as oral health is the health of gums and teeth. Despite medical advances in diagnosing and treating perform labor, complications are arising. Adverse pregnancy outcomes such as neurogenic diseases have an impact on the family and economical impacts on the society causing financial troubles during checkups and treatment. Dentists and dental hygienist should take part an active role for motivating all women of child bearing age for oral health consultation, inspections and management if it is indicated. There ought to be a good communication in between dental care providers and pre-natal care providers. At last, emergencies should deal with carefully.

Child Abuse and Neglect in Pediatric Dentistry

Subhashree Dash[1], Sonu Acharya[2]

[1]Intern, Institute of Dental Sciences, [2]Professor, Department of Pedodontics & Preventive Dentisty, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Abuse is something, which indicates disrespect and dishonest way of dealing. It is defined as any action that intentionally harms or injuries another person. Child abuse is disturbingly common findings in our civilization. It is not only the physical violence which directly hurts a child but also any form of maltreatment by a person, which puts negative impact on the psychological state of a child. The dental practitioner has a unique opportunity to notice these problems, as he/she deals with oral cavity. To prevent a child from child abuse, we should understand the child, scolding and strict punishment method can leave an emotional scar to the child, so the parent should approach the child an interactive manner, so that he/she feels comfortable and reciprocate well in that manner. By doing all these we can save children live from hindrances.

Keywords: *Abuse, Child, Neglect, Pediatric dentistry.*

Introduction

"Non accidental physical injury, minimal or fatal, inflicted upon children by persons caring for them" (Defined by Gill in 1968)[1]. CAN (Child Abuse and neglect) previously called as battered child syndrome have recently described as Non-Accidental Injury (NAI)[1]. The term battery is defined as unprivileged touching of another person's body and unusually associated with abuse. Children under ENGLISH COMMON LAW were considered property of their father, as women were considered as property of their husbands, until late 1800s. American colonists carried the tradition of children being property of their fathers to the early years of the United States. Children are abused by other persons on whom they are dependent, such as teachers, sport coach, caretakers etc. Sometimes children are subjected to abuse and ill-treatment by the offenders but not always. It is admitted that non intentional abuse to the children is also harmful which hinders their growth and development. This is a violation of the basic child rights. In order to ensure that basic right of every child is not violated in any manner by anybody or any organisation, Commission for protection of child rights have been formed in every state of our country like OSCPCR (Odisha State Commission for Protection of Child Rights) in our state and at the national level which is called as NCPCR (National Commission for Protection of Child Rights). Child abuse is something, which we all never want to see[2]. It should be noted that injuries found in children are not essential because of child abuse. Therefore the dentist should be serious and alert to these kind of injuries and if such instances come to their notice, they should follow local safeguarding policies. Child abuse includes the factors like physical and sexual abuse, evidence of bite marks and dental neglect. Bullying of children is also one type of child abuse which has serious long term effects on child. These issues maycreate problems if notified, during his/her physical examination.

A child exhibiting the following features should be included under these syndromes[1]. **Evidence of bone fracture, Subdural hematoma, Failure to thrive, Soft tissue swelling, Skin bruising.**

There are different types of child abuse such as,[1] Physical abuse, Sexual abuse, Failure to thrive, International drugging or poisoning, Munchausen syndrome by proxy, Health (medical) care neglect, Dental neglect, Safety neglect, Emotional abuse and neglect, Physical neglect[3].

Corresponding Author:

Physical Abuse: Any non-accidental injury to the body of a child by someone who has responsibility for child, like Parent, caretaker, or a stranger which resulting in severe injury(trauma) or even death of the child[1,4]. It is the physical violence against a child consequence from physical aggression. Physical abuse resulting in certain injuries which are: Learning disabilities, Physical,visual,speech and hearing disabilities, Cerebral palsy, Seizures, Behaviour disorders, Congestive impairments, Even death immediately/delayed.

Is Physical Punishmenmt the Same as Physical Abuse?: Physical aggression resulting an injury which is called as physical abuse. But physical punishment is defined as Physical force is use in such a way that causesbodypain, but not injury, for the purpose of improvement of the child. But physical punishment can easily get out of control and become physical abuse[4]. Oral injuries may be caused by using instruments such as kitchen tools, utensils or a bottle during forced feedings, hands, fingers etc. The abuse may result in injuries like burns, laceration of the tongue,lip, buccal mucosa, palate(soft and hard), gingivae,alveolar mucosa or fraenumfracture, avulsed teeth; or facial bone and jaw fractures[5,6]. Most common site for inflicted oral injuries(54%) is lip followed by oral mucosa, teeth, gingivae and tongue. Discoloured teeth are the indication of pulpal necrosis which may be result in bruises,scarring at the corners of the mouth.

Many oral cavity injuries like posterior pharyngeal injuries and retropharyngeal abscesses or any accidental injuries to the mouth are commonly seen and should be judged if it is abuse or not by taking a detailed history and also the timing and mechanism of injury. Hence the dentist could be of help to the children in protecting them from abuse. The dentist is the type of person, who can help in protecting children from injuries. If a child is detected with multiple injuries, injuries in different stages of healing or inconsistent history, strong suspicion should come to the mind of a person who deals compassionately with him/her. The role of a dentist dealing with such cases plays a vital role to ascertain its cause and suggest remedial measures.

Types of Physical Abuse[4]:

- Shaken Baby Syndrome (SBS)
- Battered Child Syndrome
- Munchausen syndrome by proxy
- Sudden Infant Death Syndrome (SIDS):

Shaken Baby Syndrome (SBS): Also known as abusive head trauma. Shaking a baby to try to stop inconsolable crying. Babie's skulls are very soft; even if they are hit by any soft object it can be harmful for them. Their heads and brains are heavier than their body and they have weak neck muscle which can't give support to hold their head straight. So haemorrhage is caused when shaking the baby. There are various sign and symptoms of shaken baby syndrome[4,7].

Common symptoms are: The muscle tone of the baby is decreased. Baby is showing extreme irritability. Poor feeding or vomiting for no apparent reason. Bruises on arm or chest are rare. The baby is not smiling. She/he has problem in sucking or swallowing. Facing difficulty in breathing. Baby's forehead appears larger than normal. He/she is not able to lift his/her head, also not able to focus. Slow heartbeat. Have problem in hearing. Retinal bleeding occurs. The skin of the baby may turn to bluish[7]. This syndrome can be diagnosed by imaging tests like MRI,CT scan.

Battered Child Syndrome: This is reported by HENRY KEMPE in 1960[4]. Multiple asymmetrical fractures at different stages of healing. Evidence of fracture at tip of the long bone. Fracture of ribs especially in the back. Battered child syndrome is diagnosed by an emergency room physician or by teachers or social workers. Investigations: Radiographs**,** MRI**,** CT scan

Treatment: Medical treatment varies depending upon the injuries affecting the child for battered child syndrome. Counselling of child's parent or guardian is necessary for an intervention plan. Both the physical and psychological therapy are often recommended as treatment for the abused child[8].

Munchausen Syndrome by Proxy: Also known as factitious disorder by proxy or paediatric condition falsification. MSP is relatively rare behavioural disorder. It affects primarily caretaker,often the mother. It is a condition in which a care giver usually the mother induces an illness in another person, usually her child to gain attention and sympathy as the "worried" parent. It was coined by Sir Roy Meadow in 1977. Munchausen syndrome was first described by Dr. Richard Asher in 1951 for adults who fabricated symptoms about themselves and produced sign of illness. The most clinically useful definition is provided by Bools et al(1992).

"Illness in a child which is fabricated by a parent or someone in loco parentis. The child is presented for medical assessment and care, usuallypersistently, often resulting in multiple medical procedures. The perpetrator denies knowledge of the etiology of the child's illness. Acute symptoms and signs of the illness decreases when the child is separated from the perpetrator".

Signs: A child with a parent having knowledge in the medical field who has unexplained medical problems, Laboratory findings that do notcorrelate with clinical features and is not responding to the usual treatments and has similar family history of illness or death[9].

Sudden Infant Death Syndrome (SIDS): Also known as cot death or crib death.The term cot death is often used in United Kingdom, and crib death in North America.SIDS may be due to any reason but child abuse can be a reason.It is the sudden unexplained death of a child of less than one year of age.

Sexual Abuse: It is also known as child molestation. Sexual abuse of a child is usually occurring below the age of 18 years by a person of any age. Generally, that person is a close relative or well known to the victim's family[1]. Generally, the oral cavity is a common site of sexual abuse in children, oral injuries or oral infections are rare to see.[6] Child sexual abuse can occur in a variety of settings, including home, school or work. UNICEF has stated that "child marriage represents perhaps the most prevalent form of sexual abuse and exploitation of girls". The effects of child sexual abuse can include depression, post-traumatic stress disorder (PTSD), anxiety, complex post-traumatic stress disorder and physical injury to the child. The global prevalence of child sexual abuse has been estimated at 19.7% for female and 7.9% for males[10].

Types of sexual assault according to the protection of children from sexual offence act: **Penetrative sexual assault:** penetration of an organ or any other objects into vagina, urethra, anus or mouth or makes the child to do vice versa.

Aggravated penetrative sexual assault: it is considered when the same is done by public or government servant, staff of any private hospital or staff of an education institution if a child is a part of it. Sexual assault is if a person touches the private part of a child without penetrating but with sexual intention or makes the child do vice versa.

Aggravated sexual assault: It is considered when the same is done by police officer, public or government servant, or staff of an education institution if a child is a part of it.

Sexual harassment: when a person with sexual intent uses inappropriate words, pornographic video or pictures.

Child sexual abuse can be characterized by a syndrome of secrecy and dependence. Suspect of an abuse(sexual) when the child has difficulty in walking or sitting.Reluctant to expose his/her body over-clothe to hide scars, full-length sleeves in hot weather. Reports of bed wetting. Behaviour not appropriate for his/her age. The girl becomes pregnant particularly if under age 14 years[11].

Failure to Thrive: It can be defined as underweight, malnourished condition. Child usually has a height and head circumference that are above the third percentile and weight that is below the third percentile on the growth curves. The clinical features of these children include gaunt faces, prominent ribs, and wasted buttocks. It is usually seen in the fast 2 years of life since this is the time when the rapid growth occurs and there is dependency of adults for feeding. The underweight infant who gains rapidly and easily in the hospital is a victim of under feeding at home.

Intentional Drugging or Poisoning: Drugging or poisoning to a child with intention is an uncommon type of abuse by parents or caretaker involving the administration of a non-prescribed or prescribeddrugthatis harmful or not intended for children. Most commonly sedatives are used. The dentist may be assigned for treating tooth injuries that has occurred when a child was not coordinated due to drugs.

Emotional Abuse: Emotional abusemeans to neglect a child continuously by parents. Verbal abuse also can be the part of emotional abuse. Abuse is a type of action which is intended to control another person byusingfear, humiliation and verbal assault. Among all the abuse, emotional abuse has more long lasting psychiatric effects. Emotional abuse includes changing of the psychological state of a child. Emotional abuse can range from simple verbal insult to an extreme form of punishment like;Ignoring,withdrawal of attention, rejection**,** Lack of physical affection**,** Lack of positive reinforcement**.** Habitual blaming, Degradation

Child Neglect: It is one of the most common form of child abuse. WHO defined neglect as "inattention or omission on the part of caregiver to provide for the development of child in all spheres-health,education,nutrition, emotional, development, shelter and safe conditions[2]." National child abuse and neglect data system (NCANDS) defines neglect as "maltreatment that refers to failure of care given by the caretaker to provide needed, age appropriate care although financially be able to do so. People in close contact are frequently the ones to know and report it."The causes of child abuse are like unwanted child especially female child, over-aspirational parents, inadequate parental skilling, economic status is poor, blaming the child because of loss of family members etc.

Types of child neglect:

Physical neglect: physical neglect is the failure to provide a child with basic life requirements such as cloth, food, shelter foe their growth and development.

Emotional neglect: the child is deprived of love, affection, care, emotional supports.

Educational neglect: it can be called as developmental neglect. The child is deprived of learning. Children are forced to do household work instead of acquiring education. Normal psychological growth and development can be impacted due to lack of confidence of the child.

Nutritional neglect: The child is depriving of nutrients which are necessary for the growth and development.

Medical neglect: Basic medical services are not reach to the child health care is a form of medical neglect.

Dental neglect: According to American Academy of Paediatric Dentistry, Dentalneglect is the "wilful failure of parent or guardian to seek and follow through with treatment necessary to ensure a level of oral health essential for adequate function and freedom from pain and infection". Dental neglect includes so many dental diseases like dental caries, periodontaldiseases, poor oral health etc. it can lead to pain infections if not treated[12].

Conclusion

From the analytical description of child abuse cited supra, it can be summed up that, it is an on-going social trauma observed in our day to day life, which retards the overall growth and development of a child. In a civilized society like ours, everybody should be aware and conscious about such type of evils and try his level best to carry on massive awareness programme in order to sensitize the wrongdoers against stringent legal action and ensure a child abuse free environment in our society. As such, everybody is required to be very careful to this aspect and ensure that a child enjoys his rights without any hindrance. A dentist plays a predominant role in this regard, while dealing with the cases of child abuse and is required to eradicate such nuisance from the society.

Stress and Oral Health: A Literature Review

Akanshya Jena[1], Swati Patnaik[2]

[1]Intern, [2]Assistant Professor, Department of Public Health Dentisty, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The mind and body are interconnected with each other. If one is ill it affects the other and the vice versa also holds true. Stress manifests itself into lot of varieties of disorders. A dental practitioner witnesses a wide variation of stress induced oral conditions. Even the most common oral conditions aggravate when the patient is psychologically compromised.

Keywords: *Stress, psychosomatic, emotional, MPDS, BMS.*

Introduction

In this fast-paced society, stress has become an integral part of our lifestyle. Stress is defined as "psychological strain resulting from demanding circumstances."Stress helps in release of various powerful neurochemicals and hormones that prepares us for the fight or flight response. If necessary, actions are not taken, this stress response can have detrimental effects on our health leading to **psychosomatic disorder.** Psychosomatic disorders are defined as "disorders characterized by physicalchanges that originate from underlying emotional factors." These diseases can be due to several biochemical disorders involving the brain neurotransmitters, incomplete connections between the oral regions and undefined complaints due to the cognitive process in the higher centers of the brain. While different individuals manifest prolonged stress in different organs; a good lot of them have oral manifestations.[1]

Classifications of psychosomatic disorders[2]: According to International classification of diseases (ICD-10; WHO-1993) (based on tissue damage)

Corresponding Author:
Dr. Swati Patnaik
Assistant Professor, Department of Public Health Dentisty, Institute of Dental Sciences,
Siksha 'O' Anusandhan (Deemed to be University),
Bhubaneswar, Odisha, India
e-mail: swatiptnk88@gmail.com

Psychological malfunction arising from mental factors: This describes a variety of physical symptoms or types of psychological malfunctioning of mental origin, not involving tissue damages, and usually autonomic nervous system (ANS) mediated.For example: Respiratory distress like hyperventilation and psychogenic cough, Cardiovascular distress like cardiac neurosis, Skin disorders like pruritis. Mental disturbances or psychic factors of any type that may have played a major role in the etiology of certain physical changes usually involving tissue damage.For example: Psychogenic conditions like asthma, dermatitis, eczema, urticaria, mucouscolitilits, ulcerative colitis and gastric ulcer.

According to Zegarelli *et al.* Psychotic disorder, Personality disorder, Psycho-physiologic disorder, Psychoneurotic disorder

Classifications of psychosomatic disorders concerning the oral cavity[2][3]

According to McCarthy and Shkalar (1980)

Oral psychosomatic disease: Aphthous stomatitis; Lichen planus; Glossitis and benign migratory glossitis

Psychological factors as etiology: Erythema multiforme; Chronic periodontal diseases; Mucous membrane pemphigoid

Emotional stress as predisposing factor of oral infections: Necrotizing ulcerative gingivitis; Recurrent herpes labialis;

Neurotic habits induced oral disease: Leukoplakia; Dental and periodontal diseases produced by bruxism; Self-mutilation of oral mucosa; Physical and mechanical irritation

Neurotic oral symptoms: Glossodynia (glossopyrosis); Mucosal pain; Dysgeusia

According to Bailoor and Nagesh (2001)

Pain related disorders: Myofascial pain dysfunction syndrome (MPDS); Atypical facial pain

Disorders related to altered oral sensation: Idiopathic xerostomia; Idiopathic dysgeusia; Burning mouth syndrome

Miscellaneous: Bruxism; Psoriasis; Oral lichen planus; Recurrent aphthous ulcers; Acute necrotizing ulcerative gingivitis (ANUG); Erythema multiforme; Cancerphobia; Anorexia nervosa

Revised simple working type classification proposed for psychosomatic disorders pertaining to dental practice by Thorakkal Shamim (2014)

Disorders related to pain: Myofascial pain dysfunction syndrome (MPDS); Atypical facial pain; Phantom pain; Atypical odontogenic pain

Disorders related to altered oral sensation: Burning mouth syndrome (BMS); Idiopathic dysgeusia; Idiopathic xerostomia; Glossodynia; Glossopyrosis

Neurotic habits induced disorders: Biting of oral mucosa (self-mutilation); Dental and periodontal diseases caused by bruxism;

Autoimmune disorders: Recurrent aphthous stomatitis; Psoriasis; Oral lichen planus; Mucous membrane pemphigoid; Erythema multiforme

Miscellaneous disorders: Necrotizing ulcerative gingivostomatitis; Recurrent herpes labialis; Chronic periodontal diseases; Cancerophobia

Pain related disorders: The international association for the study of pain (IASP) defines pain as an unpleasant emotional and sensory experience accompanying with actual or potential tissue damage or described in terms of such damage. Pain is an outcome of various components that leads to the perception of pain, which said to be a psychophysiological experience that happens when a subject is hurt physically or emotionally.[4]

Myofascial pain dysfunction syndrome (MPDS)[2-8]: MPDS is the most common form of temporomandibular joint (TMJ) disorders characterized by any abnormality in various parts of masticatory system particularly in the TMJ, muscles and its related structures which can lead to pain and dysfunction in TMJ.

Clinical features: Female predilection between age of 20-40 years, TMJ sounds, Impaired mandibular movement, Limited mouth opening, Preauricular pain, Fascial pain, Jaw tenderness on movement, Unilateral pain

Available Treatment modalities:

Non-surgical treatment

1. **Initial therapy**
   a. **Reassurance and explanation** of the nature and prognosis of the treatment
   b. Elimination of hard and chewy food from the **diet** to reduce forces and rest the TMJ.
   c. **Resting** of the jaw by making the patient aware of their unconscious postural clenching or swallowing habits
   d. **Thermotherapy** is done by applying hot moist towel or heating pad on affected areas for 10-15 minutes
2. **Supportive therapy:**

   It is of two types

   a. Pain relief
      i. Pharmacological method
         - **Analgesics** like morphine, paracetamol
         - **Anti-inflammatory agents** like aspirin, ibuprofen
         - **Anxiolytic agents** like diazepam and lorazepam
         - **Muscle relaxants** like methacarbamol and cyclobenzaprine
         - **Local anaesthesia** eliminates immediate pain to allow full stretching of muscle painlessly

ii. Physical method

There are several method of physiotherapy such as

- Spray and stretch
- Ischemic pressure
- Continuous suppleness exercises
- Electro galvanic stimulations
- Transcutaneous stimulations
- Acupuncture
- Ultrasound
- Ionotophoresis
- Cold or soft lasers

b. Dysfunction therapy:

i. **Restriction** of movement to prevent damage

ii. These **exercises** are divided into three types:

- **Active exercises** 'asking the patient to open the mouth.'
- **Passive exercises** assisted mouth opening
- **Isometric exercises**

Alternative treatment therapy

a. Relaxation therapy

b. Trigger point pressure release

c. Spray and stretch

d. Occlusal appliances like:

- Nightgaurds
- Hawley's bite plane
- Splint therapy

Atypical facial pain[9]: The diagnosis of AFP is characterized by constant chronic pain in the absence of any apparent causes in the face or brain. It is diagnosed by exclusion of previously considered conditions.

Clinical features: AFP is characterized by an intense, constant and deep pain which is burning or aching type and is poorly localized. Feeling of numbness, tenderness, tingling or warmth sensation, are common additional complaints.

Treatment modalities

1. Pharmacological treatments:
   a. **Tricyclic amines** like amitriptyline, nortriptyline is often the core drug treatment.
   b. **Analgesics and NSAIDs** for temporary relief.
   c. **Contineous use of Gabapentin combined with tricyclic anti-depressant** can make extreme pain bearable.
2. Psychological treatments
3. Physical treatments like acupuncture and TENS.

Atypical odontogenic pain / atypical odontologia[10,11]: Atypical odontologia (AO) has been defined by Merskey as "severe throbbing pain without any major pathology." Pain is fluctuating in intensity, frequently persistent and continuous with no pathology present. Primary sign is pain, located in a tooth or tooth site that may spread with time involving the entire jaw.

Clinical features: Characterized by continuous dull, burning or aching pain of moderate intensity in apparently normal or endodontically treated tooth and sometimes at extraction site which is generally not affected by cold, heat or electric stimuli on testing. Most common site affected is the molars and premolars of maxilla

Treatment: Administration of the following medications has been reported to achieve pain control in AO patients: Gabapentin, Aspirin, Clonazepam baclofen, Phentolamine infusion, Cocaine, Doxepin Opioids, Monoamine oxidase inhibitors, Injections of local anesthetics and corticosteroids Topical capsaicin

Phantom pain: Phantom pain is defined as the pain sensation in a body part which has been removed and is most commonly associated with limb amputation.[12].

The phenomenology and theory of orofacial pain in the oral cavity is graded into:

- **Phantom tooth pain** is usually associated with tooth extraction
- **Phantom bite syndrome** is defined as a patient's perception of an irregular bite although there is no abnormality on examination.
- **Intraoral stump pain**

Disorders related to altered taste sensations

Burning mouth syndrome (BMS): BMS is a multifactorial disease with psychological components manifested as burning and stinging sensation with a normal mucosa in absence of local or systemic disease[13].

Clinical features:

- Commonly seen in postmenopausal women
- Unexplained persistent burning pain or sensation oral soft tissues.
- Glossodynia and glossopyrosis
- Bitter and metallic taste.
- Normal oral mucosa
- Xerostomia
- Fissured and geographic tongue
- Painful jaw, TMJ and teeth
- Increased parafunctional activity
- Loss of comfortable jaw positions.
- Difficulty in speaking, dysphagia, nausea and gagging
- Usually bilateral in nature

Treatment and management

1. **Primary BMS (unknownetiology)**
   a. Pharmacological: Clonazepam, Chlordiazepoxide, Capsaicin, Amitriptyline, Gabapentin, Alpha lipoic acid, Oral lidocaine
   b. Behavioral interventions: Acupuncture, Low level laser therapy
2. **Secondary BMS (known etiology)**
   i. Topical and oral antifungal are used for **oral thrush**.
   ii. Oral supplements for **nutritional deficiency**.
   iii. High fluid intake and sialagogues for **xerostomia**.
   iv. Hormone replacement therapy for menopausal women.
   v. Change of medications for drug allergy management
   vi. Central nerve pain control with benzodiazepines, tricyclic anti-depressants, gabapentin, topical casaicin.
   vii. Oral lignocaine and topical steroids
   viii. Oral rinses and mouth washes

Idiopathic dysgeusia: Dysgeusia is defined as 'a persistent gustatory sensation or gustatory perception in the absence of any gustatory stimulants'. These are often perceived as abnormal bitter, sour or metallic taste[12,14].

Idiopathic xerostomia: The subjective report of oral dryness is termed as xerostomia which is the most common presentation of salivary gland disease[15].

Clinical features: The lips are cracked, peeling and atrophic; buccal mucosa maybe corrugated and pale in appearance, tongue is smooth and reddened with loss papillation. Marked increase in dental caries and erosion.

Glossodynia: The type of psychosomatic disorder in which the patient experiences chronic pain on the tongue surface is called glossodynia. It is generally associated with BMS, candida associated lesions (CAL) or a combination of both[12].

Glossopyrosis: It is the burning sensation experienced on the tongue surface preceded by long period of depression. It is generally associated with immunologic, gastrointestinal, psychiatric, dermatological and neurologic disorders; and BMS[12].

Neurotic habits induced disorders: These are the disorders induced by parafunctional habits of hard and soft tissues of the oral cavity.

Biting of oral mucosa (self-mutilation)[12,14]: Self-mutilation of the oral cavity is caused due tobiting of the oral mucosa originating as a result of chronic lip, tongue or cheek biting, most commonly observed on the lateral surface of the tongue and on the buccal and labial mucosa. These kinds of lesions are often seen in people with psychogenic background.

Treatment: Along with dental management; relaxation techniques, psychiatric treatment are helpful to the patient.

Dental and periodontal diseases caused by bruxism[12,14]: Bruxism is defined as 'the parafunctional clenching and grinding action between the upper and lower teeth.' These forces are stronger than masticatory forces if applied for longer periods of time; creates dental abnormalities like abfraction, hypersensitivity, periodontal distraction and temporomandibular dysfunction. Two most striking risk factors for bruxism include stress and anxiety.

Treatment:

- Use of splints as occlusal intervention
- Both by exacerbating the condition and innerting the effects anti-depressant drugs have great effects on bruxism like amitriptyline and nortriptylin.

Autoimmune disorders

Oral lichen planus (OLP)[16]: Lichen planus is 'a chronic mucocutaneous disorder of the stratified squamous epithelium affecting the skin, nails, scalp and oral and genital mucous membrane. It is immunologically mediated.

Clinical features: Literature describes 6 OLP classical presentation as Reticular, Erosive, Atrophic, Plaque-like, Papular, Bullous. Female predilection with age group of 30- 60 years. The characteristics of this lesion include radiating velvety greyish thread- like papules in a linear, retiform and annular arrangement. Tiny white elevated dot is seen at the junction of white lines called as **striae of Wickham**as compared to lacy, reticular white lines seen in the skin **Wickham striae of the skin. Koebner phenomenon:** the lesion appears in a linear manner following the traumatic line. Most commonly seen in the oral mucous membrane prior to the appearance of cutaneous lesions. **The 6 P's of lichen planus** are Planar**,** Purple**,** Polygonal**,** Pruritic**,** Papules**,** Plaques

Recurrent aphthous stomatitis (RAS)[17,18]: Recurrent aphthous stomatitis (RAS) is a disorder characaterized by 'recurring ulcers confined to the oral with no sign of any other disease.'

RAS is classified based on its clinical features. Those are:

1. Minor ulcers (less than 1 cm in diameter without any scars)
2. Major ulcers (more than 1 cm in diameter leaves scars on healing)
3. Herpetiform ulcers manifests as recurrent groups of small ulcers throughout the oral mucosa

Treatment modalities:

1. Cauterizing drugs like phenol, chromic acids
2. Vitamin B12
3. Milk of magnesia
4. Mucous membrane adhering compounds like orabase
5. Vaccination with cowpox vaccine
6. NSAIDs and anti-histamines
7. Topical corticosteroids
8. Systemic corticosteroid therapy if topical corticosteroids are ineffective

Erythema multiforme (EM)[19,20,21]: Erythema multiforme is a self-limiting, inflammatory, acute mucocutaneous disorder that is manifested on the oral mucosa and on skin.EM is most commonly induced by drugs such as barbiturates, phenytoin, penicillins and sulfonamides; or infection caused by HSV.EM without mucosal involvement is called EM minor whereas EM with mucosal involvement is called and EM major.

Clinical features: EM is a self-limiting eruption which resolves spontaneously in 3-5 weeks without sequelae. EM has a highlighting feature called as target lesion. It has a regular round shape. There are three concentric zones of EM; A central dusky or darker red zone, A paler pink or edematous zone, A peripheral red ring. Crusting or blistering sometimes occurs in the lesion's center

Treatment modalities: EM is generally self-limiting and will resolve in few days. If drug induced the offending drug is advised to discontinue.

HSV induced- EM the first line of therapy is anti-viral prophylaxsis: Acyclovir-400mg BID, Valacyclovir-500mg BID, Famicyclovir-250mg BID

Miscellaneous disorders

Recurrent herpes labialis[19]: It is caused by the infection of herpes simplex virus 1 (HSV1), called

herpes simplex labialis (HSL). The most common form of infection is gingivostomatitis.

Clinical features: Predominantly seen in young children. The condition is self-limiting over7-14 days. Characteristics of symptomatic cases are prodromal period of fever, malaise, dysphagia, lymphadenopathy, widespread oral ulceration and generalized gingivitis.

Treatment modalities: Treatment is done by anti-viral drug therapy-Acyclovir-400mg BID, Famicyclovir-500mg TID

Acute Necrotizing ulcerative gingivitis (ANUG) is an infection of fusospirochetes. Although there are local and systemic predisposing factors; emotional stress appears to be the most common causative element for the disease[22].

Chronic periodontal disease (CPD): emotional stress plays a major role in its etiology due to which the gingiva and periodontal structure doesn't respond to the locally irritating plaque and calculus[22].

Conclusion

Dental practitioner on a daily basis comes across so many stress induced disorders. Hence recognizing and managing it effectively has become need of the hour. Careful elimination of other etiological factors should be done before naming the source of the disorder as stress. The dentist has to work in unison with psychiatrist to provide the best treatment care to the patient; thus, closing the gap between the two specialties.

A Cross Sectional Study to Assess the Level of Patient Satisfaction in OPD Services of a Govt. Hospital

Nihar Ranjan Sahoo[1], Rashmita Sahoo[2]

[1]Assistant Professor in Department of Dental Surgery, MKCG MCH, Berhampur, [2]Tutor, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Aim: Surveys are required to know the patients' necessity and their suggestions about the services getting in the hospital. It is an important factor in evaluating the healthcare delivery service in hospital.

Methods: It is a cross-sectional study to assess the level of patient satisfaction in Medicine OPD of a Govt. Hospital (CHC Berhampur, Cuttack). 200 respondents aged above 18yrs were selected by systemic sampling technique. A pre-structured questionnaire was used to conduct the research. Patients' experience with the outdoor services, facilities of hospital and patient satisfaction level were evaluated.

Results: Most of the respondents were satisfied with the services & facilities provided in the hospital. They were also highly satisfied with the services offered by physicians, nurses, and pharmacists but were little unsatisfied with the registration services and the amount of drug availability.

Conclusion: It is evident from the study that patient's satisfaction level should be conducted periodically to regulate, improve and proper management of hospital services.

Keywords: *Patients' satisfaction, Survey, Cross Sectional Study.*

Introduction

According to Hall et al, "Patients' satisfaction was defined as the result of matching one's expectation of healthcare services with actual experiences whether it is pleasant or unpleasant."[1] If the services are not as much as the patient have expected there will be a definite low level of satisfaction. And similarly, vice versa, if the patient's expectations are addressed properly there will be an extremely high level of satisfaction. Thereafter if the patients' needs are met with additional service that what initially they have expected there will be group of highly obliged and delightful patients. According to Swan, he suggested "that patients' positive opinion about service they have received is the process of matching between a set of generally accepted quality with their personal past involvement.[2,3] India is a developing country having large no. of villages in it. Thus, most of the population live in rural areas. In rural areas the only healthcare service provider is by the govt. hospitals. Although some private hospitals have come up in recent times still the govt. hospitals are the major source of healthcare service provider in rural areas. In the daily newspapers always, there are so many issues are raised by the public about the poor healthcare delivery services in govt. hospitals. So, the government has been constantly trying to improve its healthcare services as per the patient demands with the due course of time. There are several method that are being used to keep a check and evaluate the effectiveness and credibility of the various organisations and the working employers under them. In a system of healthcare service one of the main indicators of its improvement is the Patient satisfaction. Therefore, in a hospital to monitor the health care services a survey of patient satisfaction in relation to its services and cost plays a vital role. Mostly in health care consultation services the first department that comes in contact is out patient department (otherwise known to be the first line in the consultation).

This study is to assess the patients' satisfaction level in a Medicine Outpatient Department (OPD) of a govt. hospital at CHC level located in Odisha, India.

Methods

By receiving permission from the Medical Officer, I/C of the Community Health Centre Berhampur, the research process was started with collection of data.

Study Design: A cross-sectional study had been designed to find out the patients' satisfaction level and its relationships with different socio-demographic parameters of the studied population. A pre-structured questionnaire was selected from an earlier researcher and thoroughly examined, justified and then applied accordingly.

Study Population: The Medicine OPD of the Community Health Centre, Berhampur was selected as the site of study as the no. of patient visiting is more in comparison to another department. This hospital is chosen as the study site because it is situated in the rural area but very nearer to the city of Cuttack where all types of modern treatment are easily available. So, we can know whether peoples are satisfied here or they are preferred to move to the nearest city for the common medical problems. Samples were obtained from the patients who had been visiting the OPD of the Health Centre at the moment of collecting data.

Sample Size and Sampling Technique: 200 patients were interviewed for the study who were willing to give their response without any pressure or force from the researcher.

So as to find out statistically noteworthy representatives of the population, a systematic random sampling was used to draw the interval sampling number of patients that should be skipped for every sample selection. Every fourth patient from the samples available at the time of data collection are selected to be interviewed in all shifts to ensure the proper distribution of patients who represented the total population.

Research Instruments: Adopted from a previous study, a pre-structured questionnaire was used to collect the data.[4] There were 60 questions and 1 descriptive question, divided into 3 different segments:

1. Socio-demographic description,
2. Responses on OPD
   i. Facilities available,
   ii. Doctor-patient relation,
   iii. Nurse-patient relation,
   iv. Drug dispensary system,
   v. Opd registration.
3. Accessibility to OPD
   i. Waiting period,
   ii. Schedule of working,
   iii. Procedure of the service.
4. Suggestion and comments.

The pre-structured questionnaire was tested for the reliability by systematically randomly selecting 30 patients from the medicine OPD as the samples. Then the result was analysed statistically for the reliability coefficients. The data was collected by face to face interviews. The scoring method was adopted from a previous research article. [4] Table 1 shows scores for labelling the level of experiences, accessibility and patient satisfaction.

Table 1: Scoring table

Variables	Poor/Low (First Range)	Good/High (Second Range)
Experience:		
Physical facilities	5-7	8-10
Doctor–patient relation	7-10	11-14
Nurses–patient relation	4-6	7-8
Drug delivery system	4-6	7-8
Registration services	3-4	5-6
Accessibility:		
Waiting period	3-4	5-6
Working shifts	2	3-4
Service procedure	2	3-4
Patient satisfaction:		
Convenience	7-10	11-14
Courtesy	6-9	10-12
Quality of care	9-13	14-18

Part 1. Socio-Demographic profile of the respondents: In this segment there is patient's general information that is of what is the age, gender, marital status, occupation, educational status, number of visits and their monthly income. The questions comprise of 9 multiple choice as well as fill in the blank questions.

Part 2. Responses towards medicine opd: Responses of the respondents were divided into 3 sub categories like doctor-patient relation, nurse-patient relation, experiences with drug delivery and opd registration system. 17 MCQ were asked and the answers were recorded either as yes or no accordingly.

According to the scores obtained experience levels were categorized as good and poor.

Part 3. Accessibility to opd: Accessibility to opd comprises waiting periods for getting services, working times and service processes. 12 MCQ were asked and the answers were recorded either as yes or no accordingly. The experience levels were described as good and poor according to the scores obtained.

Part 4. Patients' Satisfaction with Medicine OPD: Satisfaction level were described in terms of convenience, courtesy, and quality of care provided by the clinical staff. Each segment is composed of 22 questions. Each question was answered as eithersatisfactoryor unsatisfactory.

Part 5. Suggestion or Comments: Patient give their comments or suggestions for the improvement of opd services in the Health Centre.

Data Collection Procedure: Patients of age 18 years & above and visited the OPD during data collection were selected. The OPD registration by taking general information of the patients was done by a nurse which makes easier for the researcher to select the sample with four patient intervals. Before visiting the doctor, patients were informed about the research process and asked for consent. Then data collected once they finish their consultation. Data was collected form all shifts like morning, afternoon and evening.

Statistical analysis: The data collected was analysed statistically by using SPSS software.

In SPSS, the following tests were used to obtain the desirable results:

1. Descriptive statistics: frequency, mean, median, mode, standard deviation, chi-squared test, and fisher's exact test.
2. Correlation analyses.
3. Computing variable and recoding into different variables.

Observation & Results

Table 2: Responses towards health services

Health services	Frequency				Level of satisfaction
	Yes		No		
	#	%	#	%	
Physical Facilities:					
Ease of finding opd	195	97.5	5	2.5	High
Cleanliness of opd.	190	95	10	5	High
Enough seats in waiting room.	178	89	22	11	High
Cleanliness of toilets in waiting room.	70	35	130	65	Low
The waiting room is spacious and well ventilated.	190	95	10	5	High
Doctor–patient relation					
Doctor told the detail of treatment procedure.	135	67.5	65	32.5	High
Doctor asked your health problem in depth.	178	89	22	11	High
Doctor understood your problem.	193	96.5	7	3.5	High
You got enough chance to discuss in detail.	158	78.5	42	21.5	High
Doctor gave sufficient time for you.	88	44	112	56	Low
There are enough doctors.	170	85	30	15	High
Nurses–patient relation:					
Nurses understood and answered your complain.	147	73.5	53	26.5	High
Nurses clarified you the consultation process.	186	93	14	7	High
There are enough nurses.	176	88	24	12	High
Drug delivery system:					
Pharmacist listened to you.	138	69	62	31	High
Pharmacist explained about the use of medicines.	156	78	44	22	High

Health services	Frequency				Level of satisfaction
	Yes		No		
	#	%	#	%	
There were enough drugs.	89	44.5	111	55.5	Low
There were enough of staffs.	192	96	8	4	High
Registration process:					
Registration staff listened to you.	138	69	62	31	High
Registration staff described you detail where to go.	158	79	42	21	High
There were enough staff	180	90	20	10	High

As per the **table 2** majority of the respondents were highly satisfied with the health services available except the cleanliness of the toilets present in the waiting room, the time spent by the doctor for the respondent and the number of drugs available.

In taken as a whole, most of the patients had high-quality experience with physical facilities, and the services provided by the nurses', doctors', pharmacy's, and registration, in that order. However, there were little concern regarding the time doctor used up for consultation, amount of the prescribed drugs, and registration services.

Table 3: b. Accessibility to Health Services:

Access to Health Service	Frequency				Level of satisfaction
	Yes		No		
	#	%	#	%	
Waiting Time:					
- Time taken for registration was correct.	95	47.5	105	52.5	Low
- Time taken for consultation is acceptable.	176	88	24	12	High
- Time taken for drug delivery is acceptable.	187	93.5	13	6.5	High
Working Schedule:					
- OPD timing is suitable to you.	190	95	10	5	High
- Do sufficient staff present in all shifts.	90	45	110	55	Low
Service Procedure:					
- Registration process was done timely.	90	45	110	55	Low
- Coordination between registration, OPD, and Pharmacy section is good	180	90	20	10	High

Based on the results from the **table 3**, it seems that most of the respondents were satisfied with the time taken to receive consultation and medicines from Pharmacy. Majority of them also reported that the OPD timing was suitable and there was good coordination between different departments. However, only 45% of the respondents satisfied with the time taken for registration, available of sufficient staff in all shifts.

Discussion

This study was about the patients' experiences towards the hospital; therefore, it was conducted during working hours. So, some patients were not comfortable in giving their experiences and opinions about the hospital services. A detail introduction of the researcher, the purpose, and the use of the data collected was provided to each participant.

Most of the patients have high level of satisfaction with health services provided in Medicine OPD of the Community Health Centre. Very few numbers (47) of respondents gave their comments or suggestions even after explaining the importance of the study and its use as indicator for the improvement of the quality of care. This shows a lack of interest of the respondents in sharing their personal experiences which may be due to:

- Inability to communicate their experiences
- feeling uncomfortable in a new environment
- the busyness of life,
- the nature of the respondent

Surveys are obligatory to make out the patient's necessitate and their judgment of the service that they have received as it is used in evaluating the quality of healthcare delivery service in any particular hospital.

According to Amin Khan Mandokhail's study in 2007, Thailand, "the level of satisfaction among 225 Medicine OPD patients was high for doctor-patient and nurse-patient behavior as well as Physical facilities and pharmacy services whereas the drugs were expensive and access to the services was poor. The level of Satisfaction was also influenced by marital status and occupation."[4]

Lower the satisfaction level poorer will be the compliance to treatment and poorer will be the health outcome. In the study conducted by Asma Ibrahim in 2008, "only 10.4% of 251 patients were highly satisfied. It showed that the patients' perceptions of the services were not good in term of convenience, courtesy, quality of care, hospital fee, and physical facilities. Particularly, the patients' opinion was mainly affected by the staff's attitude."[5]

Patient satisfaction is an important parameter in judging the quality of the healthcare services provided in the hospital. According to Anjum Javed in 2005, Satisfaction level was said to have significant relationship with the distance from patients' living areas to the hospital and opd timing.[6]

It is thought that the high levels of positive opinions of patients might have some relation tothe standards of living, gender, age groups, and even status of the patients whether they are single, married, or widowed, etc. But according to **Doborah L,** "there is little relationship between socio-demographic characteristics with satisfaction level."[7] Some study shows that people who are from the same ethnic groups tend to pay more attention or to help the people who are from the same sources. This idea is also said to apply in the performance done by physicians who are from the same groups as their patients.[8] Hall J.A. & Dornan M.C in their study described, "that some social advantages such as educational backgrounds, employments, revenues, a warranty are the keys for clients to decide which services to use."[8]

In order to improve the condition of the hospital, periodic assessment of patients' satisfaction level should be done. From the obtained study in the medicine outpatient department of CHC Berhampur, Cuttack, it is seen that preponderance of the patients were satisfied with the facilities that the hospital is providing and service of doctor's, nurse's and pharmacists. The majority of the respondents were relatively less satisfied with registration service, quantity of drugs that have been and the responsiveness of the staff who is registering. So, these area needs to be enhanced.[9]

Conclusion

A satisfied patient will always convey a good representation of the treating hospital which is the important factor for the management point of view. In this study, it was found that the service receiverwas satisfied with logistic array, nursing care, doctor's services, staffing pattern etc. Education was found to have significant relationships with patient satisfaction level. Hence the OPD services is an important element to provide a good image of the hospital and the patients' opinion are essential in quality improvement.Therefore, the author recommends that"Conduction of periodical survey emphasising on patients' contentment in the hospital should be done to keep up with the amend of the technology."

Abstract

Infant mortality rate (IMR) data can be used as a statistical measure to identify the changing dynamics of children health, which can be an indicator of the welfare and progress of a society. However, these data are usually collected by authorized bodies or Government organizations on a large scale, with very little local stratification. For implementing correct policies for medical intervention, the knowledge about patterns of the cause-specific mortality is necessary. Studies included in this article were identified through a systematic analysis search of the scientific literature published between 2018 & 2019. Secondary data was extracted from vital records, sample Registration system 2019, database from "UN inter-agency" group of infant mortality estimates. The data between 2009-2019 (on or before June 2019) were collected. The infant mortality rate was calculated based for every death per 1000 live birth in the year. The data for each year was evaluated based on the information collected from secondary records. Further, the IMR data from the "Indian Sample Registration System (ISRS)". Estimated NMR for 2019 was based on assumption and data collected on or before May 2019. For the purpose analysis all publicly available data on infant mortality was used.

Keywords: *Infant mortality; Cause-specific mortality; Systematic analysis, Microbial infections.*

Introduction

Infant mortality rates (IMR) is the measure to calculate number of deaths among children the deaths of 0 to 5 years of age per 1000 live births, including the neonatal mortality rates (NMR; i.e. within 28 days from birth)."Reducing neonatal mortality"was an essential part of the third "Sustainable Development Goal (SDG)" where SDG was adopted from Millennium Development Goals (MDG) and many more goals were incorporated in it in the years 2015, which will be relatable and beneficial to end preventable child deaths.[1,2] The SDGs also specifies that every country should focus to reduce the NMR down to 12 deaths per 1000 livebirths or fewer and under-5 mortality to 25 deaths per 1000 livebirths or fewer by the year 2030. The major issue is unavailable or limited data in low-income settings, where they are most needed and estimations are necessary.[3] India is a country with a significantly high infant mortality of 32 per 1000 live births(as on May 2019), neonatal mortality 28 per 1000 live births (as on September 2017) and increasing population of 1,368,973,535 (as on 8th September 2019) with 51 live births every minute. Further, the total death rate of 7.3 per 1000 population, lower maternal literacy rate 65%, below poverty population 276 million of total population (as on 2012)and other associated factors like presence of under-five sibling in the same family, lower birth weight, inadequate breast-feeding, malnutrition, poor sanitation, geographical factors and improper hygiene and environmental factors are responsible for increasing the incidence of infectious diseases and other cause–specific deaths among infants.[3] The new born being immunologically more suppressed are prone to acquire diseases and even death.[4]

The Child Health Epidemiology Reference Group (CHERG) is working in response to international demands and to meet the need of data in magnified form of evidence-based cause-specific mortality with group of experts jointly coordinate by WHO and UNICEF together. There has been a considerable progress in the estimation of data for under 5 mortality by Interagency Group for Child mortality Estimation (IGME). Neonatal deaths worldwide are estimated to be caused due to diarrheal infections, pneumonia and malaria which accounts for huge number of deaths.[5]

Method

A complete Study which included systematic analysis search of the scientific literature published between 2018 & 2019. Secondary data for infant mortality rates was extracted from vital records, Sample Registration System 2019, database from "UN inter-agency group" of child mortality estimates. The data between 2009-2019 (on or before June 2019) were collected. The IMR was calculated based for every death per 1000 live birth in the year. The data for each year was evaluated based on the information collected from secondary records. Further, the infant mortality data from the "Indian Sample Registration System (ISRS)", whose annual estimates are consistent with those of the NFHS were also collected. Estimated NMR for 2019 was based on assumption and data collected on or before May 2019. For the purpose analysis all publicly available data on infant mortality was used.[6]

Results

Source: http://www.geoba.se/country.php?cc=IN, https://childmortality.org/data.[7]

Figure 1. Infant mortality rates from 2009-2019 per 1000 live births (10 years study). The data for 2019 is collected on or before May 2019. The decreasing rates of Infant mortality in India shows it is expected tosignificantly decrease 5% by the end of 2019.

The result obtains by analyzing 10 years IMR shows significant decrease in IMR for a period of 10 years. The IMR which was 50 per 1000 live births in 2009 decreased slowly to 47 per 1000 live births in 2010, 44 per 1000 live births in 20011, 42 & 40 per 1000 live births in 2012 & 2013 non-significantly and slowly it reached 32 per 1000 live births as on or before May 2019.This decrease in mortality rates among infants in India over the past years consequent to improving socioeconomic conditions. Factors including the improving social, cultural and health, status of women, improved health services during pregnancy and post pregnancy period and women empowerment and many other policies for and facilities for women in India are responsible for decrease IMR.

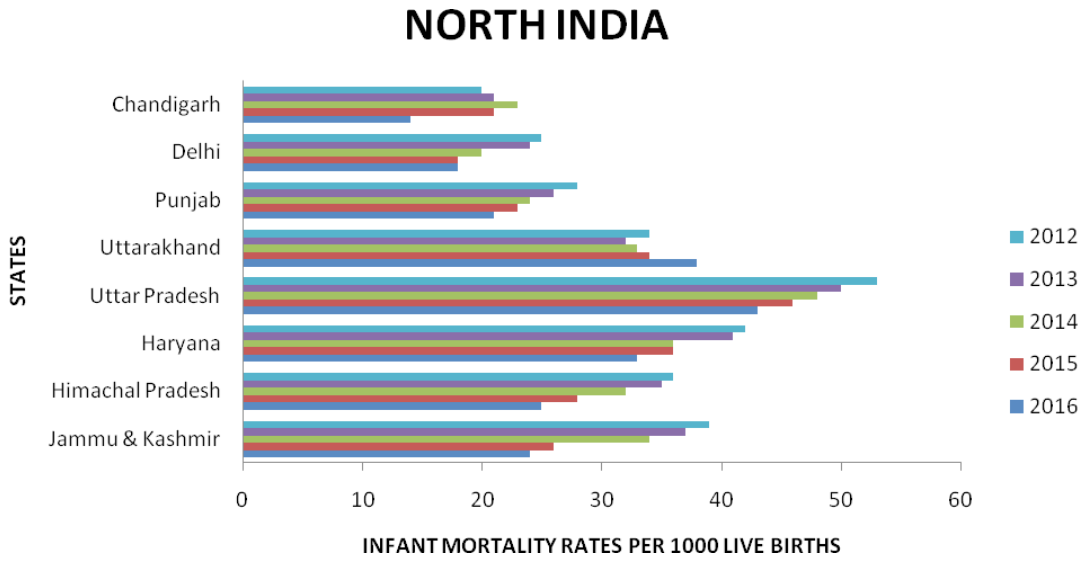

Figure 2. Infant mortality rates in North India (2012-2016)

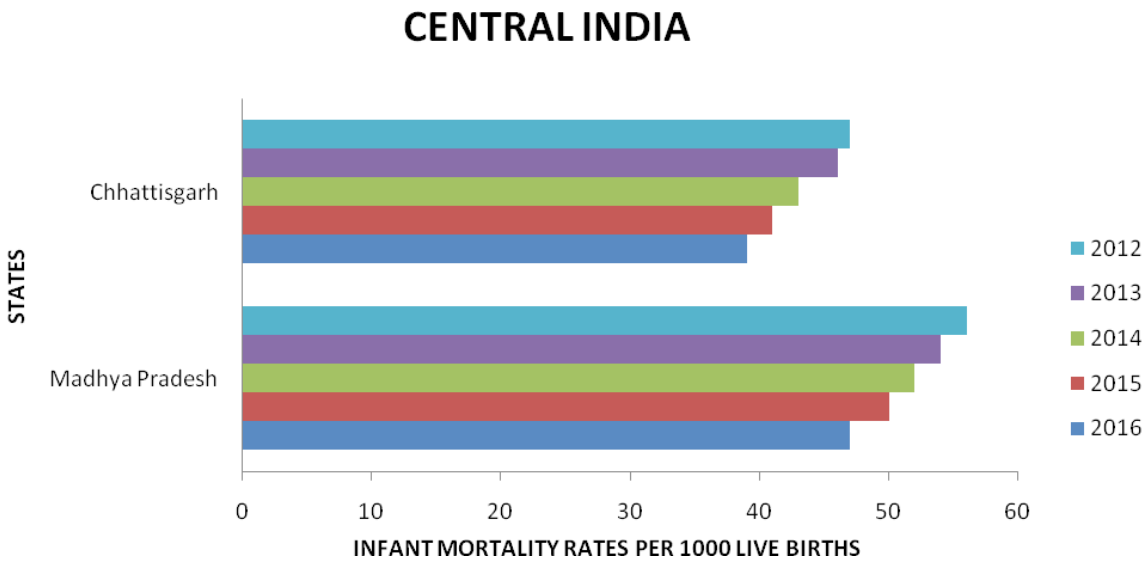

Figure 3. Infant mortality rates in Central India (2012-2016)

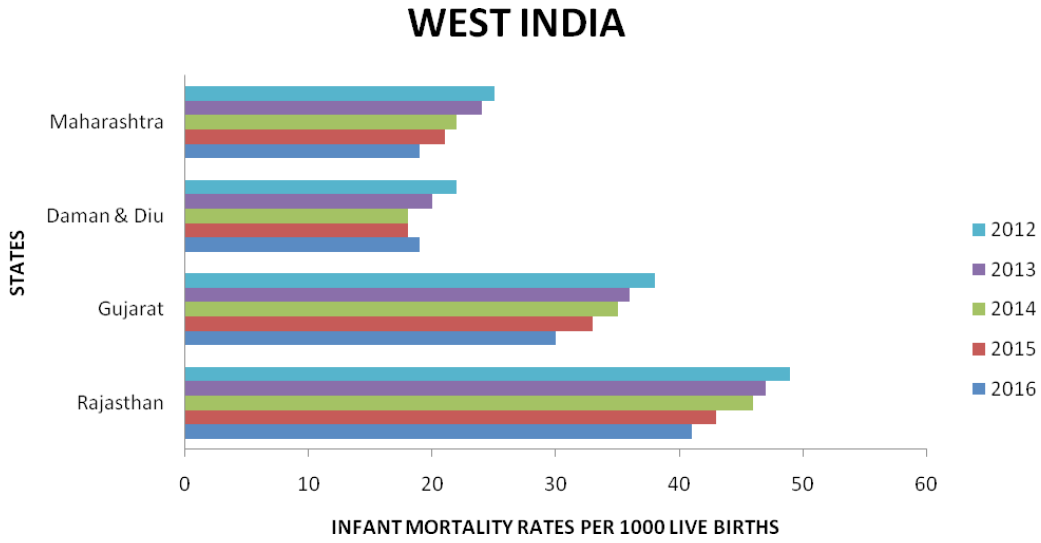

Figure 4. Infant mortality rates in West India (2012-2016)

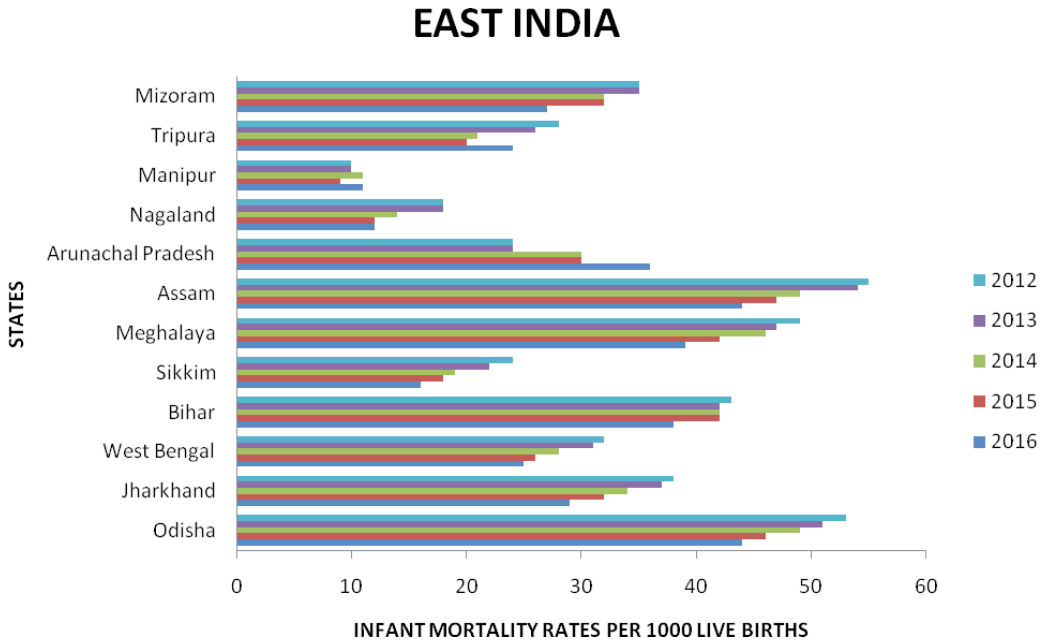

Figure 5. Infant mortality rates in East India (2012-2016)

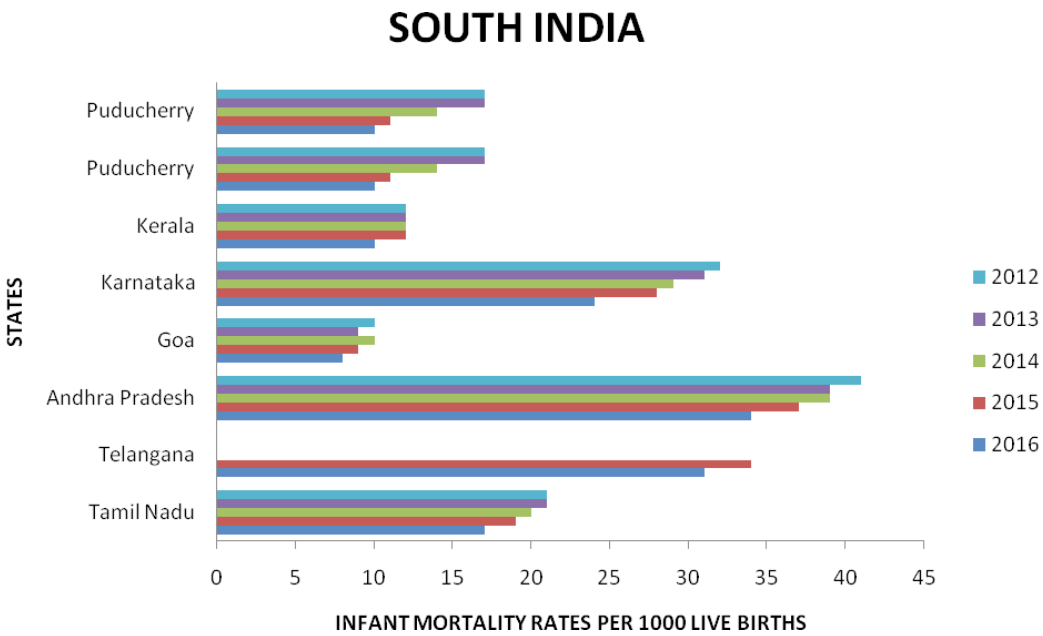

Figure 6. Infant mortality rates in South India (2012-2016)

From these above graphs it can be interpreted that the IMR has shown a significant reduction with time in different zones of India till 2016 (as of 2017 SRS data). However, in Uttarakhand, Northern zone with 38 infant deaths per 1000 live births, Tripura 24 infant deaths per 1000 live births and Andhra Pradesh 34 infant deaths per 1000 live births in the Eastern zone of India. The sudden differences of IMR in the year 2016 observed could be due to change in demographic pattern of these states, malnutrition, low-birth weight and pre-term birth. Further, epidemic, between 2008 and 2014, there were deaths cases of encephalitis in regions of Bihar and Uttar Pradesh which can be one the reason for sustainable high rates of IMR in these two regions. Moreover, dengue outbreak was recognized as one of the largest outbreak of the period, (v) most importantly climate change or natural disasters such as flood, landslides which are common in Northern regions of India, especially in Uttarakhand, (vi) other disease-specific/cause-specific reasons also might have been responsible for increased Infant mortality rates.

Discussion

The "Sample Registration System (SRS)" is a large-scale demographic survey which provides consistent yearly estimates of IMR, birth rate, death rate and other fertility & mortality indicators at the various national and state levels.[8] Initially on pilot basis by the Office of the Registrar General, India in between 1964-65 in few selected states had started and during 1969-70 it had become fully operational with about 3700 sample units. Although there has been a substantial decrease in IMR since 1990, there is still a need of increased effort to improve progress in order to achieve the SDG target by 2030.[8] Individual state government in India must be advised to consider the current mortality rates and the level of progress of IMR decreasing policies in their respective states. Among the States/Union Territories, the IMR ranges from 12 in Nagaland to 47 in Madhya Pradesh for 2017.[9,10]

Cause-Specific Mortality: Infant mortality can be due to the following infectious and systemic disorders: pneumonia, diarrhea, neonatal sepsis, malnutrition and/or anemia, fever, measles, malaria, typhoid, dengue, stillbirth, preterm birth, Low birth weight, tetanus, asphyxia, chronic diseases and miscellaneous. The miscellaneous category included mostly infective and a few systemic disorders which may cause child death.[11-14] The major causes include:

Pneumonia: Acute respiratory illnesses are major cause of deaths among children under 5 which includes pneumonia & bronchiolitis most commonly. Pneumonia is the largest killer of children causing about 20% worldwide.

Diarrhea: The most common gastrointestinal infection among infants is diarrhea and it is the leading cause of preventable deaths not only in India but also in most developing countries. It was estimated in a review that 2.2 (approximately) infants die annually from diarrhea worldwide. Water and food are some of the major source of contamination and propagation of disease, thereby causing large number of morbidity and mortality among infants.

Neonatal sepsis: Sepsis and meningitis are major cause of morbidity and mortality among infants, especially among children with low-birth weight & preterm. It is acquired by nosocomial or community source. Meningitis is a fatal infection which includes bacteria, viruses, parasites and fungi.

Malnutrition: Malnourished children and are always at an increased risk of acquiring infection and even death. The presence of characters such as stunting, wasting/underweight were determined malnourished using WHO child growth standards or the NCHS growth reference. Low birth weight is another major cause of infant death, the principal cause of death over two third of deaths occur in low birth weight (less than 2.500 Kg).

Preterm Birth: Preterm infants may suffer from asphyxia. Under developmental conditions may lead to morbidity and ultimate death within few days.

Malaria: Placental malaria is one of the major reasons for infant death. Since, there are no other understandable causes of asphyxia, malaria is considered to be most probable cause of infant death.

Conclusion

The data extracted from successful records lacks cause-specific year wise data of infant mortality. Though there is a decline in rates of infant mortality in last 10 years, for a period of 2–3 years of slower declines in the IMR which was later followed by years of very rapid decline. Future child health policies should be built based previous study outcomes and from the results of child health programs implemented in India. There should be continuous effort to sustain the achievements that have already been made and there is also need to enhance quality and efficiency of the ongoing programs. Fresh and innovative planned policies should be implemented for reducing childhood illness and developing health care system in rural and urban areas. The Government must reassess the current policies for decreasing IMR in country & must implement more holistic measures. Socioeconomic, environmental, behavioral, educational health and nutritional determinants also influence infant mortality and should be equally taken care of and maternal education, pre and post pregnancies training session should be conducted so as to reduce the incidence of preventable deaths.

Diagnosis and Management of Endodontic-Periodontal Lesions

Swagatika Mohapatra

Intern (BDS), Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India.

Abstract

Relationship between periodontal and pulpal disease was first described by Simmering and Goldberg (1964). After that Endo-Perio lesion is being used as the terminology for describing the lesions due to inflammation and its products found in the tissues of both periodontium and pulp. Studies regarding the relationship between endodontium and periodontium has been done extensively and the queries related to the correct diagnosis,treatment plan and prognosis has been always a raise.A tooth which is symptomatic,may have pain of either pulpal or periodontal origin. In determining the etiology of such problem, the nature of that pain is important. The main purpose of this article is to present the anatomical considerations of pupal and periodontal relationships, the factors initiating the pulpal and periodontal lesions, Biologic effect of pulpal infection on periodontal tissues and periodontal infection on the dental pulp, diagnostic considerations and successful management of tooth with endodontic-periodontal lesions.

Keywords: *Endo-Perio Lesions, Anatomic Considerations, Diagnosis; Treatment Strategies, Prognosis.*

Introduction

As the endodontium and periodontium are closely related to each other, the diseases of endodontiummay lead to involvement of periodontium or vice versa. In this case,correct diagnosis is very important so that appropriate treatment can be provided.From embryonic stage[1,2];Pulpal tissues and periodontal tissues are interlinked to each other.Thedental papilla which,is a precursor of dental pulp and dental sac, which is aprecursor of periodontal ligament;are of a common mesodermal origin.Inlate bell stage; epithelial root sheath separates dental papilla & dental follicle; Except at the base of the future apical foramina.So, naturally periodontium gets affected by pulpal inflammation and vice versa.[3]

Anatomic considerations: Apical foramina are the main & obvious route of communication between pulp and periodontal ligament. Advanced pulpitis will lead to pulp necrosis, which often is accompanied by inflammatory bone resorption at the root apex, as found in cases of apical periodontitis or an apical abscess[4]. This is also known as retrograde periodontitis as it presents the breakdown of the periodontium from an apical to a cervical direction. This is typically identified as a periapical radiolucency.[5]

Alternatively lateral or accessory canals may also be the routes of periodontal and pulpal communications. Prevalence of accessory root canals in various human teeth and their contribution to root canal system complexity has been well established.[6]Third root of communication between the periodontium and the pulp is through the dentinal tubules. Dentin is a permeable structure and the permeability changes at different locations along the root surface according to the size and density of the dentinal tubules. Colonisation of bacteria in dentinal tubules from infected root canals and invasion of bacteria into the dentinal tubules from the periodontal pocket proves that dentinal tubules may allow pulpal irritation which arise from periodontitis.[7,8]

In addition to the above routes there are chances of communication between pulp and periodontium by iatrogenic defects, such as vertical root fractures and tooth perforations. These are non-anatomic communication and result in spread of infection from one to another.[9]

Factors Initiating Pulpal and Periapical diseases[10]

- Microorganisms
- Trauma
- Excessive heat

- Restorative procedures
- Restorative agents
- Malocclusion

These lead to inflammatory changes in the pulp, starting from a reversible or irreversible pulpitis and ultimately progressing to pulpal necrosis and breakdown of the periodontium. Dental caries is the cause of pulpal disease and bacterial infection is the form of microbial insult to the pulp.[11]Thermal changes caused by dental procedures such as tooth preparation leads to alteration of pulpal circulation and induce pulp tissue damage. Pulpal necrosis will lead to apical periodontitis. Chemical irritants also impose measurable changes in the pulp status. Etching the dentin with high phosphoric acid content has deleterious effects on dental pulp.[12] Bonding Agents also lead to acute pulpitis and varying degrees of necrosis in teeth. Root canals overfills with gutta-percha and sealers also cause inflammatory reactions in the apical tissues but the patient might be completely asymptomatic.[13]So to make a proper diagnosis, a clinician must evaluate the symptoms, radiographic and clinical findings and the presence absence and location of any swelling or drainage.[14]

Classification of endodontic-periodontal lesions[15-17]

SIMON ET AL (1972)

1. "Primary endodontic lesions"
2. "Primary endodontic lesions with secondary periodontal involvement"
3. "Primary periodontal lesions"
4. "Primary periodontal lesions with secondary endodontic involvement"
5. "True combined lesions"

GROSSMAN (1991)

Based on the treatment strategy-

1. "Teeth that require endodontic treatment alone"
2. "Teeth that require periodontal therapy alone"
3. "Teeth that require endodontic as well as periodontal treatment"

TORABINEJAD AND TROPE(1996):

1. "Endodontic origin"
2. "Periodontal origin"
3. "Combined endo-perio lesion"
4. "Separate endodontic and periodontal lesions"
5. "Lesions with communication"
6. "Lesions with no communication"

World Workshop for Classification of Periodontal Diseases (1999):

Periodontitis associated with endodontic disease:

1. "Endodontic-Periodontal lesions"
2. "Periodontal-Endodontic lesions"
3. "Combined lesions"

VON ARX AND COCHRAN (2001)

Class 1: lesion with bone defect in the apex which may invade the buccal and lingual apex"

Class 2: Apical lesion with the concomitant marginal involvement also referred as a combined periodontal endodontic lesion, with great periodontal pocket depends around the affected tooth.

Class 3: Furcation lesion coming from the accessory canals or from iatrogenic perforation and the marginal lesion may or may not occur."

KIMANDKRATCHMAN:

A. Absence of periradicular lesion, no mobility, normal pocket depth, but unresolved symptoms after non-surgical therapies have been exhausted.

B. Presence of a small periradicular lesion in the apical quarter, clinical symptoms such as discomfort or sensitivity on percussion as sinus tract, normal periodontal probing depths and mobility."

C. Large periradicular lesions progressing coronally but without periodontal pockets or mobility

D. Clinically similar to those in Class C but with periodontal pockets more than 4mm and no communication of the pocket and the endodontic lesion.

E. Deep periradicular lesion with endodontic periodontal communication to the apex but no obvious fracture.

F. Apical lesion and complete denudement of the buccal plate but no mobility.

ROTHSTEIN AND SIMON (2006):

1. Retrograde periodontal disease: It could be of two types
   A. "Primary endodontic lesion with drainage through the PDL"
   B. "Primary endodontic lesion with secondary periodontal involvement"
2. "Primary periodontal lesion"
3. "primary periodontal lesion with secondary endodontic involvement"
4. "combined endodontic periodontal lesion"
5. "Iatrogenic endodontic periodontal lesions"
   A. "Root perforations"
   B. "Coronal leakage"
   C. "Dental injuries or trauma"
   D. "Chemicals used in dentistry"
   E. "vertical root fractures"

Etiological factors:

1. Live pathogens: Bacteria, fungi, viruses
2. Nonliving etiologic agents-Extrinsic agents, Intrinsic agents

Contributing factors[18]

1. poor endodontic treatment
2. poor restorations
3. trauma-crown fracture without pulp involvement, crown fracture with pulp involvement, crown root fractures, root fractures, concussion, subluxation,Extrusive luxation, intrusive luxation and avulsion.
4. Resorptions: external, replacement and internal.
5. perforations
6. developmental malformations

Clinical diagnostic procedures[19,20]

Visual examination: Cheeks,lips,oral mucosa, tongue, palate and muscles is examined visually. Alveolar mucosa,attached gingiva are examined visuallyto detect; inflammation, ulcerations,sinus tracts,teeth are examined to detectdental caries; faultytooth restoration; fractures; erosions; abrasions.

Palpation: Done byapplying firm pressure with the index finger on the mucosa covering roots; which detects presence of hot zones that produces a response which is painful. Positive response indicates active periradicular inflammatory process.

Percussion: Percussion is performed by the clinician by tapping on the incisal or occlusal surface of the tooth with the back end of mirror handle. The tooth is tapped horizontally & vertically.Positive response indicates that apical periodontium is inflamed.The origin may be pulpal or periodontal.

Mobility: On each side of crown;two mirror handles are used and mobility is checked. Pressure is applied on faciolingual & vertical direction. Extremely mobileteeth have poor periodontal support which indicates periodontal disease may be the primary cause. Tooth which are recently traumatised and which have fractured roots are also mobile.

Radiographs: These are important tools for detection of carious lesions,extensive or defective restorations, pulp cappings, previously endodontically treated tooth,canal obliterations, root resorption, root fractures, peri radicular radiolucency,thickened periodontal ligament and alveolar bone loss. But the clinical signs and symptoms and other clinical tests are also essential during radiographic evaluation.

Pulp Vitality Testing:

Cold test: Done usually by applying a cold substance on tooth surface. The tooth surface must be first isolated. Cold method are- "ice sticks", "ethyl chloride", "CO_2" (dry ice), "dichlorodifluoromethane". Prolonged & intense response indicates"irreversible pulpitis" & absence of response indicates "pulp necrosis"

Electric test: Done with the help of a"special pulp tester device". Tooth is cleaned; isolated; dried. On the electrode of the pulp tester; small amount of toothpaste is placed and then it is l put into contact with the particular tooth surface. Till patient reports sensation; electric current is applied gradually. False negative responses may occur if there are obliterated root canals;poor electrode tooth contact; traumatised tooth,immature apices, drugs that elevate pain threshold.

Pockets probing: It is important for differentiating endodontic and periodontal lesions. Williams's probe is used; probing depth & CAL (clinical attachment level)

is determined. Used to track a sinus resulting from an inflammatory periapical lesion that extends cervically through the PDL space. If a deep pocket is present without any periodontal disease, it indicates the infection might be endodontically or it might be a vertical root fracture.

Fistula tracking: Usually,opening of the sinus track is visible on the attached gingiva or the vestibule. The fistula is tracked by inserting a radiopaque material;into the sinus track. Gutta percha cones or silver cones are commonly used.Post insertion Radiograph will show the course of sinus track & the origin of inflammatory process.

Treatment decision making and prognosis: There is no difficulty in diagnosis of primary endodontic & primary periodontaldisease. Usually pulp gets infected,non-vital in primary endodontic disease.In case of primary periodontal disease; pulp vitality is normalso responds to pulp vitality testing. primary endodontic disease with secondary periodontal involvement,Primary periodontal disease with secondary endodontic involvement & true combined lesionsare clinically and radiographically similar. If there is no evidence of plaque induced periodontitis; lesion is treated endodontically first;then clinical probing shows soft tissue healing;recall radiograph shows bony healing;then the lesion can be diagnosed retrospectively. Degree of healing afterRCT will determine the retrospective classification. If adequate healing does not happen, thisisindicative of periodontal treatment.

Prognosis and treatment plan varies according to type of endodontic periodontal disease. There is good prognosis in primary endodontic lesionas the endodontic treatment is the only treatment of choice. In Primary periodontal disease"; prognosis depends on the extent of the periodontal disease and how the patient responses to the particular treatment Primary endodontic disease with secondary periodontal involvement" should be treated endodontically first. Results are evaluated in two-three months and after that periodontal treatment is considered. This gives adequate time for initial tissue healing and the periodontal condition is assessed in a better way[21].

Primary periodontal disease with secondary endodontic involvement and true combined diseases need endodontic and periodontal therapy. Intrapulpal infection leads to an epithelial down growth along surface of dentin. Experimentally induced periodontal defects was associated with twenty percent more epithelium.Teeth which were not infected;showed ten percent more connective tissue coverage[22].

Treatment of endodontic periodontal lesions: Primary endodontic disease: In endodontic treatment; lesiongets healed. As affected pulp is removed during RCT; sinus tract disappears in early stages of the treatment; the nit is cleaned, shaped, obturated. In chronic lesions; periodontal abscess occurs so evaluating carefully is needful for proper treatment.

Primary periodontal diseases: In Primary periodontal disease, first classical line of treatment includes scaling and root planning. Then; restorations which are poorly contoured are removed, developmental grooves are removed so that the tooth can be accessible for better maintenance and the treatment can be successful. Then the periodontal therapy begins. How much extensive is the lesion and how much efficient the periodontal treatment determines the success of the treatment.

True combined diseases: True combined lesion might be the result of faulty RCT or faulty posts or coronal restoration. In this case RCT is the first treatment of choice but one can not expect a good prognosis if the periodontal lesion is extensive. In such cases,periodontal regenerative procedure is first performed so the that prognosis depends on periodontaltreatment.

Treatingiatrogenic lesions: Thing which is to do first is to close the iatrogenic communication. Root perforations are treated according to their etiology,but Palatal perforations can't be managed surgically so that the tooth frequently leads to extraction. Root perforations can be treated successfully if early detection is made. In case of vertical root fractures,the prognosis is very poor;so it is indicated for extraction.

Conclusion

Diagnosis of endodontic periodontal lesion is most important. After that a correct treatment can be planned. The chief goal of the periodontal therapy in this scenariois the preservation of the periodontium. The aim of RCT is cleaning the root canals and shaping them followed by obturation so as to maintain the apical periodontium. The success in the treatment of endo periolesions depends on all contributing lesions are treated or not.Both endodontic as well as periodontal therapy is required for true combined lesions. Whether first the endodontic therapy is completedor the periodontal therapy should be accompanied with the endodontic treatment;the decision

making completely depends on accurate diagnosis. The dentist should be highly experienced clinically so that he is able to choose the treatment planwhich is appropriate for the condition.

Dental Administration of Patients Acquiring Anticoagulant and/or Antiplatelet Treatment

Alok Mahapatra[1], Sthitaprajna Lenka[2], Karishma Rathor[3], Prateek Kumar Sundaray[1]

[1]Intern, [2]Professor, Department of Oral Surgery, [3]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The main objective of the study is to determine,the management of patient who is under anticoagulant therapy in cardiac patients with periodontal disease and to follow up the effects of dental procedures associated with low-doses of antibiotics in relation with coronary atherosclerotic disease. Patients living with cardiovascular disease are susceptible to physical and emotional stress. This is further magnified if the patient needs dental treatment, as dental surgery itself is stress provoking. Cardiac patient may collapse and die in the dental chair, because of cardiogenic emergencies and multiple drug interactions. Cardiac patients are a great risk for dental surgeons that are why a multidisciplinary approach while managing these medically compromised dental patients is of paramount importance to achieve the desired outcome. Adequate haemostasis is a decisive factor for dental treatment.

Keywords: *Anticoagulants, Coumarin, Fibrin, Heparin, Thrombosis.*

Introduction

Haemostasis is the physiological course that blocks bleeding at the site of an injury while sustaining normal blood flow elsewhere in the body. Loss of blood is interrupted by construction of a haemostatic plug. The presence of endothelium in the blood vessel uphold an anticoagulant surface that assist to sustain blood in its fluid state, if there is injury to the blood vessel contaminated components of the soft endothelial matrix are opened to the blood. At this stage two important mechanism of haemostasis is initiated, that is formation of blood clot and aggregation of platelets and fibrin.[1]The fibrinolysis pathway also plays a major role in thrombosis. If there is thrombosis or pathological bleeding can happen whenever this course is disturbed. Appropriate equivalence between pro-coagulant systems and anticoagulant systems plays a major role in legitimate haemostasis and prevent a formation of thrombus.[2,3]

Review of Literature: The anticoagulants are mostly used to prevent all kind of cardiac diseases; aspirin is the most commonly used drugs in these patients. Extractions in these patients who are undergone replacement of valves are mostly under anticoagulant oral therapy, as these patients may complains or at a risk of post-operative bleeding complications, in recent studies most of the authors they have come to a conclusion that anticoagulant medication should not be stopped before any kind of minor surgical procedure to prevent severe thromboembolic complications.[4] To prevent bleeding probabilities in patient under anticoagulant therapy, several measures has been described by various authors. Some authors have used antifibrinolytic agent such as local haemostatic materials for blockage of post-operative bleeding. Some authors have also used fibrin glue in the dental extraction sockets.[5,6]

Many authors have suggested use of platelet-rich plasma (PRP) in the dental socket without stopping the anticoagulant drugs. The goal of PRP is to improve healing through release of platelet growth factors. Many authors also suggest to do the INR (International normalize ratio) before doing extraction any kind of

Corresponding Author:
Dr. Sthitaprajna Lenka

e-mail: sthitaprajna@gmail.com

minor oral surgical procedure. If INR is increased then patients are advised to stop the anticoagulant drugs minimum of 3 days, then INR is again checked and if it is normal then the patient can be taken for dental surgery.[7,8]

If there is increase in the value of international normalize ratio the amount of bleeding during the dental procedure will be more. In literature there are cases has been reported where the cardiac patient under anticoagulant therapy, if the anticoagulant drugs are stopped prior to minor dental procedure without checking the values of PT/INR the patients had suffered from cardiac problem (coronary artery blockage). Few authors had also explained the dental procedure which has minimal invasive in nature there is no need to stop any anticoagulant drugs prior to the procedure.[9]

In major surgeries in cardiac patient under anticoagulant therapy, where there is a chance of bleeding can be managed with small doses of fractionated heparin and local haemostatic agent should be incorporated at the site of the surgery to prevent bleeding on the operated site. These patients usually be in the bed for a longer time so the chances of deep vein thrombosis (DVT) is higher. So low molecular heparin use should be implemented during the course of surgical treatment to prevent DVT.[10]

Dental Aspect: The patient with anticoagulant therapy has a tendency to bleed so these patients' surgical extractions should be avoided and patient has to be convinced for non-invasive procedure such as root canal treatment and other rehabilitation procedures. Cardiology consultation has to obtain from the patient before taking up any procedure, a high-risk consent form has to be signed from the patient before examination of the patient, to avoid any medico legal complications.[11]

INR should be used as a gold standard test in patient who are under warfarin therapy, if warfarin is stopped before or during the procedure the prevalence and incidence of hyper-coagulability. In the day of surgery, the values of INR should be preferably analysed, if the INR value is more than 3 then any minor dental surgical procedure has to be treated in hospital under the supervision of haematologist where the warfarin medication has to be altered and patient has to be shift to heparin instead of warfarin.[12-15]

The patient is under oral aspirin therapy the recent studies are stated that there is no need to stop aspirin during or prior to the extraction, in practise aspirin hardly hampers or cause any kind of complication during dental procedures, but other authors also stated that before stopping oral aspirin prior to or during surgery INR/PT value should be obtained or checked.[13-18]

Conclusion

The management of cardiac patient under anticoagulant therapy who comes to the dental hospital for dental treatment, requires the surgeon to create a harmony between the risk of haemorrhagic complication and the fatal risk of serious thromboembolic episode. The older guidelines where to stop oral anticoagulant therapy prior to the dental procedure to avoid the risk of bleeding during procedure or after the procedure. However, in recent studies maximum author has stated that none of the cases have fatal bleeding complication during oral surgery patient who is under therapeutic levels of warfarin sodium where as a high number of cases of embolic complication has been reported where the anticoagulant has been stopped. So, concluding before stopping any anticoagulants whether on the form of warfarin, heparin, oral aspirin do not stop it immediately before taking INR. If INR values are normal in their patient then no need stop anticoagulant therapy during dental procedure.

Epidemiology of Oro-facial Clefts

Debarchita Sarangi[1], Snigdha Pattanaik[2]

[1]Ph.D. Scholar & Assistant Professor, [2]Associate Professor, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Cleft defects are very common deformations in the head and neck region. This requires immediate intervention by specialists from birth. Counseling patient and family members from the initial period is vital. Treatment is done phase by phase. There have been various factors affecting prevalence of this defect. This article is a review of the epidemiology of cleft defects, observed in different regions and in India.

Keywords: *Cleft Lip and Palate, Prevalence, Incidence.*

Introduction

Oral and Facial clefts are one of the commonest congenital deformations which may involve lip, palate to other craniofacial structures. Oro-facial clefts have a psychological, social, behavioral impact on the patient[1]. There have been wide variations in ethnicity and race regarding prevalence of oro-facial clefts. Environmental factors, genetics and morphogenesis of palate formation play a major role in cleft and palate defects[2].

Review of Literature:

The global set-up: A study of data was retrieved between 1978-1987 in the Rhône-Alpes/Auvergne birth defects registry. It confirmed 903 cases with incidence of 0.67/1,000 for cleft lips with or without palate involvement and 0.44/1,000 for cleft palatescases. Cleft lip and palate are more frequent in males, and cleft palate are found to be more frequent in females.[3] In a study conducted in Kumasi were reported Ghana, Africa, 1.31/1000 congenital cleft defects[4]. In a study conducted among Brazilian oro-facial clefts patients, prevalence was 1 out of 1010 live births. 21.2%, 23.8%, 55% cases were identified with cleft palate, cleft lip and cleft lip and palate, respectively. 15.3% patients were syndromic, 10.4% patients had cleft lips with or without cleft palate, and 33.9% patients had Cleft Palate. There is 18.52% decrease in prevalence of non-syndromic cleft patients following fortification with folic acid in Brazil[5]. Prevalence of 0.5 per 1000 was found from data collected from 7 Smile Train centers from 6 geo-political zones in Nigeria in between September 2006 to June 2011. Prevalence was found to be 0.5 per 1000. A significant gender difference for cleft palate patients was observed with more females than males[6]. 389 surgeons from Africa filled questionnaires regarding 36,384 patients out of which 34.44% were lip clefts, 58.87% clefts of lip and palate, and 6.69% clefts of the palate only. There is male predominance with male to female ratio as 1.46:1[7]. In another study, data regarding prevalence of cleft lip and palate patients between 1990 and 2014 were collected. From 28 studies meeting the first inclusion criteria, the pooled live births were 31,475,278. The prevalence of undifferentiated cleft lip and palate was 1.38 per 1000 births. But, during secondary analysis, where 4 studies met the inclusion criteria, 75,627 births were observed with a prevalence of 0.75 cleft lip and palate cases per 1000 births. There was prevalence of approximately 1 in every 730[8].

In the literature search conducted through PubMed from 1950 and June 2015, 45193 Oro-facial Clefts patients from 30,665,615 live births were counted. In Asia 1.54-1.60, North America 1.53-1.59, Europe 1.52-1.58, Oceania 1.30-1.36, South America 0.96-1.02, and Africa 0.54-0.60 oro-facial cleft patients per 1,000 live

e-mail: drbarchita2016@gmail.com

births were reported. American Indians had the highest prevalence rates and the Blacks had the lowest rate of 2.62 per 1,000 live births and 0.58 per 1,000 live births, respectively. Differences based on ethnic origin, genetic, environmental factors and method of ascertainment, were observed[9]. A total of 202 Cleft Lip and Palate case records, registered in Kuwait from January 2009 to December 2014 were collected. Prevalence was 0.57 per 1000 live births. Males had slightly higher prevalence females. Babies to Kuwaitis parents were at a greater risk than those to Non-Kuwaiti parents. The prevalence difference across gender and nationality were statistically insignificant[10].

Indian set-up: A pilot project with a motive to establish basic standards of cleft patient care in India was started by Indian Society for Cleft Lip and Palate and Craniofacial Anomalies Meeting, 2006, at Guwahati, Assam. This also helped craniofacial treatment centers in India to participate in clinical research conducted by WHO. The generated data would be useful for comparison with that of other countries and would be used to improve quality of life of cleft patients[11].

A study conducted on the basis of GBD 2016 presents a relatively lower prevalence and incidence rate of OFC as compared previous results which was done in 1990 with increase in quality of life of patients[12]. Consanguinity of parents were searched among 18,242 patients in Hyderabad. 3653 cases i.e. 20.2% of total cases with consanguinity were identified. 57.8% parents had first degree of consanguinity whereas 3.5% had a positive family history[13]. A study of 926 patient records was done over a 10 year period (2007–2016) and Male to female ratio was 1.2:1[14]. Among 126 patient data accumulated from three centers by Kharbanda and et. al, a wide variation in age at primary lip i.e. range 2-60 months and palatal surgery i.e. 4-78 months was seen. 29% required lip surgeries, 35% required nose surgeries. A high proportion of them had hearing defects, tympanic membrane afflictions, relevant speech i.e. 60%, 56.3% and 40%, respectively[15,16].

Discussion

The major approach to diseases is evidence-based interventions to improve quality of life by treating and majorly by preventing the diseases[18,19]. Due to varied ranges of ethnic groups, factors associated, lack of access to healthcare and awareness a state-wise registry to maintain congenital defects is necessary for National record maintenance which should begin at grass-root levels[20].

Conclusion

Besides,Smile Train and Operation Smile, Deutsche Cleft, Mission Smile, and Lifeline Express have extended service for cleft patients in India and other countries. Systematic categorization of centers should be done to improve quality of service. Healthcare facilities have grown, but these are not adequate and even in terms of distribution and service. Though there is penetration of NGOs and other service providers, masses in the periphery still are deprived. Quackery and lack of awareness is adding up to improper treatment and outcome. Further research and surveys would definitely give solutions towards better service, patient care, management and awareness leading towards improved quality of life of cleft and palate patients.

Clinico-pathological Correlation of three Cases of Squamous Odontogenic Tumor, a Rare Entity in the Odontogenic Tumor's Arena!

Neeta Mohanty[1], Jay Gopal Roy[2], Sayani Dutta[3]

[1]Professor and Head, Department of Oral and Maxillofacial Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [2]Professor & Head, Department of Oral Pathology & Oral Medicine & Radiology, Burdwan Dental College & Hospital, Bardhaman, West Bengal, [3]Former Post-Graduate Trainee, Department of Oral & Maxillofacial Pathology, Dr. R. Ahmed Dental College & Hospital, Kolkata, West Bengal, India

Abstract

The squamous odontogenic tumour (sOT) is a rare, benign epithelial neoplasm of odontogenic apparatus that appears to originate from the rests of Malassez, remnants of the dental lamina or gingival epithelium. From its first documentation in 1975, Since then there is limited number of reported cases, especially in the Indian subcontinent. We report three cases of SOT with varied clinicopathological presentation and management. The first two cases presented as asymptomatic swellings in maxilla whereas the third one was in body of mandible. Variable radiographic picture ranging from well-defined radiolucency to mixed radiolucent-radiopacity was noticed among the three cases. All cases responded well to the conventional treatment therapy.

Keywords: *Squamous odontogenic tumor; Benign neoplasm; Radiolucency; Histopathology, Conventional treatment.*

Introduction

Squamous odontogenic tumor (SOT) is a rare benign neoplasm, was first described in 1975 and been classified as an independent entity in recent times.[1] Though the etiopathogenesis of this locally-invasive odontogenic epithelial neoplasm still remains a dilemma, it's been reported to be considered as a hamartoma, pertaining to its multiple site involvement and particularly due to its familial multicentric variety.[2] It occurs mostly in the third decade of life with equal propensity to both jaws. Radiographic features of SOT are non-specific and been described to be either well-circumscribed semicircular radiolucency or triangular-shaped radiolucent lesion adjacent to the roots of teeth. The lesion is usually central, but sometimes it may be peripheral.[1] The typical microscopic appearance includes islands of squamous cells in a mature connective tissue stroma. The most important aspect of this lesion is its mistaken histologic identification as an acanthomatous ameloblastoma or a well differentiated squamous cell carcinoma.[3] The most amenable treatment protocol is conservative surgical removal in the form of local excision or thorough curettage in cases of SOT. Slightly more aggressive intervention may be indicated for lesions of the maxilla and recurrence has been rarely.[4]

Case 1: A 38-year-old male patient reported with an asymptomatic enlargement of the right maxilla with obliteration of nasolabial furrow and discomfort of the regional teeth for 5-6 years (Figure 1 A, B). Though the regional teeth were found to be vital the patient gave a history of root canal treatment for right upper central incisor, lateral incisor, & canine teeth 2 years back at outside centre but the swelling did not subside.

Radiographic examination revealed the presence of a poorly defined radiolucent lesion that extended from mesial surface of right central incisor to mesial surface of second molar of same side with root resorption of right central incisor & displaced lateral incisor and canine (Figure 1 C, D, E).Subsequently during apicoectomy a solid mass was noted at the site of surgery which was fragile in nature and sent for histopathological evaluation (Figure 1 F,G). Histopathological examination revealed a well-circumscribed tumor that consisted of small islands of squamous epithelial cells. These epithelial islands were rimmed by a peripheral layer of cuboidal cells or flattened cells lacking a well-polarized palisading columnar epithelium characteristic of ameloblastoma (Figure 1 H, I). Histopathological diagnosis of SOT was confirmed. The patient was followed up for 12 months but no recurrence is reported.

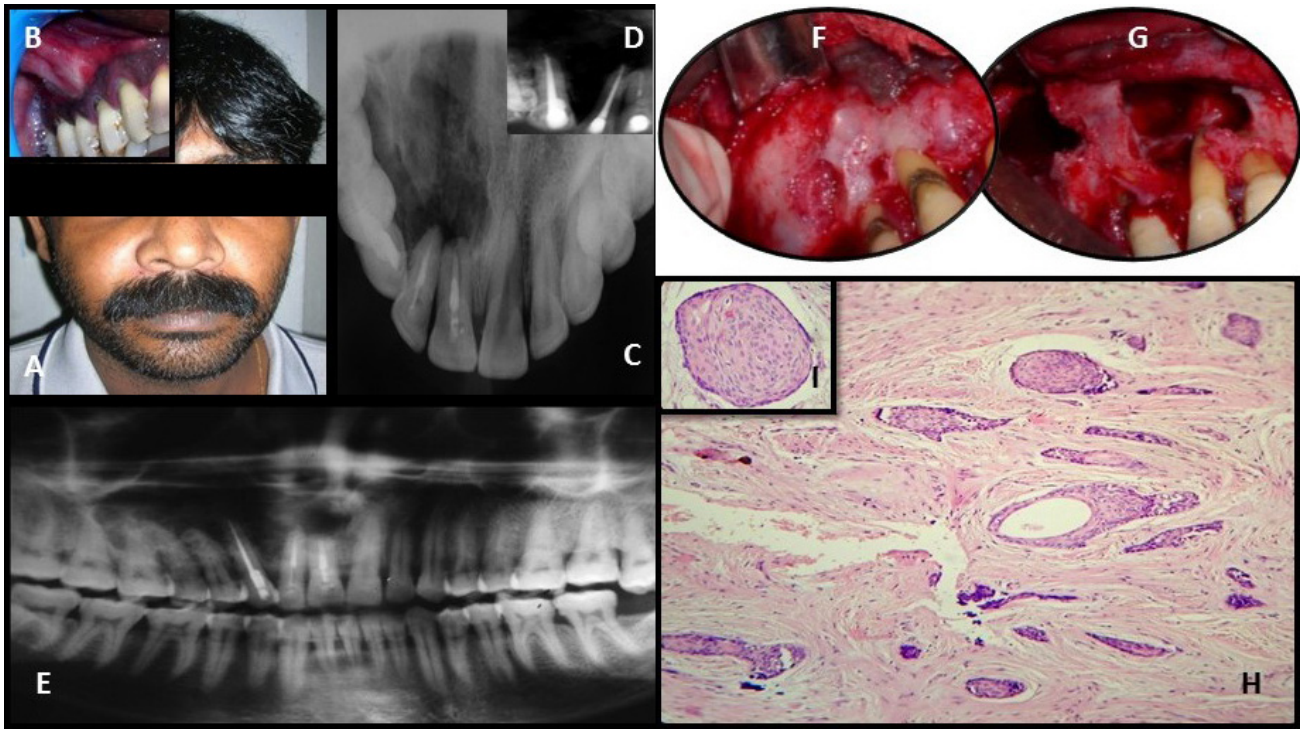

Figure 1. A: Extra oral examination showing swelling in right side of face; B: Intra oral examination revealed swelling in mucobuccal fold; C: Occlusal X-ray showing radiolucent lesion with irregular margins; D: IOPA X- ray showing displaced roots of two teeth; E: OPG X-ray of jaws showing a large radiolucent area extending from mesial surface of central incisors to mesial surface of 17 & root resorption of central incisor; H: Photomicrograph showing odontogenic epithelial islands & few areas of microcystic degeneration; I: Photomicrograph showing epithelial island surrounded by flattened epithelial cells & without any ameloblast like appearance

Case 2: A 45-year-old male patient reported with a complaint of painless swelling in the left maxillary anterior region for past 1 year. The lesion was well circumscribed with expansion of both buccal and lingual cortical plates (Figure 2 A, B). Left maxillary central and lateral incisors were extracted 4 years back. OPG showed the presence of a well-defined radiolucency without sclerotic margin causing root resorption of left maxillary canine, first and second premolar (Figure 2 C). Based on clinical and radiological findings a provisional diagnosis of cystic lesion was given. Excision of the lesion was done and tissue was sent for histopathological examination. Histological features were suggestive of the presence of islands of stratified squamous epithelium with peripheral cuboidal cells in dense fibrous connective tissue stroma. Micro cyst formation was noted in some epithelial islands and the diagnosis of SOT was established (Figure D, E, F).

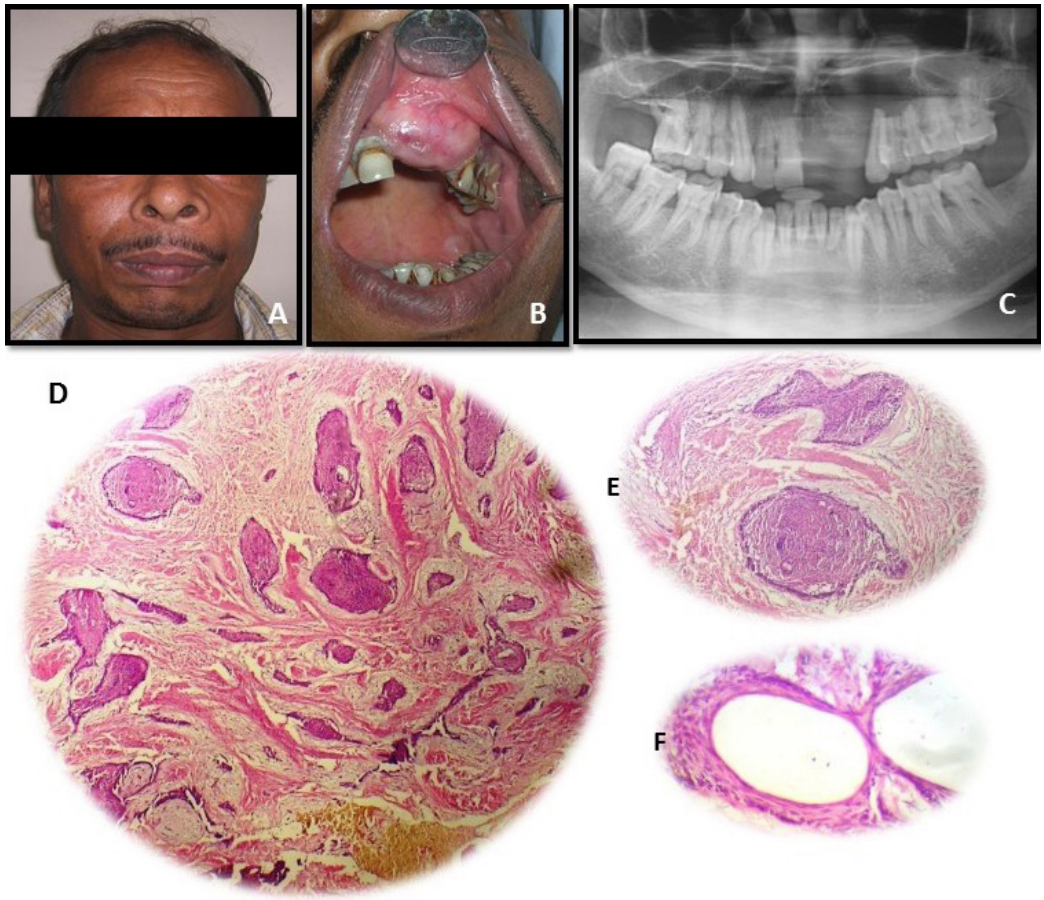

Figure 2 A: Extraoral view revealed swelling in the left upper region; B: Intraoral examination showed a well-defined swelling; C: OPG X-ray shows a well-defined radiolucency involving the anterior left maxillary region; D: Photomicrograph showing multiple islands with squamous epithelium in fibrous stroma; E: Photomicrograph showing high power view of islands with flattened peripheral cell; F: Photomicrograph showing high power view of microcysts formation within the islands

Case 3: A 20-year-old male came with a chief complaint of swelling on the right lower jaw for one year. The patient had undergone extraction of right lower molar by a local doctor due to swelling & pus discharge one & half years back. After 6 months he noticed a small swelling in the particular region which has gradually increased in size for which he was again treated by local doctor without any appreciable result. There was no relevant past medical or family history. On Extra-oral examination a bony hard, nontender swelling is noticed on the right body of the mandible. Intra- Oral examination revealed a bony hard swelling involving region of missing second molar & accompanied by bucco-lingual expansion (Figure 3 A, B). OPG of the jaws reveal relatively large radiolucent area extending distally from 43 to mesial root of 48 with multiple small radio - opaque foci of varying radiodensity & missing right second molar. Standard occlusal view shows bucco-lingual expansion of the cortical plates & missing second molar of the right side. After thorough examination of all findings, the provisional diagnosis is made out to be calcifying epithelial odontogenic tumor (CEOT). The patient was then subjected to radiographic examination. Incisional biopsy was done and the section stained with H & E revealed the presence of interlacing collagen fibers, proliferating fibroblasts, blood capillaries with R.B.C's & minimal inflammatory changes with the presence of multiple islands of squamous odontogenic epithelium & the cells at the periphery of the squamous islands are flattened(Figure 3 C,D).The overall histopathological features were confirmative of SOT. The patient was then referred to the Department of Oral Surgery for treatment & management. Conservative surgical procedure was done and regular follow ups did not reveal any recurrence.

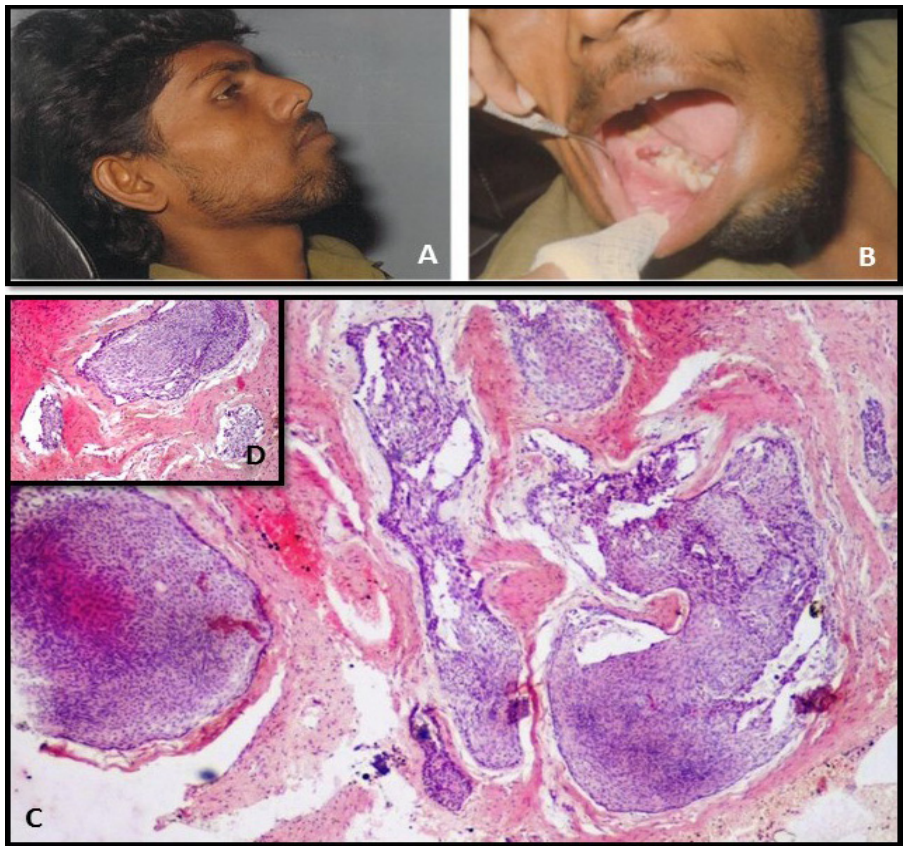

Figure 3A: Swelling on the right body of the mandible; B: Intra-swelling involving region of missing second molar with buccolingual expansion; C: H & E revealed the presence of multiple islands of squamous odontogenic epithelium; D: Higher magnification showed the cells at the periphery of the squamous islands are flattened

Investigations, Treatment & Follow Up:

Clinical differential diagnosis: Most commonly misdiagnosed with squamous cell carcinoma and ameloblastoma.

Radiologic differential diagnosis: Radiographically, the most common presentation of SOT is often semicircular or triangular, radiolucent defect between or along the roots of adjacent teeth. This is not pathognomonic and can mimic severe periodontal bone loss. Circumscription is characteristic, but the margin may or may not be corticated. Rarely multiple radiolucencies are observed in SOT.Along with periodontal bone loss other differential diagnosis can include Langerhans's cell histiocytosis, lateral periodontal cyst, odontogenic keratocyst (keratocystic odontogenic tumor) and central odontogenic fibroma.

Histopathologic differential diagnosis: The histologic differential diagnostic considerations for SOT are acanthomatous and desmoplastic variants of ameloblastoma. They can be ruled out as ameloblastic differentiation is not a characteristic feature in the SOT. Gingival squamous cell carcinomas when considered will display characteristic malignant features in contradiction to SOT. Similarly, bland islands of squamous epithelium are not featuring of primary intraosseous/odontogenic carcinomas either

Treatment: Surgical intervention was carried out

Outcome and follow-up: The patients were kept under observation and followed up for 12 months; without any signs of recurrence.

Discussion

SOT is a rare, benign epithelial odontogenic neoplasm, defined as a locally infiltrative neoplasm consisting of islands of well-differentiated squamous epithelium in a fibrous stroma with less than 50 cases

reported till date.[5]The first published case of SOT is to the credit of Pullon et al in 1975. They reported six cases and established diagnostic criteria and surgical approaches that are still followed today.[6] By screening the reported cases it is found that SOT occurs over a wide age range between 8-74 years with a mean of 38.7 years with a slight male predilection (M: F=1.8:1). However, due to paucity of documented cases relative frequency among odontogenic tumors cannot be determined.[7] It occurs in both jaws with equal propensity.[8] In maxilla lesions centre around incisor-cuspid area whereas in mandible lesions tend to occur in bicuspid molar area.[3]However, SOTs occurring in maxilla are found to be more aggressive than their mandibular counterpart because of the anatomy, porous and medullary natue of maxilla9. Multifocal variant and familial cases have also been reported.[10]

They are often asymptomatic but may present as a slow growing lesion with tooth displacement and mobility, ulceration of soft tissue, and usually without pain1. Most cases develop in the periodontium of permanent dentition. One case was associated with deciduous dentition and four cases were found in edentulous area.[7] Clinicopathologically three types are identified: intraosseous, mural (mural SOT-like proliferation in cyst), extraosseous form.[11] Radiologically the central variant shows a unilocular, triangular or semicircular radiolucent area with or without sclerotic border between the roots of adjacent teeth. Large SOTs, however, may show multilocular pattern. Root resorption is reported in some cases too as noticed in our first two cases. Surprisingly, variation in classical radiographic presentation of SOT in the present cases was observed. The first case presented poorly defined radiolucency whereas the mixed radiolucent radiopaque lesion was noticed in third case.The peripheral variant may show saucerization of underlying bone which is likely to be a pressure phenomenon rather than the result of true tumor infiltration.[6] Once such a lesion is detected thorough radiographic examination is required to exclude multiple tumours.[2]

Histologically, the tumour is composed of round to oval islands of squamous epithelium with a flattened or cuboidal peripheral cell layer in a mature, fibrous connective tissue stroma. These squamous cells have distinct intercellular bridges, individual cell keratinization but lack nuclear pleomorphism, stellate reticulum, mitotic activity or keratin pearl formation. Microcyst formation, laminar calcification, globular eosinophilic hyaline structure which is not amyloid may be found in the islands.[3] Circular areas of fibroblasts and fibrous condensation or hyalinization can be seen around some of the epithelial islands which suggest a connective tissue reaction to epithelial proliferation.[7] In our cases microcyst formation is seen but calcification and hyaline structures are not found.

SOT may pose diagnostic difficulties as it may be confused with acanthomatous ameloblastoma, desmoplastic ameloblastoma and well differentiated squamous cell carcinoma and this is a major reason for the paucity of documented cases. The fact that the peripheral cells are not ameloblastoma like and the absence of stellate reticulum should differentiate it from various types of ameloblastomas. Unlike well differentiated squamous cell carcinoma SOT does not show nuclear or cellular pleomorphisms and mitotic figures.[3]

The pathogenesis of SOT still remains unclear. SOT is histologically related to remnants of odontogenic epithelium, which includes cell rests of Serre (dental lamina rests), enamel organ and cell rests of Malassez (rests in Hertwig root sheath). Due to the widespread presence of odontogenic epithelium for a considerable time after birth some tumours may arise from residues of these cells in bone or in the soft tissue such as in gingiva (peripheral SOT). For the central variant, origin from periodontal ligament (rest of Malassez) is postulated due to its occurrence between the adjacent teeth, the pattern of bone destruction. However, in our second case the fact that the tumor was present in the edentulous area does not take away the possibility that it originated from rest of Malassez of teeth formerly present there.[7]The origin of peripheral SOTs is putatively from gingival rests of Serres or from gingival surface stratified squamous epithelium.[3]The nonperiodontal lesions can be attributed to genetic etiologies like mutation in ameloblastin gene which has an important role in epithelial-mesenchymal signaling during odontogenesis.[7]

SOT like proliferations have been reported in few cases arising from the wall of odontogenic cyst but they neither transform into a neoplasm nor alter the prognosis or the behavior of the cyst. Hence, they are considered as a reactive process only.[3,7]Biologically, SOTs are less aggressive than ameloblastomas but are more aggressive than SOT like proliferation in the cysts, except for those arising from the walls of odontogenic keratocysts.[7] Multicentric lesions are less aggressive

almost hamartomatous. However, care must be taken to differentiate such proliferation from the tumour itself.[2]

Immunohistochemical studies of SOT have confirmed the proliferative activity of odontogenic epithelial cells indicated by heavy staining for keratin 13\16, and the squamous differentiating cells in the centre of islands have shown a strong positive reaction for involucrin staining.[7]The treatment of SOT is conservative surgical removal in the form of local excision, enucleation, or thorough curettage. However, tumors located in the maxilla have to undergo a more radical treatment because of the aggressive potential of SOT in this location.[5]According to Hopper et al., the type of radiographic border may help define the type of treatment to be adopted since a more aggressive lesion has poorly defined radiographic border.[12]Recurrences seem to be extremely rare and are reported in only one case by Pullon et al and are most likely due to insufficient removal.[6]

Conclusion

SOT is a rare odontogenic neoplasm. The tumor is often asymptomatic, as a number of cases are accidental finding in routine dental radiographs, although it can present with symptoms of pain and tooth mobility. Clinical and radiologic appearances of such tumours may be similar to the other odontogenic neoplasms encountered in the jaw bones.As characteristic histopathological features of SOT are sufficient to elucidate the diagnosis from other mimicking aggressive lesions i.e. ameloblastoma and epidermoid carcinoma, evaluation of the entire clinicopathologic picture is necessary to forbid the over or under treatment of the same.

Malocclusions and Orthodontic Management of Syndromic Patients: A Review

Abhik Sinha

Former Post-Graduate Trainee, Department of Orthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A good oral health is important for one and all, and especially in patients with syndromes. A syndrome is defined as "a set of signs or a series of events occurring together that often point to a single disease or condition as a cause". Early diagnosis is important for having an effective treatment in these patients. The oral findings are generally the basis for diagnosis in early adolescence and is usually the time when a comprehensive orthodontic treatment is sought. Thus, orthodontists should be thoroughly aware of the patients syndrome and the clinical features with which they relate. The treatment intervention would likely require–aligning of teeth, management of cleft, management of functional shift such as–deviation, habitual posturing, arch coordination, and dis-impaction of teeth.

This review article aims to compile various clinical features of syndromes that are encountered in the dental office and the orthodontic aspects to be considered while treating such cases.

Keywords: *Oral health, syndrome, early diagnosis, orthodontic treatment, impaction.*

Introduction

The humans have diverse facial patterns and a wide variety of craniofacial morphologies are possible due to a combination of environmental and genetic factors.[1] The environmental factors often include–hormonal imbalances, trauma, poor nutrition, muscle dysfunction, mandibular posture habits, diseases of the pituitary gland, caries, premature loss of deciduous tooth, prolonged habits, enlarged tonsils and a low socioeconomic status.[2] The genetic factors could be–a disproportionate size of the teeth and the jaws; or a disproportionately positioned, sized or shaped mandible and maxilla.[3] Both of these factors interact to manifest as a malocclusion.

Malocclusion can be defined as "a significant deviation from an ideal or normal occlusion".[4] Lauweryns reported that genetic factors contribute to about 40% of the malocclusion.[5] Sometimes, these malocclusions associated with severe skeletal discrepancies are a result of a genetic syndrome. A Syndrome is defined as "a set of signs or a series of events occurring together that often point to a single disease or condition as a cause". Chromosomal aberrations, transpositions, deletions or breakage leads to a malformation of the first branchial arch. This further results in orofacial clefts, micrognathia, oligodontia, facial asymmetry and malocclusions. Cohen, Proffit, Bell and White classified syndromes which are commonly associated with malocclusions.[6] **(Figure 1)**

Various syndromes and their associated malocclusions

Pierre Robin syndrome: This was first described in 1923 by the French surgeon Pierre Robin. The genetic cause is usually a mutation in the SOX9 gene which causes formation of the Meckel's cartilage. It may also occur due to a deficiency in the Transforming growth factor–TGFB.3 and extreme flexion of the fetal neck.[7]

The characteristic feature is a bird face due to micrognathia. Butow et al in 2009 reported the presence of cleft palate in 75-100% of the cases. The tongue is abnormally dorsally positioned (glossptosis) resulting in respiratory difficulty, vagal syncope and problem with feeding. Tooth agenesis is prevalent in the permanent dentition between 30-50%, mostly affecting the mandibular 2nd premolars.[8]

Treacher Collins syndrome (also known as**Mandibulofacial dysostosis, Franceschetti syndrome):** It is an Autosomal dominant condition affecting 1:50,000 live births. It mostly occurs due to a mutation in the gene TCOF1 located on 5q32-q33.1 chromosome. This results in a failure in the differentiation of the maxillary mesoderm in the developing embryo.[9]

The Craniofacial features include–downward slanting palpebral fissures, coloboma of the lower eyelids, conductive deafness, atresia of the external ear, malar and mandibular hypoplasia, facial symmetry, hypoplasia of the soft tissues of the face, narrow arched palate and cleft palate (about 30%). Abnormalities in the Temporomandibular joint may also lead to a limited mouth opening and an anterior open bite. Obstructive sleep apnea syndrome (OSAS) have also been reportedly associated with this disease. The dental findings include–tooth agenesis in the mandibular 2nd premolars, followed by maxillary 2nd premolars, lateral incisors and maxillary canines. Malpositioned maxillary central incisors, ectopic eruption of the maxillary 1st molars and impacted maxillary supernumerary teeth have also been reported.[10]

Marfan syndrome: It is an autosomal dominant connective tissue disorder which is caused by a defect in the FBN1 gene encoding the connective protein Fibrillin-1.

The clinical features include–disproportionately increased height with long limbs and digits, moderate joint laxity, aortic aneurysm, mitral valve prolapse, GERD, degenerative disk disease, deviated septum, early cataracts, glaucoma, dislocated lenses, coloboma of iris, emphysema, flat feet, osteopenia, scoliosis and obstructive lung disease. The dental features include–high arched palate, retrognathia, temporomandibular joint disorders, dental crowding with an increased overjet and dentinogenesis imperfect.[11]

Beckwith Weidemann syndrome: This syndrome occurs due to a defect in the short arm of chromosome 11. The clinical features include–Congenital hernia, gigantism, midline abdominal wall defects such as–omphalocele, umbilical hernia, ear pits, and neonatal hypoglycaemia. The orofacial features include–macroglossia, macrosomia, and an increased facial height.[12]

Goldenhar syndrome (also known as **Hemifacial Microsomia, Oculo-Auriculo-Vertebral (OAV) spectrum, Facio-Auriculo-Vertebral (FAV) sequence):** This syndrome occurs due to a duplication in the OTX2 gene, resulting in an anomalous development of the first and second branchial arches. Environmental causes may include a fetal exposure to drugs like–Thalidomide, retinoic acid, and primidone.

The clinical features include–an incomplete development of the ear, nose, lip, soft palate and mandible on one side of the body. There will be associated hearing loss, coloboma of the upper eyelid, hypoplasia of the zygomatic bone and facial muscles usually on one side, obstructive sleep apnea and cleft palate (10% of cases). It may also involve internal organs like–heart, kidneys and lungs.

Cephalometrically, the patients demonstrate an upward cant of the occlusal plane, smaller body and ramus of mandible on the involved side, steep gonial angle and convex facial profile. The dental features include–shorter mesiodistal dimension of mandibular 1st permanent molar on the affected side, and tooth agenesis most notably in the mandibular 2nd premolar and 2nd molar.[13]

Neurofibromatosis (also known as **Von Recklinghausens disease):** This is classified as a Gingivodental syndrome having both gingival hyperplasia and dental manifestations. The cause is a mutation in the NF1 gene on chromosome 17q11 and shows an incidence of 1 in 2000-3000 live births.

The characteristic Neurofibromas are benign tumors that appear along nerves and in proximity to the spinal cord. Other hallmark features include–café-au-lait spots and iris Lisch nodules. These will be variably accompanied by Hypertension, scoliosis and facial paralysis. The craniofacial features include–macrocephaly, short maxilla, mandible and cranial base, low facial height, marked antegonial notch, increased length of the coronoid process, hypoplastic condyles and zygomatic processes. Intraorally, unilateral hyperplasia of the gingiva is evident. Alongside, impacted, missing,

displaced or supernumerary teeth and spacing may be present.[14]

Crouzon's syndrome: This syndrome is characterized by premature craniosynostosis and follows an autosomal dominant trait. The clinical features include–brachycephaly with a large frontal bony swelling, hypertelorism, exophthalmos, hypoplasia of maxilla, mental retardation, resemblance of nose with parrot's beak. The oral features are–crowding of teeth, V-shaped arch, high arched palate, complete cleft palate, bifid uvula, cross bite or open bite and partial anodontia.[15]

Aperts syndrome: This is an autosomal dominant disorder resulting from mutation in the FGFR2 gene on chromosome 10. The syndrome is characterized by malformations of the skull, face, hands and feet. The clinical features include–craniosynostosis, brachycephaly, prominent forehead with a flat posterior skull, maxillary hypoplasia, mandibular prognathism and syndactyly. The oral features are usually–high arched palate and crowded teeth.[16]

Downs syndrome: Downs syndrome is caused due to the presence of an extra 21st chromosome (trisomy 21). The clinical features include–mental retardation, epicanthal folds, brushfield spots in iris, dysplastic ears, congenital heart disease, simian crease, clinodactyly, brachycephaly, flat facial profile, and flat nasal bridge. The oral findings demonstrate–large protruding tongue, ANUG, open bite, anterior or posterior crossbite and smaller sized teeth.[17]

Cleidocranial dysostosis (also known as **Cleidocranial dysplasia** and **mutational dysostosis**)**:** This is an autosomal dominant disorder caused due to a mutation in the RUNX2 gene located in the short arm of chromosome 6 and affects osteoblastic differentiation. The clinical features include–underdeveloped or missing clavicle, marked frontal, parietal and occipital bossing, delayed closure of fontanelles and sutures, hypertelorism, brachycephaly and reduced lower anterior facial height. The oral features involve–high arched palate, complete palatal cleft, supernumerary teeth, underdeveloped maxilla, delayed eruption of both deciduous and permanent teeth.[18]

Orthodontic management of syndromic patients[19]**:** Several obstacles are encountered during the therapeutic access of these patients, such as–reduced understanding and apprehension, limited cooperation, uncontrolled movements, exaggerated gag reflex, and drooling. Thus, even routine dental procedures like–impression taking and radiography becomes quite difficult.

Tooth brushing is not properly practiced by such patients which is manifested by presence of food debris, plaque and gingival inflammation. This makes the patient more prone to caries. Restorations and root canal treatment should be carried out prior to the start of orthodontic treatment.

The orthodontic treatment plan should be redirected towards more limited goals and provided on a modular basis. The following adaptive modifications can be made during treatment -

1. Removable appliances should be preferred over fixed appliances wherever possible. If fixed appliances are to be used, then straight wire appliance or tip-edge appliance with simple mechanics should be prescribed. Arch expansion can be carried out in shorter modules separately.
2. The material of choice for impression taking should be Elastomeric impression material as it is patient friendly, do not induce gag reflex like alginates might do, and multiple casts can be retrieved from a single impression.
3. Syndromic patients may have problems with excessive salivation. Thus, antisialogogue drugs should be prescribed before procedures, an newer generation of etchants with moisture controlled primers should be used.
4. Indirect bonding of brackets should be preferred to reduce the chairside time.
5. Self-ligating brackets should be promoted as it reduces the chairside time and allows less frequent visits, while also avoiding lacerations and a better oral hygiene can be achieved too.
6. The orthodontic intervention would likely require–aligning of teeth, dis-impaction of teeth, management of cleft, and management of functional shift such as–deviations, habitual posturing and arch coordination.
7. Both removable retainers and bonded lingual splints can be used for an extended period of retention with a little cooperation from the patient. Sedation sessions can help for bonding procedures.

For patients with Hemifacial microsomia, use of hybrid functional orthodontic appliances and distraction osteogenesis can be helpful to treat moderate asymmetries. Staged orthognathic surgery would be an appropriate treatment for severe craniofacial asymmetries.[20]

In patients with Treacher Collins syndrome, a detailed evaluation from an Otorhinolaryngologist should be done as reduced nasal airway volume and subsequent impaired phonation and Obstructive sleep apnea are likely.[21]

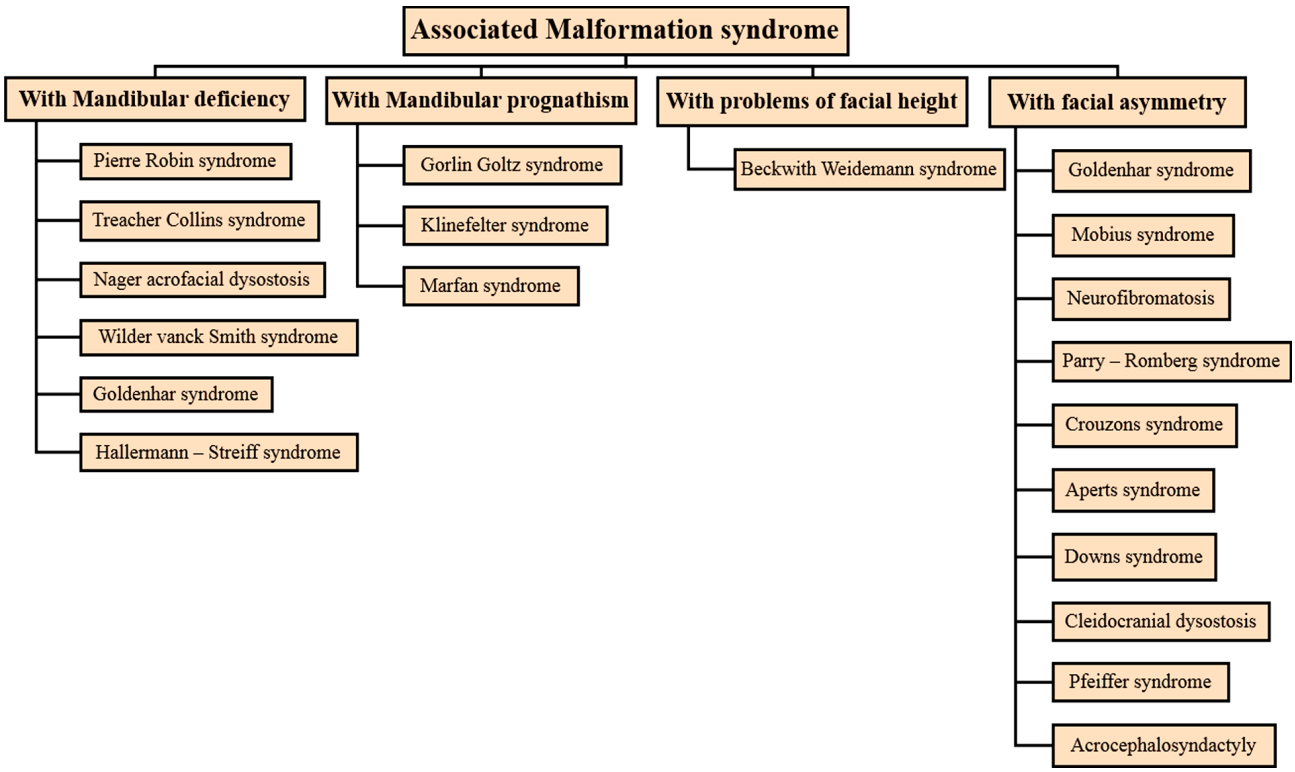

Figure 1: Cohen, Proffit, Bell and White's classification of syndromes which are commonly associated with malocclusion

Conclusion

The dental development and facial growth only completes at around 14 and 18 years respectively. Thus, early detection of syndromes and interventions concerning the timing of orthodontic and surgical treatment becomes difficult.

The orthodontists should be thoroughly aware of the patient's syndromes and the clinical features with which they relate. The treatment plan should be designed keeping in mind factors such as–increased root resorption, hypomaturation of bone and teeth, delayed healing, supernumerary teeth, missing teeth and presence of any cysts. Thus, treatment should be aimed at removing the hurdles in performing routine activity rather than keeping high expectations on outcome.

A Clinical Study on Evaluation of Vertical Accuracy of Interocclusal Registration Materials in Centric Relation

Abhilash Mohapatra[1], Jayshree Mohan[2], Debarchita Sarangi[3], Paul Simon[4]

[1]Professor, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [2]Professor and HOD Department of Prosthodontics and Crown & Bridge, Vinayaka Mission's University, Salem, Tamil Nadu, [3]Assistant Professor, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [4]Professor, Vinayaka Mission College, Salem, Tamil Nadu, India

Abstract

Purpose: The purpose of this study is to evaluate the ability to accurately record, maintain and reproduce vertical interocclusal relationship of four bite registration materials i.e. (Aluwax, zinc oxide eugenol, polyvinylsiloxane, bisacrylic resin bite registration materials).

Statement of problem: It is necessary to evaluate recording materials for their accuracy to record, maintain and reproduce these maxillo-mandibular relationships as they are transferred from the mouth to the articulators.

Materials and method: Maxillary & mandibular cast were articulated in maximum intercuspation in split cast technique on the Whipmix articulator. This position was adopted as reference position for displacement measurement of the four materials. Two arbitrary points are selected on the right and left side of the cast to avoid operator tendency of repetition of the value. The measurements were calculated as the difference between the readings of the two points. The interocclusal records were placed and the measurements were taken. The difference in the two reading gave the vertical discrepancy with each material.

Results: ANOVA and Tukey test were used. The result was statistically significant. Wax plus zinc oxide eugenol and wax plus aluwax showed significant difference statistically & clinically in recording the relationship.

Conclusion: The bisacrylic resin and polyvinylsiloxane bite registration materials can record the interocclusal relationship accurately. Wax plus zinc oxide eugenol paste and wax plus aluwax produced significant discrepancies in recording the relationship.

Keywords: *Aluwax, bisacrylic resin, interocclusal records, Lucia Jig, polyvinylsiloxane.*

Introduction

An accurately recorded maxillo-mandibular relationship is important for success of any prosthesis and it should be accurately transferred to the articulator. These relationships are dynamic and change during life. Recording of jaw relations in prosthodontics treatment aims at facilitating the adaptation of prosthesis to optimum level of comfort and function to the patient. To achieve this goal, the recording must include various jaw relations, in order to develop occlusion that will function in harmony with existing masticatory apparatus.

The centric relation record is the most important and most difficult maxillo-mandibular relation record to make. In centric relation, stable occlusal contact can be developed. Registration of correct centric jaw

relation is the primary objective of any prosthodontist to establish harmony within stomatognathic system, improve functional ability and masticatory efficiency. A recording material is necessary to register the patient's inter-arch relationship. Inter-occlusal recording material records the centric and eccentric relationship and aid in replicating them on mounted casts on articulators.

A satisfactory inter-occlusal registration, the materials must have the following characteristics: low viscosity, low resistance to mandibular closing, no adherence to the teeth, plasticity, appropriate working time, rigidity after setting, precision of details, dimensional stability, easy handling, acceptability to the patient, and low cost[2,3,4,5,6].

In the present study, four interocclusal registration materials in centric relation in two techniques were compared, materials were used alone or combinations of materials were utilized which are as follows:

- baseplate wax with aluwax,
- baseplate wax plus zinc oxide-eugenol paste,
- Luxabite bis-acrylic resin, and
- Jetbite bite registration polyvinylsiloxane material

The aims of the study were t*o evaluate the vertical distance using Aluwax bite registration material*, wax plus Neogenate Zinc oxide–eugenol paste, Luxabite, bisacrylic based bite registration material and Jetbite polyvinylsiloxane bite registration materials and to compare the various materials used for the study for its accuracy in recording the maxillo-mandibular relationship in right and left side of the patient, individually and on the whole.

Materials and Methods

This present in-vivo study was conducted in the Department of Prosthodontics, during 2007-2010. Comparison of the vertical distance of four different materials against the vertical distance at maximum intercuspation in the right and left side of the patient was done. The vertical distance is assessed by travelling microscope with a precision of 0.001cm and magnification of 10X.

Five male patients in the age group of 20 -35 years were selected for the study and they met the following inclusion criteria : Complete dentition up to the second molar, Normal systemic and physiologic histories, Angle's class I, Absence of signs and symptoms of temporo-mandibular disorder, Diagnostic cast showing stability in centric occlusion position.

Impression of maxillary and mandibular arches were obtained using dual mix, dual impression method with polyvinylsiloxane impression material and poured with Type IV die stone. Base-former was used to pour the base. The graph paper was cut and glued to the base in the right and left region of both maxillary and mandibular casts.

The method utilized in this study **for obtaining the centric relation for fabrication of baseplate wax record[7,8]** is a combination of bimanual manipulation and anterior stop technique given by H. Shillinburg[8]. The bimanual manipulation programs the muscle from centric occlusion position to the trained centric relation position and the jig helps to retrude the condyle where it is influenced by the posterior slope of the fossa.[48] An anterior programming device or jig is made to establish the predetermined stop to vertical closure with the condyles in optimum position and was given by Lucia. A small piece of aluminum foil 0.2µm was burnished to the lingual surface and incisal edge of the maxillary incisor. Then 2ml of auto-polymerizing monomer and 4ml of acrylic polymer were mixed in a dapen dish and at a dough stage it was applied to the foil on the cast and gently molded to a sloping ramp. Before the acrylic set it was transferred to patient mouth and using the thumb and index finger the resin was adapted in the lingual side and the patient was made to close in the previously trained centric relation position. The mandibular incisor indentation in the jig was checked and it was trimmed till there was a separation of posterior teeth by 1mm. With the jig in place the baseplate wax record was re-softened and placed in position using the canine flaps as index.

For registration of record using aluwax[8,9]: 10 registrations of double thickness baseplate wax records were obtained using the jig in centric relation. The areas of indentation of the teeth in the record were removed and the aluwax was flowed over the area. The record was again placed in the mouth with the jig in place and the registrations were recorded. The registrations were removed after the wax was cooled, disinfected and kept in container with water until analysis was done.

For **Registration of record with wax plus zinc oxide - eugenol impression paste[8,9]:** 10 registrations of

double thickness base plate wax records were obtained using the jig in centric relation. Zinc oxide- eugenol bite registration paste were taken out in small quantity i.e 6mm in length of base and accelerator along with a small amount of petrolatum and mixed thoroughly on a clean glass slab with cement spatula. The teeth are first coated by petrolatum then a small amount of the paste is then placed in the indentation area of both the maxillary and mandibular teeth on the wax record and replaced in the mouth with the patient instructed to close until the mandibular incisor firmly contacts the programming device. After the material has set the excess registration paste is removed i.e 1.5mm from the cusp tip in all direction[4]. The registration's were then disinfected and kept in moist environment for further analysis.

For Registration with luxabite bisacrylic resin: Adequate amount of luxabite registration material were applied on the left and right side of the occlusal surface of the molars. Luxabite were composed of bisacrylic resin and were supplied in a double cartridge in 4:1 ratio form and are dispensed with an automix–dispenser supplied by manufacturer. With the jig in place, the mandible was placed in centric relation position. The material was allowed to set for 40-60 seconds and the patient was instructed to slightly separate the teeth and reclose to ensure that the bite registration is not locked on. An additional 2 minutes was allowed for the materials to final set and then it was removed. 10 such registrations were made and finished with acrylic trimmers. The deep grooves and occlusal embrasures are removed that may not be well registered in the model.

For Registration with Polyvinylsiloxane (Jetbite registration paste)[9]: 10 registrations were made by placing the bite registration material on the occlusal surface of the right and left side molars and premolar and with the jig in position the mandible was closed in centric relation position. The Jetbite polyvinylsiloxane are supplied in auto- mixing cartridges with a spiral mixing tip and spreader tip as provided by the manufacturer. The cartridge was loaded in the auto-mixing gun and the two tips are attached as instructed by the manufacturer. Registrations were removed from the mouth, disinfected and stored in plastic packets (humidor) in absence of humidity for further analysis.

For measuring the vertical distance: The maxillary cast was seated in the indentation on the Quickmount facebow and was attached to the Whipmix articulator. The cast was attached to mounting ring with low–expansion, fast-setting plaster. The mandibular cast was manually articulated in maximum intercuspation to the maxillary cast in a split cast technique with the articulator in an inverted position. It was then maintained in the same position by stabilization with plastic tongue blade & sticky wax. And this position was adopted as reference position for displacement measurement in four different studied materials & technique. Two arbitrary points are selected on the right and left side of the cast to avoid operator tendency of repetition of the value and the measurements were calculated as the difference between the readings of the two points. Mandibular cast was then disarticulated and to relate the mandibular cast properly to the maxillary cast, the incisal pin should be lowered sufficiently to compensate for the thickness of the centric relation record. On the occlusal surface of the maxillary cast the interocclusal records are placed, and the mandibular cast was seated on the record with the Lucia jig in place. The cast was stabilized with plastic tongue blade & sticky wax and articulated in a split cast technique for each record. Then the readings of the vertical distance are taken from the two arbitrary points with a travelling microscope. Difference in reading of the vertical distance with the material and at maximum intercuspation is calculated individually for each record in the left and right side. And the data was then statistically analysed.

All the interocclusal records were evaluated under the same procedure. Only one investigator made all the measurement in the study. To minimize the polymerization shrinkage polyvinylsiloxane were stored in plastic packet & distortion the materials were prevented by storing in humid environment. And the records were taken to the laboratory for measurement as soon as possible. To minimize error the average vertical discrepancy was calculated on both the right and left side of the cast.

The mean and standard deviation were calculated for the vertical discrepancies associated with different materials for the right and left side under which the study was performed. Because the distribution of the sample was normal, the analysis of variance (ANOVA), and Tukey test were used.

Results

The measurements were taken taking the difference of individual records in vertical distance from maximum intercuspation vertical distance. Analyses of variance

(ANOVA) were done comparing the 4 materials. Since the P value is less than 0.01 there is significant difference in the 4 materials. There is no significant difference in between wax plus Aluwax and wax plus zinc oxide eugenol records. The polyvinylsiloxane & bisacrylic shows significant difference when compared individually with the other materials. And also bisacrylic is the best among all of them as it showed the least mean in the right side.

The measurements were taken taking the difference of individual records in vertical distance from maximum intercuspation vertical distance. Analyses of variance (ANOVA) were done comparing the 4 materials. Since the P value is less than 0.01 there is significant difference in the 4 materials. On the left side no significant difference was found in the polyvinylsiloxane and bisacrylic material. But the wax plus aluwax and wax plus zinc oxide eugenol showed a significant difference when compared with other materials. And also as the mean value of bisacrylic is least it's the best among the four materials on the left side.

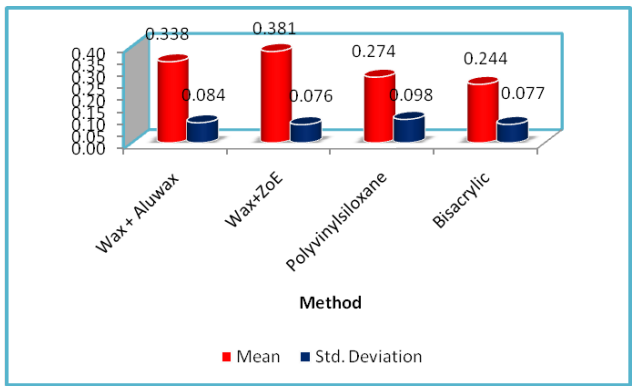

Figure 1: Graph I - Mean and standard deviation of four materials for the 5 patients on the right side.

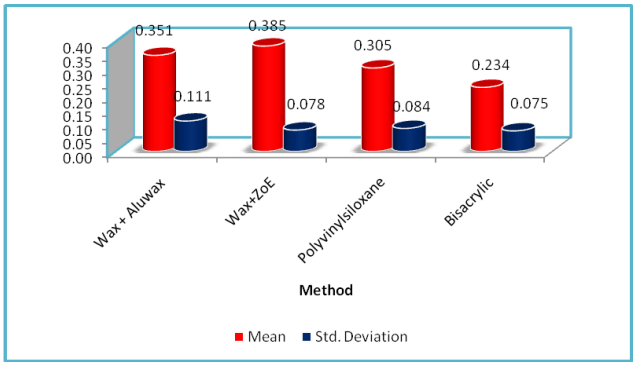

Figure 2: Graph II - Mean and standard deviation of four materials for the five patients on the left side.

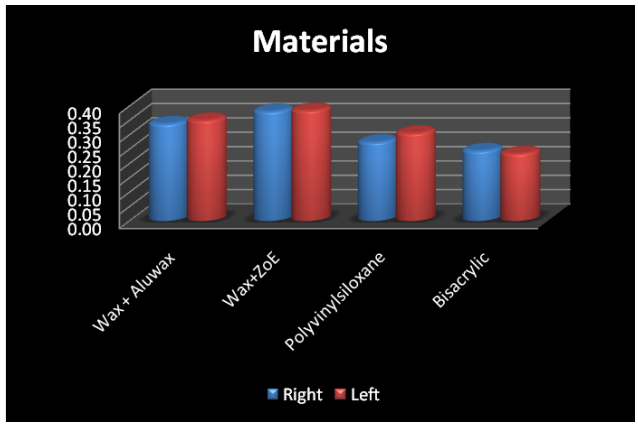

Figure 3: Graph III - Comparison of mean and standard deviation of four materials for the five patients on the left and right side.

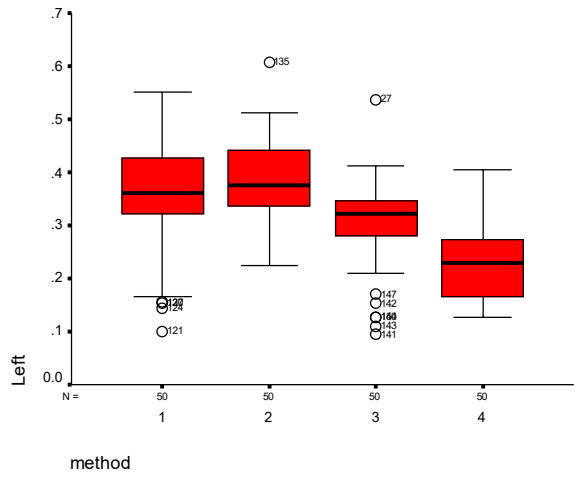

Figure 4: Graph IV- Averages, range of variation, and standard deviation on the left side.

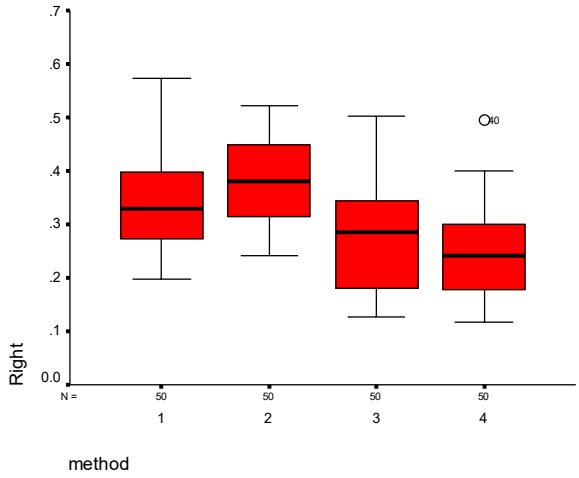

Figure 5: Graph V - Averages, range of variation, and standard deviation on the right side

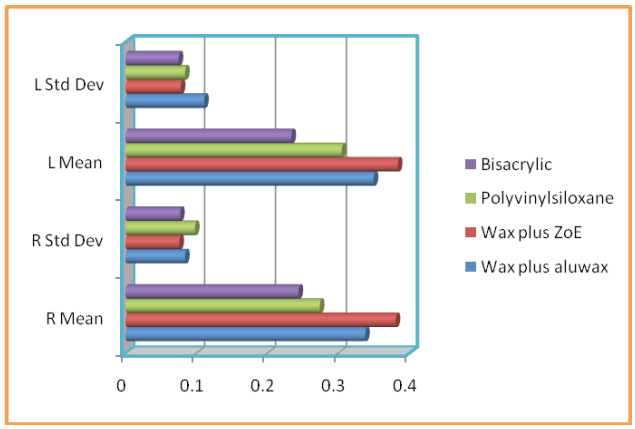

Figure 6: Graph VI - Comparison of mean and standard deviation of right and left side.

Discussion

The four main method of recording centric relation are as follows; 1) unguided method, 2) chin point guidance with anterior jig by Anderson & Tanner, 3) P. Dawson's bimanual manipulation and 4) tongue to palate technique. Kantor[10] compared all these method and found that bilateral manipulation gave the greatest replicability in patients.

The materials most frequently used for making centric inter-occlusal records can be broadly classified as physical, thermal and chemically setting e.g zinc oxide-eugenol pastes and non eugenol pastes, impression plaster, waxes, acrylic resin, polyvinylsiloxane and polyether materials. Waxes have been used in the shape of quadrant strips, wafers and complete or partial arch wafers since long time[11].

Dawson[12] stated that, criteria for accuracy in making inter-occlusal records include

- Recording material must not cause any movement of teeth or displacement of soft tissues.
- Recording material must fit casts as accurately as it fits the teeth intra-oraly.
- Accuracy of the jaw relation that has been made should correlate in the mouth and on the casts.

Freilich and Wahle[13] stated that apart from dimensional stability and accuracy, relative elasticity and rigidity are also relevant to duplication of intra oral inter-occlusal relationship on articulator. When the study was analyzed it was evident that bisacrylic resin Luxabite and polyvinylsiloxane Jetbite gave constantly accurate interocclusal registrations. So these materials can be advocated in routine recording of interocclusal registration instead of waxes which are most popular among the clinicians.

In Figure 1, the graph shows that the mean and standard deviation of each material were compared for five patients on the right side. The standard deviation and mean was found to be least for bisacrylic records and highest for wax plus zinc oxide eugenol records. Figure. 2 shows the mean and standard deviation of each material compared for the five patients on the left side. The standard deviation and mean was found to be least for bisacrylic records and highest for wax plus zinc oxide eugenol records. Figure. 3 shows the comparison of mean of the right and left side of four materials in the five studied patients. The mean is least for bisacrylic on the left side and most for the wax plus zinc oxide eugenol on the left side. Figure 4 shows a comparison of the mean, range of variation and standard deviation in centric relation of each four materials for the five patients in left side. Figure. 5 shows the averages, range of variation and standard deviation of centric relation position with each material in the right side. In Figure. 6, when comparison was made of mean and standard deviation of right and left side it was found to be without any significant difference. On the right & left side the aluwax and polyvinylsiloxane were the materials with highest standard deviations and range of variance. The mean was highest for wax plus zinc oxide eugenol and least for bisacrylic resin in both left and right side.

Conclusion

Bisacrylic resin Luxabite was a material of choice for interocclusal registration. It has the advantage of ease of handling, and rigidity, dimensional stability after setting. Polyvinylsiloxane Jetbite was found to be second best materials statistically and clinically in the study. The wax plus aluwax, and wax plus zinc oxide eugenol material were found to be comparatively inaccurate bite registration material in the present study. In place of dentate patient, partial edentulous patient with prepared tooth can be taken for further studies. Some research should be done to reduce the dimensional change that is observed in aluwax and polyvinylsiloxane bite registration materials. The bisacrylic resin which becomes very hard when it set, and had to trimmed to articulate properly, so some modification can be done on this material to reduce this.

Pleomorphic Adenoma: An Overview

Subhashree Priyadarshini

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The salivary glands are exocrine glands which that produces saliva through ducts. Two types of salivary gland MAJOR and MINOR salivary glands. Salivary glands can be as serous, mucous or seromucous (mixed). The secretion is mediated by parasympathetic stimulation, acetylcholine in the active neurotransmitter and binds to muscarinic receptors in the gland, leading to increase salivation. The salivary glands consist of major and minor glands. The salivary gland tumors are divided into benign and malignant tumors. Pleomorphic adenoma is the most common benign tumor affecting salivary gland. It majorly affects the parotid gland and palate most commonly the hard palate. It develops in both major and minor salivary gland. This article represents a case of pleomorphic adenoma in the minor salivary gland of hard palate.

Keywords: *Pleomorphic Adenoma, Salivary Glands, Minor Myoepithelioma, Submandibular Gland, Salivary Gland Neoplasms.*

Introduction

Pleomorphic adenoma constitutes more than 50% of all tumors and 90% of all the benign tumors of salivary glands. It can affect both the major and minor salivary gland but mostly affects the parotid gland and also affect the rest submandibular glands. It arises from the myoepithelial cell of salivary glands. Both epithelial and connective tissue elements are seen in the tumor so it is named as MIXED TUMOR. It mostly affects the palate and may as affect the lips, buccal mucosa and retromolar region[1]. It mostly affects women more than men in the 4th, 5th, 6th, decade of life. Pleomorphic adenoma affects the palate most commonly (42.63%), followed by the lip (10%), buccal mucosa (5.5%), retromolar area (0.7%) and the floor of the mouth.

These are readily movable without fixity to the deeper tissues or to the overlying skin. The size of the tumor can increase but will not ulcerate[2]. Tissue destruction, pain or facial paralysisis not seen. Tumors in the oral cavity like Pleomorphic adenoma usually starts as painless small nodules which gradually grows. The tumor is the hard palate is seen early because f difficulty in chewing, swallowing or talking. It shows fixity in the palate due to underlying done but doesnot invade the bone. It is usually asymptomatic due to painless intermittent growth[3].

The diagnosis is usually based on physical, radiographic, histopathologic examination.

Differential diagnosis

Lipoma

Hyperplastic lymph nodes

Neurilrmmona of the facial nerve

Wartin's tumor

Squamous cell carcinoma–Both may contain squamous epithelium with keratinization and may be difficult to differentiate in small biopsy or cytology material. Myoepithelioma and myoepithelial carcinoma–contain exclusively myoepithelial cell. Epithelial components is less Radiology increases the risk of developing pleomorphic adenoma[4,5].

Histology: The tumor consists of epithelial and connective tissue components arranged in complxed manner. Myoepithelial cells are the particular features of pleomorphic adenoma. A rare type immune cell known as plasmacytoid myoepithelial cell are special feature

Intern, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University
e-mail: subhashreepriyadarshini@gmail.com

of minor salivary gland tumor. Spindle cells, clear cells and oxyphilic cells may also be present. The tumor is surrounded by pseudocapsules or false capsules[6]. Area of scale like metaplasia and epithelial pearls may be present. The histology may differ in appearance which varies in every individual tumor. The tumor extends through normal glandular parenchyma in the form of finger like pseudopodia,which is not a sign of malignant transformation[7].

The intraoral pleomorphic adenomas which affects the minor salivary gland palate are noticed early because of difficulties in mastication speech etc. They grow slowly in a painless manner without any ulceration with intermittent growth in size.

The diagnosis of this mixed salivary gland tumor is based on basic history,physical examination, histopatology. On physical examination we can see a non tender,fixed,consistent growth. CT scan and MRI are done to provide size location and extension of tumor. The CT scan may reveal no perforation but cupped out resorption of the pallet. There may not be any major changes in hematology investigations but by performing biopsy we can see several histologic changes[8,9].

Treatment: The treatment of pleomorphic adenomas are mainly surgical excision. Needle biopsy can also be performed before the surgery to confirm the diagnosis. More specific surgical treatment or supportive radiotherapy can be performed on the basis of the development of the tumor into benign or malignant the parotid gland tumors are removed with adequate margins where as the intra oral regions can be removed by performing conservative surgery. The benign parotid gland tumors are treated with superficial or total paroitdectomy. The facial nerves should always be conserved when possible[10,11]. Submandibular tumors in case of that, excision of the gland with the tumor is performed. The removal of the tumor shoud be removed by careful dissection[12]. Wide excision with negative margins is the optimal strategies for the management of pleamorphic adenoma.Irradation is contraindicated as the tumors is radioresistant. The tumor does not reoccurs if the excision is done properly[13].

Complications: Infection, salivary fisula, hemorrhage, hematoma, numbness, asthetic irregularities are the common complications of parotidectomy. If the excision is left incomplete it may lead to recurrence[14]. If the adenoma is left untreated for long time it may lead to malignancy. The tumor which has ulcerations and causes facial paralysis have the potency to get malignant[15].

Conclusion

Pleomorphic adenoma is a uncommon salivary gland tumor which can be removed by local excision if diagnosed early or else we have to undergo the removal of whole tumor. Reconstruction is only necessary if there is full thickness defect in the bone otherwise excellent results is seen when the wound is allowed to heal itself. The recurrencs unknown but the long followed process is required.

Abstract

The use of tobacco is not new to the society, similarly the extreme consequences of the abuse of the same is not hidden. The product is best known for killing its most loyal customers. The use of tobacco is global it kill almost half of the people who consumes it. Geographically covering the Indian subcontinent, Southeast Asia and some areas covering the locations of western Pacific. With furthermore migration to inner city areas of many countries, this habit is known to be present in its practitioners. This habit has been having on communities a major cultural and social role. The effect of usage of is still a mystery to many dentists due to lack of knowledge and awareness about the prevalence of the diseases caused in the oral cavity. The acknowledgement of the role of these products in the development of pre malignant lesions in oral cavity and oral carcinomas is very vital for a dental practitioner to know. This emphasizes on the importance of acquiring knowledge about the encouragement to habit cessation as it is directly affecting the improvement in mucosal lesions clinical symptoms.

Introduction

The habit of betel quid or areca (BQ) chewing is not new, it has an ancient background in whole. The imprints of this is not just limited to our country or any specific age group, the spread is global and often includes every section of the society even involving women as well as children[1]. Social acceptability, perceived health benefits, religious beliefs and constant addiction are the four main factors that influence a chewer of betel nut and maintain its popularity. In the positioning of most commonly consumed psychoactive materials in the globe after caffeine, alcohol, nicotine is followed by betel nut, hence ranking the fourth most used product. Betel nut is obtained from Areca catechu palm tree, is present in number of products including paan masala, mawa, paan, gutkha, khaini etc[2].

The term "quid" may be defined as "a substance or mixture of substances (in any mass-produced or treated form), placed in the mouth or chewed and remains in contact with the mucosa, usually containing one or both of the two basic ingredients, tobacco, or betel nut, in raw or any manufactured or processed form". Thus, BQ is to be considered as a specific variety of quid; it indicates any type of mixture or quid that includes betel leaf.

Various categories of BQ include:

1. Quid with betel nut but without tobacco products (betel nut quid) which may involve chewing only the betel nut or betel nut quid wrapped in betel leaf (paan)
2. Quid with tobacco products but without betel nut(tobacco quid) including chewing tobacco, chewing tobacco plus lime, mishri (burned tobacco applied to the teeth and gums), moist snuff, dry snuff, niswar (a different kind of tobacco snuff), and naas (a stronger form of niswar)

3. Quid with betel nut as well as tobacco products (tobacco and betel nut quid).

It is believed the use of this product results in attaining euphoria, increasing salivation, achieving satiation, reducing fatigue and even believed to reduce toothache[3]. The use of Betel nut is harmful to health. Even after knowing about the deleterious effect on human health it still continues to prevail as the highest consumed product in the South and Southeastern Asia, covering up to (10–20) % of the world population[4]. Betel Quid (BQ) has been ranked as Group 1 human carcinogens by the International Agency for Research on Cancer and the World Health Organization[5]. In the past few years several researches and large scale studies have proven even just using quid in the absence of slaked lime and tobacco it may result in potentially malignant lesions in the oral cavity followed by malignancies. The effect of these can be broadly divided into 2 sections. Firstly, its effect on dental Hard tissues (includes tooth, which is supported by the periodontium and the TMJ i.e. Temporomandibular Joint) and the second is the Soft tissues (comprising of the mucosa which lines the oral cavity)[6].

Effects on Hard Tissues:

Attrition, Abrasion and Fracture of tooth: The most common problem that is seen in the users are loss of occlusal tooth surface also knows as attrition, loss of cervical tooth structure also known as abrasion and chipping off of tooth fragments mainly incisors and cuspal loss i.e. fracture of tooth, is because of the hard fibrous texture of the betel nut. The above mentioned problems result in hyper sensitivity and often resulting in pain in advance stages. The degree of damage is directly dependent on the hardness of the betel, duration it is kept in the oral cavity and the frequency of its consumption[7].

Staining: The chewing results in a copious red saliva. With the chronic use of BQ this stains embed in the teeth and the soft tissues around the tooth. And with the increase duration and frequency the staining ranges from red to slowing transforming into black. Polymers of orthoquinones have been proven to be the reason of blackening of the tooth.

Dental Caries: The prevalence of dental caries have been lower in BQ users than in non-chewers[8]. The possible hypothesis to this statement are several. Some of them are as follows:

a. The coating formed by the use of BQ often forms a physical barrier of the tooth in turn helping in preventing demineralization.

b. Tannin in BQ is believed to have antimicrobial activity which in turn result in the cariostatic activity

c. The loss of occlusal tooth structure releases the pits and fissures hence resulting in no food accumulation in those complex areas which is more prone to caries.

d. The use of BQ is seen to increase salivation and often in addition of slake lime the overall pH of the oral cavity is noted.

e. The attrition resulting in sclerosed dentine may deliberate the protection from the invasion of microbes causing caries.

However the above mentioned hypothesis are yet to be proven. Many researchers have been working on this field and some have shown that there is no such significant decrease in the caries index of the BQ users than compared to non-users in the Asian population[9].

Temporomandibular Joint (TMJ) Disorders: The masticatory forces that are being used in BQ users could result in Temporomandibular dysfunctions. It is often confusing the exact cause of TMJ deterioration as the pathologic conditions associated with the BQ chewing results in secondary changes in TMJ for example in Oral sub mucous fibrosis that is the stiffness in fibrotic bands often results in trismus.

Effect on Soft Tissues:

Diseases of the periodontium: The cytotoxic nature of BQ towards the periodontal fibroblasts often accelerated the already present periodontal problems and ultimately resulting in the detachment of periodontal ligament and subsequent increase in calculus deposits. [10] The establishment of the statement cannot be done firmly as there are several other factors that is associated with the declining periodontal health including dietary factors, oral hygiene habits, dental health status etc.

Oral Mucosal Lesions: These are mainly comprising of 2 categories:

a. Lesions and conditions that are outlined diffusedly and are involving not just only one site but several site causing a field alteration, for example the lesions resulting from mechanical trauma or chemical reaction.

b. Various intraoral lesions and conditions fall into this category, the exclusions include staining's caused by quid[11]. These are often the site of lesion are restricted to the site of placement of the BQ.

Chewers Mucosa: The peeling up of the oral mucosa or its desquamation due to the traumatic action and condition results in detached tags of mucosa can be often found in these users. The areas of desquamation often appear wrinkled and pseudomembranous. The locality might also show imprints of reddish or brownish stains in the mucosa. This can be easily found and seen in the chronic users[12]. These lesions clinical appearance as well as histologic appearance is somewhat similar as of cheek biting, lip biting, morsicatiobuccarum and/or labiorum. Hence it is very important to differentiate the same by thorough examination and proper history taking as well as correlating with age related habits. The exact pathogenesis of the chewer mucosa is unknown but it is somewhat established that the physical and chemical factors plays a significant factor. BQ consumption results in a ROS (reactive oxygen species) production and has a direct relation in the commencement processes in tumor, followed by mutation, genotoxicity and/ or making the oral mucosa vulnerable to the elements present in BQ and the toxicants that are present in the environment. This ultimately changes the structure of the oral mucosa. At the moment BQ chewers mucosa doesn't come under pre malignant lesions, although this is anyhow related to other mucosal lesions like OSMF (Oral submucous fibrosis), tobacco induced lichenoid reactions, leukoplakia etc. which comes under the classification potentially malignant lesions.

Quid-Induced Lesion: These lesions often occur in the site of regular placement of the BQ, hence it is often localized lesion. The most important characteristics of these lesions are as follows:

- Alteration in the color of the mucosa
- Appearance is mostly wrinkled
- Mucosa is often thickened
- Epithelial surface may or may not be scrapable
- Incidence of ulceration

Betel nut related lesion: Lesions resulting from tobacco and lime, sniff induced and BQ induced. Often it is noted that there may not be any significant changes in the oral mucosa of a user unilaterally or bilaterally, however present of greyish white patch often unscrapble is present. The consistency can be described as rough linen like texture and if seen histologically the slide shows epithelium that is ortho-keratinized or/and para-keratinized[13].

Lichenoid reaction: There has been widely reporting of quid induced lichenoid reaction. The lesion is somewhat similar to lichen planus but with some noticeable minor differences. The clinical features include whitish, fine wavy lines, which do not intersct with each other often in zig zag pattern, often smooth and in many lesions radiating from an erythematous areas center. These are often seen at the site of quid abuse. Earlier this lesion was termed to be Lichen Planus like lesion, but with time this has got a new name that is 'betel quid lichenoid lesion'. This lesion reduces with many factors including the number of time it is consumed, the duration of time kept in mouth and the different site change during the chewing process. On complete cessation of habit there have been cases reported about total reversion of the lesion[11].

The pathogenesis of these BQ related lesion are under Type IV contact hypersensitivity reactions.

Oral Leukoplakia: It can be defined as "predominantly white patch or plaque on the oral mucosa that cannot be characterized clinically or pathologically as any other disease and is not associated with any other physical or chemical agent except tobacco."

Leukoplakia has been classified into several types. One of which is based on its appearance clinically:

- Homogeneous Leukoplakia (often white in color)
- Speckled Leukoplakia (both red and/or white in color)
- Verrucous Leukoplakia
- Nodular Leukoplakia[14]

Several epidemiological data shared proves the correlation between BQ use and leukoplakia[15,16].

Oral submucous fibrosis (OSMF): OSMF was coined in the year 1966 by Sirsat and Pindborg, was defined as "as an insidious, precancerous, chronic disease that may affect the entire oral cavity and that sometimes extends to the pharynx[17,18]."

The lesion is often associated with blanching or marble like appearance often marked by restricted mouth opening and fibrous bands present in the buccal mucosa,

restricted tongue protrusion and shrunken uvula because of the inflammatory reaction in the sub epithelial layer which is then followed by changes in the lamina propria (fibro elastic changes) and then followed by atrophy of the epithelium. Often results in burning while eating normal to spicy food.

There are basically 3 stages clinically to evaluate:

- Somatitis phase (oral mucosa is erythematous and appearance of vesicles is see)
- Fibrosis (the vesicles in the previous stage then eventually rupture to form ulcers which then in the process of healing get fibrosed.)
- Sequelae (then finally the fibroses lesion extends and disrupts various mouth functions)[17]

Trismus is often a resultant of fibrosis.

Oral Squamous cell carcinoma: BQ use has been proven and establish to cause oral carcinoma[19, 20].

Conclusion

Clearly it is proven that BQ has adverse effect not only in hard tissues of oral cavity but also the soft tissues of the oral cavity. Awareness among the users as well as the practitioners is much needed in this scenario. Working hand in hand and understanding this subject will play a vital role in eliminating the ailments associated with BQ consumption.

Role of Mass Media in Dentistry

Deekshya Drishadvati

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Mass media plays a key role in our day to day life, its impact can be negative or positive depending upon the way its used. Mass media has a very broad range of audience, who can be made aware by repeated broad casting or advertising oral care messages using TV, radio, internet, newspaper etc. Majority of public who does not have access to dental treatments and are unaware of the consequence of poor oral hygiene live in rural areas. Some are illiterate some not well to do but everyone is connected to mass media in some form or other. The awareness messages then compete with commercial promotion of products, addiction and habits.

Keywords: *Dental Health Education, Mass Media, Radio Communications, Television.*

Introduction

India is a developing country with a bulk of its population living in rural areas.India's overall dentist to population ratio- 2.7 lakh registered dentists for a population of 134 crore- is about one dentist for 5000 people, well above the WHO recommended ratio of one for 7500. But the problem is extensive in rural areas because the dentists are clustered in urban areas[1]. Also the dental infrastructure is very lacking in rural areas and many people still consider oral health and dental hygiene are of secondary priority[2].

According to NOHP (National Oral Health Program)'s survey conducted in 2007, dental diseases affecting the majority of Indians are periodontal diseases, dental caries, cleft lip & cleft palate, malocclusion, and oral cancer. Periodontal diseases are most common with a prevalence of >90% (advanced disease in 40%), then dental caries with a prevalence of 40-45%, oral cancer per lakh population and so on. Since past few decades disorders related to oral health are the most prevalent disease groups in India, particularly oral cancer due the extensive consumption of tobacco in India. India is considered the world capital of oral cancer. This is why it's very crucial to provide dental health education on a large scale as prevention is better than cure.

Mass media refers to mass communication through different technologies. Mass media can be divided into print media, outdoor media and electronic media. Print media can include books, newspapers, magazines, etc. Electronic media consists of television, movies, internet, social media, radio, etc and outdoor media consists of posters, billboards, etc. Individuals who are not conscious about dangers of poor oral health and does not have regular dental check up, can gain considerable amount of information from news media, which includes both newspapers(print media) and television(electronic media). Societal accountability of mass media to provide accurate and evidence based information to the community can not be ignored[3].

Role of Social Media: Internet and social media now has become the most important portal from which we can glean knowledge regarding oral health and related information. Some of the most popular social media platforms are facebook, youtube and twitter.

Benefits:

- All the informationis open and easily accessible for the users.
- Dental education- Teaching staff and professors use social media to engage with students and get feedback from them, which they can use to modify or improve their traditional teaching style. It also

Corresponding Author:
Dr. Deekshya Drishadvati
Intern, Institute of dental sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: deekshya@gmail.com

helps the students to improve their knowledge, peer teaching etc. the students can use sites such as 'Junior Dentist Blog' or 'Student Dental Network Forum' to further their knowledge[4].

- Social media can be used by Dental schools and Universities to attract students.
- It can also be used by various dental hospitals and clinics to attract patients through direct communication by the dentist, informing them, answering their queries, blogging, posting videos of various procedures alleviates their fear and anxiety.
- Patients can also be recruited for online surveys, online studies and various clinical trials.
- Consumers and patients can give feedback (consumer ratings) on dental product or services which then influences other consumers in their decision.
- In the past, there was an intermediary approach towards the health care service but now it has changed to apomediary approach which refers to cutting out the middle man that is the health care professionals and getting the information directly with the help of apomediaries which guide them to relevant information[5].
- Social media also works as free marketing when patients post their experiences, its works as modern day word of mouth for dentists and dental clinics. But on the other hand if the posts are about bad experiences, it can affect their reputation.
- Online presence of dentists helps to advertise their practice and facebook is the most popular platform for it.
- 'Dental Buzz', 'Dental Town', 'Dental Lab Network' are some of the popular sites where dentists can communicate, discuss other dentist's approach to a certain case and debate with each other. Using these sites they can remain up-to-date with latest dental news and recent advances or technology in the field of dentistry.
- Social media can give access to specialists in other fields who can give suggestions related to clinical cases and procedures.
- Learning from each other by sharing and discussing cases. But special care should be taken so as to not betray any doctor patient confidentiality during posting of the cases. Social media should not be used as way of raising concern.
- Various online support groups are there and can be helpful for patients having rare diseases and disorders.
- Social media facilitates communication between patients-doctor and patient-patient discourse.
- Online consultations are getting popular nowadays.
- Easy to refer a patient and remain in contact when the patient is shifting.
- Health information can be accessed from the internet any where at any point of time from various sites[6].

Limitations:

- There is a lot of information online and self diagnosis by the patients can be harmful.
- Lack of interest in visiting dental clinics and hospitals if the service is available online at home.
- Various diseases are diagnosed by inspection, palpation and percussion, which are not possible during online consultation and can lead to misdiagnosis.
- It happens to be expensive at times and cannot be afforded and accessed by everybody.
- Sometimes people access sites that are unauthorized and unscientific and end up with some sort of vague and misleading information.

Role of Print Media and Outdoor Media in Dentistry: Print media is defined as "The means of mass communication, which uses printed publications, such as newspapers, tabloids, magazines, books, journals, pamphlets, etc. to disseminate information to the general public"[7]. After the advent of social media and television people were disguised of the misconception that print media will become irrelevant. Far from it, magazines and newspaper reading is a popular and widespread tradition in India even after the arrival of television and internet[8].

Newspaper caters to a very wide range of people and of various age groups, especially in rural India its still very much a part of their life."Print media offers a more physical, tangible medium to consumers." Print media can also have a localized presence that is harder to achieve with digital media. Newspapers can be local, regional or national published in daily, evening, weekly or Sunday editions[9].

Benefits: Advertising on billboard and posters gives the opportunity to reach patients that are on the move. Outdoor advertising when done properly with research and is informative, it will be beneficial for both the practitioner and the patients as it simultaneously attracts patients and makes them aware about oral health[10].

In case of social media we reach out for information which is selective and need-based on the other hand print media covers a wide range of topics. When boards and posters (on oral health) are displayed on various landmarks it is hard to ignore and stays in our mind for a long time.

One of the most ordinary and common form of mass communication is through posters, which are very effective even in low awareness and literacy areas. The main advantage of posters is that the messages displayed are simple, to the point, artistic and very eye catchy. Their placement should be in places where large masses of people gather regularly like bus stands, hospital, etc and to maintain their effect they should be changed regularly[11].

Newspapers and magazines are very effective, popular and affordable visual aid for educating as well as communicating oral health information.

Role of Electronic Media in Dentistry: Very efficient and effective as oral health care practices like tooth brushing techniques can be demonstrated through audio visual aids like television and computer. They are the most effective form of communication of oral health education among children[12].

In case of print and social media people need to be educated to be able to read the information provided but one does not need education to understand the information provided audio visually. Display of oral cancer ads before the start of the movie and during interval time in movie theatres. Dentists can advertise their practice. Commercial dental product advertisement who uses real dentists and not only promotes their product but also informative for example sensodyne[13].

Promoting Oral Health through Mass Media:

Schools: If the children are educated about oral health in their formative years and its practice incorporated into their daily routine, oral care will become a habit for them.

Some of the programs are:

- Colgate's "young India" bright smiles, bright futures school dental health education program
- (Chacha Neheru Sehat Yojna) school health scheme, New Delhi
- Pit and fissure sealant pilot project- National oral health program (NOHP), AIIMS, New Delhi
- Trinity care foundation–Bangalore

Role of mass media: Regular organisation of oral screening/treatment camps, slogan/essay writing, poster, glass painting competitions are effective among students. Teachers and parents should be involved actively. The laws pertaining to banning of tobacco products within 100 yards of educational institutes and selling of tobacco products to individuals less than 18 years of age should be strictly practiced. Teachers and parents should encourage healthy eating habits among the students and teach them healthy oral care practices such as brushing twice daily, flossing after eating, etc[14].

Tobacco and Oral Cancer: India ranks second in producing and consuming tobacco. Mortality due to tobacco in India is 8-9 lakh (approx.) individuals per year. Over 80% of oral cancers are due to the use of tobacco. Use of tobacco (smoke/smokeless) can cause aggressive periodontitis;loss of tooth, delayed wound healing, pre-cancerous and cancerous lesions, etc. One of the most popular, extensive and influential mass media campaign in India is oral cancer and tobacco cessation which caused many positive changes.

National Tobacco Control Programme

- COTPA (cigarette and other tobacco product act) in 2003
- Govt. of India ratified WHO's FCTC (framework convention on tobacco control) in 2004
- NTCP (National Tobacco Control Program) launched by MOH & FW

Role of mass media: As directed by Ministry of Broadcasting (MoIB) and Central Board of Film Certification (CBFC) directs that movies and TV programs that show tobacco use should display hazards of tobacco use 30 sec at the beginning and 20 sec at the middle of the program. There should not be any advertising and promotion of the use or sale of tobacco and related products as directed by M/O I & B and

Advertising Standard Council of India (ASCI). Over the years many NGOs, advertising companies and publishing houses have helped the cause[7]. CPAA (cancer patient's aid association) is one such NGO which organises awareness programs at factories, hotels, schools, offices, etc. and distributes information brochures. Various infomercials, short films, posters, etc helps to raise awareness. Organisation of lectures, mass pledges, posters and slogan writing competitions on the subject piques the interest of students. Free screening camps, creation of support groups helps to persist because the chances of faltering are greater in an individual[8].

Fluorosis: Fluoride constitutes as an important caries preventive but in excess may affect bones, teeth, kidney, thyroid, etc adversely. According to WHO, acceptable level of fluoride intake should remain between 0.5-1.0mg/L. In case of dental flourosis, affected individual becomes aesthetically compromised and show stained chalky white teeth with pitting on it. In 2008-2009 govt. of India started National Program for Prevention and Control of Flourosis (NPPCF) to manage flourosis[5].

Some of the programs by govt. of India to tackle flourosis issue through safe drinking water are-

- Flourosis mitigation in Nuapada District, Odisha (2005)
- National rural drinking water program (NRDWP) IN 2009, etc.

Role of mass media: People should be made aware about the impact; exposure to flourosiscan have on health. Talks, lectures, demonstration of deflouridation techniques should be done in areas with high fluoride content. Creating awareness about drinking water and diet through group discussions, posters, boards, etc. The priority should be in setting up of diagnostic facilities, surveillance and encouraging community participation.

Recently AIIMS along with Union Health Ministry launched, 'e-Dant SEVA' which contains list of all dental collages and services and a distinctive feature called the 'symptom checker'. Some of the programs launched by IDA or in association with IDA are 'Swachh Mukh Abhiyaan', 'healthy Mouth healthy Body', and 'Healthy Smile Happy Smile' which is targeted for school children.

Conclusion

India constitutes of very huge and diverse group of people with varying awareness about oral health. It requires enormous amount of resources and commitment to provide necessary oral care knowledge to each one of them. Mass media to some extent alleviates that problem. Oral health awareness camps, roadside rallies and street plays are also a part of mass media. Where technology is unable to help, that extra effort through plays and rallies could be of help. Mass media should be used as a tool through which to spread knowledge and understanding among public. There is no warranty that they will put them into practice but without knowledge there is no choice. Wide-spread media campaigns facilitate dialogue amongst the masses which may further lead to policy change.

Orthodontic Considerations in Diabetic Patients: A Review

Abhik Sinha

Former Post-Graduate Trainee, Department of Orthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Orthodontic patients traditionally had comprised of only the young and healthy people. With its gaining awareness, elder patients with systemic disorders have also been seeking treatment. This means, an increased number of diabetic patients also report to the orthodontic office. Diabetes mellitus is defined as "a chronic, progressive metabolic disease characterized by hyperglycaemia resulting from defects in insulin secretion, action or both". Thus, it becomes necessary for the orthodontist to have knowledge pertaining to the types, cardinal signs, and oral manifestations of diabetes mellitus and keep them in mind while planning for orthodontic treatment. This article reviews in detail Diabetes mellitus from its historical perspective, prevalence, classification, cardinal signs, pathogenesis, oral manifestations, and the management options to be considered in terms of–before and during treatment along with the emergencies that might pop up in case such a patient is undergoing treatment in an orthodontic set-up.

Keywords: *Diabetes mellitus, metabolic disorder, hyperglycemia, prevalence, emergencies.*

Introduction

Orthodontic treatment has traditionally been considered a treatment choice for the young and the healthy. An increase in the esthetic awareness among the masses has, however, resulted in adults seeking orthodontic treatment. Many of these adults suffer from various chronic diseases and one among them is definitely Diabetes mellitus. Diabetes mellitus is defined as "a chronic, progressive metabolic disease characterized by hyperglycaemia resulting from defects in insulin secretion, action or both".[1]

Historical perspectives: Aretaeus of Cappadocia, an ancient Greek physician coined the term 'Diabetes' meaning Siphon. He noticed that the ants were enticed by the wonderfully sweet urine. Cullen added the word 'mellitus' to the name 'Diabetes', which means 'honey', considering the sweetness that a diabetic urine has. Celsus described the cardinal signs–polyuria, polyphagia, polydipsia and a loss of weight.[2]

Incidence and prevalence: Diabetes is the most common amongst all endocrinological disorders, which is characterized by pancreatic β-cell destruction and a resultant dysfunction in glucose metabolism, insulin resistance, inadequate insulin and glucagon secretions. Data from 2010 reports suggest that an estimated 221 million people worldwide are suffering from Diabetes.[3] Its peak incidence is usually in the 5th decade of life, however, below the age of 20, approximately 0.24% was found to have diabetes. Among these, 3-10% have Type 1 diabetes. There is no gender predilection for type 1 diabetes. Type 2 diabetes is more common globally. Almost 5% of all children and adolescents are estimated to have Type 2 diabetes due to a high caloric diet, mental stress and a decrease in physical activity.[4]

Classification

I. Type 1 diabetes (β-cell destruction, usually leading to absolute insulin deficiency)–
   - A. Immune mediated
   - B. Idiopathic

II. Type 2 diabetes (may range from predominantly insulin resistance with relative insulin deficiency

Corresponding Author:
Abhik Sinha
Former Post-Graduate Trainee, Department of Orthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

to a predominantly secretory defect with insulin resistance)

III. Other specific types–

A. Genetic defects of β-cell function–Chromosome I2, Chromosome 7, Chromosome 20, Chromosome I3, Chromosome I7, Chromosome 2, Mitochondrial DNA

B. Genetic defects in insulin action–Type A insulin resistance, Leprechaunism, Rabson-Mendenhall syndrome, Lipoatrophic diabetes

C. Diseases of the exocrine pancreas–Pancreatitis, Trauma/Pancreatectomy, Neoplasia, cystic fibrosis, hemochromatosis, Fibrocalculouspancreatopathy

D. Endocrinopathies–Acromegaly, cushing's syndrome, glucagonoma, phaeochromocytoma, hyperthyroidism, somatostatinoma, aldosteronoma

E. Drugs- or chemical- induced–Vacor, pentamidine, nicotinic acid, glucocorticoids, thyroid hormone, diazoxide, β-adrenergic agonists, thiaxides, dilantin, γ-interferon

F. Infections–congenital rubella, cytomegalovirus

G. Uncommon forms of immune-mediated diabetes–"Stiff-man" syndrome, anti-insulin receptor antibodies

H. Other genetic syndromes sometimes associated with diabetes–Down syndrome, Klinefelter syndrome, Turner syndrome, Wolfram syndrome, Friedreich ataxia, Huntington chorea, Laurence-Moon-Biedl syndrome, Myotonic dystrophy, Porphyria, Prader-Willi syndrome

IV. Gestational diabetes mellitus

Diagnosis of Diabetes: The general clinical symptoms of diabetes are–polyuria, polydipsia, polyphagia, fatigue and weight loss. For young type 1 diabetic patients, the first presentation is of Diabteic ketoacidosis and recurrent infections in the skin and mucous membrane. The diagnostic criteria established by the American Diabetes Association (ADA) includes[5]–

i. Fasting plasma glucose level > 126 mg/dL

ii. 2-h plasma glucose level >200 mg/dL with 75 g glucose and Oral Glucose Tolerance Test (OGTT)

iii. Random plasma glucose > 200 mg/dL in clinically suspected patients

The criteria for gestational diabetes mellitus is a little different, allowing a 2-h level of upto 140 mg/dL, above which is considered diabetic.[6]

Pathogenesis: The processes that lead to the development of diabetes are–

i. Genetic defects

ii. Destruction of the islet cells by inflammation, cancer or trauma

iii. Endocrine disorders such as anterior pituitary hyperfunction, Cushing's disease and phaeochromocytoma,

iv. Administration of corticosteroids

The type 1 diabetes develops due to–environmental, immunologic and genetic factors and causes destruction of the pancreatic β cells.

Type 2 diabetes, on the other hand, develops due to–resistance to insulin secretion, and an inadequate insulin secretor response. Type 2 has a stronger genetic component and has almost a 60–90% chance of being present in monozygotic twins.[7]

Diabetes mellitus also manifests with–microvascular, macrovascular and neuropathic complications. The disease also shows dental complications. The following theories have been put forward to explain these complications–

i. Diabetic related microangiopathy theory: The small and medium sized blood vessels are affected, resulting in a reduced blood flow to the organs and tissues. This further leads to–ischaemic toothache, tenderness of gums, bone erosions and tooth loss.[8]

ii. Polymorphic dysfunction theory: This theory explains the recurrent oral infections and ulcers.

iii. Protein metabolism impairment theory: The presence of hyperglycemia impairs protein metabolism, resulting in collagen disruption and a delay in wound healing.

Oral manifestations of Diabetes in patients seeking orthodontic treatment: Orthodontic treatment was more common initially among adolescents and young adults. Nowadays, even elders seek orthodontic treatment and hence patients with diabetes are also encountered.

The oral symptoms associated with diabetes include–Xerostomia, glossopyrosis, acetone smell from mouth of poorly controlled patients, brittle teeth, dental caries, recurrent candida infections, ulcerations from mouth, altered taste sensation, delay in the healing of injured mucous membrane. They also bring about teeth disposition and misalignment, periodontitis and gingivitis.[9]

Gingival inflammation is evident even in patients with well-controlled diabetes mellitus.

Orthodontic treatment considerations:

Considerations before deciding orthodontic treatment: Diabetes often causes erosion of gum bones and hence teeth get misaligned and undesirable changes in position occur. Thus, an increasing number of patients report to an orthodontist's clinic seeking treatment.

Orthodontic treatment should not be performed if a patient is having uncontrolled diabetes. If HbA1C > 9%, then an improvement in the Blood glucose control has to be considered. Also, it is necessary to perform a full-mouth periodontal examination and render therapy before beginning orthodontic treatment.

Considerations during the process of orthodontic intervention: Both fixed and removable appliance therapy can be practiced, giving importance to oral hygiene when fixed appliances are used. Plaque retention, leading to tooth decay and periodontal breakdown can be prevented by using fluoride–rich mouth rinse. Microangiopathy can occur resulting in odontalgia, percussion, sensitivity, pulpitis or even a loss of vitality of tooth.

It is advised to apply light physiologic forces to the tooth to prevent further damage.[10] They should also be prescribed antibiotic prophylaxis during procedures such as–Band placement, separator placement, and miniscrew insertion to prevent oral infection as they may already have a compromised immune system.[11]

Diabetic emergencies during orthodontic treatment: The most serious emergency that pops up during orthodontic treatment is Hypoglycemia, when the serum blood glucose level drops below 50 mg/dL. There are 2 distinct stages that should not be missed by the orthodontist.

Neurogenic (or adrenergic) stage: During this stage, there is an activation of the sympatho-adrenal system resulting in–shivering, tremors, tachycardia and cold sweating.

Neuroglycopenic stage: The symptoms would include–dizziness, confusion, generalized weakness, blurred vision, leading to coma and death.

When hypoglycemic symptoms are recognized early, oral glucose of 50 g can be administered. If the symptoms are recognized when the patient is already conscious, then 1 mg intramuscular glucagon or intravenous dextrose should be given immediately.[12]It is advisable to ensure that the patient consumes a morning meal on the day of the orthodontic procedure.

Conclusion

In today's world, due to a high prevalence of diabetes mellitus, the practicing orthodontist is likely to encounter patients in his clinic with the disease. Thus, a responsible orthodontist is expected to have a basic knowledge of the signs and symptoms of the disease. A well–controlled diabetic patient can undergo orthodontic treatment whereas it is contraindicated in patients with uncontrolled diabetes. The patients should be advised to maintain a good oral hygiene, periodontal health should be checked regularly along with the vitality of the teeth. During treatment light physiologic forces should be applied and antibiotic prophylaxis should be prescribed as deemed necessary.

Types of Mandibular Distraction & its Implementation: A Review of Literature

Aditi Ava Rath[1], Sthitaprajna Lenka[2], Sobhan Mishra[3], Karishma Rathor[4], Santosh Kumar Subudhi[2]

[1]Post Graduate Trainee, Department of Oral & Maxillofacial Surgery, [2]Professor, Department of Oral & Maxillofacial Surgery, [3]Professor & HOD, Department of Oral & Maxillofacial Surgery, [4]Tutor, Department of Public Health Dentistry, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Distraction osteogenesis is a widely accepted modern technique in the field of orthopaedic surgery. Ever since the first application of Ilizarov principles of distraction osteogenesis for mandibular bone reconstruction, several case reports, research findings, systematic reviews and subject reviews have been published. These published data focoused on the sequential development of the distraction osteogenesis technique, its practice, success rate and comfort to the congenital and acquired patients of mandibular deficiency and disorder as well. As on date the craniofacial surgeons, across the globe, prefer the distraction osetgenesis technique over conventional reconstructive surgery by bone graft. This paper attempts to review the scientific principles, protocols, indications, advantages, limitation and future scope of the mandibular distraction osteogenesis and the latest developments in the field.

Keywords: *Mandibular Reconstruction, Bone Nails, Mandibular Distractor, Surgeons, Esthetics.*

Inroduction

The mechanical appliance of distraction is commonly known as a distractor or DD. Device creates tension and gives vector to the osteomized bone fragments. In the MDO process mainly two types of distractors viz. extra-oral and intraoral are used. Extra oral one is the external device which is fixed to the osteotomised segment by percutaneous pins and attached to externally placed fixation clamps with distraction beam[1,2]. The distractor when activated stretches the bone fraction apart[3]. The external devises are in the use since last few decades due to its mechanical advantages of multidirectional vectors. This device is easy to operate and remove too. As the major disadvantages, it has a risk for inferior alveolar nerve and leaves scar on external pins zone. The intra-oral devices are placed internally along the mandible spanning the osteotomised segments at subcutaneous position or within the oral cavity. The internal devises are relatively new, innovative and of more aesthetic over the external devises. The major drawback of the system is pointed as unidirectional linear vector movement.

The DD if attached to bone or teeth are named as bone-borne or tooth borne respectively. Hence based on types of anchoring system distractors are placed under bone-borne or tooth borne group. Third category distractors are available which is fixed both to bone and teeth called hybrid type of distractor[4,5].

On the basis of vectors distractors can be categorised to unidirectional, bidirectional and multidirectional. The unidirectional device leads the bone fragment to move in one direction whereas bidirectional and multidirectional distraction devises have the scope for distraction in two or multiple directions respectively. The vectors of distraction for mandible reconstruction may be vertical, horizontal and oblique. The case specific vector selection of mandibular distractor and its placement is of surgeons' choice[6,7].

Indication of MDO[8-12]: Some of the major correction and reconstruction indications are outlined below.

i. Correction of hemifacial microsomia to restore the facial symmetry and oral function through distraction of ramus, angle, or posterior body of the ipsilateral/contralateral mandible.

ii. Improvement over sever micrognathia condition with bilateral mandibular advancement to alleviate the airways obstruction and facial height in infants and children.

iii. Vertical alveolar distraction to regenerate the bony base for dental implantation and correction of malocclusion.

iv. Midline horizontal distraction for correction of arch deformity and cross bite as well.

v. Transport distraction for neo-condyle generate to restore the temporomandibular joint function after surgical reduction ankylosis

vi. Posttraumatic rectification or reconstruction of bone and soft tissue

vii. Reconstruction following oncogenic or cystic jaw excision.

Types of mandibular distraction: The MDO is a biomechanical tool for reconstruction of congenital deficiency of the bone and soft tissue or acquired loos of the same. Based on the aetiology and requirement one of the following types of distraction process are adopted to meet the target. So far, the osteotomy is concerned it may be classified as the unifocal, bifocal or t multifocal to create required number of osteotomised segments. In monofocal osteotomy a single fracture forms a single distraction gap which is gradually filled by tension and stress principle resulting in simultaneous expansion of soft tissue and bone formation. In bifocal or multifocal osteotomy two or more bone segments are created along the mandibular axis[13-17].

Transport distraction osteogenesis is one of the bifocal osteotomy techniques where the movement of osteomized healthy bone segment leads to reconstruct the defective mandibular bone. The defect may be due to trauma, oncogenic resection or congenital anomaly. In this technique transport disk (the osteomized healthy bone segment) of host moves gradually across the area of defect under the biomechanical influence of an appropriate distraction device and the new bony regenerate bridges the gap. When the transport disk completes its movement the fibro- cartilage tissue of the leading edge must be removed for complete union of transport and host bone segment by compression[18,19].

In cases like microsomia where both mandibular and maxillary hypoplasia are the aetiology, a simultaneous distraction procedure can be adopted for reconstruction which can increase the bone stock of both maxilla and mandible. As an example, Le Fort osteotomy on maxilla and the mandibular osteotomy on ramus can be done simultaneously with suitable DD. Similarly, in case of the TMJ ankylosis, surgical reduction of ankylose tissue, gap arthroplasty and ramal height improvement can be done simultaneously which is named as simultaneous distraction technique[20]. One of the common problems in the dental implantation in mandible is lack of adequate alveolar height and width. The alveolar deficiency may appear due to periodontal pathological diseases, trauma or congenital diseases, recently alveolar distraction osteogenesis (ADO) has been proved as a promising technique for alveolar ridge augmentation to the mandible alveolar deficiency before planning any implant placement. The appropriate distractor creates an environment to gain a natural formation of bone between the distracted alveolar segments[21--25].

Timeline landmarks on DO: The attempts to rectify the broken bone with traction force were described by Hippocrates during 460 B.C. Over the year's science has been added to this practice of bone reconstruction and management. Ever since Barton, 1826 osteotomy was performed for orthopaedic surgery. Significant research achievements have been recorded in this sector during 20th Century. Codvilla (1905) reported limited success of limb bone lengthening by distraction principle[1]. Kazanjian (1937) approached the same with a device of elastic bands. Gavril Ilizarov, a Russian orthopaedic surgeon established the DO and popularise the same by practice and publications[2,3,4]. The first success of mandibular distraction osteogenesis with Ilizarov's principle was recorded by Synder **et al.**[5] during 1973. First ever mandibular bidirectional osteodistraction and transport distraction osteogenesis were reported by Molina and Ortiza-Monasteio and Constantino **et al.** respectively.[6,7]. Fixation of extra-oral devices and mandibular distraction was successfully credited to McCatrhy during 1989 and subsequently he designed and applied the multiplanar distractor in mandible satisfactorily [8,9]. Guerrero **et al.** [10] for the first time initiated the application of intra oral tooth-borne device on mandible during 1987 and massive success was reported during 1990. Further Wangeriin *et al.* (1996), Diner and Vasquez (1997) design improvised and simplified intraoral devices which could be used in

mandibular distraction[11,12]. Distraction osteogenesis is also applied to resolve the alveolar anomalies. The first alveolar reconstruction was achieved and reported by Chin and Tooth[13] during 1996. Another land mark in the mandibular distraction osteogenesis is the simultaneous distraction, performed by Molina and Ortz Monasterio[14] during 1995. However, the patient friendly intra-oral and extra oral devices and their application in mandibular distraction osteogenesis reconstruction are reviewed time and again [15-17]

Discussion

Hegab and Shuman[18] in their review have out lined the common indications of mandibular distraction as : a) Unilateral distraction of ramus, angle or posterior body b) Bilateral distraction and advancement ramus body c) Alveolar height correction through vertical distraction d) Cross bite correction through horizontal distraction at midline; and e) Transport distraction for neo-condylar regenerate. Horacio *et al*.[19] suggested mandibular distraction osteogenesis as an appropriate treatment for obstructive hypoventilation syndrome of neonatal and infants. However, the success in distraction osteogenesis is quite dependent upon biomechanical factor as well as biological mechanism. Several biomechanical factors such as selection of befitting distractors, their placement for recommended vector and force, suitable operational protocol and standardised operational period for different phases of the distraction osteogenesis also plays vital role for creation of a DO environment. Broadly the distraction devises are of extra oral, subcutaneous and intra oral. The intra oral devises may further put under two categories viz. sub mucosal and extra mucosal[20]. Suitable extra oral and intra oral distractors and their chronological improvement are recorded and reviewed currently by Sharma et al. and Mahajan *et al.*[21,22]. Review of several clinical records describe the potentiality of placement of devices in vertical, horizontal and oblique orientation to the mandible[23, 24,25]. Vertical placement generally increases the ramus height. Whereas the sagittal projection of mandibular body and symphysis is achieved by horizontal placement. Similarly, oblique placement promotes the osteogenesis in both horizontal and vertical dimensions [26]. In dentoalveolar distraction procedure the distractors are fixed on the lateral side of the alveolar bone attached to the transport and host segment as well [22]. Separation of bone as the first step of distraction osteogenesis of mandible was initiated ascorticotomy preserving osteogenic tissue with periosteal and endosteal blood supply[6]. Latter on many maxillofacial surgeons preferred complete osteotomy of the bone and claimed better reconstruction over the corticotomy protocol due to easy movement of the bony segment as per the planned vector [27]. Diversified opinions are in place for duration of the latency period in mandibular osteogenesis. Being the highly vascularised bone it takes relatively shorter latency period over limb bone[28]. In a review of clinical studies of distraction osteogenesis among 3278 patients Mofid *et al.*[29] could not find any significant difference between a defined and non-defined latency period. During growing period, children experience a high rate of bone metabolism which could shorter the latency period. As described by Chin[13] some craniofacial surgeons give 0-day latency to reduce the treatment period without any adverse effect on reconstruction. Snyder *et al.* reported seven days while Costantino *et al.* opined for ten days period respectively[5,7]. Despite several different opinions, case specific latency duration four to seven days is recommended imperially. In a prospective case study of several micro gnathic treatment Baskaran *et al.*[30] described the pick latency period ranged between 5-7 days. Effect of magnitude and frequency of distraction force determine the quality of reconstruction under distraction osteogenesis. Ilizarov law of "Tension-stress" postulated the distraction rate of one mm per day for limb bone [3,4] lengthening. It was suggested that distraction rate at 0.5 mm or 0.25 mm twice or four times a day respectively was more conducive to osteogenesis. Further he added that increasing the rate of distraction per day may lead to poor bone formation and soft tissue contracture. Whereas minimisation of distraction rate may result in early consolidation. The above finding of earlier worker has also been recommended for mandibular distraction with mere modification to achieve the target with distraction period of 2- 4 weeks and consolidation period of 4-8 weeks[18]. Moreover in a few cases of micrograthic rectification (10-20 years age group) the mandibular distraction at 1.5 mm rate per day gave very promising result[30].

Conclusion

We conclude that distraction osteogenesis is a welcome alternative to conservative orthognathic surgical procedure especially for correction of severe craniofacial deformities which necessitate large movements, where relapse is commonly encountered in the postoperative period. The osteoinductive potential seen in distraction osteogenesis along with the associated histogenesis is desirable to correct most of

the craniofacial deformities.It is seen in our study that the improvement of mandibular length, chin position and velopharyngeal space is remarkable following distraction, though a larger sample size and a longer follow-up period would help us to assess the stability of the regenerate post distraction and the behaviour of the newly created Temporomandibular joint and its effect on growth of the distracted skeleton.

Rehabilitation of Mutilated Dentitions with Precision Attachments: A Conservative Approach!

Mirna Garhnayak[1], Gulshan K. Tomar[2], Abhijita Mahapatra[3], Sangram Panda[4]

[1]Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [2]Senior Lecturer, Department of Prosthodontics, Uttaranchal Dental & Medical Research Institute, Dehradun, Uttaranchal, [3]Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [4]Reader, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Rehabilitation of mutilated dentitions, especially the distal extension cases are intimidating, when dental implants are ruled out. This case report presents a conservative approach to treat distal extension cases, with a combination of extra coronal precision attachment (RHEIN 83 OT CAP attachments system) and cast partial denture.

Keywords: *Rehabilitation, Mutilated dentitions, conservative, Extra coronal Precision Attachment, Cast Partial Denture.*

Introduction

Rehabilitation of distal extension and long-span partial edentulous arches has always been taxing. It can be ascribed to an unfavorable number and position of abutment teeth required for fixed dental prosthesis. A viable treatment alternative is implant prostheses, provided, there are no medical, anatomical and financial limitations.[1] Routinely these cases are treated with removable partial dentures.[2] Of particular anguish is the detrimental effect of these unstable prostheses have on the supportive tissue and abutment teeth, during functional and parafunctional activity.[3] Attachment retained removable prosthesis can be a savior in such a situation.[4] They are not only retentive but also aesthetically pleasing with good patient acceptance.[5] Literature shows a survival rate of attachment retained prostheses to be 83.3% up to 5years, 67.3% up to 15years and 50% up to 20years.[6] So they can be considered as a definitive treatment option for distal extension cases.

Precision attachment types of prostheses have two components.[7] The male part or Patrice is attached to fixed restoration and the female part or matrix in the intaglio surface of the denture. A precise and separable joint is formed when they are joined together. They are available in a variety of rigid and semi-rigid attachments forms.[8]

This case report describes in detail, the rehabilitation of a patient with distal extension maxillary and mandibular arches, using a combination of precision attachment and cast partial denture prostheses.

Case Presentation: A 65 years old male patient reported to the Department of Prosthodontics with chief complaints of looseness of the denture, inability to chew tough food and speak properly. He was not having any relevant medical history. On extraoral examination, characteristic features of reduced vertical dimensions like drooping of commisure, deepened nasolabial fold and poor tonicity of the facial muscles was present (Figure 1a). Intraoral examination revealed Turner's I situation, with lost occlusal vertical dimension, missing posterior occlusal stop and altered occlusal plane

e-mail: mirnagarhnayak@gmail.com

(Figure 1b).[9] The maxillary arch was of Kennedy class I modification 2 type whereas mandible was of Kennedy class II modification 1 type (Figure 1 c, d).[10] Teeth number 16, 13, 12, 11, 21, 22, 24, 25, 28, 37, 43, 44, 45 and 48 were present whereas 23 and 28 were root stumps (Figure 2). The examination of old prosthesis showed non-retentive maxillary and mandibular acrylic partial dentures. Different treatment options comprising cast partial denture and implant-supported prosthesis were discussed with the patient. Implant therapy was ruled out as the patient was apprehensive of surgery and have a financial constraint. Cast partial denture prostheses were also excluded to avoid the objectionable display of metal clasp. After a comprehensive discussion with the patient, it was planned to restore the remaining teeth with porcelain fused metal crowns and replace the missing teeth using cast partial dentures (CPD) retained with precision attachments for both maxillary and mandibular arch.

Figure 1a:Preoperative extraoral view; Figure 1b: Preoperative intraoral (frontal) view; Figure 1c: Maxillary occlusal view; Figure 1d: Mandibular occlusal view

Figure 2: Preoperative panoramic view

Pre prosthetic phase: After obtaining consent from the patient, clinical procedures were initiated. The tooth has a poor prognosis (13, 16, 48) and root stumps (23, 28) were extracted (Figure 2). Root canal treatments were performed in teeth number 12, 22,24,25,37,43,44,45 followed by post and core restoration of 43.

Fabrication procedure: Teeth of both maxillary and mandibular arch were prepared to receive porcelain fused to metal crowns. Impressions of prepared abutments were made with putty reline technique (Imprint II, 3M ESPE) and were poured in type IV die stone (Kalrock, Kalabhai Karson Pvt Ltd., Mumbai, India). The working models were then mounted on the articulator using the face bow and jaw relation record.

Wax patterns of abutment teeth were prepared for PFM crown and milled for the most guiding plane surface. The patrices of precision attachments (OT Caps, Rhein83 Inc., USA) were then added to axial surfaces of the wax patterns of abutment using a dental surveyor. Precautions were taken to attach the patrices lingual to the center of the proximal contour of the abutment. This ensured that the bulk of matrice did not interfere with the aesthetics of buccal cusp of replacing denture teeth. The copings along with the attached patrices were then invested and casting was carried out by lost wax technique.

Try-in of metal copings with patrice was then done to evaluate the fit of the casting. This was followed by shade selection and bisque try-in of PFM crowns (Figures 3a, b). PFM crowns were provisionally cemented and a pickup impression was made using putty and light body (Imprint II, 3M ESPE) (Figures 3c, d). Working casts were obtained from these pick-up impressions using type IV die stone (Kalrock, Kalabhai Karson Pvt Ltd., Mumbai, India).After block out of undercuts, they were duplicated in refractory material (Wirovest, Bego, Germany) using agar hydrocolloid (Wirogel M, Bego, Germany). Wax patterns (Bego, Germany) of cast partial denture framework were fabricated over the refractory casts to which the female components were attached. This was followed by the casting procedure to obtain the metal framework.

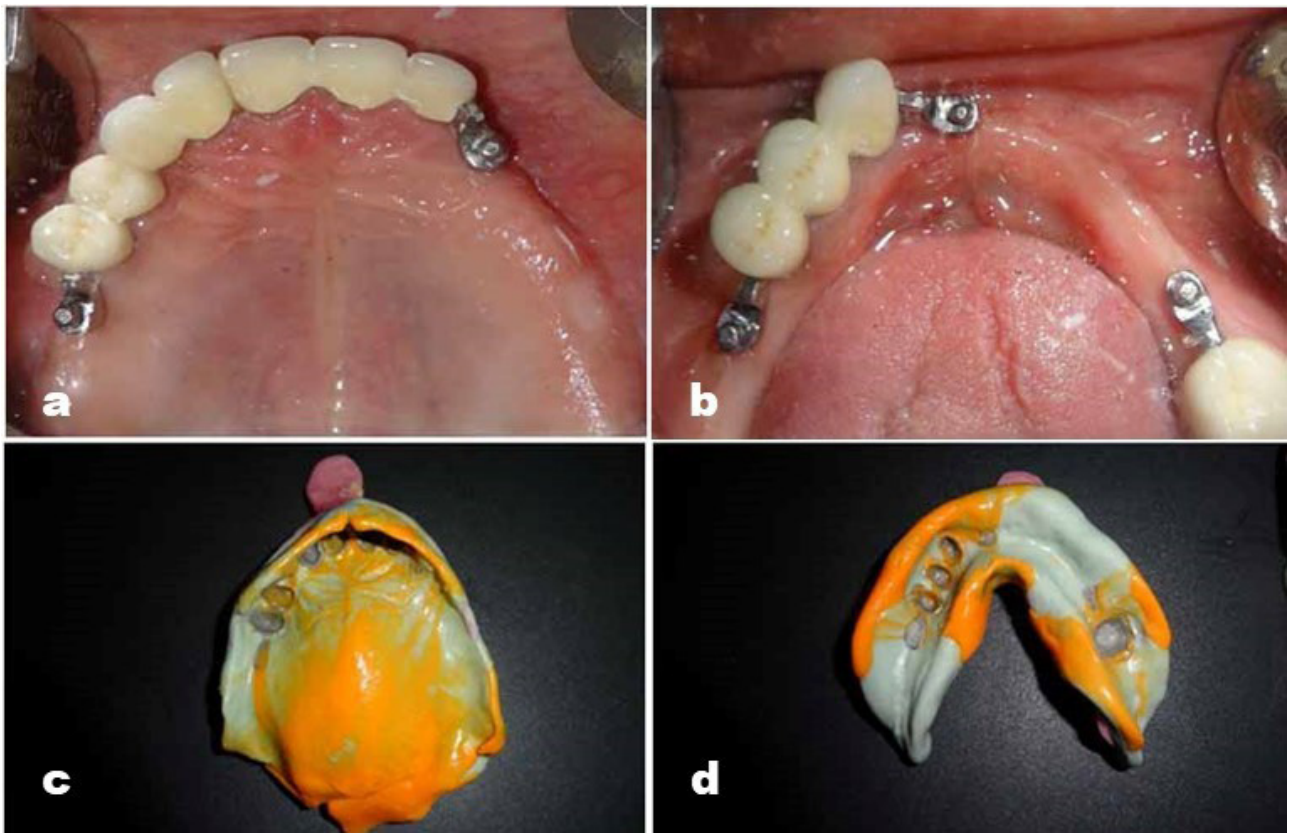

Figure 3a: Maxillary bisque try-in of PFM crowns with attached patrices; Figure 3b: Mandibular bisque try-in of PFM crowns with attached patrices; Figure 3c: Maxillary pick up impression; Figure 3d: Mandibular pickup impression

Figure 4. Try-in

The metal framework was then evaluated in the patient's mouth for passive fit, followed by a jaw relation record. Try in of dentures were done after the posterior teeth arrangement (Figure 4). A group function was given as the lower anterior teeth were missing.[11,12] This was followed by glazing of PFM crowns and acrylization of attachment retained partial denture (Figure 5a, b).As standard retention was required, a pink color elastic cap (OT Caps, Rhein83 Inc., USA) was chosen for the matrix. They were placed in the female counter slots of CPD using the insertion tool (Figure 5 c, d). These elastic caps not only act as stress breakers but also make the prosthesis retentive and stable. Cementation (Gc Fuji 1) of PFM crowns was done with the CPD attached to avoid any change in the path of insertion of CPD (Figure 6a, b, c). The patient was recalled at an interval of 24 hours, 1 week, 2 weeks, 1 month and every 3 months for one year for routine check-up and maintenance of hygiene. He was highly satisfied, as the stable prosthesis resulted in improved retention, mastication, speech and better aesthetics (Figure 6d). Moreover, it was a non-invasive and cost-effective palliative procedure.

Discussion

Rehabilitation of the present distal extension case required restoration of the lost vertical dimension, function and aesthetics of the patient. The patient was neither satisfied with the existing acrylic prosthesis nor convinced for the implant prostheses. Further, the position of remaining teeth precluded the use of a fixed partial denture. A simple CPD could have transferred excess stress to the remaining abutment teeth along with an objectionable metal display of clasp. So, the case was rehabilitated with cast partial denture and made retentive by use of precision attachment (RHEIN 83 OT CAP attachments system).

The height of the abutment teeth, in this case, was adequate (>3mm), which made the situation favorable for precision attachment.[13] These attachments not only made the CPD more retentive but also aesthetically pleasant, as it eliminated the objectionable metal display of clasp. Further, the resiliency of precision attachments redirected the forces to the residual ridge whereas, the CPD helped in cross arch load transfer during functional and parafunctional activities.[14] Together they stabilized the prostheses without the use of implants. Stress was further reduced by broad coverage, stable denture base and splinting of dentition.[15]

An extra coronal type of attachment, Rhein 83 system was chosen for this case based on the remaining teeth, their location in the arch, intra and inter arch relationship, aesthetic and financial aspect.[16] It is simple and offers spherical retention. This along with elastic retentive caps of precision attachment improved the retention of the prosthesis.[17]These types of retainers offer vertical resiliency, universal stress relief and easy replacement of worn attachments.[18] Favorable long term retention and less wear of ball are also seen when a combination of a precious gold alloy matrix and a titanium ball is used.[19]

However, the main deterrent for use of such prosthesis is cost because of complex laboratory, clinical procedure and the wearing of attachment components. They are also contraindicated in short clinical crowns as they cannot house the attachment

components and effectively offset the leverage forces exerted on the crown.[13] Adequate inter arch space is also another prerequisite for the corresponding attachment components to be housed within the RPD framework and optimal artificial tooth replacement.[6]

Conclusion

Precision attachment retained CPD was found to be superior to the conventional acrylic RPD used by the patient in terms of improved retention, aesthetic and hygiene maintenance. Again, they can be used as long term definitive kind of prosthesis, where the use of implant-supported prosthesis is either contraindicated or not affordable. As it is a non-invasive procedure, it can also be used by the general practitioner, with adequate knowledge and proper treatment.

Abstract

Melatonin, an endogenous hormone, is a wonderful tool in the field of dentistry. It has got myriad qualities which can be used in every branch of dentistry. It is basically a night hormone, playing a component in the circadian sequence of the body. But it has been observed that it has got true potential when incorporated in dentistry. Apart from the treatment part, it can also be used to neutralize the toxicity part from the restorative materials used in dentistry. Right from the oral ulcer to the treatment of oral cancer, melatonin can be of utmost importance in the implant dentistry, extensively. The aim of this review is to decisively analyze and review by focusing on the capability of melatonin in the field of dentistry.

Keywords: *Melatonin, anti-oxidant, melatonin as a hormone.*

Introduction

Periodontal disease is a globally challenged infectious disease which resulted from the disturbance between the pathogenic agent and host immunity. Targeting the root cause of periodontitis by non-surgical therapy has been always the gold standard. Hence, the pharmaco-therapeutic agents have become very significant in the management of periodontal disease which has given rise to the popularity of the usage of the sleeping Hormone "Melatonin".[1]

Melatonin was revealed in extracts of the bovine pineal gland and synthesis in this organ was determined in 1958. It ranges from 1 to 5 pg/ml in the day and upto 50pg/ml at night. Melatonin is an endogenous molecule that controls basically the circadian rhythm. The circadian secretion protocol of Melatonin goes similar in serum and saliva. But salivary melatonin level do not always imitate absolute melatonin concentration of serum. As in the blood stream, melatonin can beleap to 70% of albumin and the rest is present in the free fraction which becomes able to diffuse passively from the submandibular glands to the saliva which is only 24 to 33%. Hence, in the oral cavity, particularly the anti-oxidant function of the Melatonin involves in the pathogenic process of periodontal diseases. However, it also regulates and modulates a wide variety of pathophysiological processes together with the modulation of immune response, anti-inflammatory, anti-oxidant, anti-tumoral, anti-parasitic and neuroprotective processes. Melatonin is a significant biomarker in the diagnosis and also plays a significant role in the treatment of periodontal disease. It also possesses a potent antimicrobial activity on multidrug resistant, gram positive as well as gram negative bacteria also.[2] It is available in the topical form, spray, Gel, and also can be taken systematically. Ramelton, a melatonin derivative was the first melatonin receptor agonist accepted for human use. It has much of therapeutic values then the Melatonin and it has a higher lipophilicity and can be more easily taken up and retained by tissues.[3,4]

Effects of Melatonin: Melatonin and periodontal health: Melatonin has been much beneficial on useful mechanisms regulating the fibroblasts migration and proliferation throughout gingival healing on periodontal repair.

They function by 3 following mechanisms:

1. By dropping the making of cytokines, chemokines and pro-inflammatory proteins produced by leukocytes melatonin prevents the devastation of cells and other structures.
2. By neutralizing ROS, melatonindefends the fibroblasts from noxious substances that brelease Ros and helps in reversing the effects of oxidative damage.
3. By enhancing the mechanism of wound healing.[5]

ROS formed by keratinocytes, fibroblasts and a variety of other inflammatory cells mightconsequence in disequilibrium among the pro-oxidants and antioxidants. Reactive oxygen metabolites lead to devastation and damage to cell membranes by lipid peroxidation. Commercially available melatonin gel can be functional in the oral cavity is effective in reducing mucosal lesions.[5]

Melatonin against inflammation/periodontal disease: As periodontitis is an inflammatory disease, caused mainly by the bacterial infection. During the infection, the bacterial LPS produces nitric oxide, IL-6, lipid peroxidation which is the main concern in the development and initiation of chronic periodontitis. Melatonin exerts alpha protective role against periodontal inflammatory process by its anti-oxidant and anti-inflammatory action. Also the free scavenging potential of melatonin aids in lowering the massive reactive species (ROS) confined by bacteria. Antioxidant capability of melatonin helps up in the treatment of the local inflammatory conditions and there by fastens up the healing process. Melatonin exerts its inflammatory actions by inhibiting the prostaglandin synthesis, production of adhesion molecules and NF-kB binding to DNA. Apart from this, it also reduces the leukocyte-endothelial adhesion and leukocyte transendothelial cell migration. Not only this, it also decreases the PMNL to the inflammatory sites. It also inhibits inflammatory enzymes COX-2 by binding to the active sites of COX-1 and COX-2 and hence inhibits the activity of the enzymes and aids in inflammation. It is an anti-bacterial agent which has been a strong antimicrobial agent on various bacteria and viruses.[6] The straight action of melatonin as an antimicrobial, synergistically by its immunomodulatory and anti-oxidant properties may prove to be a potent weapon against numerous oral infections. It rescues the injured oral epithelial cells from apoptosis process.It enhances phagocytic activity by its immunomodulatory function.[4] Melatonin also influence fibroblast activity and bone regeneration.[6] Melatonin mediates the effect of immunomodulatory action through receptors on localized preosteoblasts which leads to the production of the bone sialoproteins, alkaline phosphatase, osteopontin, osteocalcinin in their cells, hence significantly shortening the tissue needed for their differentiation into mature osteoblast from 21-12 days. RANKL is an important protein in osteoblastic differentiation and proliferation. Osteoprotegrin(OPG) interferes with its biological potential. Hence RANKL plus OPG plays a critical role in the development of periodontal disease resulting in periodontal destruction from the up regulation of RANKL. SO the triad is (RANKL, OPG, RANK) responsible for destruction, which is altered by the modulating effects of melatonin. Treatment of Melatonin generatesthe abundance, segregation, action of osteoblasts. It acts at the level of osteoclast lacunae because of antioxidant and free scavengers, hence neutralizes reactive species and inhibits bone resorption.

Salivary melatonin level may improve the organism's defensive response to the periodontal inflammatory process. Melatonin strongly suppresses the nitric oxide (NO) and IL-6 production induced by LPS from P. intermedia. Studies showed that as the degree of the periodontal disease is increased, salivary and GCF melatonin level gets decreased indicating Melatonin is taking care of the disease.[7]

Melatonin and Porphymonasgingivalis associated Periodontal Disease: Melatonin has shown a significant role on "keystone" periodontal pathogens like *P.intermedia, P.gingivalis*. It acts on the virulence factors of *P.gingivalis*, such as proteinases, gingipains, fimbriae, LPS, cytotoxic and haemolytic molecules like KgP. It suppresses the production of nitric oxide and IL-6 produced by the LPS of *P.intermedia*. And this virulence factor was a necessity for growth and survival of *P.gingivalis*, as nutrients as well as adherence to lots of host cells surface playing a vital role in the breakdown of host defencemechanism, the penetration and progressive damage of the host connective tissue. Also melatonin breaks down the virulence factors like LPS which would have stimulated the production of inflammatory mediators like interleukin carrying inflammation.

Melatonin level is seen significantly reduced in patient with periodontal disease. Hence it can be applied as a potential treatment of periodontal disease. It has a

tremendous anti-inflammatory effect on *P.gingivalis* virulence and *P.gingivalis* induced inflammation by affecting the gingipains and haemolytic activities of them. Melatonin also inhibits biofilm formation and thus decrease the biofilm viability of *P.gingivalis*. Not less, melatonin also has a potential to inhibit *P.gingivalis*LPS induced IL_6 and IL-8 secretion.[6]

The level of salivary and GCF melatonin level decreases in case of periodontitis then the healthy individuals, which may be a risk indicator for the development of severe kind of periodontitis in future. Melatonin level gets depleted here because of response to an oxidative stress which is increased by a shortage of antioxidant to balance the same and the bacterial attack present in periodontitis.[1]

Melatonin can alter the development of the periodontal disease as it can act on PGE2 thereby inhibiting the differentiation of the osteoclasts induced by cell to cell contact between osteoclasts and osteoblasts. Melatonin can also modulate all the proteins that regulate the resorption process in the periodontal diseaseand interact with other biological agents such as calcitonin, parathromone, IL-2, IL-8, IL-6, osteoprotegrin. And hence diminishes bone resorption and promotes the bone marrow cell differentiation.[2]

Melatonin downregulates the expression of pro-inflammatory factors such as c reactive protein, IL-6, TNF alpha but also downregulates the receptor activators of nuclear factor kappa Beta ligand/osteoprotegrin ratios to reduce periodontal inflammation.[5] Topical application of melatonin can be used as an adjunct with non-surgical therapy and also during the surgical debridement to improve the outcomes of periodontal therapy.

Melatonin and diabetic induced periodontal disease: Melatonin significantly inhibited hyperglycaemia induced oxidative stress and alveolar bone loss through its anti-oxidant effect. Melatonin reduces the magnitude of inflammation in the periodontal tissues by its anti-inflammatory and antioxidant properties. It also scavenges the ROS produced by diabetes and hence reduces the inflammatory effects of diabetes in periodontium.[5] Melatonin not only benefit local oral environment but also can contribute to ameliorate glucose levels, helping to prevent chronic diabetes complications. Periodontitis known as a sixth complication of diabetes can also be improved by the therapeutic effects of melatonin.[3]

Melatonin and stress induced periodontal disease: Stress causing depression also plays a contributory role in periodontitis. Oral hygiene is impaired because of low maintenance and results in periodontitis. Melatonin can be of tremendous help here as an anti-oxidant and an antidepressant.[3]

Melatonin and oral cancer: Melatonin is a promising anti cancer agent.Reactive oxygen species and free radicals are the main factors for oral cancer. In the precancerous cases of bothleucoplakia and lichen planus, Melatonin plays a preventive role as well as a therapeutic role against oral cancer.It may impede the metastasis of oral cancer by suppressing metalloproteinase -9 activator. It is a strong anti-oxidant having immense anti-proliferative action on the cancer cells, anti-tumor activity, antiapoptotic effect, immune stimulator, anti-inflammatory and antiangiogenic agent which makes melatonin to exert oncostatic action on cancer by all the biological mechanisms.[6]Also, Melatonin has been used as the palliative therapy for cancer because of anti-cachectic, antiasthenic, thrombopoietic properties. It is used as preventive tool to neutralize the side effects of chemotherapy. Melatonin is successfully administered in medical oncology in the supportive concentration of untreatable advanced care. Hence, oral melatonin gels, oral melatonin rinses and melatonin tooth pastes are helpful to impede and prevent oral cancer.[4]

Melatonin in xerostomia: Melatonin has the therapeutic potential to regulate and balance the activity of the salivary glands and their rate of the salivary flow as well. It acts directly on the secretory unit of the salivary level.[6]

Melatonin andOral mucositis/oral ulcers: By suppressing the inflammatory enzyme Cox-2 as a potent anti-inflammatory agent as well as by its antioxidant capacity, Melatonin helps in treating the local inflammatory condition like oral mucosities. Also, it protects DNA damage against the ionizing radiation. In case of radiation mucositis, oxidative damage and toxic cytokines is very painful and is relieved by the usage of melatonin gel. It also prevents the damage of the environmental dangers like lead, arsenic, and fluoride into the body by neutralizing the toxicity. Melatonin by its free radical scavenging capacity regulates the apoptotic process otherwise there would have been massive cell death by the ROS. It is also a potent antiapoptotic agent.[6]

Melatonin and bone formation: By stimulative synthesis of Type 1 collagen fibers and by its free radical scavenging capacity, Melatonin prevents ROS which may otherwise resulted in promoting the osteoclastic activity. And thereby, it protects organisms from bone resorption by its anti-oxidant and free radical scavenging properties.[6]

Melatonin and viral infection: Acyclovir and melatonin beneficial effects are compared and was found that Melatonin seems to be better than the former. The antiviral potential of melatonin on herpes is enhanced by stimulation of products like IL-1B, cytokines, IL-2 and INF–gamma leading to the increased activity of NK cells and CD4 cells. Immunomodulator formulations is 2.5 mg of melatonin and 100mg SB-73(a mixture of Magnesium, phosphate, fatty acids, protein extracted from *Aspergillus oryzae*. SB-73 when given either before and after viral infection amplified the number of bonemarrow granulocyte macrophage progenitor cells. Hence, aid in immunity.[6] Melatonin prevents the untoward effect of the drug acyclovir and hence decreases the toxicity. [7]

Melatonin and candidiasis: Melatonin as an immunomodulator agent has got the shielding effects in severe sepsis/shock induced by bacterial LPS in animal models. Itsuppresses IL-6 level and becomes a therapeutic agent in animals with candida sepsis. The level of TNF-alpha and adhesion molecules seems to be in a suppressed level in the animals treated with melatonin as compared to the animals not treated with melatonin hence, used as an antimycotic agent for the oral candidiasis. It can be used either as a topical agent or can be taken systemically. Also, some studies have shown phagocytic functions of melatonin and at the same time reduces oxidative stress originating during candidiasis.[6]

Melatonin and dental materials: It are observed that the restorative and the esthetic dental materials comprises of methacrylates polymers with some additives. Often, there is incompleteness in polymerization or material in situ because of masticatory shearing, salivary enzymes, enzymatic degradation, which doesn't allow the whole monomer to undergo polymerization. Hence, there is leech of methacrylate monomers from the restoration into the pulp and the oral cavity by which they get accumulated in the distant organs through blood. And there they produce toxicity like cytotoxicity and genotoxicity with the help of the oxidative actions of the monomers in both the vivo as well as in vitro.[8] Freely available monomers induce DNA double-stand breakdown and irreparable damage to the fibroblasts because of the oxygen and nitrogen-based reactants of the monomers, Melatonin also helps in the reparative action of DNA in the same way and also prevent it from apoptosis. Melatonin sublingual tablet can be added on tooth paste, gels and mouth washes. Also, it is seen that the traditionally amalgam fillings have been replaced by the composite material because of the high toxicity of the mercury in amalgam.[9] And composite materials are nothing but a combination of organic polymers with inorganic fillers belonging to the methacrylate group. Hence, Melatonin here is a boon acting as a powerful antioxidant in neutralizing the toxicity.[6,10]

Conclusion

Dietary melatonin supplements can be taken asa supplement to enhance the periodontalparameters. Hence to analyze its possibility as a long termbeneficial agent for the management of periodontitis, melatonin should be accepted in routine dental practise. More research is still needed to see the effect. Antioxidants have anoutstanding role in the maintenance of periodontal health and melatonin is one of them which have emerged as anoutstanding adjunct that can develop the outcome of conservative periodontal therapy. Melatonin can be a prominentdistinction by a remarkable stabilityamong health and disease.

The Night Hormone "Melatonin" in Implant Dentistry

Rashmita Nayak[1], Rinkee Mohanty[2], Abhaya Chandra Das[3], Anurag Satpathy[4], Saurav Panda[5], Gatha Mohanty[6]

[1]Professor, [2]Professor & Head, [3]Reader, [4]Professor, [5]Reader, [6]Senior Lecturer, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Melatonin (N-acetyl-5-methoxy tryptamine) is a substance secreted by different organs in vertebrates. Adding up to in performance a part in the circadian cycle of the body, melatonin also plays a significant role as an anti-oxidant, anti-inflammatory, immune-modulatoryspecial effects on human tissues. Melatonin has been playing a very significant role in the dentistry in various roles. Apart from this melatonin also plays a very powerful and a significant role in Oral implant dentistry.Furthermore,melatonin has been observed to improve osseointegration and bone regeneration. Topical management of melatonin has a helpful effect on periodontal health and osseointegration and also promotes the curing of tooth extractionsockets by impeding the progression of resorption of bone. It also helps in suppressing the peri-implant microflora too. Melatonin positive regulation of bone formation and homeostasis, in combinationwith the inhibitory effects on bone resorption, highlights the potential use of melatonin as a marker of periodontal and periimplant bone-related diseases. Hence this review is to critically evaluateand summarize the effects of melatonin in the bone metabolism, bone repair and healing till the osseointegration in the field of Implant dentistry.

Keywords: *Melatonin, osseointegration, Hormone in implant.*

Introduction

Melatonin is a very powerful biomimetic agent and it mimics many biochemical processes which becomes a blessing for dentistry especially in the implant dentistry. For the remarkable success outcome of Implant, the quality and the quantity of the bone plays an important role. At the low concentration, Melatonin (indole group of melatonin) can stimulate, synthesis and can produce Type 1 collagen fibres in osteoblasts of human being. Melatonin has got myriad properties which is very much benefitted for the implant dentistry.[1] Melatonin has the powerful potential of osteogenesis, anti-inflammatory, immune-modulatory,antioxidant, free scavenging of ROS and many more. Together with all these wonderful potentials of Melatonin, it makes a powerful entry to the implant dentistry. It is available in the form of powder, gel, and tablets. It can be nicely merged with any type of bone grafts or growth hormones at the time of implant placement which gives a remarkable outcome in the follow up period after 3 months.[2]

Because both the bone graft and melatonin together act here as bone stimulators and thereby enhance the synthesis and differentiation as well as proliferation with early matrix production and mineral deposition. So, one should go without a single doubt in mind about placing combination of bone graft along with the melatonin for good osteogenesis and osseointegration especially for the immediate implant.[1,3]

Melatonin has a great scavenging potential for the free radical species generated by the inflammatory cells. It detoxifies and scavenge the free oxygen radicals and then prevent them from acting on the osteoblasts in resorbing the extracellular matrix. Otherwise, it would have led to a greater degree of resorption. Melatonin because of the antioxidant properties and capacity to counteract the active species, it retards the resorption of

Corresponding Author:
Prof. (Dr). Rashmita Nayak
Professor, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: rashmitanayak@soa.ac.in

bone, by downregulating the RANKl, as the RANKL is the main source of formation and regulation of osteoclast lacunae.The anti-inflammatory and the antioxidant properties have a reinforce action on the microorganisms by squeezing to the minimum production of reactive species and hence prevents bone resorption.

As melatonin is dosedependent, application of Indolamin at the micromotor concentration of 5 to 500 micrometres, is able to help in the expression of mRNA and osteoprotegerinin the proosteoblast cell which helps in increasing in the bone mass due to the constriction of osteoclast activation.Also, melatonin has got potential of anxiolytic and analgesic. Melatonin suppresses the pain from inflammation by blocking the pathways of nitric oxide production.As melatonin is an immunomodulator and a neuro endocrine hormone, it helps in influencing angiogenesis and healing of wound by the proliferation of fibroblasts. Hence, it helps at the time of immediate implant placement if there is peripaical pathology, lack of complete tissue closure or absence of keratinized tissue.[4]

Melatonin being a pleiotropic multitasking molecule, topixc application of melatonin has got a tremendous suppressing effect on IL-6, IL-B which are the inflammatory mediators, causing soft tissue destruction by stimulating the production of PGE and collagenase synthesis.[5]Melatonin has an antioxidant, immunoenhancing promotes the fibroblast activity and bone regeneration. Melatonin with Vitamin c has a synergetic antioxidant effect. Melatonin has the ability to maintain the bone health by forming good quality as well as sufficient amount of bone formation around the implant, by being a biomimetic agent, leads to good osseointegration.[6]

1. By acting on the osteoclasts directly as an antioxidant and a free scavenger it prevents resorption of the extracellular matrix by producing free radicals. This helps in prevention of the bone resorption.
2. Melatonin can induce osteoblastogenesis by regularly RANKL and osteoprotegrin synthesis. And this in turn helps in development of the bone sialoprotein and the other important protein bone markers. Once this bone marker is developed in the osteoblast, they in turn helps in differentiation of osteoblasts by reducing the time from 21 normal days to 12 days.
3. Melatonin gel or powder can be used as a bone graft material added with any type of growth factor, at the site of extraction before placing the implant.
4. Studies after 1 month shows the group used melatonin as a gel during immediate implant placement showed good perimeter of bone, increase in the bone density, new bone formation and increase in the bone at the inter thread area and hence increases the stability of the implant. Because of the stability of the implant is directly correlated with the significance increase in the inter thread new bone formation. Even, melatonin can act incase of aggressive placed implant where there is bone compromised and there is too much necessity of remodelling with repair and regeneration of bone at the quickest.

Biological effects of melatonin and its principal actions[7]

1. Firstly, melatonin increases pre-osteoblast/ osteoblast/osteoblast–like cell proliferation, improves the expression of type 1 collagen and bone marker protein (e.g. alkaline phosphatase, osteopontin, bone sialoprotein, and osteocalcinin and stimulates the mineralized matrix in these cells. Melatonin also prevents the differentiation of osteoclasts by reducing the expression of RNA and increase in both the mRNA and protein levels of osteoprotegrin.
2. Melatonin can in some way regularize bone metabolism via the exchanges and systemic hormones (e.g. PTH, calcitonin, oestrogen)or other molecules. Oestradiol treatment has got the potential toextend the properties of melatonin to boost bone remodelling.
3. Osteoclasts generateelevated levels of superoxide anions through bone resorption that is correlated to the degradative process. Melatonin can eliminate these free radicals and defendthe cells of the bone from oxidative attacks.

Melatonin can also be benefitted for the post-menopausal women undergoing HRT and is a case for immediate implant placement.Surface modification of dental implant is a pre-requisitive factor to increase the bioactivity before the implant placement. Once again, melatonin has shown a remarkable viable alternative tool to stable the coating of the implant. And this is carried out by the balance of the bioactive coating ion leakage and residue particle. And by doing this, there is a remarkable

significant increase in the inter thread bone formation and bone mineralization. Melatonin can prevent the drawbacks of the modified implant by preventing delamination of the bioactive coating, ion leakage and particle residues. Melatonin a viable alternative to stable the implant coating powdered melatonin on the implant site leads to increase significantly in the inter thread bone formation and bone mineralization.[7]

Melatonin can indirectly give a bonus strength to the osteogenic potential of xenografts in the case of a calcium coated titanium implant. However, still the synergistic effect is seen in adding up the growth hormone on the melatonin dust over the implant site.

Even the studies have shown a remarkable significant profound one implant contact on the administration of intra peritoneal melatonin injection added with growth factors like FGF to the titanium and zirconium implant. A fantastic osseointegration is been observed after 3 months because of the fantastic osteoconductive potential of the implant.

1. Melatonin in bone remodelling: As we know, hormones are mainly responsible for the bone remodelling processes and melatonin is one of them. Melatonin helps in bone remodelling in 3 phases and act on the action of
2. It enhances the pattern of a mineralized matrix in these cells.
3. At all the level of the pre-osteoblast/osteoblast/ osteoblast like cell proliferation which in turns promotes the expression of type 1 collagen and bone marker proteins which helps in remodelling of the bone.
4. It stops the differentiation of osteoclasts via the decline in the expression of RANK and mRNA and increase in both the protein level and mRNA of osteoprotegrin which in turns helps in remodelling of the bone.
5. Melatonin interact with the systemic hormones indirectly and thus regulate the bone metabolism like PTH. Many literatureshave stated that the oestrogen in the body or if the body is under oestradiol treatment plan. Post-menopausal women or under HRT, oestradiol can prolong the effect of melatonin and helps in bone augmentation. So, here good quality of oestradiol is necessary to make the melatonin properly act on the bone.
6. During bone resorption, much elevated levels of superoxide anions are liberated bythe osteoclasts which enhance the degradative process. As melatonin is an excellent free radical scavenger and antioxidant, melatonin empties the free radical given up by the osteoclasts at the time of bone resorption, and hence prevents the bone cells from the oxidative attacks.[5]

Melatonin and bone repair: As we know repair of bone is always a continuous process and also a complex one. And this bone repair requires 3 biological stages: Inflammatory phase, proliferative phase and the Remodelling phase. And the sequence in the bone repair starts from the infiltration of the inflammatory cells, vascularisation, angiogenesis, followed by the cell differentiation and cell proliferation and then the deposition of the collagen, formation of the granulation tissue and finallyby the deposition of the mineral matrix. As melatonin is a strong antioxidant, it helps in the healing process of the bone by regenerating the bone cells and also promotes the action of angiogenesis. And also, melatonin it promotes the action of angiogenesis. As melatonin is a free scavenger of free radicals, it also scavenges the free radicals generated bythe inflammatory cells and hence prevent from the impaired healing of bone.Or else it may lead to cell damage via the lipid peroxidation. Here melatonin is a significant pineal hormone at both the physiological and pharmacological concentration. Melatonin promotes neo vasularization and thus helps in healing. As osteogenesis is formed after the angiogenesis process, hence the repair of the new bone was dependent upon the blood vessels for the supply of mineral elements and the migration of angiogenesis and osteogenic cells takes place into the scheduled places. Hence, melatonin promotes the remodelling process.[5]

Melatonin and osseointegration of the dental implant: Melatonin may be a powerful biomimetic mediator in the placement of endoosseous dental implant. Studies have shown that the application of melatonin has significantly increased the bone perimeter which is in straight contact withthe treated implant, bone density and new bone formation and inter-thread bone in contrast with the control implants.It was found that the increase in osteoblast proliferation withthe peri-implant zone is bythe help of melatonin.[5] These actions brought by melatonin on osseointegration are of significant beneficial as it can be used to apply melatonin in different forms of dental implant surgery where melatonin acts

as a biomimetic agent during the traumatic extraction of tooth, when melatonin is placed at the site and that followed by the immediate implant placement, melatonin is normalized the level of reactive oxygen species, lipid peroxide, nitrates and nitrites production at reaction to tooth extraction.[11, 12] If bone growth factor plus PRF and melatonin is given, it is remarkable.

Melatonin promotes utterly positively the peri-implant bone response. In many of the studies done on vitro, it shows that melatonin as akeymoderator in bone configuration and stimulation, enhancing osteoblast differentiation. Here, melatonin acts on the bone as a confined growth factorwith paracrine effect on nearby cells. Melatonin also has shown a positive effect on the precursors of bone cells in various animal studies. Indolmane is proved to be a major modulator of calcium metabolism and interacting with other bone regulating factors such as PTH, Calcitonin, and PGE, it prevents osteoporosis and hypocalcaemia. It is shownthat bone-to-implant contact (BIC) and total peri-implant bone area at 4-12 weeks are higher in melatonin treated implant then in controls. The larger amount of bone tissue in direct contact withthe implant that received melatonin mayreproduce greater synthesis of bone matrix in the peri implant area. The reason may contribute to either the quantity of osteoblasts enhanced, may be due to the active osteoblastic activity or may be due to the constraints of the osteoclast activity. Melatonin seems to help in the formation of the bone cells. Also it has been keenly observed lots of cells which are newly formed with clear bone trabeculae in direct contact withthe implant surface is observed after the administration of melatonin with growth factors like FGF-2 by promoting new preosteoblasts which are carried from the bone marrow to the alveolar bed via the vascular system.[8]An additional action of melatonin, is at the pre osteoblast level, boost new bone formation by prompting of gene expression of assured proteins in the bone matrix. Melatonin constrains the production of ROS by peri-implant blood vessels.

Melatonin improves results for cell adhesion, proliferation, differentiation, on different titanium surface modification, by the additional usage of topical melatonin. Here melatonin acts as a biomimetic agent.[10] Melatonin has dual effects on both osteoblast and osteoclast. Bone remodelling is accountable for bone mass maintenance, regulation of bone potency and or mineral homeostasis all along human lifetime.[2] Melatonin is dose dependent and is maximum at the concentration of 50 micrometer. At concentration ranging from 5 to 500 micrometre, melatonin minimizes the expression of mRNA from the RANK and increases the level of both osteoprotegrin as well as mRNA from thepreosteoblast cell lines. This positive potential of melatonin on bone makes it to act as a biomimetic agent during endosseous implant surgery.[9-11]

Conclusion

Therefore, melatonin may inhibit bone resorption or promote bone-marrow cell differentiation. It is important to note that the stimulation of osteoblastic differentiation by melatonin may influence bone formation through the induction of bone sialoprotein and alkaline phosphatase and osteocalcin that are essential proteins for bone maturation. Hence, melatonin may play a major role in the regulation of the bone resorption as well as formation but always ends up in favouring of the bone formation. Hence Melatonin can be considered as a therapeutic agent, either alone or combined with both grafts and growth factors in the implant cases. It is a promising tool for implant dentistry having multiple beneficial properties under one name of melatonin.

Outcome Assessment of Operative Treatment of Humeral Shaft Fractures by Antegrade Unreamed Humeral Nailing (UHN)

Vivekanandhan P.[1], Anand N.N.[2]

[1]Post Graduate, [2]Professor, Department of General Medicine, Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

The motive behind this inquiry was to study the out-and-out cracks in the Humeral shaft handled with Unreamed Humeral Nailing System (UHN). Infatuation of the glenoid shaft cracks in this evaluation was performed by an insubstantial UHN structure entry point, without the use of its proximal locking features. Thirty-five patients have been handled along these lines. Useful status for the shoulder and elbow Surgery (SASES) scoring system. 1 example of deep was monitored during the follow-up period. The average association period was 16.8 weeks. SASES shoulder and elbow capacity were brilliant or large in 94.28 per cent of patients. Difficulties included non-union in 1 (2.38 percent) and spiral nerve paralysis in 1 (2.86 percent). Antegradunreamed humeral Nailing is a worthy, safe and reliable therapy for humeral shaft breaks.

Keywords: *Humeral shaft, Fractures, Treatment, Antegrade, Humeral nailing, Unreamed.*

Introduction

Humeral shaft breaks are amongst the most excellently-known orthodontic issues, responsible for about 3% of all cracks[1]. Treatment techniques for this form of wound continue to advance in both usable and non-usable approaches[9 10]. It is often acknowledged that most splits in the humeral shaft are best controlled extra-operatively., While a few signs of essential or optional usable techniques include poly-injury with important neck or potentially head damage, ipsilateral splitting of the two lower arm bones [1112](drifting knees), wide-neighbor related injury, such as joint, brachial plexus, muscle or ligament, absence of decrease of the humeral shaft fracture by closing, and obsessive humeral shaft. Cracking[13 14].

Despite the big connection since-effects in non-employable administration, there are still a few issues, such as long-term therapy and patient prejudice, especially between young and dynamic patients regularly speak about usable administration to experts and professionals. The empowering outcomes that have been accounted for by the late developments in inward obsession. Systems and instruments have led to the growth of cautious indications of such breaks[4]. Obsession of plate techniques was regarded to be the normal method. Issues linked to this method include injury inconveniences, e.g. illness, raised likelihood of deferred blend (particularly when the trial of plaque fixation have not been actually directed Non-affiliation and fixation on disappointment[5,6]. Intra-medullar pinning is additional proper careful methodology that could be actualized over both wager evaluation and retrograde approachs. There are unmistakable outcomes in the composition of unreamed humeral nailing (UHN) and a few preliminary studies have revealed distinct rates of non-association[7, 8]. In the light of the shoulder, we recognize that joint's A broad range of motion of UHN with a bet assessment strategy without distal locking, apart from a tiny increase in The danger of pre-association will not cause significant uncertainty, but may decrease the time of procedure and decrease the opportunity of extensive nerve damage[15,16,17]. The objective of this evaluation is to assess the results of the

UHN through a risk assessment strategy in patients with breaks in the humeral shaft.

Materials and Method

The point is to tentatively investigation the "practical result of antegrade intramedullary interlocking nailing in crack shaft of humerus" at the Department of Orthopedics in Sree Balaji Medical College and Hospital chrompet Chennai. The enrollment time of this examination will be from March 2017 to February 2018 (a year). The subsequent period will be for a base time of 7 months (extend: 7 to 19 months). Radiological association, practical result and intricacies were evaluated.35 patients with shut intense humeral shaft cracks requiring employable administration They were handled with UHN. The criteria for account were: (1) humeral shaft cracks which indicated usable therapy and were monitored by intersecting and (2) patients with a duration of more than 18 years. Rejection criteria were: (1) patients under 18 years of age, (2) segmental cracks, (3) breaks within 4 cm of anterior or distal humerus finish..All patients had a fair clinical and radiological evaluation before they decided to make a cautious decision. intercession. All breaks were characterized by the Muller AO arrangement. Subsequent to utilizing the consideration and prohibition Criteria, we included 41 UHN patients. For the proximal enactment, an entry point of 1–2 cm was intentionally placed on the anterolateral tad of the shoulder in order to limit harm to the deltoid muscle, and an intramedullar nail (Russell-Taylor type) was applied to the rotator sleeve bet analysis. (Fig. 1). The significant speculation in this examination is that as per the shoulder's wide scope of movement regardless of whether not locking the distal segment causes some degree of non-association, it would not cause any revolution limit. Failure to lock the distal portion would significantly reduce the interaction span and reduce the risk of overspread nerve damage. Dynamic and detached movements of the elbow and pendulum activities of the shoulder were begun on POD-3 and following two weeks, dynamic and latent flexion and snatching of the shoulder were begun. Failure to lock the distal portion would significantly reduce the interaction span and reduce the risk of overspread nerve damage.Association status was researched utilizing control radiographies. Reactions were noted for every patient. The utilitarian status of the shoulder and elbow was assessed utilizing the Society of the American Shoulder and Elbow Surgery (SASES) scoring framework (see Appendix 1). Scores (98 to 100) were viewed as magnificent, (95 to 98) great and under 95 were unsuitable. As characterized by the standard, span for ordinary association is 8 to 12 weeks, postponed association is 3 to a half year and for non-association it is over a half year. The particular time it takes for each patient to come back to the day by day exercises has been registered. Factual investigation was completed by method for Programming SPSS 18.0 for Windows. Results are reported as techniques ± SD and understudy t of the experiment was conducted for their correlation. Estimates of probability under.05 were considered to be critical.

Findings: Findings of our study (2017-2018) can be summarized as follows:

(a) Our male to female ratio, in the sampled age group of 31 to 55 years, was 5:2. Hence there was a clear male dominance in the sampled total of n=35 patients. On critical analysis of this, while the male preponderance dropped when we move up the age scale, many female recruits had joined the study beyond age 46 to 55 years. Thus this bimodal model is as distinctly reflected in our study too.

(b) Right sided injuries predominated at 77.14% (n=27) in our study.

(c) In the younger age group of 31 to 45 RTA was the predominant mode of injury. As we move up the age scale from 46 to 55 years, trivial fall constituted the majority of recruits, who also happened to be females.

(d) As per the 2018 AO-OTA adult diaphyseal classification system adopted in our study, type 12 B 3 constituted 40% (n=14) cases, followed closely by type 12 B 2 at 31.42 % (n=11).

(e) Our average injury to surgery time lapse was at 5.9 days (range : 0 to 11 days). From surgery to discharge our time of hospitalization was at 14.7 days (range : 8 to 19 days)

(f) 34.29 % (n=12) cases in our series of 35 cases, had an associated skeletal injury.

(g) Our average time for bone union in 97.14% (n=34) cases was 16.8 weeks (range : 12 to 21 weeks). We encountered 2.86% (n = 1) cases of non-union in a 55 year old female, who had hysterectomy done at age of 38 years for DUB at 6 months and was appropriately subjected to LCP with bone grafting which united in 5.3 months. This particular case type 12 B 3 AO-OTA grade at index fixation.

(h) Of the total complications that we encountered, 8.58 % (n=3) were minor complications like; superficial wound infection, shoulder impingement and radial nerve palsy. All resolved without affecting the final clinical or functional outcome. We did encounter a 2.86% (n = 1) of major complications of non-union, as described earlier and resolved with resurgery.

(j) Our functional outcomes as assessed by the ASES criteria was at 94.28% (n = 33) for good to excellent, at 2.86% (n = 1) of fair and 2.86 % (n = 1) of poor result.

(k) The poor outcome (n = 1) as already detailed underwent plate osteo-synthesis with bone grafting and achieved union at 5.3 months post resurgery and had a good outcome as assessed by the ASES criteria.

Discussion

This research was conducted with two primary hypotheses:

1. The failure to lock the distal bit will not cause a major problem for patients due to the broad range of motion of the shoulder, and may assist the association process by Placing your weight on the site.

2. The loss of the rotator cap would be minimal if the infinitesimally obstructive approach in the distal enactment with an strategy of 1–2 cm were used in the anterior section of the chest.

3. Pretell et al.[15] performed humeral pathological shaft breaks by intramedullary nailing techniques and average operating time was 48 minutes (extended 35–160 min). Koike et al.[16] evaluated the clinical and radiographic effects of intramedullary nailing reflexively and the mean duration of operation was 84 min (go 54–114 min). In the context of the mentioned inquiries, our scheme can significantly reduce the operating time of the complement of nails in patients with humeral shaft breaks (P<0.05). McCormack et al.[17] believes that the out-happening of the humeral shaft breaks through the intra-medullary nailing and the dynamic pressure plate and the speed of the shaft, The non-association in the collection of nails was 9.5 percent. In addition, Singisetti and Ambedkar[4] considered the clinical after-effects of nailing and plating in the planned report, and the rate of non-associated nailing was 5%. As far as the above studies are concerned, our scheme induces a marginally increased non-association rate.McCormack et al. [17] detailed 1 instances of post-usable outspread nerve paralysis among 35 patients who experienced intra-medullary nailing (2.86 %). In our patients, just one instance of post-usable spiral nerve paralysis was recognized, and the patient recouped after around about a month and a half of activity.

In our examination, the pace of connection was perfectly sufficient, and the components of the shoulder and elbow were fantastic, or if nothing else, in the vast number of the patients ; two suppositions ended up being correct.The important point is that each of the patients who had spread nervous paralysis had delayed their connection. What's more, the primary example of non-association was a patient with extensive nerve paralysis.

Conclusion

Overall, it appears that the use of infinitesimally obtrusive bet grade UHN without distal lock method is protected, easy and suitable for cracks in the femur shaft, and reduces the risk of spiral nerve damage and connection.

To Study Prevelance of Insulin Resistance in Acne Vulgaris

Paavai S.[1], Jayakar Thomas[2]

[1]Post Graduate, [2]Professor, Department of DVL,Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education and Research, Chennai-73.

Abstract

To study prevelance of insulin resistance in acne vulagaris. 30 patients were included in the study. Informed consent was obtained from all patients. we were looking insulin resistance in these patients. Among 30 patients 8 patients had insulin resistance. We found a positive correlation between insulin resistance and acne vulgaris. These findings suggest that treatments prescribed for insulin resistance are worth investigating as treatment for severe acne vulgaris.

Keywords: *Vulgaris, Insulin, acne, insulin resistance.*

Introduction

Acne is commonly a disorder of late childhood and adolescence, despite the fact that it may persist into, recur, or begin during adulthood.[1] [2] [3]Although acne has been reported in otherwise healthy children as young as 8 years, and even earlier in those with abnormal virilization or precocious puberty, most cases occur between the ages of 14 and 19 years[4-9].Skin manifestations of insulin resistance have been described to be reliable and consistent with the euglycemic insulin clamp test results. As mentioned previously, insulin resistance is defined as the reduced responsiveness of a target cell or an organ to the concentration of insulin to which it isexposed: inpractice,[10-13]it refers to the state in which insulin secretion associated with an abnormal glucose response (e.g., impaired glucose tolerance or diabetes)

Materials and Method

Study Design: Cross sectional study.

Study Area: Skin Outpatient Department, Sree Balaji Medical College and Hospital

Study Population: All male patients age above 18 attending skin OPD, who are clinically diagnosed with acne vulgaris.

Study Method: Investigational study.

Sample size: 30

Inclusion criteria:

1. Males aged above 18 years with acne 2. Consenting for the study.
3. Good general health
4. No usual intake of drugs (except acne therapy) 5. consenting for investigation

Exclusion criteria:

1. Known case of Diabetes Mellitus Type 1 or Type 2 Patients affected by other dermatological diseases or performing treatment for other endocrinopathies
2. Not consenting for the study
3. Patient not willing for the investigations 5. Patients receiving psychotropic drugs

Materials Used for Data Collection: A pre-structured and pre-tested proforma was used to collect data. Baseline data including age and sex and the recruited patients were subjected to the following

1. Full History Taking

Corresponding Author:
Paavai S.
Post Graduate, Department of DVL, Sree Balaji Medical College & Hospital Bharath Institute of Higher Education and Research, Agharam Road, Selaiyur, Chennai-73

2. Thorough General Dermatological Examination. 3. Clinical pictures

Biochemical Analysis Done for the Following

i. FASTING BLOOD SUGAR (70-110mg/dl)

ii. FASTING INSULIN LEVEL (<25mIU/L)

iii. INSULIN RESISTANCE BY–HOMA-IRSCORE

Category	HOMA-IR Score
1. Normalinsulinresistance	<3
2. Moderateinsulinresistance	Between 3 and 5
3. Severeinsulinresistance	>5

The index of insulin resistance by homeostasis model assessment (HOMA-IR) is also based on a mathematical model that allows quantifying the extent of insulin resistance. For calculating HOMA-IR was used the formula published by Matthews: HOMA-IR = [fasting insulin (μU/mL) x fasting glucose (mg/dL)]/405. This study was undertaken after obtaining clearance from the ethical committee of SBMCH. The consent form, proforma and the master chart are enclosed.

Findings: Among 30 patients 8 patients had insulin resistance, whose HOMA-IR level are more than 3.

Discussion

Acne vulgaris is a disease of pilosebaceous gland that usually affects people from puberty to young adulthood. It is seen commonly on the face, neck, trunk, and arms. Its severity differs and its pathogenesis is multifactorial. The main pathogenic factors of acne are increased sebaceous gland secretion, follicular hyper proliferation,, Propionibacterium. Four major factors play an important role in the pathogenesis of acne vulgaris: (1). Hyperplasia of sebaceous glands, (2). Increased sebum production, (3). Hyperkeratinization of (4). Propionibacterium acnes colonization and periglandular dermal inflammation. Acne is a widespread skin disease affecting individuals of all ages, particularly between the ages of 15 to 17 years. In Western populations, 79–95% of the adolescents are affected [61].Acne is also seen in adulthood although seborrhea, follicular hyperkeratinization, Propionibacterium acnes colonization, and inflammation are found to be responsible for the pathogenesis, the mechanism of acne is not known clearly. Relationship between diet and acne has been uncertain in recent years. Several studies have been conducted over the years to support this hypothesis, but they have yielded contradictory results. Therefore, in this study, we aim at investigating the relationship between severe acne vulgaris and insulin resistance.

Conclusion

We found a positive correlation between insulin resistance and acne vulgaris. These findings suggest that treatments prescribed for insulin resistance are worth investigating as treatment for severe acne vulgaris.

A Study on Age Incidence of Thyroid Nodule in Our Institution

Renuka Devi M.R.[1], Devaki P.R.[1]

[1]Professor, Department of Physiology, Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Thyroid swellings or nodule can present as both mutlinodular and solitary nodular goitre. A discrete swelling in an otherwise impalpable gland is termed as solitary nodule of thyroid. Prevalence ranges from 4% to 10% in general adult and 0.2 to 1.5% in children. The study was done Sree Balaji Medical College & Hospital from June 2017 to October 2018 in the department of General surgery. Incidence of thyroid nodule in different age groups It is concluded from the present series that peak incidence of thyroid nodule is from 50-60 years of age.

Keywords: *Thyroid nodule, MNG, SNG.*

Introduction

Thyroid nodule is a palpable clinically or radio logically over the gland[1-10]. There is a high risk of malignancy in STN than in multiple nodules. So for this, Solitary thyroid nodules have to be treated with high suspicion. Solitary thyroid nodules (STN) occur in 4-7% of the population who presented with thyroid swellings[11-20]. They are more common in females (6.4%) than males (1.5%). A preoperative through workup of thyroid nodules to differentiate benign from malignant nodules is important to avoid unnecessary surgery and related problems[21]

Material and Method

A study was carried out on 60 patients who were admitted and operated for thyroid nodule Sree Balaji Medical College. During the period ofmarch 2017 to October 2018 in the department of General surgery. All the patients were assessed for age at which they presents with thyroid nodule All the patients underwent both FNAC & post-operative Histopathology for the final diagnosis. It is prospective study.

Findings: In our study out of 60 patients were 7 were male and 53 were female patients. Solitary thyroid Nodule observed in 15 cases (Male 1-Female 14) Multinodular goitre observed in 45 cases (Male-6, Female-39). The incidence of SNG & MNG in male & female have been shown in table-1. The age incidence of SNG & MNG has been shown in table 2. & figure 1

Table 1: Sex Incidence

Sex	Solitary Nodular Goiter	Multinodular Goitre

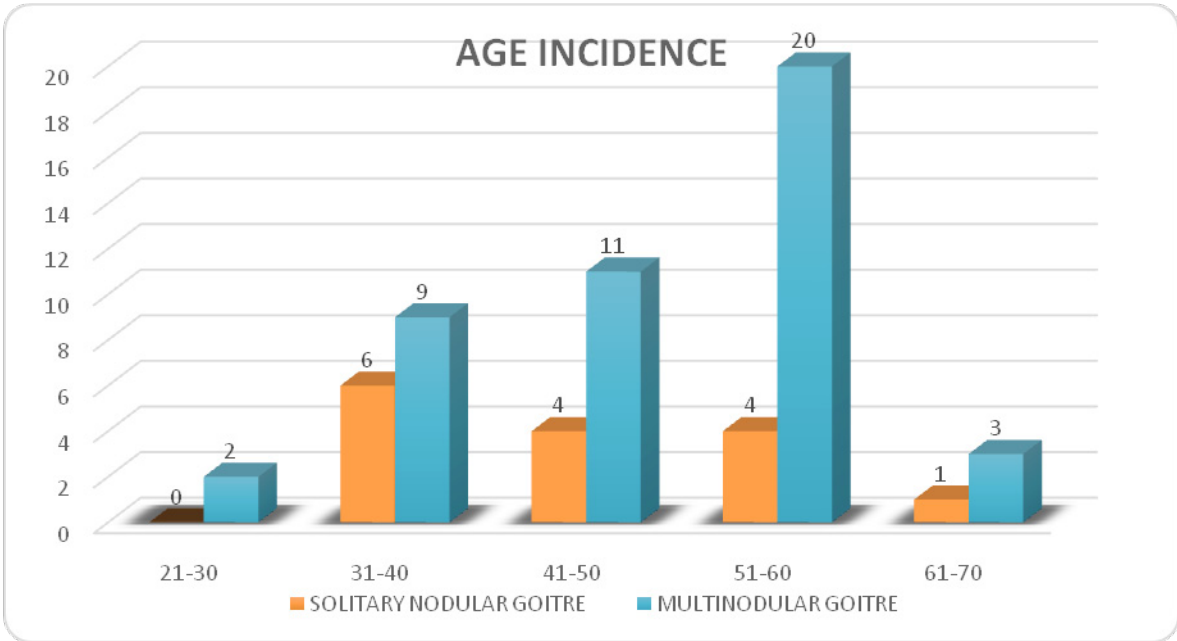

Figure 1 : age incidence of thyroid nodule as MNG & SNG

Discussion

FNAC is easy to perform and safe with minimum complication rate. Care must be taken to obtain an adequate specimen-most authors recommend between 3 to 6 aspirations is needed. Satisfactory specimen contains at least 6 groups of 10 to 15 well preserved cells. They are categorized by their appearance to benign, indeterminate or suspicious and malignant. The diagnosis of papillary thyroid carcinoma by FNAC on the basis of characteristic nuclear changes is reliable and accurate with sensitivity and specificity both approaching 100%.

Oliver H beechars *et al* stated that goitres were frequently seen in women however, the incidence of carcinoma in man is greater than in women. In our study among 60 cases, the incidence of carcinoma in Male (1.6%) is greater than in female (15%). This is in accordance with various published reports. Fenn A.S *et al*1976 found that there was no great sex predominance in the incidence of malignancy. [20]According to Dr. C. Suryaprakash Rao et al,–Andhra Pradhesh–Adenoma thyroid was the commonest benign lesion and papillary carcinoma was the commonest malignant lesion. Prof. R.L Gupta Delhi analyses 370 cases of solitary nodule. In his study, about 38.7%. OF HPE report was different from FNAC. His study showed the fact that FNAC is not full proof and surgery with HPE report remain the only method of confirmation. [21]

As Per Hossein gharib and papini*et al.* [8] nodule size is not predictive of malignancy. They have reported the following features are associated with increased risk of malignancy in thyroid nodule.

H/o of childhood head and neck radiation

Family H/o of PTC, MTC, or MEN 2 (multiple endocrine neoplasia)

Age 20 or >70 yrs

Male sex

Abnormal cervical adenopathy

Fixed nodule

Vocal cord paralysis.

They concluded that risk of cancer is not significantly higher for solitary nodular than for glands with multiple nodules. But in our study the incidence of carcinoma in solitary nodular goitre (6.66%) is more than multinodular goitre (20%). Raghuveerpedamullu, et al, conducted a retrospective study of 98 cases of MNG who underwent total thyroidectomy at Guntur government general hospital (India) from 2001 to 2004 he found the prevalence of MNG in female 88% in males 12% and incidence of female 88%. He concluded that inspite of negative FNAC the patients can still

harbor a malignant focus due to high sampling error with MNG [12]. In our study FNAC showed 50 cases of nodular colloid goitre but histopathology showed only 42 nodular colloid goitre cases, the 8 cases turned out to be, papillary carcinoma in 3 cases, follicular adenoma in 4 cases, hashimoto's thyroiditis in one case.

Conclusion

Results were compared with available literature reported previously. The patients admitted with thyroid nodules were seen in the age group of 50-60 years of age were more There are no cases below 10 years of age. Papillary carcinoma is the commonest malignancy observed constituting to 80% of the malignancies.

A Study on Cutaneous Hyperandrogenism in Adult Male with ACNE

Paavai S.[1], Thomas Jayakar[2]

[1]PG Student, [2]Professor, Department of DVL, Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

To study cutaneous hyperandrogenism in adult male with acne. 30 patients were included in the study. Informed consent was obtained from all patients. we were looking for cutaneous hyperandrogenism in male above 18 years of age. Among 30 patients 21 patients had acanthosis nigricans, 20 had alopecia, 22 had seborrhea, 8 had insulin resistance. To conculde, Male acne Patients with clinically diagnosed cutaneous hyperandrogenism need not have elevated hormonal levels, however there was an association with insulin resistance was found.

Keywords: *Cutaneous hyperandrogenism, Male, ACNE.*

Introduction

Acne is frequently a disease of late childhood and adolescence, despite the reality that it may persist, recur or start in adulthood. Although acne has been recorded in otherwise healthy children as young as 8 years of age and even sooner in those with unusual virilization or precocious puberty, most instances happen between 14 and 19 years of age.[1-5]

Commonness expanded with age more quickly among more youthful than more established young people, from 39% at age 12 years to 86.4% at age 17 years, and the expansion in pervasiveness with age was more fast and predictable among young men than young ladies[6-9]. Progressively extreme facial skin inflammation (characterized in the overview as at any rate comedones, little pustules, and an inclination toward aroused sores more profound than the follicular opening) was available in an a lot littler extent of adolescents.[10-12]

It is observed that hyperandrogenism occurs in men. The manifestations are usually in the form of patterned alopecia, Acanthosis nigricans, and acne. The name APAAN (acne, patterned alopecia, acanthosis nigricans) syndrome is suggested for this presentation in men.

Materials and Method

Study Design: Cross sectional study.

Study Area: Skin Outpatient Department, Sree Balaji Medical College and Hospital.

Study Population: All male patients age above 18 attending skin OPD, who are clinically diagnosed with acne vulgaris.

Study Method: Investigational study.

Sample Size: 30

Inclusion criteria:

1. Males aged above 18 years with acne
2. 2. Consenting for the study.
3. Good general health
4. No usual intake of drugs (except acne therapy)
5. 5. consenting for investigation

Exclusion criteria:

1. Known case of Diabetes Mellitus Type 1 or Type 2
2. Patients affected by other dermatological diseases or

performing treatment for other endocrinopathies

3. Not consenting for the study
4. Patient not willing for the investigations 5. Patients receiving psychotropic drugs

Materials Used for Data Collection:

1. A pre-organized and pre-tried proforma was utilized to gather information. Benchmark information including age and sex and the enlisted patients were exposed to the accompanying
2. Occupied History Taking
3. Detailed General Dermatological Examination.
4. Clinicalpictures

Biochemical Analysis Done for the Following

1. DHEAS. (35–430 µg/dl),
2. TOTAL TESTOSTERONE. (2.4-12ng/ml),
3. FASTING BLOOD SUGAR.(70-110mg/dl)
4. FASTING INSULIN LEVEL (<25mIU/L)
5. INSULIN RESISTANCE BY–HOMA-IRSCORE

Category	HOMA-IR Score
1. Normalinsulinresistance	<3
2. Moderateinsulinresistance	Between 3 and 5
3. Severeinsulinresistance	>5

The record of insulin obstruction by homeostasis model appraisal (HOMA-IR) is likewise founded on a scientific model that permits measuring the degree of insulin resistance.For computing HOMA-IR was utilized the equation distributed by Matthews:HOMA-IR = [fasting insulin (µU/mL) x fasting glucose (mg/dL)]/405. This investigation was embraced in the wake of acquiring freedom from the moral advisory group of SBMCH. The assent structure, proforma and the ace graph are encased.

Result

Correlation of apaan syndrome with fasting insulin, fasting glucose, insulin resistance, dheas, and total testosterone.

Independent Samples Test							
APAAN_syndrome		**N**	**Mean**	**Std. Deviation**	**Std. Error Mean**	**t value**	**p value**
Fasting insulin	No	14	9.445	5.657	1.512	2.006	0.055
	Yes	16	13.966	6.564	1.641		
Fasting glucose	No	14	84.857	6.024	1.610	3.053**	0.005
	Yes	16	93.063	8.322	2.081		
HOMAIR	No	14	2.011	1.329	0.355	2.175*	0.038
	Yes	16	3.279	1.789	0.447		
DHEAS	No	14	280.791	97.313	26.008	0.427	0.673
	Yes	16	264.311	112.145	28.036		
Total testosterone	No	14	7.286	1.465	0.391	0.688	0.497
	Yes	16	6.919	1.457	0.364		

*p<0.05 **p<0.001

Fasting glucose level: among 30 cases 16 were with APAAN syndrome and 14 were without APAAN syndrome. Fasting blood glucose was statistically high (93.063) with APAAN syndrome patient when compared to patients without APAAN syndrome patients (84.857). off p-value 0.005* which is more significant. Insulin resistance level: it was calculated by standardized HOMA IR formula. Insulin resistance was high with APAAN syndrome (3.279) when compared with the absence of APAAN syndrome patients (2.011) off pvalue 0.673 ** which is found to be statistically more significant. Fasting insulin level was high in APAAN syndrome patients (13.9660) when compared to patients with absence of APAAN syndrome patients which was (9.4445) which is statistically more significant of p-value 0.055. DHEAS was less in presence in APAAN

syndrome (264.311) when compared with the absence of APAAN syndrome (280.791) which is found to be statistically less significant of p-value 0.673. Total testosterone level was found to be less in APAAN syndrome present patient (0.364) when compared with the absence of APAAN syndrome (0.391) of p-value (0.497) which is found to be statistically less significant.

Findings and Discussion

Acne is mostly a disease of late childhood and adolescence, despite the reality that it may persist, recur or start in adulthood. Although acne has been recorded in otherwise healthy children as young as 8 years of age and even sooner in those with unusual virilization or precocious puberty, most instances happen between 14 and 19 years of age.

Four central point assume a significant job in the pathogenesis of skin inflammation vulgaris: (1). Hyperplasia of sebaceous organs, (2). Expanded sebum generation, (3). Hyperkeratinization of pilosebaceous pipes and (4). Propionibacterium acnes colonization and periglandular dermal aggravation. Androgens animate the generation of sebum, the development of the sebaceous organs and hyperkeratinization. Clinical manifestations of hyperandrogenism are acanthosis nigricans, alopecia, seborrhea.

It is observed that hyperandrogenism occurs in men. The manifestations are usually in the form of patterned alopecia, Acanthosis nigricans, and acne. The name APAAN (acne, patterned alopecia, acanthosis nigricans) syndrome is suggested for this presentation in men

The pathogenetic procedure of skin break out seems to initiate with androgenic hormonal incitement of pilosebaceous units, the thickness of pilosebaceous units is most noteworthy on the face and scalp (400–800 organs/cm2) and least on the furthest points (50 organs/cm2). Before the degrees of coursing androgens increments, pilosebaceous units comprise of delicate, fine, unpigmented vellus hair and little sebaceous organs. Circling androgens tie to androgen receptors that are limited to the basal layer of the external root–sheath keratinocytes of the hair follicle and to sebaceous organs. “In sexual areas, such as the axilla, pilosebaceous units begin to differentiate into large terminal hair follicles. In sebaceous areas, such as the face, pilosebaceous units become sebaceous follicles while the hair remains vellus. Without circulating androgens, the sebaceous glands remain small. The gonads and adrenals produce the majority of circulating androgens. During the period of prepubertal, adrenal androgens appear to be the major determinant of sebaceous gland activity.” In the two young men and young ladies, plasma centralizations of the adrenal androgens dihydroepiandrosterone (DHEA) and dihydroepiandrosterone sulfate (DHEAS)’’ ordinarily start to increment at adrenarche, or adrenal pubescence, which commonly happens at about age 8 years, and keep on ascending through adolescence. Conditions like adrenal hyperplasia or polycystic ovary sickness are related with hyperandrogenism. Skin manifestations of insulin opposition have been depicted to be dependable and steady with the euglycemic insulin brace test outcomes. As referenced already, insulin obstruction is characterized as the decreased responsiveness of an objective cell or an organ to the convergence of insulin to which it is uncovered: by and by, it alludes to the state where insulin emission related with an unusual glucose reaction (e.g., hindered glucose resilience or diabetes).

Conclusion

To conculde, Male acne Patients with clinically diagnosed cutaneous hyperandrogenism need not have elevated hormonal levels, however there was an association with insulin resistance was found.

Platelet-Rich Plasma Injections for Chronic Plantar Fasciitis

Vivek K.[1], G. Jagan[2]

[1]Post Graduate, [2]Professor, Department of General medicine,Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

The purpose of this study was to assess the safety and preliminary clinical results of platelet-rich plasma (PRP) injections for treating chronic plantar fasciitis. The present sample size of 40 patients were analysed prospectively by injecting platelet rich plasma in plantar fasciitis. The study was conducted in sreebalaji medical college and hospital from March 2017 to March 2018 with a follow up period of 3 months duration. The visual analogue scales (VAS) for pain were used to evaluate the clinical results. The mean difference between in VAS scoring system at the time of presentation was 8.4%, and there was gradual and significant improvement in VAS scoring system in plantar fasciitis. Which showed as 4.925% at 1st month, 3.375% at 2nd month, and 1.925% at 3rd month respectively. In this single-centre, uncontrolled, prospective, preliminary study, results indicate that treating chronic plantar fasciitis with PRP injections is safe and has the potential to reduce pain.

Keywords: *Platelet rich plasma, and plantar fasciitis.*

Introduction

Platelet rich plasma (PRP) injections are widely studied for treating various musculoskeletal disorders due to its increased healing properties.[1] The contains growth factors such as Platelet-Derived Growth Factor, Insulin-Like Growth Factor, Transforming Growth Factor, Epidermal Growth Factor (EGF), Vascular Endothelial Growth Factor (VEGF), Fibroblast growth factor. Interaction of this growth with differentiation factors, and the adhesive protein factors such as fibronectin and vitronectin are responsible for the healing response promoting the regenerative process of chemotaxis, self proliferation, tissues debries, angiogenesis, extra cellular matrix formation, osteoid production and collagen synthesis, which enhance the healing rate in chronic tendinopathies.[2]This methodology of treating chronic tendinopathies has general importance as this form a connecting approach between conservative management as well as surgical management.[3]The common cause of heel pain is plantar fasciitis which affect 10% of the general population. The age group of 40-70 years most commonly occurs.[4] It tends to occur more often in women, middle aged, military recruits, athletes and the obese persons.[5] The inflammation is due to repeated trauma from overuse or injury. The degeneration occurs at origin of the plantar fascia at the medial tuberosity of the calcaneum.[6]Various method have been advocated for treating this condition like rest, non-steroidal anti inflammatory drugs, night splints, keeping appropriate wedge on shoe, soft heel pad, plantar stretching exercises, ultrasound massage to heel, extracorporeal shock wave therapy (ESWT), local corticosteroid injections, and operative treatments.[7]The purpose of this study was to assess the safety of PRP injections for treating chronic plantar fasciitis and provide initial clinical assessment of its effectiveness.

Materials and Method

The present sample size of 40 patients were analysed prospectively by injecting platelet rich plasma in plantar fasciitis. The study was conducted in sreebalaji medical college and hospital from March 2017 to March 2018 with a follow up period of 3 months duration.

Inclusion criteria:

1. Plantar fasciitis diagnosed patients.
2. Patients should have minimum three months duration of symptoms.
3. Patients should undergo conservative treatment for a minimum period of three months.
4. Pain scores more than seven at the time of injection.
5. Local steroid injection in the last 2 months.
6. Both male and female
7. Age group above 20 years.

Exclusion criteria:

1. Plantar fasciitis of less than three months duration.
2. Pain scores less than seven.
3. Patients without any trial of conservative treatment.
4. Recent local steroid injection.
5. Patients suffering from other causes like rheumatoid arthritis, Sero negative spondylo arthritis.
6. Infection or ulcer at the injection site.
7. Patients less than 20 years.
8. Cancer.
9. Women in lactation and pregnancy

Pain assessment:

Visual Analogue Scale (VAS):

No pain ***Worst Possible Pain***

Method of preparation of platelet rich plasma: Initially a venous puncture is done and specific volume of autologous blood is collected from the patient (10ml of venous blood sample) into a tube containing an anticoagulant (sterile sodium citrated tubes) At 1800 rotations/minute (rpm) for 15 mins centrifugation takes place separating plasma from packed red blood cells. The top layer consists of plasma and bottom layer consists of red blood cell. The plasma is shifted to a sterile tube following which the packed cell layer is discarded. The second centrifugation takes place at 3500 rpm for 10 min which yields concentrated platelet layer after extraction of platelet poor plasma.

Injection technique: Patient in supine position and palpate most tenderness point and marked using skin marker. The area was prepared and draped for injection. Initially,a local block of lignocaine is infiltrated subcutaneously. Under proper aseptic precaution a 21-g needle is used to inject, 1ml platelet rich plasma is injected over the maximum tenderness while the remaining platelet rich plasma is injected into the surrounding tissue. (figure 1).

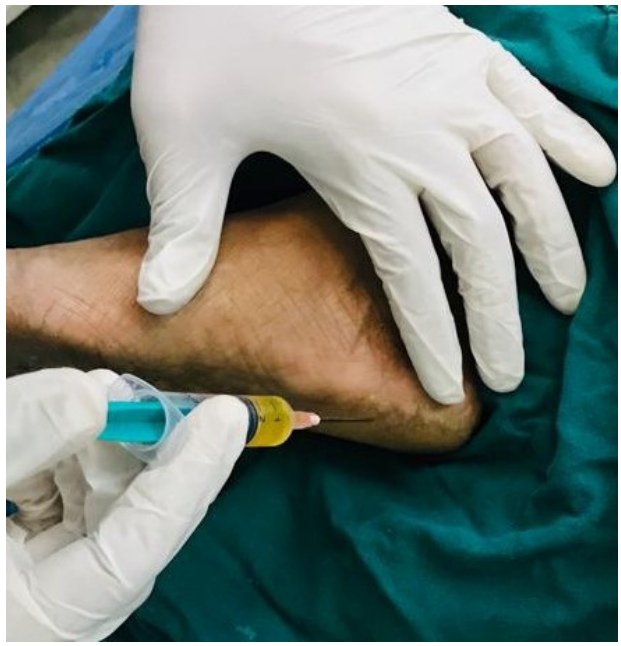

Figure 2: Injecting platelet rich plasma in plantar fasciitis patient.

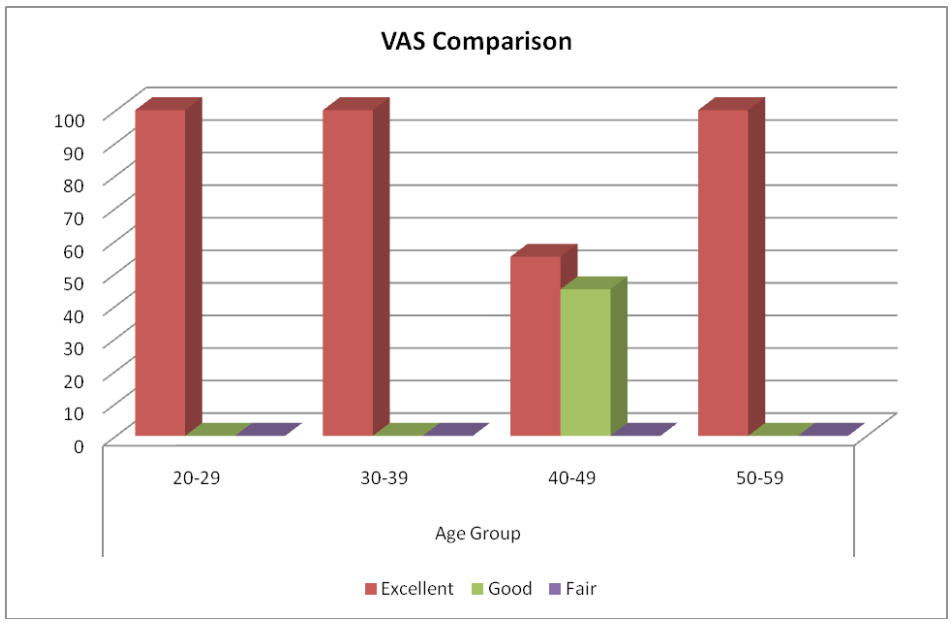

Follow Up: Patients were followed up for 3 months. Follow ups was done at 1st, 2nd and 3rd month. Patients were assessed subjectively using the visual analogue score.

Findings: SPS software system was used to do statistical analysis by comparing the results. Patients were analysed for pain relief subjectively at 1st 2nd and 3rd month post injection therapy and there pain is tabulated using visual analogue score (VAS) (pain score).

Table 1: Comparison of VAS score with age in Plantar Fascitis:

VAS Score	Age Group				Total
	20-29	30-39	40-49	50-59	
Excellent	2 (100)	8 (100)	11 (55)	10 (100)	31 (77.5)
Good	0	0	9 (45)	0	9 (22.5)
Fair	0	0	0	0	0
Total	2 (100)	8 (100)	20 (100)	10 (100)	40 (100)
Chi sq	11.613		P value	0.009*	

*-Significant ($p<0.05$)

Mean Pain Score: Pain score was assessed at the time of injection. The mean pain score of all the patients was 8.4%. The mean pain score at 1,2,3 months was 4.925%, 3.375%, and 1.925% respectively.

Table 2: Mean pain score:

Patient	Mean pain score at the time of injection	Mean pain score at 1st month	Mean pain score at 2nd month	Mean pain score at 3rd month
Plantar fasciitis (40)	8.45%	4.925%	3.375%	1.925%

Result

The mean difference between in VAS scoring system at the time of presentation was 8.4%, and there was gradual and significant improvement in VAS scoring system in plantar fasciitis. Which showed as 4.925% at 1st month, 3.375% at 2nd month, and 1.925% at 3rd month respectively.

Discussion

The growing trend in using platelet rich plasma injection for condition like plantar fasciitis had significantly improved in last decade. The steep rise in use of platelet rich plasma is because of good functional outcome of this modality.

We have taken up this study to evaluate the efficacy of platelet rich plasma in plantar fasciitis. We selected a sample size of 40 patients who were suffering from plantar fasciitis. Comparison of VAS score at each group for plantar fasciitis had a significant difference at the end of mean follow up period of 3 months. The P value was 0.009. Which was found to be significant.

The comparison of these groups for plantar fasciitis at different age groups had shown significant difference in their outcome at the end of 3 months. Therefore usage of platelet rich plasma injection in plantar fasciitis has show significant outcome due to its healing properties.

The mean VAS score system shows significant difference in pain varying from time of injections till the end of 3rd month. Initial VAS score was (8.4%), at the end of one month (4.925%), two months (3.375%) and three months were (1.925%) respectively. This shows significant outcome of improvement in plantar fasciitisIn our study, there were certain limitations such as multiple scoring technique, volume of patient, and long term follow up study needs to be done for knowing the better outcome of platelet rich plasma injection.

Conclusion

In conclusion, we consider that platelet rich plasma injection in plantar fasciitis has served as an effective tool in management of these conditions. The significant difference in P value in different age groups had shown a proportionate improvement due to platelet rich plasma injection in varying age groups. Hence this type of management decreases the progressiveness for surgical management of plantar fasciitis.

The Functional Outcome of Antegrade Unreamed Humeral Interlocking Nailing in Adults

P. Vivekanandhan[1], Venkatachalam K.[2]

[1]Orthopedics Post Graduate, [2]Professor, Department of Orthopaedics, Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Fractures of the humerus shaft account for roughly 1% of all fractures handled. The method of interconnecting nails reflects a newer approach to the therapy of humeral broken bones. The aim is to prospectively study the "functional outcome of antegrade intramedullary interlocking nailing in fracture shaft of humerus" at the Department of Orthopaedics in Sree Balaji Medical College and Hospital chrompet Chennai. The recruitment period of this study shall be from March 2017 to February 2018 (12 months). The follow-up period shall be for a minimum period of 7 months (range: 7 to 19 months). Radiological union, practical outcome and problems have been evaluated. By the end of 6 months, the Union rate was 97.14 per cent. According to Rodriguez-Merchan EC, of the 35 patients evaluated, 16 patients had outstanding functional ratings, 12 had good ratings, 4 had reasonable ratings and 3 had bad ratings. There was 1 case of non-union, 1 case of superficial infection, 1 case of profound infection and 1 case of shoulder stiffness. Unreamed humeral interlocking nail is an efficient means of fixing severe humeral fractures.

Keywords: *Interlocking, Nailing, Adults.*

Introduction

Fractures of the humerus shaft account for roughly 1% of all fractures treated [1]. Historically, injuries in the humeral shaft have been categorized by fracture place, injury pattern, connected soft tissue injury and tissue quality. This fracture was handled by closed decrease & cast application with/without cast compression and by open decrease & inner fixation using dynamic compression. Many authors have recorded the general good result following the fixation of the compression plate [2 3 4],which is still regarded to be the gold standard for the intelligence analyst treatment of acute humeral shaft fractures. Although plate fixation has resulted in elevated levels of bonding, it includes comprehensive soft tissue stripping, potential injury to the radial nerve, and bad bone fixation. Later flexible nails of many types have been used [56]. The benefits of intramedullary nailing are minimal surgical awareness, better biomechanical obsession, minimal soft tissue disruption and early mobilization of adjacent joints.

The method of interlocking nails reflects a newer approach to the therapy of humeral fractures. Intertwining nailing also prevents problems such as absence of rotational control, migration of nails and the need for additional bracing [7 8]. The Seidel nail was the first to be medically tested. Ultimately several nail systems developed [3 7 9 10 11]

The published surveys of Cox MA and Crates Junion rates were 87.9% and 94.5% respectively for antegrade interlocking nailing. Antegrade overlapping nailing has a greater rate of rigidity of the shoulder. The unheard intramedullary nail has its own separate theoretical benefits, such as removing the risk of idiopathic fractures, saving cortical blood supply and reducing harm.[12-16]

The objective of this research was to assess the functional result after an antegrade previously unheard interlocking of the humeral fracture shaft, the rate of association and the triggers of bad outcome.

Materials and Method

The aim is to prospectively study the "functional outcome of antegrade intramedullary interlocking nailing in fracture shaft of humerus" at the Department of Orthopaedics in Sree Balaji Medical College and Hospital chrompet Chennai. The recruitment period of this study shall be from March 2017 to February 2018 (12 months). The follow-up period shall be for a minimum period of 7 months (range: 7 to 19 months). Radiological union, functional outcome and complications were assessed. All the nails have been placed through an entry point, only medial to greater tuberosity. Reaming was not performed to prevent harm to the radial nerve and to decrease harm to the rotator cuff. All of these fractures were resolved by means of a universal humeral nail with a diameter of 6.7 mm and a suitable length calculated intraoperatively. Distal locking was performed by freehand method using escalation of the picture. The next lock was performed using the jig. In all cases, the rotator cuff was repaired. In 35 patients, the operated limb was restrained for 2 days and the active facilitated shoulder insurrection began on the 3rd preoperative day. We followed up 35 patients for at least 7 months postoperatively.

The radiological union was described as the existence of bridging calluses of their cortices in two orthogonal positions(7). Delayed union was described as a 4-month fracture failure. Non-union was characterized as a six-month fracture failure or proof of a fixing failure.(3) The operational result was evaluated using the Rodriguez-Merchan EC criteria(10). The range of movements was measuredby a single observer using a goniometer.

GRADING	ELBOW ROM	SHOULDER ROM	PAIN	DISABILITY
EXCELLENT	EXTENTION 5 FLEXION 130	FULL ROM	NONE	NONE
GOOD	EXTENTION 15 FLEXION 120	<10% LOSS OF TOTAL ROM	OCCASIONAL	MINIMUM
FAIR	EXTENSION 30 FLEXION 110	10-30% LOSS	WITH ACTIVITY	MODERATE
POOR	EXTENSION 40 FLEXION 90	>30% LOSS	VARIABLE	SEVERE

Shoulder stiffness was defined as per Benjamin Shaffer(12) and Douglas(13) criteria.

1) History of injury or repeated trauma or operation with a rigidity start that structurally limits the use of the severity.
2) Assessment with restricted shoulder movement in a particular direction, multi-directional or worldwide.
3) Radiograph with a standard cartilage joint area.
4) The range of movement of the shoulder, which was less than 90% of the spectrum when the distal shoulder was not affected.

Findings: In this cross sectional study, an analytical approach was adopted to assess Functional result of the antegradeintramedullar intertwining nailing in the bone shaft of the femur at the Department of Orthopaedics in Sree Balaji Medical College and Hospital chrompet Chennai. Functional outcome was assessed with rodriguez-merchan criteria.

Study Groups Based on Outcomes	Poor	Percentage
Poor	3	8.57
Fair	4	11.43
Good	12	34.29
Excellent	16	45.71
Total	35	100.00

It is evident from the age distribution table that majority of poor outcome subjects belonged to 51-60 years age category (66.67%) with a mean age of 48.67 years, majority of fair outcome subjects belonged to 51-60 years age category (100%) with a mean age of 44.00 years, majority of good outcome subjects belonged to 41-50 years age category (58.33%) with a mean age of 43.83 years and majority of excellent outcome subjects belonged to 31-40 years age category (45.71%) with a mean age of 40.48 years. The data subjected to one way ANOVA test reveals the existence of statistically significant association between the age distribution and study groups ($p < 0.05$).

It is evident from the gender status table that majority of poor outcome subjects are males (66.67%), majority of fair outcome subjects are females (75.00%), majority of good outcome subjects are males (91.67%) and majority of excellent outcome are males too (68.75%). The data subjected to chi squared test reveals the existence of statistically non-significant association between the gender status and study groups ($p > 0.05$).

It is evident from the side involved status table that majority of poor outcome subjects had right side involvement (66.67%), majority of fair outcome subjects had right side involvement (75.00%), majority of good outcome subjects had right side involvement (66.67%) and majority of excellent outcome had right side involvement too (87.50%). The data subjected to chi squared test reveals the existence of statistically non-significant association between the side involved status and study groups ($p > 0.05$).

It is evident from the mode of Injury table that majority of poor outcome subjects had trivial fall (66.67%), majority of fair outcome subjects right had trivial fall (75.00%), majority of good outcome subjects had RTA (58.33%) and majority of excellent outcome had RTA too (50.00%). The data subjected to chi squared test reveals the existence of statistically significant association between the mode of injury and study groups ($p < 0.05$).

It is evident from the fracture pattern status table that majority of poor outcome subjects had B2 fracture pattern (66.67%), majority of fair outcome subjects had B2 fracture pattern (50.00%), majority of good outcome subjects had A1 fracture pattern (41.67%) and majority of excellent outcome had A1 fracture pattern too (56.25%). The data subjected to chi squared test reveals the existence of statistically non-significant association between the fracture pattern status and study groups ($p > 0.05$).It is evident from the associated injuries status table that majority of poor outcome subjects had no associated injuries (100%), majority of fair outcome subjects had no associated injuries (100.00%), majority of good outcome subjects had no associated injuries (66.67%) and majority of excellent outcome had associated injuries (50.00%). The data subjected to chi squared test reveals the existence of statistically non-significant association between the associated injuries status and study groups ($p > 0.05$).It is evident from the injury to surgery interval table that majority of poor outcome subjects had injury to surgery interval 12-15 days (66.67%), majority of fair outcome subjects right had injury to surgery interval 12-15 days (75.00%), majority of good outcome subjects had injury to surgery interval 0-3 days (42.86%) and majority of excellent outcome had injury to surgery interval 0-3 days too (50.00%). The data subjected to chi squared test reveals the existence of statistically significant association between the injury to surgery interval and study groups ($p < 0.05$).It is evident from the complication status table that majority of poor outcome subjects had complications (100%), majority of fair outcome subjects had no complications (100%), majority of good outcome subjects had no complications (91,67%) and majority of excellent outcome had no complications too (100%). The data subjected to chi squared test reveals the existence of statistically significant association between the complication status and study groups ($p < 0.05$).It is evident from the time for union distribution table that majority of poor outcome subjects had time for union of 13 weeks (50.00%) with a mean time for union of 12.50 weeks, majority of fair outcome subjects had time for union of 13 weeks (50.00%) with a mean time for union of 12.50 weeks, majority of good outcome subjects had time for union of 12 weeks (41.67%) with a mean time for union of 13.00 week.

Discussion

In our study the age distribution between poor, fair, good and excellent outcome groups were meaningfully significant. This is evident by the increased mean age in poor outcome group compared to fair outcome group (mean increased difference of 4.67 years, 10% higher), increased mean age in poor outcome group compared to good outcome group (mean increased difference of 4.83 years, 11% higher) and increased mean age in poor outcome group compared to excellent outcome (mean increased difference of 8.29 years, 17% higher). A negative correlation is observed between age and the functional outcome. in Ante grade intramedullary interlocking nailing in fracture shaft of humerus surgeries as age of patients increases poorer outcome occurs more commonly.

In our study the mode of injury status between poor, fair, good and excellent outcome groups were meaningfully significant. This is evident by the increased incidence of trivial fall as mode of injury in poor and fair outcome groups compared to good and excellent outcome groups (percentage increased difference of 66.67 points, 94% higher) and the increased incidence

of RTA as mode of injury in good and excellent outcome groups compared to poor and fair outcome groups (percentage increased difference of 25.00 points, 46% higher). An associative pattern is observed between mode of injury and the functional outcome. Ante grade intramedullary interlocking nailing in fracture shaft of humerus surgeries due to RTA is associated with better outcomes and due to trivial injuries is associated with poorer outcomes commonly as RTA is usually associated with younger patients who have a better outcome due to age factor compared to older patients who suffered fractures due to trivial falls.

In our study the mode of injury status between poor, fair, good and excellent outcome groups were meaningfully significant. This is evident by the increased incidence of injury to surgery interval of 12-15 days in poor and fair outcome groups compared to good and excellent outcome groups (percentage increased difference of 33.33points, 89% higher) and the increased incidence of injury to surgery interval of 0-3 days in good and excellent outcome groups compared to poor and fair outcome groups (percentage increased difference of 51.04 points, 100% higher). An associative pattern is observed between mode of injury and the functional outcome. Ante grade intramedullary interlocking nailing in fracture shaft of humerus surgeries with shorter injury to surgery interval is associated with better outcomes and loner injury to surgery interval is associated with poorer outcomes commonly.

In our study the complications status between poor, fair, good and excellent outcome groups were meaningfully significant. This is evident by the increased incidence of complications in poor outcome groups compared to fair, good and excellent outcome groups (percentage increased difference of 97.2 2points, 97% higher). An associative pattern is observed between complication status and the functional outcome. Ante grade intramedullary interlocking nailing in fracture shaft of humerus surgeries with arising complications is associated with poorer outcomes commonly.

Conclusion

In our research, while evaluating the functional result of the antegradeintramedullar intersecting nailing in the fracture structure of the femur at the Department of Orthopaedics in Sree Balaji Medical College and Hospital chrompet Chennai, on internal comparison the following significant conclusions were observed:

Gender, side involved, fracture pattern, associated injuries, nail size, follow up interval and time for union have no significant association with functional outcomes

- Increasing age is a factor associated with poorer outcomes (> 50 years)
- Excellent surgical outcomes are commonly seen in cases as result of road traffic accidents
- Poor surgical outcomes are commonly seen in cases as result of trivial falls
- Longer injury to surgery interval is a factor associated with poorer outcomes (> 12 days)
- Poor surgical outcomes are commonly seen in cases with arising complications
- Ideal candidate to predict excellent outcome
- Patient aged < 50 years with fracture shaft of humerus as a result of road traffic accidents with injury to surgery interval < 8 days with no complications
- This study is a hypothesis proving study.

Distribution of Age and Sex in Patients with Facial Trauma Referred for Computed Tomography Scan

M. Prabakaran[1], Ramachandra Prasad T.[1]

[1]Professor, Department of Radiodiagnosis, Sree Balaji Medical College, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Young kids are generally under parental supervision in safe settings and are therefore less probable to be subjected to significant accidents, occupational trauma, or interpersonal violence typical of adult facial fractures. Understanding the causes, seriousness and particular features of paediatric fractures is vital to avoid esthetic and functional deficits and will enhance our capacity to avoid accidents.

Keywords: *Facial trauma, Tomography.*

Introduction

The skull is made up of eight cranial bones and 14 bones of the face. There are few of these bones in pairs. Maxilla, palatine bones, zygomatic bones, lacrimal bones, nasal bones, and lower nasal conchae are the combined bones of the body. The vomer and mandible are the single bones.

There are many sutures that hold the facial bones together and keep them aligned, some of the sutures are frontozygomatic suture, frontomaxillary suture, frontolacrimal suture, frontonasal suture, temporozygomatic suture, zygomaticomaxillary suture, lacrimomaxillary suture, nasomaxillary suture and internasal suture.Facial bone and soft tissue injuries are a prevalent disease. Their prevalence varies from 20% to over 50% of traumatic emergency space admitted instances. The most common causes of these pathologies include traffic injuries (up to 80% of instances), immediate force, mostly during an attack (up to 60% of instances), falling (up to 25% of instances), and sports incidents (up to 10% of instances) [1–5].

In the pediatric age bracket, facial skeleton injuries are uncommon relative to adolescents. Retrospective surveys of maxillofacial injury involving both males and kids showed that less than 15% of such injuries occur in kids under the era of 16 and less than 1% of all facial injuries occur in kids under the era of [6,7].

Pediatric facial bones are shielded by the small face-to-head volume ratio of children, which enables the cranium to absorb most of the violent effect, rather than the head. In addition, the facial bones of children are more susceptible to fractures owing to their greater elasticity, absence of sinus pneumatization, heavier osseous walls encircled by adipose tissue, and stability of the mandible and maxilla by unraveled teeth[8].

Young kids are generally under parental supervision in safe settings and are therefore less probable to be subjected to significant accidents, occupational trauma, or interpersonal violence typical of adult facial fractures[9,10].

Understanding the causes, seriousness and particular features of pediatric fractures is vital to avoid esthetic and functional deficits and will enhance our capacity to avoid such accidents[11].

Materials and Method

- The research population consisted of 150 clients who had CT facial skull injury assessments to the emergency department in Sree Balaji Medical College and Hospital, Chennai attached to the Bharath University.

  Study Design: Descriptive study.

Corresponding Author:
M. Prabakaran
Professor, Department of Radiodiagnosis, Sree Balaji Medical College, Bharath Institute of Higher Education and Research, Agharam Road, Selaiyur, Chennai-73

Study Period: March 2017 to October 2018.

Inclusion Criteria: All individuals with clinical proof of facial bone injury who are subjected to multi-slice CT testing and are found to be favorable for fractures.

Exclusion Criteria: Patients with injury to facial skeleton in whom a CT examination is contraindicated. Eg. Pregnancy.

Findings:

Data Analysis:

Age distribution of patients in the study: In this research team consisting of a total of 150 participants, the majority of participants belonged to the age communities of 21-30 and 31-40.

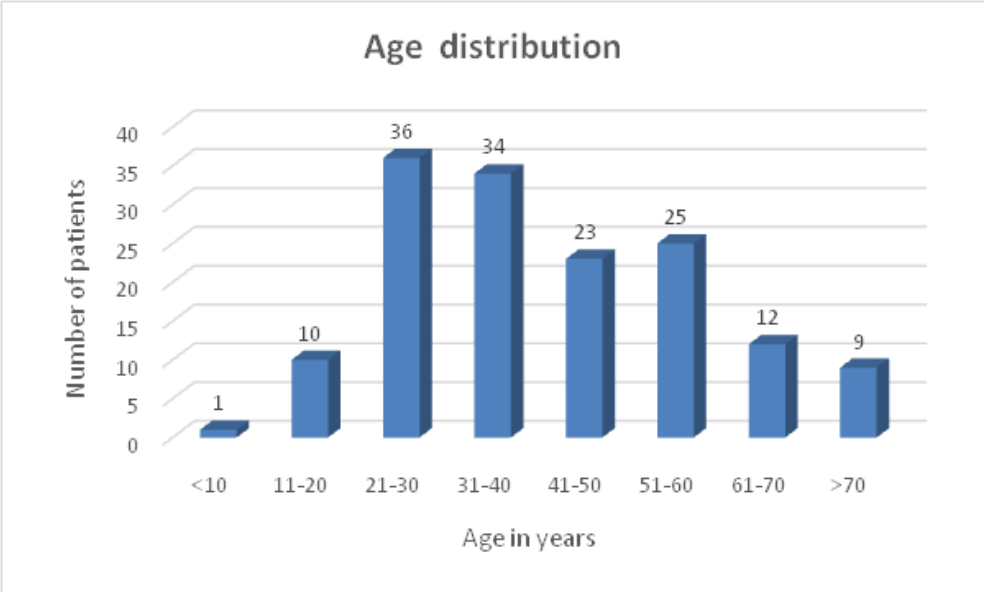

Chart 1: Age distribution of patients presenting with facial fractures.

Sex distribution of patients in the study: Among 150 patients included in this study. 63% were males and 37% were females having facial bone fractures.

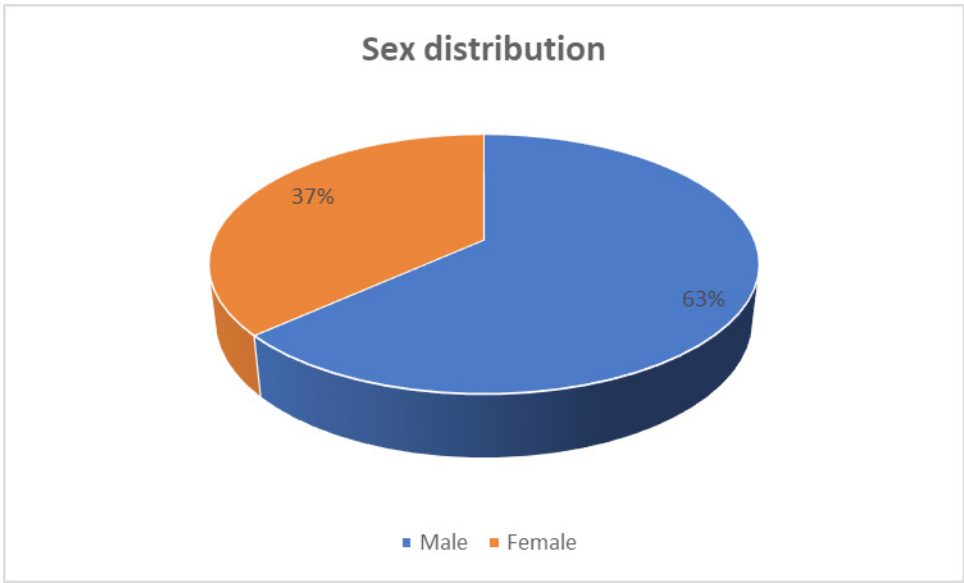

Chart 2: Pie chart showing the comparative percentages in the research set of men and women.

This study shows that there is male preponderance in facial trauma with suspected facial fractures and young age group of 21-40 years is most commonly involved.

Discussion

Facial trauma is an isolated injury or portion of polytrauma and is clinically essential because the disturbance of smooth tissues and facial bones creates facial asymmetry and disfiguration that creates mental and cosmetic problems. [12].

More adult-like lifestyles had evolved in patients aged > 13 years. This shift in behavior outcomes from increased involvement in socializing or contact sports, a considerably greater incidence of attacks, and a overall decline in oversight [13]. In our research, the masculine predominance also agrees with that of several latest[14-16] research. Due to involvement in more physical operations than women, men are more probable to maintain trauma and violence compared to women. Our research also discovered that because of violence, kids were more probable to suffer fractures.

In Japan, Iida and Matsuya 16 showed that facial fractures were more prevalent in men and that violence was more prevalent cause in adolescents over the era of 13, while bicycle crashes were the most prevalent cause in all age groups, which might have been connected with Japan's culture based on bicycles. They also stated that the incidence of bicycle crashes is likely to decline considerably owing to the latest advent of television and computer games, leading to kids spending more time indoors than before.

Conclusion

In comparison, in a research with 1,251 fractures in Portugal, Ferreira et al. 10 discovered that pediatric face fractures were more frequent in men and in the winter, that traffic accidents were a major source, and that the most prevalent form of mandible fractures.In a research of pediatric patients with facial fractures, Munante-Cardenas et al. [17] indicated that facial fractures happened more frequently in children, bicycle crashes were the most prevalent source of fractures, and mandible fractures were the most prevalent among all facial fractures. In summary, this research offers an analysis of facial bone fractures between different sex and age groups, helping to demonstrate fracture patterns and features.

Prevalence of Hypertension among Rural Adult Population of Kancheepuram, Tamil Nadu

S. Nambi[1], Priya Sivashankar[2]

[1]Professor, [2]Associate Professor, Department of Psychiatry, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Cardiovascular diseases (CVDs) are a cluster of heart and blood vessel illnesses that include heart disease, stroke, peripheral arterial disease, rheumatic heart illness, congenital heart illness, profound vein thrombosis, and lung embolism. Cardio-vascular disease (CVD) is the leading cause of suicide worldwide and an approximately 17.7 million individuals died from CVD in 2015, comprising 31% of all fatalities worldwide. CVD is the leading source of morbidity and mortality in India and accounts for 25% of all fatalities and is expected to improve to 50%. The cross-sectional study was carried out to assess the prevalence of hypertension among the Kancheepuram District rural age population, Tamil Nadu.

Keywords: *Cardiovascular diseases, hypertension.*

Introduction

Worldwide, the epidemiological transition has resulted in a tremendous rise in the older population in emerging nations with a simultaneous rise in life expectancy. The bulk of the world's older population is projected to be living in emerging nations by the year 2025. Therefore, developing nations are probable to experience a huge strain of acute non-communicable diseases (NCDs) in the close future compared to communicable diseases that were once a significant issue.[1-4] In terms of disability-adjusted life-year (DALY) declines, the worldwide allocation of illness burden suggests that communicable illnesses account for 41% DALY losses, non-communicable illnesses account for 43%, and accidents account for 16%. Comparison between high, small, and middle-income nations shows that low-and middle-income nations bear the strain of communicable diseases more than 6 times (43.8 percent) relative to high-income countries (7.2 percent). As far as India is concerned, the DALY losses owing to communicable illnesses account for 50%, compared with 33% for non-communicable illnesses, and 17% for accidents.[5]

Non-communicable diseases (NCDs) are a cluster of non-communicable chronic diseases. They are described as long-term illnesses and slow development. Globally, NCDs are the major source of adult mortality and morbidity.[6] Cardiovascular diseases, tuberculosis, acute respiratory diseases, and diabetes are the four primary kinds of non-communicable diseases.[7] Globally, early mortality from these four major NCDs decreased by 15 percent between 2000 and 2012 This decrease level is inadequate to fulfill the one-third growth aim of 2030.[8]Nearly 38 million individuals die from non-communicable diseases worldwide each year.[9] Based on present patterns, by 2020, these NCDs are anticipated to account for 73% of worldwide fatalities and 60% of the worldwide disease burden.[10] According to the 2015 World Health Organization (WHO) survey, every fourth Indian dies from an NCD before the era of 70. Globally, India is the first nation to create particular objectives and indices in this sector to reduce the toll of NCD fatalities worldwide by 25 percent by 2025.[11]

The risk factors for non-communicable disease are grouped into 3 categories they are behavioural, metabolic and biochemical risk factors. Behavioural risk factors include tobacco use, alcohol use, unhealthy diet and

Corresponding Author:
S. Nambi
Professor, Department of Psychiatry, Sree Balaji Medical College, Bharath Institute of Higher Education and Research, Agharam Road, Selaiyur, Chennai-73

lack of physical activity. Metabolic risk factors include overweight, obesity, diabetes and hypertension (HTN). Biochemical risk factors include hypercholestremia and hypertriglyceridemia. The National Program on Diabetes Prevention and Control, Cardiovascular Diseases and Stroke (NPDCS) has been introduced to address the growing strain of Non-Communicable Diseases, Ministry of Health and Family Welfare, Government of India.[7]

Cardiovascular diseases (CVDs) are a cluster of heart and blood vessel illnesses that include heart disease, stroke, peripheral arterial disease, rheumatic heart illness, congenital heart illness, profound vein thrombosis, and lung embolism. Cardio-vascular disease (CVD) is the leading cause of suicide worldwide and an approximately 17.7 million individuals died from CVD in 2015, comprising 31% of all fatalities worldwide. CVD is the leading source of morbidity and mortality in India and accounts for 25% of all fatalities and is expected to improve to 50%.[12]

Objectives:

- To evaluate hypertension incidence among the survey group
- To determine the connection between hypertension and socio-demographic variables.

Materials and Method

This cross-sectional study was carried out to assess the prevalence of hypertension among the Kancheepuram District rural age population, Tamil Nadu. It is a community-based cross-sectional survey undertaken in the Sree Balaji Medical College and Kancheepuram District Hospital's rural field practice region. The training region of the sector includes 5 villages.

The calculated sample size was 1250 using Formula 4 PQ/L2. The selection of research respondents was based on a systemic random sampling technique. To gather information from the survey population, a pre-tested organized questionnaire was used. Information was acquired on socio-demographic features, risk variables, hypertension, and the research population's physical measurements. In MS Excel, the information was reached and analyzed using SPSS software (version 22). Descriptive and analytical statistics were used to describe the study variables[13-18].

Results

Socio-demographic characteristics of the study population: The research population's socio-demographic features are shown in Table 1. Among the respondents in the research, 44.2% belonged to the era of 51-60, 24.2% belonged to the era of 20-30 and 20.8% belonged to the era of 31-40. About 57.4% of the study participants were females and 42.6% were males. Nearly 82.4% are married and 5.44% were unmarried. Almost 18.7% of the study samples had no formal education,30.2% had middle school education and 21.3% had high school education. Among the participants around 43.7% were unemployed, 32.2% are engaged in unskilled occupation and 17.8% are involved in semiskilled occupation. According to the modified BG Prasad socio economic classification 49.6% belonged to lower middle socio economic category and 21.8% belonged to upper lower socio economic group. In this study 56.8% of them belong to nuclear family and about 30% belonged to joint family and the rest were belonging to three generation family.

Table 1: Socio demographic characteristics of the study population

	Joint Family	438	35.0
	Three Generation Family	102	8.2

Occurrence of hypertension: The incidence of hypertension is shown in Figure 1.as we can see that the incidence of hypertension in this research is 23.6% (298) and pre-hypertension incidence is 22.4%. Only54% of the study participants were normotensive individuals. Among them 73.2% (218) were known hypertensive and 26.8% (80) were newly diagnosed hypertensive's.

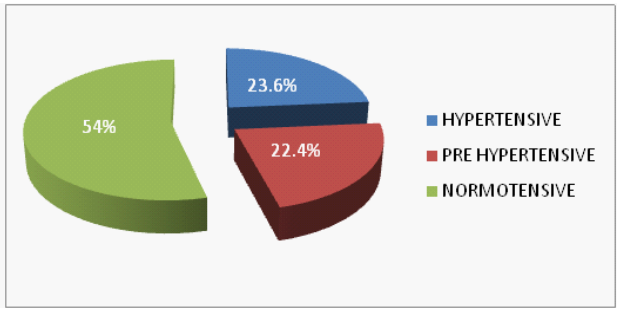

Figure 1: Occurrence of hypertension in the study population

In this study, the variables that are significantly associated with hypertension are age (p value-<0.0001), marital status (p value-<0.0001), education (p value-0.015), occupation (p value-0.003), socio economic status (p value-<0.015),family type (p value-<0.0001),positive family history (p value-0.009),co morbidity (p value-<0.0001),knowledge about hypertension (p value-<0.0001) and BMI (p value-<0.0001).There was no association found between other variables and hypertension.

Table 3: Association between sociodemographic variables and hypertension among the study population

Discussion

Occurrence of hypertension: The prevalence of hypertension in this study is 23.6% (298) and 76.4% of them were non hypertensive. Among them 73.2% (218) were known hypertensive's and 26.8% (80) were newly diagnosed hypertensive's. Pre-hypertension incidence in this research is 22.4 percent. The incidence level of hypertension in a research undertaken by Agarwal is 15.7 per 1000 of the overall rural population.13 The incidence of hypertension in the Beegom survey undertaken in southern India is 18.9 percent [19-22]. The results of the present research are similar to research undertaken by Chaturvedi S, Ibrahim MM, Shanthirani CS, Anand MP, Kaur,in which the overall prevalence of hypertension is 27.5%,26.3%,21.1%,26.8% and 21.4% respectively.[15-19] Results of the study were varied from studies conducted by Hazarika NC, Malhotra P, Ganesh SK, Joshi SV and Sathish Kumar in these studies the prevalence of hypertension was 60.8%, 4.5%, 44.3%, 7.8% and 34% respectively.[20,21,22]This broad variability in hypertension incidence in these research is due to variability in the research population's sociodemographic features.

Conclusion

The study reveals that, Among the study participants, 44.2% belonged to 51-60 years of age and About 57.4% of the study participants were females. As far as marital is concerned nearly 82.4% are married. According to the modified BG Prasad socio economic classification, 49.6% belonged to lower middle socio economic category.

Among the study population 23.6% were hypertensive and 22.4% were pre hypertensive. 73.2% were known hypertensive's and 26.8% were newly diagnosed among the hypertensive's. in this study.

It can be stated from the research results that the incidence of hypertension and prehypertension in the research region is large. There is also quite a heavy burden of undiagnosed situation. There is no gender difference in hypertension incidence. This study also shows that there is still gaps in the diagnosis and treatment of hypertension in the study area. Among those treated also adherence, incidence of complications and co morbidities are worrisome. The level of awareness among the study participants about this disease is lower than expected which is quite alarming. Though there is an existing program to address this disease there is few lacunae identified in this study which prevents the program from reaching the needful. All these lacunae must be bridged by effective interventions.

Ethical Clearance: No ethical clearance was necessary for this research work

Risk Factors for Ocular Morbidity among School Going Children in Kancheepuram District, Tamil Nadu

S. Sundari[1], P. John Solomon[1]

[1]Professor, Department of Paediatrics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

India is a country in transition and needs to simultaneously address preventable and treatable causes of childhood morbidities. Children require support in recognising eye problems and hence screening becomes essential. Moreover their issues need to be tackled at the earliest for treatment to be effective. The selected risk factors for ocular morbidity among school going children and the nutritional factors affecting ocular morbidity among school going children were studied.

Keywords: *Risk factors, Morbidity, Nutritional factors, Treatment.*

Introduction

Globally, the prevalence of blindness among children is estimated to be approximately one tenth of that in adults, at around 0.7 per 1000. However, blindness in childhood has far reaching implications for the affected child and family, and throughout life profoundly influences educational, employment, personal, and social prospects. Thus, the control of childhood blindness has been identified as a priority of the World Health Organisation's (WHO) global initiative for the elimination of avoidable blindness by the year 2020.[1,2]

India is a country in transition and needs to simultaneously address preventable and treatable causes of childhood morbidities. Children require support in recognising eye problems and hence screening becomes essential. Moreover their issues need to be tackled at the earliest for treatment to be effective[3].

Ocular health is a fundamental part of early child development and of overall health and wellbeing. Early childhood is a sensitive period for the development of the visual system and any ocular disorders that occur during this period, if untreated can lead to visual impairment or blindness[4, 5].

Materials and Method

Study Design: This study is a community based cross-sectional study conducted in urban area of Kancheepuram district, Tamil Nadu.

Study Area: This study was conducted in **Anakaputhur** which is the urban field practice area of the Urban Health and Training Centre (UHTC) attached to our Institution (Sree Balaji Medical College and hospital.

Anakaputhur is a municipality city in the district of Kancheepuram, Tamilnadu. It is divided into 18 wards for which elections are held every 5 years. The study was conducted in Anakaputhur which is located at a distance of 7 kilometres from the institution with an area covering approximately 16 sq. kilometres. (Annexure)

Study Population: According to the 2011 census, Anakaputhur urban field practice area had a total population of 48,050 of which 24,158 were Males, 23,892 were Females and 9850 were Children (6-16 years of age). Among the children 5045 were Males and 4805 were Females. Total number of houses in Anakaputhur is 12,146 The study was done among Children (6-16 years of age) residing in the study area permanently at the time of the study.

Study Period: The study was carried out from. December 1st2017–May 31st 2018

Sample Size: Sample size was calculated from a previous study conducted by Deshpande Jayant D in a rural area of North Maharashtra in the year 2011.The study recorded a prevalence of 27.6% This was taken as the reference value for calculating sample size. The sample size was calculated using the formula:

$N = Z\acute{a}^2pq/[L]\ 2$

Where, Z = 1.96 at 95% confidence interval

p = Prevalence of disease/event (referred value)

q = 100–P

L =Relative precision, which is assigned as 13% of p (15% of 27.6-3.588 for this study

Substituting it in the formula,

[Z = 1.96, p = 27.6%, q =72.4 (100-27.6), L = 3.588]

N = 1.96 x 1.96 x 27.6 x 72.4/3.588x3.588 = 599

Accounting 10% for non-response, the final sample size was calculated as 658 (rounded off to 672). [N = 672]

Inclusion Criteria: The inclusion criteria for the study were children of age group (6-16 years) residing in the study area, who gave consent to participate in the study.

Exclusion Criteria: The exclusion criteria for the study were Children who were mentally retarded, who are severely ill and those who didn't give consent to participate in the study were excluded.

Sampling Method: Anakaputhur had a total population of 48,050 as per 2011 census. As per the data available in the UHTC register there were 9850 children (6-16 years) residing in the study area. The sampling technique followed for this study was Systematic random sampling.

Total number of children belonging to 6-16 years of age, N=9850; which was divided by the total sample size, n = 672, to obtain the k value.

K value = N/n = 9850/672 = every 14th participant.

Every 14th participant from the records was chosen and the name and address of the person was noted and was visited for the data collection. if the person corresponding to the number did not give informed consent or was absent, the next number within the respective ward was chosen and the 14th person from that particular person was selected and interviewed. Likewise, 672 children who gave informed consent and willingly participated in the study were identified.

Study Tool: A pretested structured questionnaire was used as study tool for data collection, by interviewing the study participants. The questionnaire was prepared in English and translated to Tamil. The interview was conducted by the investigator herself and their responses were recorded in the questionnaire. The questionnaire consisted of the following sections:

Section I: Socio-Demographic Factors: Family background characteristics, including socio-demographic factors (age, sex, standard, family income, religion family type, and socio-economic status).

Section II: History Regarding Refraction: History regarding refraction like whether wearing spectacles, duration, refractive power, family history of refractive error.

Section III: Eye Complaints: History of eye complaints like redness, watering, itching, difficulty in night vision, difficulty in reading books etc.

Section IV: Nutritional Status: History of fruit and vegetable intake and history of Vit A supplementation.

Section V: Physical Measurements: Physical measurement such as, Height, weight, BMI were taken from the study participants.

Section VI: Ophthalmic Measurements: Ophthalmic measurements like visual acuity, corrected visual acuity and colour vision were taken using Snellen chart and ishihara chart respectively.

Informed Consent: Informed Consent was obtained from each participant prior to the administration of the interview schedule. The Informed Consent was prepared in the local language and is based on ICMR guidelines [Annexure]

Ethical Approval: The study proposal was presented and approval from Institutional Ethics Committee was obtained prior to the pretesting. The approval letter is enclosed in Annexure.

Pilot Study: A pilot study was carried out among 70 participants in the Anakaputhur area, which is a in Kancheepuram District. The questionnaire consisted of socio-demographic characteristics, details regarding the risk factors for ophthalmic morbidity, history regarding refraction, nutritional status and physical measurements. Based on the results of the Pilot study, the necessary changes were incorporated in the questionnaire and the study was conducted. The samples included in the pilot study were not included in the present study.

Data Collection Period: Data was collected from the study participants for a period of 6 months from December 2017 to May 2018.

Data Collection Method: Using Multi stage Sampling technique samples were selected. The data was collected by visiting the designated place of residence as per the sampling frame. On obtaining the informed consent, the interview was conducted by the investigator herself. Each participant was interviewed for 10 to 15 minutes.

Findings:

Table 1: Frequency Distribution of Family Related Factors

Variable	Frequency	Percentage
WHETHER FAMILY MEMBERS WEARING SPECS (N=672)		
YES	237	35.3
NO	435	64.7
FAMILY MEMBER WEARING SPECS(n=237)		
MOTHER	90	37.9
FATHER	112	47.2
SIBLING	35	14.7

As in table 1, regarding the family related factors of the study subjects, 64.7% of them had no family history of wearing spectacles. Out of the subjects with positive family history, 47.2% of the subjects had a father who wore spectacles, wheareas 37.9% and 14.7% of the subjecta had a mother and a sibling who wore spectacles respectively.

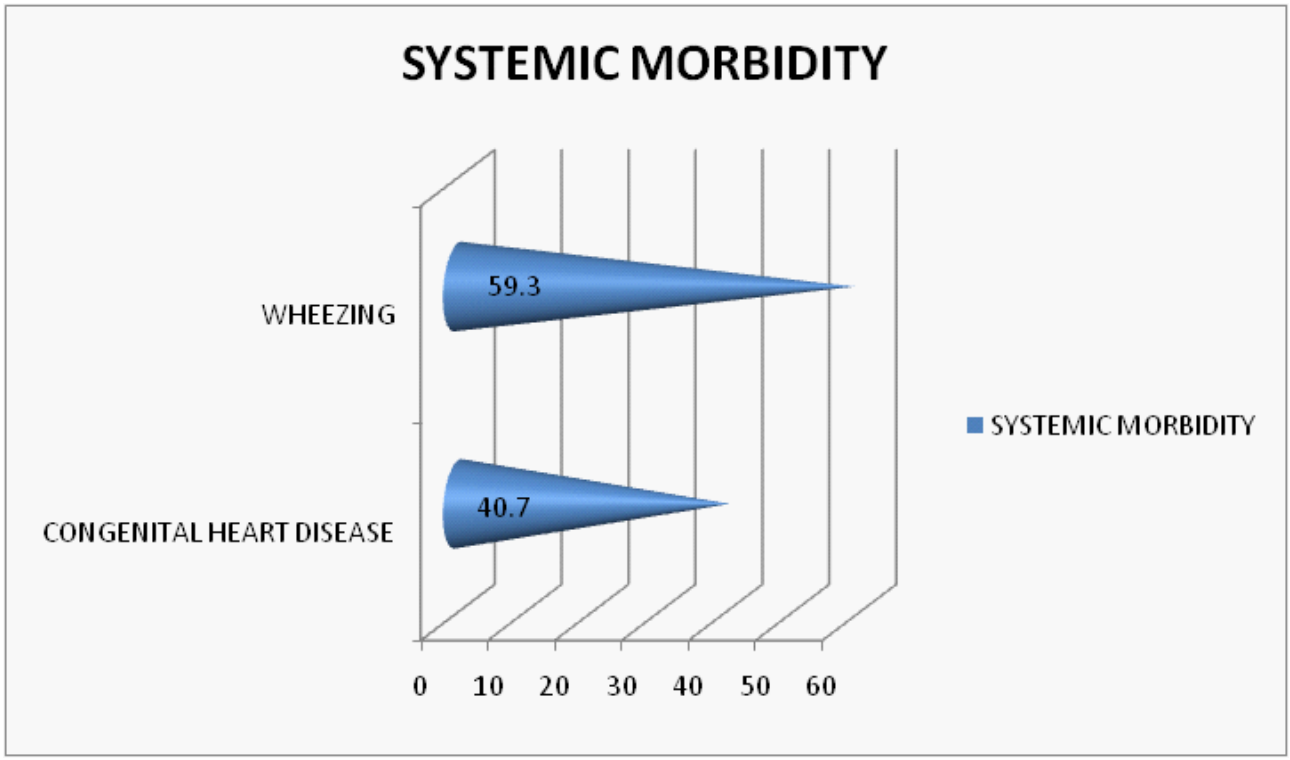

Figure 1: Percentage Distribution of Systemic Morbidity Among The Students With Systemic Morbidity (N=27).

Among the students presenting with systemic co-morbidities,wheezing (59.3%) was more prevalent than congenital heart disease(40.7%) as in figure 1.

Table 2: Frequency Distribution of Risk Behaviour Concerning Ophthalmic Morbidity Among The Study Population.

Variable		Frequency	Percentage
WATCHES TV FROM NEAR	YES	262	48
	NO	410	52
BENCH SEATED IN CLASSROOM	FIRST	310	46.1
	MIDDLE	283	42.1
	LAST	79	11.7

The distribution of risk behaviour among the subjects as tabulated in table 2,is as follows.48% of the study population succumbed to watching television from nearby.And 46.1% were seated in the first benches and had a possibility of having difficulty reading the black boards from a distance.

Discussion

In our study, the most common systemic co morbidities were asthma and congenital heart disease. In a study done by Gui king Wang,the most common disease found in the past medical history of participants related closely to the eye diseases was hypertension (*n*=273, 24.5%), and its prevalence increased with age. Hypertension can lead to multiple ocular diseases, leading to visual impairment and blindness. Diabetes mellitus, a major cause of health problems in developed countries, can also lead to visual impairment and blindness.

In our study, the distribution of risk behaviour among the subjects as tabulated in table 5,is as follows.48% of the study population succumbed to watching television from nearby.And 46.1% were seated in the first benches and had a possibility of having difficulty reading the black boards from a distance.According to a study done by A J Lee[6], the risk behaviours associated with occurrence of ocular morbidities was found to be pterygium ($p<0.001$, multivariate odds ratio (OR) 1.8; 95% CI 1.4 to 2.5) and history of current cigarette smoking ($p=0.05$, multivariate OR 1.5; 95% CI 1.0 to 2.2).

Conclusion

- Majority of the ocular diseases observed were either preventable or treatable.
- If these morbidities are not attended at the right time they may progress to severe disabilities or blindness and may also affect the child's performance in the school.

Ethical Clearance: The study proposal was presented and approved from Institutional Ethics Committee prior to the pretesting.

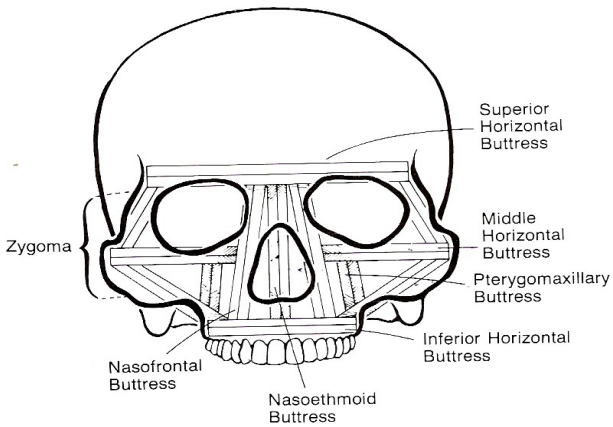
Comparison of CT Multiplanar Reconstruction with Axial Sections in Diagnosing Facial Bone Fractures

V. Vijay Narasimman Reddy[1], A. Sivakumar[1]

[1]Professor, Department of Orthopaedics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73



Abstract

MPR is generally helpful when it is not possible to correctly evaluate pathology on axial pictures alone. Most situations involve pathological interfaces parallel to the axial plane or structures that cannot be fully exhibited as they pass through a amount of slices. In these instances, MPR can be used to generate problem-oriented imaging aircraft. The performance of these pictures relies heavily on overlapping image reconstruction and thin slice collimation. The diagnostic accuracy of Multiplanar reconstruction protocol in comparison with axial section in traumatic patients with facial bone fractures were evaluated.

Keywords: *Axial Facial bone.*

Introduction

The face skeleton is not just a set of single bones, but a scheme of horizontal and vertical reinforcements that support each other (and therefore have a much greater mechanical strength than other bone components), transferring forces and pressures. Each bone has many attachments to the neighbouring bones which hold them together firmly.

Corresponding Author:
V. Vijay Narasimman Reddy
Professor, Department of Orthopaedics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Agharam Road, Selaiyur, Chennai-73

It outlined an amount of facial buttresses 1. There are four main groups of facial skeletons with vertical buttresses: three are bilateral and peripheral and one is centrally situated. Furthermore, it describes three horizontal buttresses: superior, centre and lower.

Figure 1: Schematic facial buttresses image. The human midface's multiple vertical and horizontal buttresses are shown schematically.

Horizontal Buttresses[1]: Superior horizontal buttress consists of facial bone orbital sheets, ethmoid air cell structures, and ethmoid cribriform plate. The center horizontal consists of the temporal bone's zygomatic process, zygoma's body and temporal system, zygoma's infraorbital process, maxilla's orbital surface, and maxilla's facial process. The lower horizontal buttress consists of the alveolar ridge and tough palate and functions as a significant bridge that stabilizes the two maxillary bodies.

Developed in the early 1900s, basic tomography overcame some of the limitations in radiographs. In this method, the X-ray emitter moves through a body area of concern during radiation exposure, while the transferred picture is recorded by a portable movie recorder behind the patient.

Since spatial resolution along the z-axis used to be bad and ground step artifacts were prevalent, MPR was not used much in standard CT. With the introduction of

Spiral-CT with overlapping image reconstruction, it is possible to nearly eliminate stair step artifacts, but image quality still relies on procurement parameters (efficient part width). Excellent outcomes are achieved by using slender collimation.[3-7]

MPR is generally helpful when it is not possible to correctly evaluate pathology on axial pictures alone. Most situations involve pathological interfaces parallel to the axial plane or structures that cannot be fully exhibited as they pass through a amount of slices. In these instances, MPR can be used to generate problem-oriented imaging aircraft. The performance of these pictures relies heavily on overlapping image reconstruction and thin slice collimation[2].

Therefore, the complex anatomy and fractures of the facial bones are shown extremely well by CT, and also helps in determining soft tissue complications. In the past few years radiographic facial series has been almost replaced by CT, and is now used only in specific situations, such as very focal facial trauma like nasal bone fracture, or when CT is unavailable.

CT gives better spatial resolution and allows reconstruction of images in multiplanar reconstruction (MPR) and volume rendering (VR) which enhances the ability to identify and report facial fractures.

Aim and Objectives: To evaluate the diagnostic accuracy of Multiplanar reconstructionprotocol in comparison with axial section in traumatic patients with facial bone fractures.

Materials and Method

Source of data: The study was conducted in patients with facial trauma referred for computed tomography (CT) to the Department of Radio Diagnosis at Sree Balaji Medical College and Hospital, Chennai-600044.

Method of collection of data:

- The research population included 150 individuals facing facial bone injury with CT assessment to the emergency department in Sree Balaji Medical College and Hospital, Chennai attached to the Bharath University.
- The CT was done on the advice of the referring physician and for the sole purpose of this study no patient was made to undergo CT.

  All the CT scan patients gave consent
- The scans were acquired with the use of spiral data acquisition technique in the transverse plane.
- The Multiplanarreconstructions (MPR) were obtained for each patient.
- Two reviewers evaluated the axial-sections and MPR individually.

Study Design: Descriptive study.

Study Period: March 2017 to October 2018.

Inclusion criteria: All individuals with clinical proof of facial bone injury who are subjected to multi-slice CT testing and are found to be favorable for fractures.

Exclusion criteria: Patients with facial bone injury who are contraindicated by a CT examination. Eg.Pregnancy.

Data acquisition

CT protocol used for this study:

Slice thickness: 1.25 mm.

Voltage: 120 kV.

Current: 300 mA.

Table speed: 27.5 mm/sec.

Pitch: 1.375:1

Rotation: 0.6 sec.

Post traumatic fractures were classified on the origin of anatomical location of fractures:

1. Frontal bone fractures
2. Orbits, with classification into the orbital walls
3. Nasal bones
4. Maxillary bones with inclusion of maxillary sinus walls
5. Zygomatic arches and bones
6. Body, ramus, and condylar process of mandibular bones

Findings: The sensitivity of each reconstruction formats was calculated by using the standard formula.

Frontal bone fractures: In assessment of frontal bone fractures, axial section shows maximum number

of fractures.

Considering sensitivity of axial section as the gold standard, MPR lacks by 11% in detection of fractures.

Chart 1: Number of frontal bone fractures detected in various formats.

Orbital bone fractures: In assessment of orbital bone fractures, axial section and MPR shows maximum and equal number of fractures. Considering sensitivity of axial section as the gold standard, MPR shows the equal sensitivity in detection of fractures.

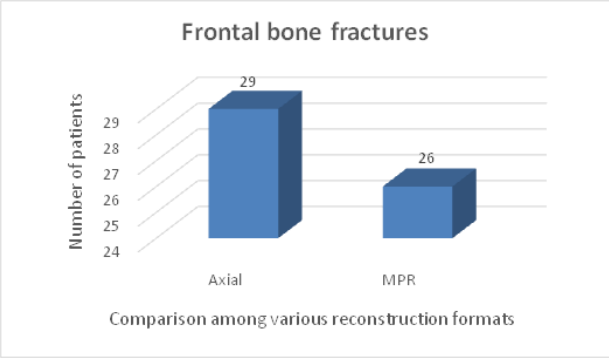


Chart 2: Number of orbital bone fractures detected in various formats.

Nasal bone fractures: In assessment of nasal bone fractures, axial section shows maximum number of fractures.

Considering sensitivity of axial section as the gold standard, MPR lacks by 43% in detection of fractures.

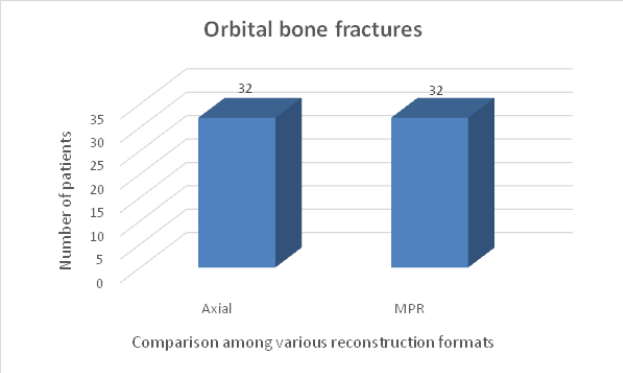

Chart 3: Number of nasal bone fractures detected in various formats.

Maxillary bone fractures: In assessment of maxillary bone fractures, axial section shows maximum number of fractures.Considering sensitivity of axial section as the gold standard, MPR lacks by 14%in detection of fractures.

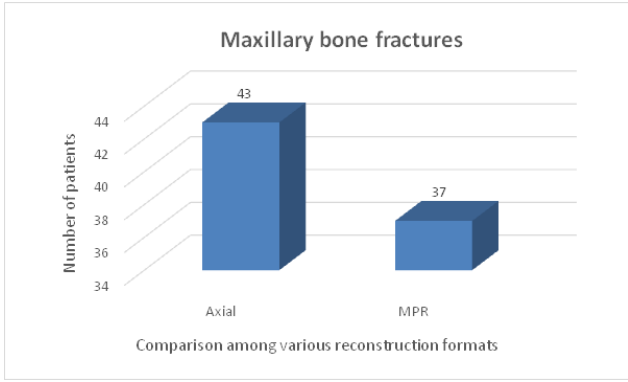

Chart 4: Number of maxillary bone fractures detected in various formats.

Zygomatic bone fractures: In assessment of zygomatic bone fractures, axial section and MPR shows maximum and equal number of fractures.

Considering sensitivity of axial section as the gold standard, MPR shows the equal sensitivity in detection of fractures.

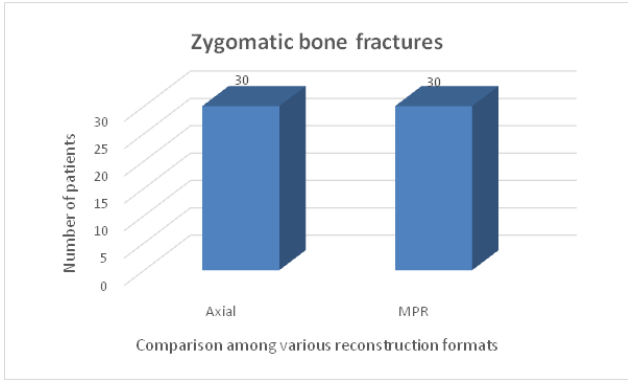

Chart 5: Number of zygomatic bone fractures detected in various formats.

Mandibular bone fractures: In assessment of mandibular bone fractures, axial section shows maximum number of fractures.

Considering sensitivity of axial section as the gold standard, MPR section lacks by 18% in detection of fractures.

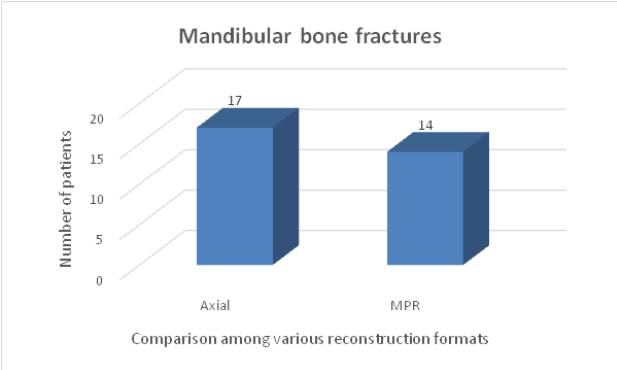

Chart 6: Number of mandibular bone fractures detected in various formats.

Table 1: Shows the sensitivity of detection of fractures by various sections in different bones.

Sensitivity Table (% age)		
	Axial	**MPR**
Frontal bone	100	89
Orbital bone	100	100
Nasal bone	100	57
Maxillary bone	100	86
Zygomatic bone	100	100
Mandibular bone	100	82

Axial section is considered as the gold standard as it identifies the maximum number of fractures. MPR sections are found to be equally sensitive as axial sections in fractures of orbital bone and zygomatic bone. MPR is nearly sensitive to axial sections in fractures of frontal bone, maxillary bone and mandibular bone.

In this study none of the reconstruction format shows the false positive results. So, considering the false positive as zero, if we calculate the specificity it comes to 100% for all the formats.

Discussion

Facial trauma is an isolated injury or portion of polytrauma and is clinically essential because the disturbance of smooth tissues and facial bones creates facial asymmetry and disfiguration that creates mental and cosmetic problems.[3] Plain radiographs were the initial modality of choice for imaging in these patients, but they can be inadequate due to superimposition of bony structures [4].

CT is the imaging method of selection opposed to conventional radiography to show the multiplicity of pieces, the degree of rotation and displacement or any participation of the nucleus of the skull. [5]Tanvikula R, Erol B [6]study shows the comparison and superiority of CT over plain radiography and classification of all facial fractures.

In a study done by Fox et al [7] showed that in the zygomatic region, they were able to recognize the presence of injury better on VR (88%) than axial sections (64%), and both of these modalities were superior to MPR(0%). Whereas in the orbit and maxilla, axial sections (62%,50%) showed better sensitivity in detecting fractures over VR (50%,44%) and MPR (33%,11%). In fractures involving nasal region, axial (50%) and VR (50%) are more sensitive than MPR (16%). Overall, axial images had higher average sensitivity values than the other two modalities.In our study, axial sections were considered as the gold standard as it identified the maximum number of fractures.MPR sections is found to be equally sensitive as axial sections in fractures of orbital bone and zygomatic bone.

Conclusion

MPR is nearly sensitive to axial sections in fractures of frontal bone, maxillary bone and mandibular bone. According to Tanvikula R, Erol B [6], Axial and coronal CT pictures are suitable for the diagnosis of medial orbital wall fractures and confirm the supremacy of coronal CT in the diagnosis of orbital floor fractures and blow-out fractures, particularly in individuals who may experience diplopia or enophthalmos.

A Study on Risk Factors for Hypertension among Rural Adult Population of Kancheepuram, Tamil Nadu

A. Thumjaa[1], Shanthi Ramesh[1]

[1]Associate Professor, Department of Paediatrics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Non-transmittable ailments (NCDs) are gathering of interminable ailments that are not transferable. They are characterized as sicknesses of long term and moderate movement. NCDs are the real reason for grown-up mortality and dismalness globally. The 4 primary sorts of non transferable sicknesses are cardiovascular infections, malignant growths, constant respiratory illnesses and diabetes. The determinants of hypertension among the study population and the association between various risk factors and hypertension were determined.

Keywords: *Hypertension Children.*

Introduction

Epidemiological transition worldwide has lead to a tremendous increase in the elderly population in the developing countries with concomitant increase in the life expectancy. It is estimated that by the year 2025 the majority of the elderly population worldwide will be residing in developing countries. Developing countries are thus likely to face an enormous burden of chronic non-communicable diseases (NCDs) in the near future in comparison to communicable disease which were once a major problem.[1-4]In terms of disability-adjusted life-year (DALY) declines, the worldwide allocation of illness burden shows that communicable illnesses account for 41% DALY losses, non-communicable illnesses account for 43%, and accidents account for 16%. With regard to India, the DALY losses due to communicable diseases account for 50%, compared to 33% for non-communicable diseases, and 17% of injuries.[5]

Non-transmittable ailments (NCDs) are gathering of interminable ailments that are not transferable. They are characterized as sicknesses of long term and moderate movement. NCDs are the real reason for grown-up mortality and dismalness globally.[6] The 4 primary sorts of non transferable sicknesses are cardiovascular infections, malignant growths, constant respiratory illnesses and diabetes.[7] Globally, untimely mortality from these four fundamental NCDs declined by 15% between 2000 and2012this pace of decrease is deficient to meet the 2030 objective of a 33% decrease.[8] Nearly 38 million people die each year globally from Non communicable diseases.[9] Based on current trends, by the year 2020 these NCDs are expected to account for 73% of global deaths and 60% of the global burden of disease.[10] As per the World Health Organisation (WHO) 2015 report, every 4th Indian die from an NCD before the age of 70 years. Globally India is the first country to develop specific targets and indicators in this field, which are aimed at reducing the burden of deaths from NCDs globally by the year 2025 by 25 per cent.[11]

The risk factors for non-communicable disease are grouped into 3 categories they are behavioural, metabolic and biochemical risk factors. Behavioural risk factors include tobacco use, alcohol use, unhealthy diet and lack of physical activity. Metabolic risk factors include overweight, obesity, diabetes and hypertension (HTN). Biochemical risk factors include hypercholestremia and hypertriglyceridemia.[7]

Cardio Vascular Disease (CVD) is the number 1 cause of death globally and an estimated 17.7 million people died from CVD in 2015, representing 31% of all global deaths. CVD are the major cause of morbidity and mortality in India and accounting for 25% of all deaths and projected to increase to 50%.[12]

Objectives:

- To identify the determinants of hypertension among the study population.
- To determine the association between various risk factors and hypertension.

Materials and Method

This cross sectional study was conducted to estimate the prevalence,of hypertension among the rural adult population of Kancheepuram District, Tamil Nadu. It is a community based cross sectional study, conducted in the rural field practise area of Sree Balaji Medical College and Hospital of Kancheepuram District. The field practice area covers 5 villages.

Information regarding socio demographic characteristics, risk factors, regarding hypertension and physical measurements of the study population were obtained. The data was entered in MS Excel and analysis was done using SPSS software (version 22). Descriptive and analytical statistics were used to describe the study variables.

Findings:

Lifestyle characteristics of the study population: Lifestyle characteristics of the study population is shown in Table 1.60.2% of them are involved in sedentary work and 35.5% were engaged in moderate type of work. Only 21.4% has the habit of doing regular physical exercise. Among them 39.6% do exercise for duration of 1-2 hours per week and 27.7% do exercise for duration of 2-5 hours a week.

Table 1: Lifestyle characteristics of the study population

Sl No	Lifestyle Characteristics	Frequency	Percentage (%)
1.	Job Type (N-1250)		
	Sedentary Work	752	60.2
	Moderate Work	444	35.5
	Heavy Work	54	4.3
2.	Exercise (N-1250)		
	Yes	268	21.4
	No	982	78.6
3.	Duration of Exercise (N-268)		
	< 1 Hour/Week	20	7.4
	1-2 Hours/Week	106	39.6
	2--5 Hours/Week	74	27.7
	> 5 Hours/Week	68	25.3

Table 2: Prevalence of behavioural risk factors among the study population

Sl No	Risk Factor	Frequency (N-1250)	Percentage (%)
1.	Tobacco Use		
	Yes	160	12.8
	No	1090	87.2
2.	Alcohol Use		
	Yes	232	18.6
	No	1018	81.4
3.	Physical Inactivity		
	Yes	828	66.2
	No	422	33.8
4.	Unhealthy Diet		
	Yes	906	72.5
	No	344	27.5

Prevalence of risk factors among the study population: Prevalence of risk factors for hypertension is depicted in Table 2 and 3.in this study 12.8% use tobacco in any form, 18.6% use alcohol, 66.2% of the participants are physically inactive and 72.5% are consuming unhealthy diet. Among the study participants 21.4 % had a positive family history of hypertension,3% of them are under oral contraceptive pills and 24.8% are suffering from various co morbidities.

Table 3: Associated risk factors among the study population

Sl No	Risk Factors	Frequency (N-1250)	Percentage (%)
1.	Family History of Hypertension (N-1250)		
	Yes	268	21.4
	No	982	78.6
2.	Oral contraceptive Pill Intake Among Females (N-718)		
	Yes	38	3.0
	No	680	97.0

3.	Co-Morbidity (N-1250)		
	Yes	310	24.8
	No	940	75.2

Prevalence of obesity among the study population: As per the Asian Adults BMI criteria (Figure 1), 26.2% were overweight,22.% were pre obese and 12.6% belonged to obese category. Central obesity was assessed based on the waist hip ratio. About 83.4% of the study participants have central obesity.

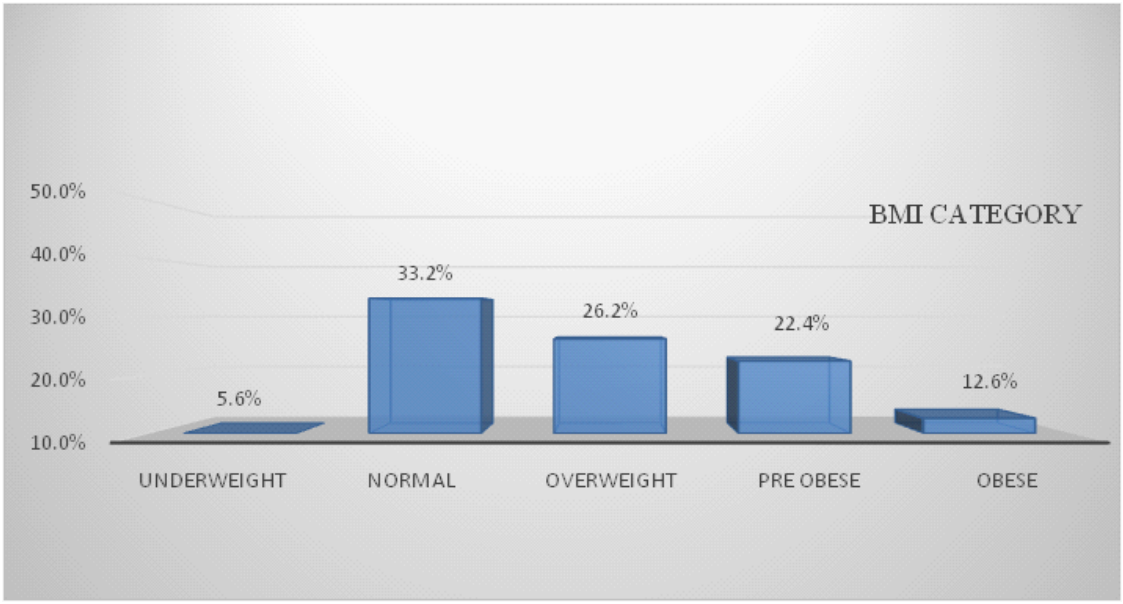

Figure 1: BMI classification of the study population

Among the males 86.5% have central obesity and 80.3% of females have central obesity in this study (Figure 2).

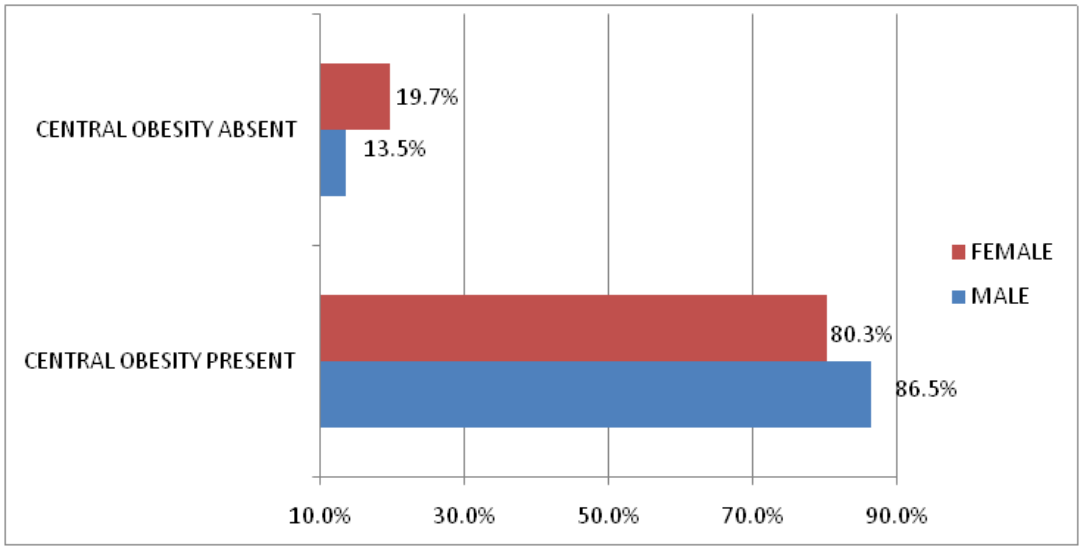

Figure 2: Prevalence of central obesity among the study population

Blood pressure category among the study population: Blood pressure was classified based on JNC 8 criteria. Table 4 depicts the blood pressure category. Nearly 64% of the study participants belonged to normal BP category, 22.4% were pre hypertension,9.3% belonged to stage 1 hypertension category and 4.3% belonged to stage 2 hypertension category.

Table 4: Blood pressure category among the study population

S. No	BP Category	Frequency (N-1250)	Percentage (%)
1.	Normal	800	64.0
2.	Prehypertension	280	22.4
3.	Stage 1 Hypertension	116	9.3
4.	Stage 2 Hypertension	54	4.3

Discussion

Risk factors for hypertension

Tobacco use: In this study among the study participants 12.8% use tobacco and of which 3.5% use smokeless tobacco. In a study by Chataut J 40.2% of the study population has the smoking habit.[13] 25.5% of the ever used tobacco in a study by Maroof KA In Uttar Pradesh.[14] In Peter Lloyd-Sherlock study 64.6% had never smoked and 24.1% are smoking daily.[15] 15.9 % are smoking daily and 73.2% are using smokeless tobacco in a study by AroorBhagyalaxmi which was conducted in a rural area of Gujarat, India.[16]

Alcohol use: In this study 18.6% are current alcohol users and 1.1% was past users of alcohol.40.9% are consuming alcohol in a study by Chataut J.[13]In a study by K. A. Maroof 35.5% had ever used alcohol and the remaining 64.5% had never used alcohol.[14] 76.8% had never consumed alcohol in their lifetime in a study conducted by Peter Lloyd-Sherlock.[15]

Physical activity: In this study 66.2% were physically inactive and only 33.8% were physically active as per the operational definition and this showed that majority of the study participants are following an unhealthy lifestyle habits. In Chataut J study 51.8% are involved in moderate physical activity and 8% are engaged in sedentary activities.[13] 28.5% are physically inactive in a study done by Peter Lloyd-Sherlock.[15]AroorBhagyalaxmi study showed that 14.1% of the study samples were physically inactive.[16]

Unhealthy diet: 72.5% of the respondents in this study were following unhealthy diet. In a study conducted by AroorBhagyalaxmi most of the study participants i.e. 96.4% were following unhealthy diet.[16] 94.5% were taking low fruit and vegetables in a study by Garg A.[17] Bhattacherjee S conducted a study in west Bengal in which 60.4% were consuming unhealthy diet.[18]

Overweight and obesity: In this study, as per the Asian Adults BMI criteria, 26.2% were overweight, 22 % were pre obese and 12.6% belonged to obese category.12% of the study population were overweight in a study by Aroor Bhagyalaxmi.[16] In a study done by Prabhakaran D 35% of them were overweight and 3.3% of the study participants belonged to obese category.[19] 20.5% were overweight and 4.2% were obese in Midha T.[20]

Central obesity: In this study central obesity was assessed based on the waist hip ratio. About 83.4% of the study participants have central obesity. AroorBhagyalaxmi showed that central obesity was present in 38% of the samples.[16]In a study by K. A. Maroof 30.5% were centrally obese.

Association between sociodemographic variables, risk factors and hypertension: In this study the variables that are significantly associated with hypertension are age, marital status, education,occupation, socio economic status,family type,positive family history,co morbidity, knowledge about hypertension and BMI.[21]Jonas JB conducted a study in which prevalence of hypertension was associated with higher age, higher body mass index, body height, Higher blood hemoglobin levels and elevated blood urea concentration.[22]

Conclusion

In this study 12.8% use tobacco in any form, 18.6% use alcohol, 66.2% of the participants is physically inactive and 72.5% are consuming unhealthy diet. Among the study participants, 26.2% were overweight,22.% were pre obese and 12.6% belonged to obese category.21.4 % had a positive family history of hypertension,3% of them are under oral contraceptive pills and 24.8% are suffering from various co morbidities.

From the findings of the study, it can be concluded that the prevalence of hypertension and prehypertension are high in the study area. The burden of undiagnosed case is also quite high. There is no sex difference in the prevalence of hypertension. This study also shows that there are still gaps in the diagnosis and treatment of hypertension in the study area. Among those treated also adherence, incidence of complications and co morbidities are worrisome. The level of awareness among the study participants about this disease is lower than expected which is quite alarming. Though there

is an existing program to address this disease there is few lacunae identified in this study which prevents the prevents the program from reaching the needful. All these lacunae must be bridged by effective interventions.

Ethical Clearance: No ethical clearance was necessary for this research work

Association of Selected Variables with Ocular Morbidity among School Going Children in Kancheepuram District, Tamil Nadu

S. Nambi[1], Priya Sivashankar[2]

[1]Professor, [2]Associate Professor, Department of Psychiatry, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Refractive errors are the leading cause of ocular morbidity in school-aged children of India.Children do not complain of defective vision and may not even be aware of their problem.Children in the school-going age group (6-16 years) represent 25% of the population in the developing countries. They offer significantly representative material for these studies as they fall best in the preventable blindness age group.

Keywords: *Variables,children,Morbidity.*

Introduction

The scenario of paediatric ocular diseases varies worldwide. The pattern of ocular diseases in children is very important because some eye conditions cause ocular morbidity while others invariably lead to blindness. The majority of blindness is either potentially curable or preventable.[1] Childhood ocular abnormalities are more debilitating and disabling than the senile onset, because the child has to live their whole life ahead with that morbidity.[2]

During a child's first 12 years of life 80% of all learning comes through vision, and yet most children have not had a comprehensive eye examination prior to entering primary school.[3]The school eye health program is one through which children can be screened for diseases, such as refractory error, strabismus, amblyopia and trachoma[6] In most of the countries school screening programs are done routinely to detect the prevalence rate and causes of ocular morbidity.[4]Refractive errors are the leading cause of ocular morbidity in school-aged children of India.Children do not complain of defective vision and may not even be aware of their problem. They adjust to the poor eyesight by sitting near the blackboard, holding the books closer to their eyes, squeezing the eyes and even avoiding work requiring visual concentration. This warrants early detection and treatment to prevent permanent disability.[5]

Children in the school-going age group (6-16 years) represent 25% of the population in the developing countries. They offer significantly representative material for these studies as they fall best in the preventable blindness age group, are a controlled population i.e. they belong to a certain age group and are easily accessible and schools are the best forum for imparting health education to the children. Schools are also one of the best centres for effectively implementing the comprehensive eye healthcare programme.[5]

Materials and Method

Study Design: This study is a community based cross-sectional study conducted in urban area of Kancheepuram district, Tamil Nadu.

Study Area: This study was conducted in **Anakaputhur** which is the urban field practice area of the Urban Health and Training Centre (UHTC) attached to our Institution (Sree Balaji Medical College and hospital.

Anakaputhur is a municipality city in the district of

Corresponding Author:
S. NAMBI
Professor, Department of Psychiatry, Sree Balaji Medical College, Bharath Institute of Higher Education and Research, Agharam Road, Selaiyur, Chennai-73

Kancheepuram, Tamil Nadu. It is divided into 18 wards for which elections are held every 5 years. The study was conducted in Anakaputhur which is located at a distance of 7 kilometres from the institution with an area covering approximately 16 sq. kilometres. (Annexure)

Study Population: According to the 2011 census, Anakaputhur urban field practice area had a total population of 48,050 of which 24,158 were Males, 23,892 were Females and 9850 were Children (6-16 years of age). Among the children 5045 were Males and 4805 were Females. Total number of houses in Anakaputhur is 12,146 The study was done among Children (6-16 years of age) residing in the study area permanently at the time of the study.

Study Period: The study was carried out from. December 1st2017–May 31st 2018

Sample Size: Sample size was calculated from a previous study conducted by Deshpande Jayant D in a rural area of North Maharashtra in the year 2011.The study recorded a prevalence of 27.6% This was taken as the reference value for calculating sample size. The sample size was calculated using the formula:

$N = Z\acute{a}^2pq/[L]\ 2$

Where, Z = 1.96 at 95% confidence interval

p = Prevalence of disease/event (referred value)

q = 100–P

L =Relative precision, which is assigned as 13% of p (15% of 27.6-3.588 for this study

Substituting it in the formula,

[Z = 1.96, p = 27.6%, q =72.4 (100-27.6), L = 3.588]

N = 1.96 x 1.96 x 27.6 x 72.4/3.588x3.588 = 599

Accounting 10% for non-response, the final sample size was calculated as 658 (rounded off to 672). [N = 672]

Inclusion Criteria: The inclusion criteria for the study were children of age group (6-16 years) residing in the study area, who gave consent to participate in the study.

Exclusion Criteria: The exclusion criteria for the study were Children who were mentally retarded, who are severely ill and those who didn't give consent to participate in the study were excluded.

Sampling Method: Anakaputhur had a total population of 48,050 as per 2011 census. As per the data available in the UHTC register there were 9850 children (6-16 years) residing in the study area. The sampling technique followed for this study was Systematic random sampling.

Total number of children belonging to 6-16 years of age, N=9850; which was divided by the total sample size, n = 672, to obtain the k value.

K value = N/n = 9850/672 = every 14th participant.

Every 14th participant from the records was chosen and the name and address of the person was noted and was visited for the data collection. if the person corresponding to the number did not give informed consent or was absent, the next number within the respective ward was chosen and the 14th person from that particular person was selected and interviewed. Likewise, 672 children who gave informed consent and willingly participated in the study were identified.

Study Tool: A pretested structured questionnaire was used as study tool for data collection, by interviewing the study participants. The questionnaire was prepared in English and translated to Tamil. The interview was conducted by the investigator herself and their responses were recorded in the questionnaire.

Informed Consent: Informed Consent was obtained from each participant prior to the administration of the interview schedule. The Informed Consent was prepared in the local language and is based on ICMR guidelines [Annexure]

Ethical Approval: The study proposal was presented and approval from Institutional Ethics Committee was obtained prior to the pretesting. The approval letter is enclosed in Annexure.

Pilot Study: A pilot study was carried out among 70 participants in the Anakaputhur area, which is a in Kancheepuram District. The questionnaire consisted of socio-demographic characteristics, details regarding the risk factors for ophthalmic morbidity, history regarding refraction, nutritional status and physical measurements. Based on the results of the Pilot study, the necessary changes were incorporated in the questionnaire and the

study was conducted. The samples included in the pilot study were not included in the present study.

Data Collection Period: Data was collected from the study participants for a period of 6 months from December 2017 to May 2018.

Data Collection Method: Using Multi stage Sampling technique samples were selected. The data was collected by visiting the designated place of residence as per the sampling frame. On obtaining the informed consent, the interview was conducted by the investigator herself. Each participant was interviewed for 10 to 15 minutes.

Findings:

Table 1: Age And Standard Characteristics of the Population

Variable	Minimum value	Maximum value	Mean		Standard deviation
			Value	Standard Error	
Age	6	16	11.25	0.105	2.734
Standard	1	12	6.20	0.108	2.792

Table 2: Association of Sociodemographic Variables with Ophthalmic Morbidity

Sociodemographic characteristics	Variable	Total frequency	Ophthalmic morbidity			
			Frequency	Chi square value	P value	Odds ratio (95%CI)
Sex	Male	311	57	5.431	0.020*	1.66 (1.08-2.56)
	Female	361	43			
Age	< 10 yrs	206	38	38.57	0.000*	1.473(0.947-2.293
	≥ 10 yrs	466	62			
Socio-economic status	Upper	479	55	35.238	0.000*	0.420(0.272-0.651)
	Lower	191	45			
Religion	Hindu	571	81	2.041	0.564	0.704(0.405-1.224)
	Others	101	19			

The mean age of the study population was found to be 11 years wherein the subjects varied from 6 to 16 years of age. The mean standard of the study subjects was found to be 6th standard wherein the study subjects were distributed between 1st and 12th standard.

As in table 2,the variables that are significantly associated with ophthalmic morbidity are sex (p value <0.020-OR value-1.66), age (p value<0.000-OR value-), socio-economic status (pvalue<0.000-OR value-) and school type(p value<0.043-OR value-).Other factors are not significantly associated with ophthalmic morbidity.

Discussion

The sociodemographic variables that are significantly associated with ophthalmic morbidity are sex (p value <0.020-OR value-1.66), age (p value<0.000-OR value-), socio-economic status (pvalue<0.000-OR value-) and school type(p value<0.043-OR value-).Other factors are not significantly associated with ophthalmic morbidity.

In a study done by Deshpande,[46] the variables that were significantly associated with ophthalmic morbidity are religion, socio-economic status, literacy of head of family, BMI. Factors that were not significantly associated with ophthalmic morbidity are sex and family type. In a study done by V Kalikivayi,[50] the sociodemographic factors that were significantly associated with ophthalmic morbidities were age, literacy, family type. Other factors were insignificant.

Conclusion

- The socio-demographic variables that are significantly associated with ophthalmic morbidity by univariate analysis are age, sex, socioeconomic status and family type.
- Majority of the ocular diseases observed were either preventable or treatable.
- If these morbidities are not attended at the right time they may progress to severe disabilities or blindness

and may also affect the child's performance in the school.

- As the burden of blindness is already high in our country we have to have a blindness prevention approach, beginning right from the childhood and school eye-screening programme should be an integral part of it.

Comparison of CT Volume Rendring Images with Axial Sections in Diagnosing Facial Bone Fractures

Lionel John J.[1], G. Pugazhendhi[1]

[1]*Associate Professor, Department of Orthopaedics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73*

Abstract

Wounds of facial bones and delicate tissues are an extremely normal pathology. Their rate ranges from 20% to over half of cases admitted to horrendous crisis. The idea of three-dimensional display of CT-data is not much older than CT itself. For three-dimensional presentation purposes the components of these voxel ought to be as little as could be expected under the circumstances. The diagnostic accuracy of volume rendering image protocol in comparison with axial section in traumatic patients with facial bone fractures were evaluated.

Keywords: *Normal pathology, Ct Data, Diagnostic Accuracy, Facial bone fractures.*

Introduction

The skull comprises of 8 cranial bones and 14 facial bones. Maybe a couple of these bones exist two by two. The matched bones of the face are the maxilla, palatine bones, zygomatic bones, lacrimal bones, nasal bones, and second rate nasal conchae. The single bones are the vomer and mandible [1].

Wounds of facial bones and delicate tissues are an extremely normal pathology. Their rate ranges from 20% to over half of cases admitted to horrendous crisis. The most regular reasons for these pathologies incorporate are transportation wounds (up to 80% of cases), direct power, for the most part during an ambush (up to 60% of cases), falls (up to 25% of cases), and mishaps during games (up to 10% of cases) [2–5].

Cracks including the facial skeleton might be disconnected or complex.

Detached breaks include single life systems structures and are typically a consequence of alow energy blow[6]. The three most common isolated facial fractures are:

- Nasal fractures.
- Zygomatic fractures.
- Orbital floor fractures.

Complex fractures are due to high energy impact injuries to the mid face and involve several structures, examples of these are:

- Le-fort fractures.
- Nasoethmoid mid-facial fractures.

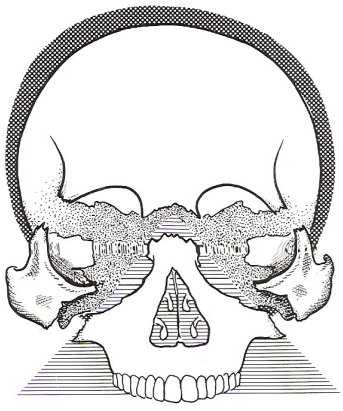

Figure 1: The human skull composed of an ovoid-shaped cranium, a pyramid shaped mid face consisting of the maxilla and the triangle shaped zygomas

The idea of three-dimensional display of CT-data is not much older than CT itself. Basic work on this topic was performed by Gabor Herman and published in several articles [7]. Further fundamental research and development was done by Marc Levoy and Robert Drebin[8,9].The littlest component of volumetric pictures is called voxel (for example volume component) and contains the properties (for example forces) of the checked volume, comparable to the two-dimensional pixel (for example picture component). As a volume can be envisioned as a three-dimensional network, the subsequent estimation of one single voxel is the normal incentive over the framework[10-15]. For three-dimensional presentation purposes the components of these voxel ought to be as little as could be expected under the circumstances. One single voxel, being of limited size, may contain various tissue types. With rate grouping this physical reality can be portrayed precisely [16, 17].

Aim and Objectives: To evaluate the diagnostic accuracy of volume rendring image protocol in comparison with axial section in traumatic patients with facial bone fractures.

Materials and Method

Source of data: The study was conducted in patients with facial trauma referred for computed tomography (CT) to the Department of Radio Diagnosis at Sree Balaji Medical College and Hospital, Chennai-600044.

Method of collection of data:

- The study population included 150 patients who underwent CT evaluation of face when they presented with injury to facial skeleton to the emergency department in Sree Balaji Medical College and Hospital, Chennai attached to the Bharath University.
- The CT was done on the advice of the referring doctor and no patient was made to undergo CT for the sole purpose of this study.
- All the CT scan patients gave consent
- The scans were acquired with the use of spiral data acquisition technique in the transverse plane.
- The Volume rendring (VR) images were obtained for each patient.
- Two reviewers evaluated the axial-sections and VR individually.

Study Design: Descriptive study.

Study Period: March 2017 to October 2018.

Inclusion criteria: All patients with clinical evidence of injury to facial skeleton who undergo Multi-slice CT examination and are shown to be positive for fractures.

Exclusion criteria: atients with injury to facial skeleton in whom a CT examination is contraindicated. Eg. Pregnancy.

Data acquisition: All the CT scans in this study were performed using Hitachi 16-slice CT scanner.

CT Protocol used for this study: Slice thickness: 1.25 mm.

Voltage: 120 kV.

Current: 300 mA.

Table speed: 27.5 mm/sec.

Pitch: 1.375:1

Rotation: 0.6 sec.

Post traumatic fractures were classified on the basis of anatomical location of fractures:

1. Frontal bone fractures
2. Orbits, with classification into the orbital walls
3. Nasal bones
4. Maxillary bones with inclusion of maxillary sinus walls
5. Zygomatic arches and bones
6. Body, ramus, and condylar process of mandibular bones

Findings: The sensitivity of each reconstruction formats was calculated by using the standard formula.

Frontal bone fractures: In assessment of frontal bone fractures, axial section shows maximum number of fractures.

Considering sensitivity of axial section as the gold standard, VR lacks by 35% in detection of fractures.

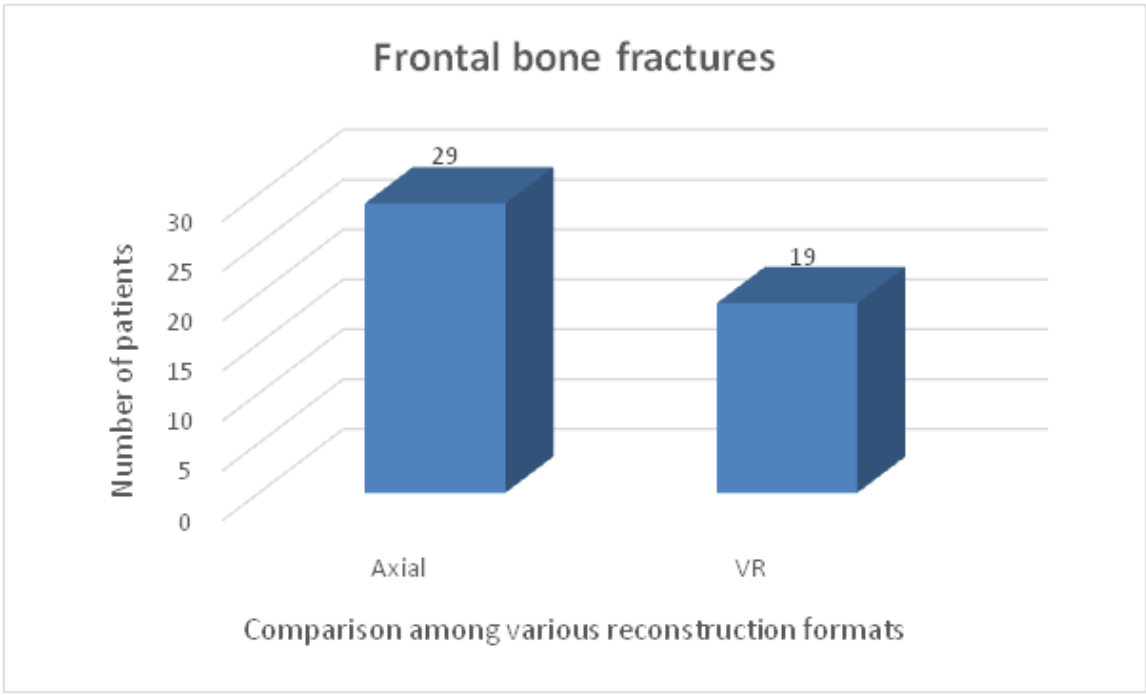

Chart 1: Number of frontal bone fractures detected in various formats.

Orbital bone fractures: In assessment of orbital bone fractures, axial section shows maximum number of fractures.

Considering sensitivity of axial section as the gold standard, VR lacks by 44% in detection of fractures.

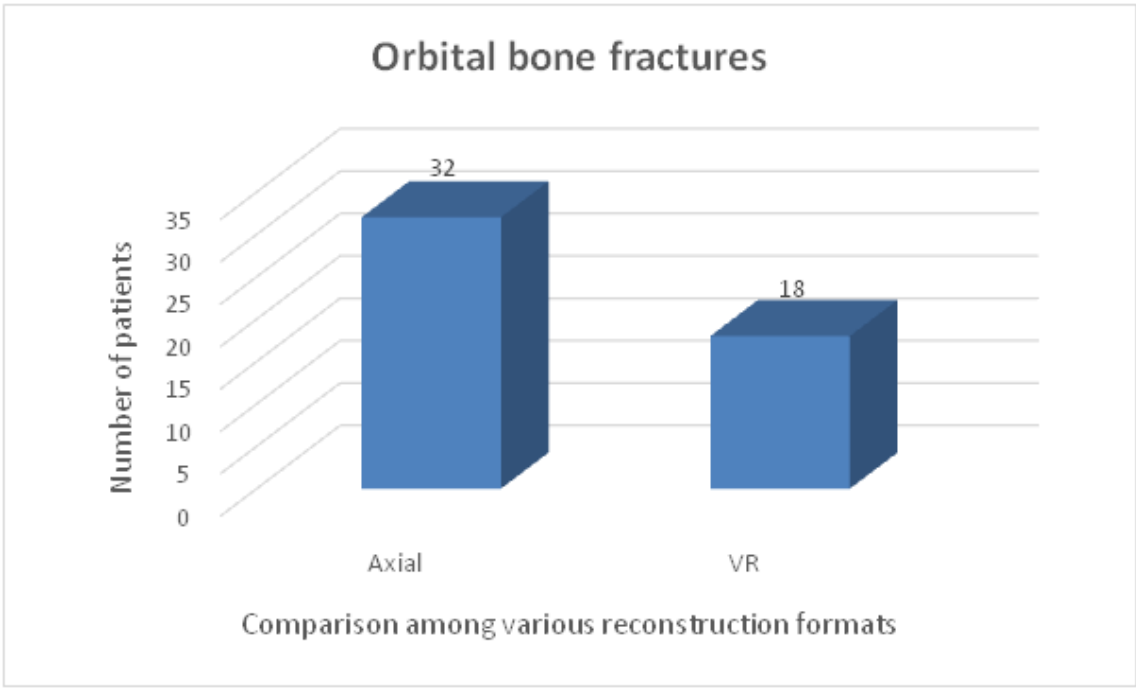

Chart 2: Number of orbital bone fractures detected in various formats.

Nasal bone fractures: In assessment of nasal bone fractures, axial section shows maximum number of fractures.

Considering sensitivity of axial section as the gold standard, VR lacks by 49% in detection of fractures

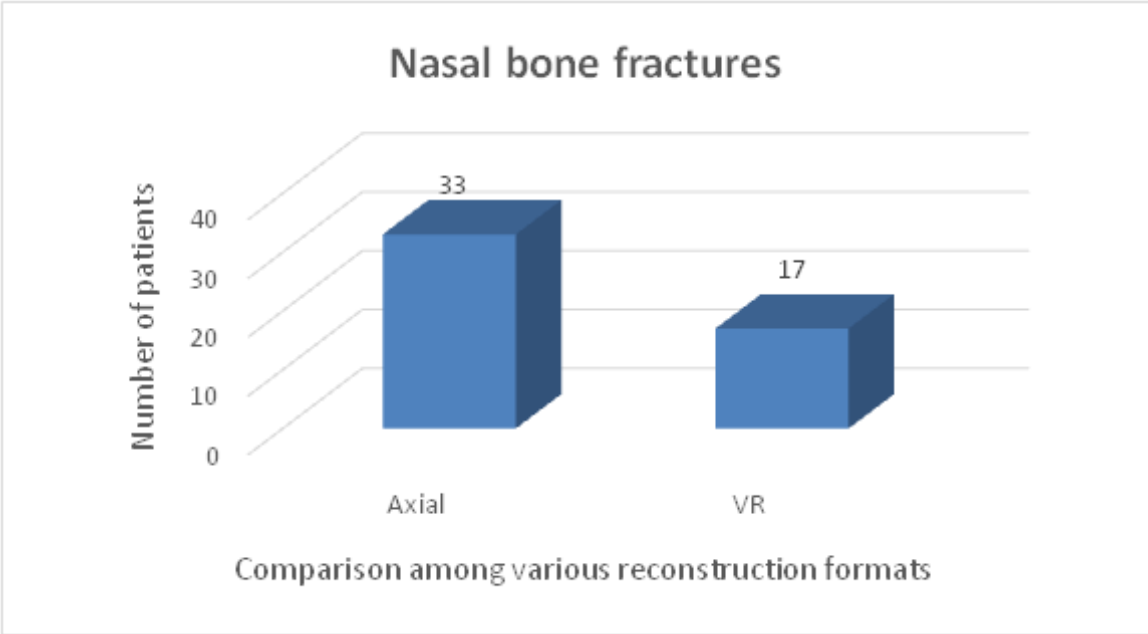

Chart 3: Number of nasal bone fractures detected in various formats.

Maxillary bone fractures: In assessment of maxillary bone fractures, axial section shows maximum number of fractures.

Considering sensitivity of axial section as the gold standard, VR lacks by 51% in detection of fractures.

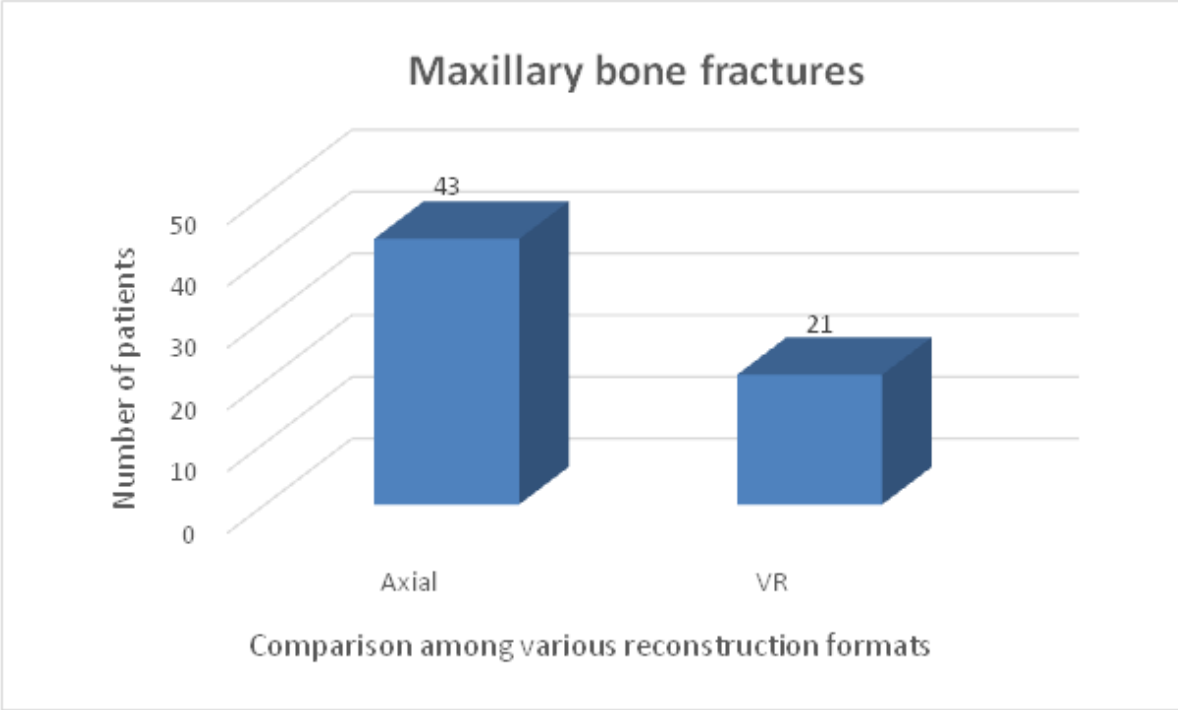

Chart 4: Number of maxillary bone fractures detected in various formats.

Zygomatic bone fractures: In assessment of zygomatic bone fractures, axial section maximum number of fractures.

Considering sensitivity of axial section as the gold standard, VR lacks by 10% in detection of fractures.

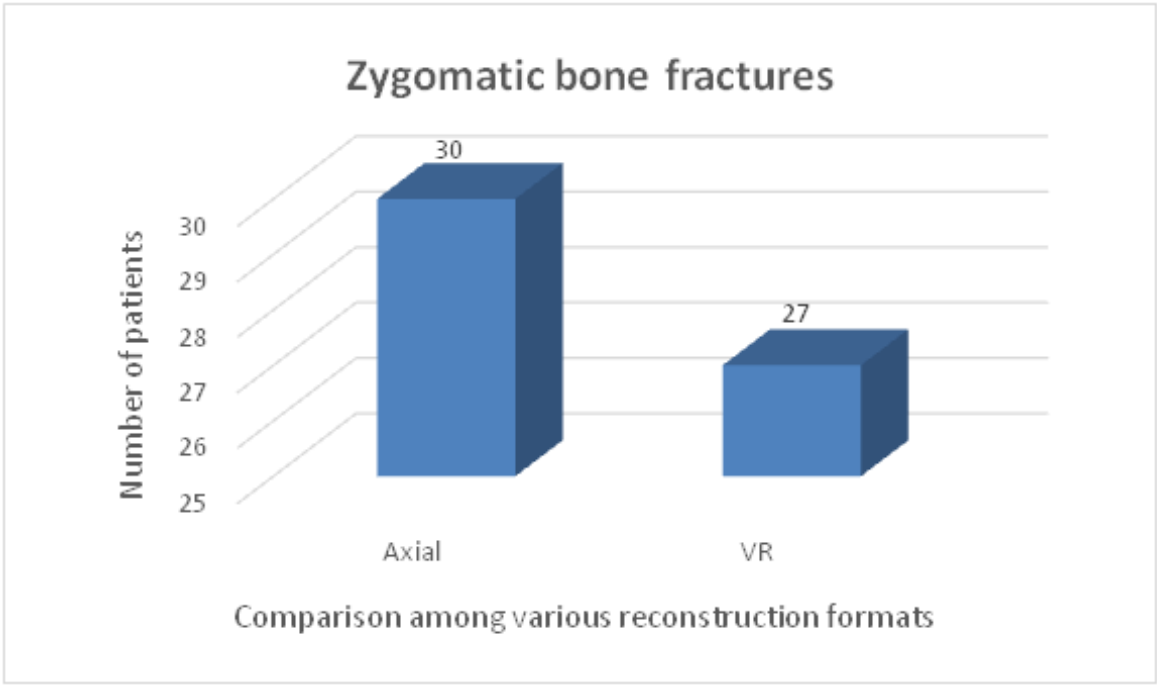

Chart 5: Number of zygomatic bone fractures detected in various formats.

Mandibular bone fractures: In assessment of mandibular bone fractures, axial section shows maximum number of fractures.

Considering sensitivity of axial section as the gold standard, VR sections lacks by 18% in detection of fractures.

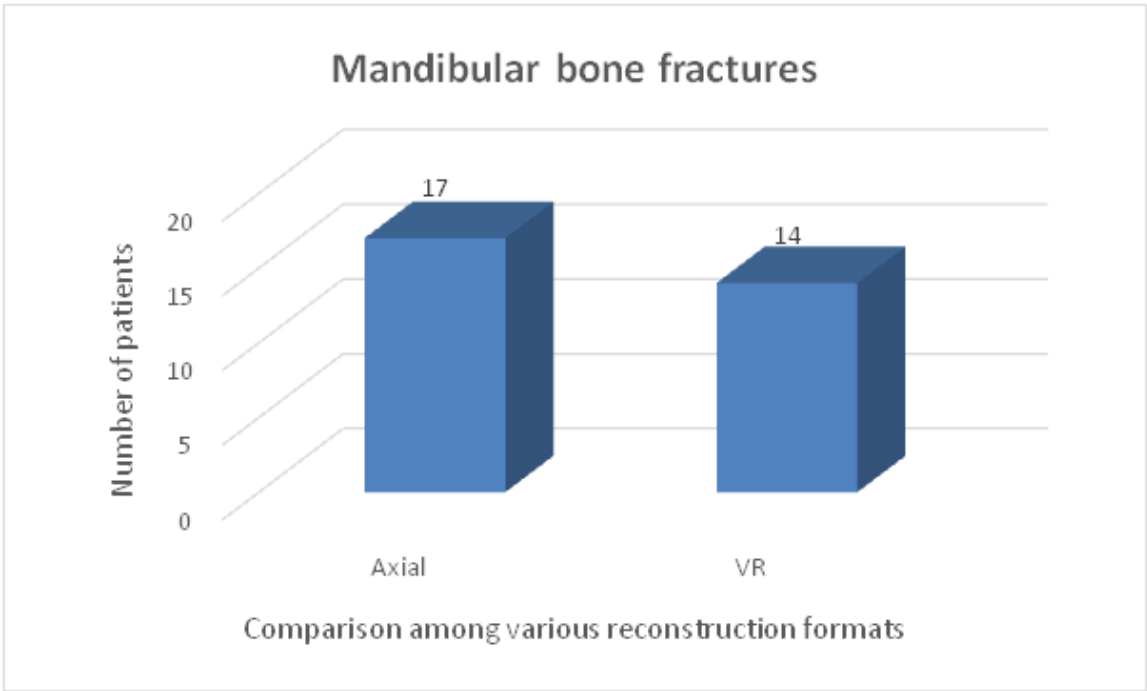

Chart 6: Number of mandibular bone fractures detected in various formats.

Table 1: Shows the sensitivity of detection of fractures by various sections in different bones.

Sensitivity Table (% age)		
	Axial	VR
Frontal bone	100	65
Orbital bone	100	56
Nasal bone	100	51
Maxillary bone	100	49
Zygomatic bone	100	90
Mandibular bone	100	82

Axial section is considered as the gold standard as it identifies the maximum number of fractures. VR images didn't show significant sensitivity over axial sections in any of the facial bone regions but was nearly sensitive in zygomatic and mandibular bone.

In this study none of the reconstruction format shows the false positive results. So, considering the false positive as zero, if we calculate the specificity it comes to 100% for all the formats.

Discussion

Plain radiographs were the initial modality of choice for imaging in these patients, but they can be inadequate due to superimposition of bony structures [18,19].

In a study done by Fox et al [20] showed that in the zygomatic region, they were able to recognize the presence of injury better on VR (88%) than axial sections (64%), and both of these modalities were superior to MPR(0%). Whereas in the orbit and maxilla, axial sections (62%,50%) showed better sensitivity in detecting fractures over VR (50%,44%) and MPR (33%,11%). In fractures involving nasal region, axial (50%) and VR (50%) are more sensitive than MPR (16%). Overall, axial images had higher average sensitivity values than the other two modalities.

In a study done for comparison of facial bone fractures by VR and axial images done by Gillespie et al [21], VR showed poor detection rates than axial images in all the orbit fractures; showed 50% poor detection rate and 50% similar in zygomaticomaxillary fractures.

In a study done by Remmler et al [22], VR was superior than axial images when fractures involving the naso-orbito-ethmoid region are considered (mainly in the inferior orbital rim, piriform aperture and nasomaxillary buttress) but axial was better than VR at lateral nose and medial orbital wall. Diagnostic accuracy of axial images ranged from minimum of 25.9% at the piriform aperture to a maximum of 88.9% at the medial orbital wall, whereas VR varied from 63.0% at the medial orbital wall to 88.9% at the piriform aperture.

Conclusion.

In our study, axial sections were considered as the gold standard as it identified the maximum number of fractures.VR images didn't show significant sensitivity over axial sections in any of the facial bone regions but was nearly sensitive in zygomatic and mandibular bone. Fox et al [20] found that 3D recreated CT sweeps were deciphered all the more quickly and all the more precisely and that 3D CT was increasingly exact at surveying zygomatic cracks yet was substandard compared to hub pictures for assessing orbital breaks.Many studies have noted that 3D reconstructed images are helpful in the evaluation of fracture comminution, displacement components, and complex fractures involving multiple planes [23].

The degree of communitive breaks is better exhibited on the 3D-CT, where the size, shape, and uprooting of individual sections are unmistakably uncovered. The blend of multislice CT and 3D volume rendering procedure permitted a few enhancements in imaging translation.

3D imaging isn't shown, in any case, for little cracks of the orbital floor or confined breaks of the maxillary divider, in which the break is constrained to one plane. Here, inspecting 3D examines alone can give false-negative outcomes.

A Study on Awareness Treatment and Control of Hypertension among Rural Adult Population of Kancheepuram, Tamil Nadu

S. Gopalakrishnan[1], J. Krishnakumar[1]

[1]Professor, Department of Com. Med., Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Developing countries are thus likely to face an enormous burden of chronic non-communicable diseases (NCDs) in the near future in comparison to communicable disease which were once a major problem. Cardio Vascular Disease (CVD) is the number 1 cause of death globally and an estimated 17.7 million people died from CVD in 2015, representing 31% of all global deaths. CVD are the major cause of morbidity and mortality in India and accounting for 25% of all deaths and projected to increase to 50%. The association between various risk factors and hypertension were determined in this study.

Keywords: *Hypertension, Epidemiological transition.*

Introduction

Epidemiological transition worldwide has lead to a tremendous increase in the elderly population in the developing countries with concomitant increase in the life expectancy. It is estimated that by the year 2025 the majority of the elderly population worldwide will be residing in developing countries. Developing countries are thus likely to face an enormous burden of chronic non-communicable diseases (NCDs) in the near future in comparison to communicable disease which were once a major problem.[1-4] The global distribution of disease burden in terms of disability-adjusted life years (DALY) losses indicates that communicable diseases account for 41% DALY losses, non-communicable diseases account for 43%, and injuries account for 16%. Comparison between high-, low-, and middle-income countries reveal that low-and middle-income countries shoulder more than 6 times (43.8%) the burden of communicable diseases, as compared to high-income (7.2%) countries. With regard to India, the DALY losses due to communicable diseases account for 50%, compared to 33% for non-communicable diseases, and 17% of injuries.[5]

Non-communicable diseases (NCDs) are group of chronic diseases that are not communicable. They are defined as diseases of long duration and slow progression. NCDs are the major cause of adult mortality and morbidity globally.[6] The 4 main types of non communicable diseases are cardiovascular diseases, cancers, chronic respiratory diseases and diabetes.[7] Globally, premature mortality from these four main NCDs declined by 15% between 2000 and2012this rate of decline is insufficient to meet the 2030 target of a one third reduction.[8] Nearly 38 million people die each year globally from Non communicable diseases.[9] Based on current trends, by the year 2020 these NCDs are expected to account for 73% of global deaths and 60% of the global burden of disease.[10] As per the World Health Organisation (WHO) 2015 report, every 4th Indian die from an NCD before the age of 70 years. Globally India is the first country to develop specific targets and indicators in this field, which are aimed at reducing the burden of deaths from NCDs globally by the year 2025 by 25 per cent.[11]

The risk factors for non-communicable disease are grouped into 3 categories they are behavioural, metabolic and biochemical risk factors. Behavioural risk factors include tobacco use, alcohol use, unhealthy diet and

Corresponding Author:
S. Gopalakrishnan
Professor, Department of Com. Med, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Agharam Road, Selaiyur, Chennai-73

lack of physical activity. Metabolic risk factors include overweight, obesity, diabetes and hypertension (HTN). Biochemical risk factors include hypercholestremia and hypertriglyceridemia. To contain the increasing burden of Non-Communicable Diseases, Ministry of Health and Family welfare, Government of India, has launched the National Programme on Prevention and Control of Diabetes, Cardiovascular diseases and Stroke (NPDCS).[7]

Cardiovascular diseases (CVDs) are a group of disorders of the heart and blood vessels and they include coronary heart disease, cerebrovascular disease, peripheral arterial disease, rheumatic heart disease, congenital heart disease, deep vein thrombosis and pulmonary embolism. Cardio Vascular Disease (CVD) is the number 1 cause of death globally and an estimated 17.7 million people died from CVD in 2015, representing 31% of all global deaths.CVD are the major cause of morbidity and mortality in India and accounting for 25% of all deaths and projected to increase to 50%.[12]

Objectives

- To identify the determinants of hypertension among the study population.
- To determine the association between various risk factors and hypertension

Materials and Method

This cross sectional study was conducted to estimate the prevalence,of hypertension among the rural adult population of Kancheepuram District, Tamil Nadu. It is a community based cross sectional study, conducted in the rural field practise area of Sree Balaji Medical College and Hospital of Kancheepuram District. The field practice area covers 5 villages.

The sample size calculated was 1250 using the formula 4 PQ/L2.Systematic random sampling method was used to select the study participants. A pre tested structured questionnaire was used to collect data from the study population. Information regarding socio demographic characteristics, risk factors, regarding hypertension and physical measurements of the study population were obtained. The data was entered in MS Excel and analysis was done using SPSS software (version 22). Descriptive and analytical statistics were used to describe the study variables.

Findings.

Knowledge regarding hypertension among the study population: In this study 47.5% of the participants have adequate knowledge about hypertension as shown in Figure 1. As seen from Table 1 about 89.1% of them have measured their BP. Among them 20.1% measured their BP in the last month and 61.6% measured their BP in the last 6 months.

Table 1: Measured BP among the study participants

Sl No	Measured BP	Frequency	Percentage (%)
1.	Measured BP in their Lifetime (N-1250)		
	Yes	1114	89.1
	No	136	10.9
2.	When Was the last time you measured BP(N-1114)		
	< 1 Month	224	20.1
	1-6 Months	686	61.6
	6 Months--1 Year	130	11.7
	1---2 Years	30	2.6
	> 2 Years	26	2.3
	Don't Remember	18	1.7

Knowledge about normal BP value among the study participants: Among the study participants when asked whether they know the normal blood pressure value, 24.8% said they know the normal blood pressure value and among them only 60% said the correct blood pressure value and 40% said incorrect value.

Table 2: Diagnosis characteristics of hypertension among the study population

Sl No	Diagnosis Characteristics	Frequency (N=218)	Percentage (%)
1.	Mode of Diagnosis		
	Symptomatic	84	38.6
	Incidental	112	51.4
	Master Health Check up	22	10
2.	Duration since Diagnosis		
	< 1 Year	60	27.5
	1--5 Years	96	44
	5-10 Years	24	11
	> 10 Years	38	17.5

Diagnosis and treatment characteristics of the study population: Among the known hypertensive

51.4% were diagnosed incidentally and 38.6% presented with symptoms at the time of diagnosis (Table 3). Around 44% were hypertensive for the past 5 years and 17.5% are hypertensive for more than 10 years. Among the hypertensive's 98.1% are under treatment. Nearly 51.4% of them are getting treatment from private facility and 47.7% are getting treatment from government facility.

Table 3: Treatment characteristics of hypertension among the study population:

Sl No	Treatment Characteristics	Frequency	Percentage (%)
1.	Under Treatment (N-218)		
	Yes	214	98.1
	No	4	1.9
2.	Treatment Duration (N-214)		
	< 1 Year	60	27.6
	1--5 Years	96	44.6
	5-10 Years	22	11.2
	> 10 Years	36	16.6
3.	Treatment facility(N-214)		
	Government	102	47.7
	Private	110	51.4
	Others	2	0.9

Table 4: Drug characteristics among study population

Sl No	Drug Details	Frequency	Percentage (%)
1.	Claim to Know DrugName (N-214)		
	Yes	136	63.6
	No	78	36.4
2.	Group of Drug (N-214)		
	ACE Inhibitors	54	39.7
	Beta Blockers	32	23.5
	Calcium Channel Blockers	32	23.5
	Others	18	13.3
3.	How many Drugs (N-214)		
	Single Drug	180	84.1
	Multiple Drugs	34	15.9

Drug characteristics among study population: Among the participant 63.6% know the name of the drug they are taking. About 39.7% are treated with ACE inhibitors and 23.5% are under beta blockers and calcium channel blockers. About 84.1% are under single drug treatment and 15.9% of them are under multiple drug combinations.

Table 5: Side effects to treatment among the study population

Sl No	Side Effects	Frequency	Percentage (%)
1.	Side Effects to Drugs (N-214)		
	Yes	18	8.4
	No	196	91.6
2.	What Type of Side Effects (N-18)		
	Gastritis	12	66.7
	Low Back Ache	2	11.1
	Giddiness	4	22.2

Side effects and adherence to treatment among study population: Among those under treatment 8.4% suffer from any form of side effect and among them 66.7% suffer from gastritis and 22.2% suffer from giddiness. Adherence to treatment was assessed using Morisky 4 item questionnaire. Only 44% of them were adherent to treatment and 66% were non adherent to treatment.

Expenses for hypertension among the study population: Among the hypertensive's 69.1% are spending 100-500/month for hypertension, 16.3% are spending < 100/month and 10.1% are spending more than 1000/month for hypertension. The expenses include expense for treatment, travel and investigations.

Table 6: Expenses for hypertension among the study population:

Expense for Hypertension		Frequency (N-214)	Percentage (%)
Expense	< 100/Month	18	16.3
	100--500/Month	76	69.1
	500--1000/Month	4	3.6
	> 1000/Month	12	10.1

Discussion

This study was done to assess the awareness, treatment and control of hypertension among rural adults in the study area. The study was conducted in the Rural field practice area covered by our institution and included 1250 samples selected from the study area. Many interesting results were obtained from this study and were explained already. Findings of the study is discussed in comparison with similar studies done elsewhere.

Knowledge, Treatment and control of hypertension: In this study 47.5% of the participants

had knowledge about hypertension. Among the hypertensive's 98.1% were under treatment. Nearly 51.4% of them are getting treatment from private facility and 47.7% were getting treatment from government facility. Among the hypertensive under treatment, 68.8% have their blood pressure under control and 31.2% have uncontrolled hypertension. In a study by Deepa R 50% of the hypertensive's were on treatment and among them only 40% of them had their BP under control.[13] 16.8% of hypertensive patients were aware of their disease,31.8% are under treatment and only 11.4% had normal BP in a study done by Avadaiammal Vimala.[14] Sathish Kumar conducted a study in which only 31.0% of the hypertensive's were aware of their hypertensive status, 23.2% of the hypertensive's are on treatment and only 11.2% of them are under control.[15] In II Meshram study among hypertensive about 10% were aware about the condition and about 8% were on treatment. The level of awareness and treatment seeking behaviour was more among women and among educated subjects.[16]

Conclusion

Among the hypertensive's 98.1% are under treatment and in that under treatment, 68.8% have their blood pressure under control.From the findings of the study, it can be concluded that the prevalence of hypertension and prehypertension are high in the study area. The burden of undiagnosed case is also quite high. There is no sex difference in the prevalence of hypertension. This study also shows that there are still gaps in the diagnosis and treatment of hypertension in the study area. Among those treated also adherence, incidence of complications and co morbidities are worrisome. The level of awareness among the study participants about this disease is lower than expected which is quite alarming. Though there is an existing program to address this disease there is few lacunae identified in this study which prevents the program from reaching the needful. All these lacunae must be bridged by effective interventions.

Mechanism of Unstable Inter-Trochanteric Fractures in the Elderly

S. Santhosh[1], K. Subramanian[2]

[1]Post Graduate, [2]Professor, Department of Orthopaedics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

There is an increased incidence of hip fractures with aging due to decrease in muscle mass around the hip and osteoporosis. This is becoming more common as the proportion of elderly people in the population has been steadily increasing. Our study shall aim to evaluate the clinical, functional and radiological outcomes of bipolar hemi-arthroplasty and compare them to those treated by dynamic hip screw fixation, for communized, osteoporotic, displaced trochanteric fractures in the elderly population.

Keywords: *Hip Fractures, osteoporosis, Hemi Arthroplasty.*

Introduction

Proximal femoral fractures in the elderly individuals have a tremendous impact on both the health care system and society. It occurs with both mild and moderate trauma[1,2]. During an impact, the large amount of energy that is released is absorbed by the skin, fat, and muscles which surround the hip. There is an increased incidence of hip fractures with aging due to decrease in muscle mass around the hip[2] and osteoporosis. This is becoming more common as the proportion of elderly people in the population has been steadily increasing[3].

Upon treatment of inter-trochanteric factures with conservative management, itusually unites with a mal-union and with shortening, but the problem of trochanteric fractures has never been union but because of complications associated with prolonged recumbency and its associated morbidities. Trochanteric hip fractures in the elderly patients have benefited from advances in internal fixation.In the last 2 decades these newer implants have been helping in early mobilization and thereby preventing complications of recumbency. Early failure of internal fixation occurs however in a number of cases[4]. The failure after internal fixation has been due to the initial fracture pattern, communition, sub-optimal fracture fixation and poor bone quality[5]. The problems associated with fixation of these fractures area loss of fixation, avaruscollapse and implant cut-out of the lagscrew[6]. As a result there is profound functional disability and pain[7]. In these patients treatment with primary bipolar hemi-arthroplasty decreases the post-operative complications due to prolonged immobilization or implant failure and also quickly returns the patients to their pre-injury activity level[6,8].

Our study shall aim to evaluate the clinical, functional and radiological outcomes of bipolar hemi-arthroplasty and compare them to those treated by dynamic hip screw fixation, for communited, osteoporotic, displaced trochanteric fractures in the elderly population.

Materials and Method

This study was conducted at Sree Balaji Medical College and Hospital, Chrompet, Chennai from March 2017 to October 2018 on 40 elderly osteoporotic patients with unstable inter-trochanteric fractures who were divided into two groups with Group A-bipolar prosthesis (20 cases approximately) and Group B–DHS (20 cases approximately). The recruitment of patients was from March 2017 to February 2018 [12 months], so that there would be a minimum follow-up of 8 months [range: 8 to 20 months].

Findings:

Table 1: Age and Sex Distribution

AGE (in years)	GROUP A (BPHA group) Sex and 'n'		GROUP B (DHS group) Sex and 'n'		SAMPLE SIZE 'n' Group A + Group B	% Age of patients in the total sample.
	Male 'n'	Female 'n'	Male 'n'	Female 'n'		
56-60	3	5	5	3	16	40
61-65	3	3	1	4	11	27.5
66-70	1	2	1	1	5	12.5
71-75	1	2	2	3	8	20
Total	8	12	9	11	40	100
% age in total	20	30	22.5	27.5	Net total	100%
% age within group	8/20 (40%)	12/20 (60)	9/20 (45%)	11/20 (55%)		

In our study, of the total 40 patients recruited, most of them were in the age group of 56 to 60 (40%). Females out-numbered males in both the groups,60% in group A and 55% in group B. Together in both groups put together the females were 57.5%.

- Eight patients were in the age group of 56 to 60, of these 3 were male and 5 were female patients.
- Six patients were in the age group of 61 to 65, of these 3 were male and 3 were female patients.
- Three patients in the age group of 66 to 70,of these 1 was male and 2 were female patients.
- There was one male and 2 female patients in the age group of 71 to 75 years

Group B: Sex Distribution In Group B (DHS Group):

Among the 20 patients, there were 9 male (45 %) and 11 female (55 %) patients as far as group B (DHS group) was concerned.

Age Distribution in Group B (DHS Group):

- Eight patients were in the age group of 56 to 60, of these 5 were male and 3 were female patients.
- Five patients were in age group of 61 to 65, of these 1 was male and 4 were female patients.
- Two patients were in the age group of 66 to 70,of these 1 was a male and 1 was a female patient.
- Five patients were in the age group 71 to 75, of these 2 were males and 3 were female patients.

Table 2: Type of Fracture (Classification of Ao-OTA)

Classification	AO Type			Total
Types	A2.1	A2.2	A2.3	
Group A (BPHA Group)	03	11	06	20
Group B (DHS Group)	05	10	05	20

In group A (BPHA group), according to AO classification type A2.2 was more common in11 patients (55%), type A2.3 in 6 patients (30%) and type A 2.1 in 3 patients (15%).

In group B (DHS group), according to AO classification type A2.2 again was more common in 10 patients (50%), type A2.3 in 5 patients (25%) and type A2.1 in 5 patients (25%).

Table 3: Mechanism of Injury Distribution Table

Mode of Injury	Male		Female		Net Total 'n' % age
	Group A (BPHA) 'n'% age	Group B (DHS) 'n'% age	Group A (BPHA) 'n'% age	Group B (DHS) 'n'% age	
RTA	03	02	02	03	10(25%)
Trivial trauma	01	01	04	03	9(22.5%)
Accidental fall and others	04	06	06	05	21(52.5%)
Total	8(40%)	9(45%)	12(60%)	11(55%)	40(100%)

- 10 patients had accidental fall of which there were four male and six female patients.
- 5 patients had road traffic accident of which there were three male and two female patients.
- 5 patients had trivial trauma of which there were one male and four female patients.

In group B (DHS group):

- 11 patients had accidental fall of which there were six male and five female patients.
- 5 patients had road traffic accident of which there were two male and three female patients.
- 4 patients had trivial trauma of which there were one male and three female patients.

Osteoporosis Evaluation: In both the groups, grade 3 was more common in 13 patients. Six patients had grade 2 in group A and seven patients in group B. Grade 1 osteoporosis was seen in one patient in group A.

Surgical Approach:

Group A (BPHA group):

- Lateral–14.
- Posterior-06.

Group B (DHS group):

- Lateral–20.

Table 4: Time Elapsed From Injury To Surgery

Time Interval from Injury to Surgery (In Days)	No. of Patients 'n'	
	Group A (BPHA group) 'n' (% age)	Group B (DHS group) 'n' (% age)
0-4	6(30%)	7(35%)
5-9	8(40%)	9(45%)
10-14	6(30%)	4(20%)
Total	20(100%)	20(100%)

The mean time elapsed from injury to surgery was 7 days in the group A (BPHA) and 6.25 days in the group B (DHS)

Table 5 .Operative Time Distribution Chart

Operative Time (mins)	Group A (BPHA) 'n' (no. of patients)	Group B (DHS) 'n' (no. of patients)
61-90	6	4
91-120	12	15
121-150	2	1
Total	20	20

Average surgical time in Group A (BPHA) = 99.5 minutes., Average surgical time in Group B (DHS) = 101 minutes., P value: 0.0004.

Table 6. Blood Loss Evaluation Chart

Blood Loss (in ml)	Group A (BPHA) 'n' (no. of patients)	Group B (DHS) 'n' (no. of patients)
81-100	07	00
101-120	04	03
121-140	06	12
141-160	03	05
Total	**20**	**20**

P value: 0.0310., Mean blood loss for Group A(BPHA group): 111 ml., Mean blood loss for Group B(DHS group): 148 ml.

This prospective study was conducted at Sree Balaji Medical College and Hosital, Chrompet, Chennai from March 2017 to October 2018. The recruitment period was till February 2018 (12 months). The minimum follow-up period was 8 months (range: 8 to 20 months). 40 cases of unstable inter-trochanteric hip fractureswere recruited, in this12 months, which satisfied our inclusion criteria. They were sub-divided into two groups of 20 cases each. The first group A set [BPHA], were surgically treated with bipolar hemi-arthroplasty and the second group B set [DHS], were surgically treated with dynamic hip screw fixation

The following observations were made out in this study:

Discussion

Inter-trochanteric fractures in elderly patients are associated with notable morbidity and mortality. Internal fixation in these patients has reduced the mortality associated with these fractures[20], however failure rate in certain literature are as high as 56%[21,22] and early mobilization is avoided in these cases because of osteoporosis, poor screw fixation and comminution.

The weak and porotic bone in these patients do not provide for a firm purchase of screw which leads to early bio-mechanical failure[23]. As aresultthefemoral head collapses and migrates into varus and retroversion. This leads to limping gait due to shortening and decreased abductor muscle lever arm[24].

Another cause for functional disability and pain in these patients is cutting out of the screw from the femoral head. Although the mortality rate is somewhat decreased with internal fixation, the complication rate still ranges from 4 to 50 percent[25].

In study by Broos et al[26];BipolarVandeputte prosthesis was implanted in ninety four elderly patients.

Results were better with bipolar hemi-arthroplasty group with respect to shorter average operating time, lower mortality rate and better functional results.

In study by Rodop et al[27];BipolarLeinbach hemi-prosthesis was implanted in fifty four elderly patients. There were no cases of stem loosening or dislocations. Harris Hip Scoring showed good to excellent result in eighty percent of thesepatients.

In our study, there was female preponderance in both the groups accounting for 60% in group A (BPHA) and 55% in group B (DHS). This is due to post-menopausal osteoporosis and lower peak bone mass.

The results in group A (BPHA) were better than group B (DHS) with respect to blood loss, operative time, peri-operative blood transfusion this compares favourably with the study alone bySinno K et al[18]; where one hundred and two patients participated in the study. Bipolar hemi-arthroplasty was done in 48 patients and 54 patients were treated with dynamic hip screw fixation.The mean operative time was just less in group A (BPHA) (99.5 minutes) than that in group B (DHS) (101 minutes),which coincides with study by Sinno K et al[18] where it is 112 minutes.The amount of blood loss (mean) was lower in group A (BPHA) (111 ml) than in group B (DHS) (148ml) with a P value of 0.03,which is similar to the study by Sinno K et al[18]; where it was reported 129 ml in the hemiarthroplasty group with a P value of 0.005.

The mean blood transfusions (units)was higher in group B (DHS) (1.9 units) than in group A (BPHA) (1.4 units) with a P value of 0.02.This compares well with the study by MdEmami et al[37]; where the mean blood transfusions was greater in internal fixation group (1.9 units) than in Bipolar hemiarthroplasty group (1.37 units),withaP value of0.01.Early mobilization with full weight bearing in group A (BPHA) compared to non-weight bearing or partial in group B (DHS) shows reduction in pulmonary complications (5%). This is in concurrence with the study done by Grimsurdet al[15]; where they studied 39 patients treated with bipolar arthroplasty. It allowed for early weight bearing and had low rate of pulmonary complications and bed sores.

Conclusion

From our clinical observation we would suggest that unstable intertrochanteric fractures in elderly result most frequently from accidental fall(52.5%), being the most common described mechanism of injury.

Assessment and Evaluation of Etiological Factors in Cases of Female Primary Infertility

Mohana T.[1], R. Yuvarani[2]

[1]Post Graduate, [2]Professor, Department of OBG, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Objectives: The aim of the study is to assessment and evaluation of etiological factors in case of female primary infertility.

Place of Study: Gynaecologyopd, Sree Balaji Medical College and Hospital, Chennai.

Period of Study: August 2016 to February 2018 (18 months).

Study Design: Prospective study.

Materials and Method: All the reproductive age group women coming to Gynaecologyopd out patient clinic with history of anxious to conceive.

Those patients who satisfy the above criteria are to be selected for the study.

The test has to be carried out in hospitalized patients.

1. A detailed history was taken.
2. General physical and systemic examination was done.
3. Ovarian factors and uterine factors ruled out
4. Fortubal cannulation

The data collection technique adopted in this technique is structured questionnaire on the evaluation of infertility in couple of less than 35 years of age in a period of infertility less than 5 years from infertility OPD for one and half years of Sree Balaji Medical College and Hospital. Detailed history obtained from the couple and evaluate, inform at ion with the help of various investigation in evaluating an infertile couple.

Results: The prevalence of infertility in the age group 21–29 years were about 76% in women. This showed that maximum number of female attain menarche at the age group of 12 to 14 years. In our study, it is observed that there is a strong relation of infertility with BMI, the prevalence of infertility increases as BMI Increases in population. 22% of thew omen has BMI above 30 (obese). In our study, 8% of the women has hydrosalpinx, 4%of the women had fibroids and 6% of the women haspolyps. We observed that 4% of the women had unilateral fallopian tubal block and 2% had bilateral fallopian tubal block**.**

Conclusion: In modern era of economically growing world we have concluded that the prevalence of infertility is about 76% in women age group of 21-29, 40% of the women have attained menarche at 12-14 years, observed hydrosalpinx in 8%, polyps in 6% and fibroids in 4%.

Introduction

According to WHO, positive reproductive health of awoman is a state of complete physical, mental and socialwell-being and not merely absence of disease

related toreproductive system and functions. Infertility implies apparent failure of a couple toconceive, while sterility indicates absolute inability toconceive, for one or more reasons[1-4]. If a couple fails to achieve pregnancy after 1 yea r of 'u nprotected' and r egular intercourse, it is an indication to investigate the couple. This is based on the observation that 80% of normal couples achieve conception within a year. It is observed that 50% conceive within 3 months of regular, unprotectedintercourse, 75% in 6 months and 80–85% conceive withina year. (1) Primary infertility if conception has never occurred[5-7].

Materials and Method

A prospective study was planned on women with primary infertility. All the reproductive age group women coming to Gynaecologyopdout patient clinic with history of anxious to conceive.Those patients who satisfy the below criteria are to be selected for the study.

Inclusion Criteria:

- Primary infertility who are less than 35 years of age.
- Couples practicing regular timed intercourse without using contraception.
- Couples aware of fertile period

Exclusion Criteria:

- Patients who are on hormones, anti-psychotic drugs.
- History of pelvic inflammatory disease, endometriosis
- History of tuberculosis

The test has to be carried out in hospitalized patients.

1. A detailed history was taken.
2. General physical and systemic examination was done.
3. Ovarian factors and uterine factors ruled out
4. For tubal cannulation.

The data collection technique adopted in this technique is structured questionnaire on the evaluation of infertility in couple of less than 35 years of age in a period of infertility less than 5 years from infertility OPD for one and half years of Sree Balaji Medical College and Hospital. Detailed history obtained from the couple and evaluate, informat ion with the help of various investigation in evaluating an infertile couple. Obtaining the history would be as followed

Day 1; Detailed history collection from the couple, including menstrual history, coital history, husband history with any significant past history

DAY 2; Baseline scan for the female to evaluate any uterine structural abnormalities and to look for pre-antral follicles and hormonal study.

DAY 8; To do hysterosalpingography to rule out any pathological tubal factor association with fallopian tube or D-lap.

If any abnormalities to be found at this factor, refer the patient to higher center for tubal reconstruction surgery

DAY 9; To look for any spontaneous ovulation in a woman through follicular tracking, starting from the day of the cycle and main factor found to be normal.

If patient is not conceiving with 3 cycle of ovulation, indication to assess cervical factors to plan for intra uterine insemination and follow the patient. History of evidence of any hormonal irregularities to be corrected.

Findings: In this study maximum female 38 was found in age group of 21-29 years followed by 12 cases in the age group of 31-34 years

Table No. 1: Age Group of Respondents

S. No	Age group	Female	Percentage
1	21-29 years	38	76%
2	31-34 years	12	24%
3	Above 35 years	00	0%
Total		50	

In this study female attend menarche at the age of 11 was found to be 8 followed by 40 cases in the age group of 12-14 years followed by 02 cases in age group of 15-17 years.

Table No. 2: Female Patients Age at Menarche in Years

Age at Menarche	Patients	Percentage
11	08	16%
12-14	40	80%
15-17	02	04%
>18	0	0%

In this study maximum 22 women had regular cycle 28 had irregular cycle

Table No. 3: Female Patients Menstrual Cycle

Menstrual Cycle	Patients	Percentage
Regular	22	44%
Irregular	28	56%

In this study 27 cases married in the duration of 1-3years followed by 36 cases married in the duration of 4-6 years followed by 22 cases in the duration of 7-9years followed by 15 cases above 10 years…..

Table No. 4: Female Body Mass Index (BMI)

Duration of Married Life	Patients	Percentage
1-3	27	27%
4-6	36	36%
7-9	22	22%
Above 10	15	15%

In this study 3 women are less than 18.5 BMI (underweight) followed by 9 women 18.5 to 24.9 BMI (healthy) followed by 27 women BMI 25 to 29.9 (over weight) followed by 11 women BMI above 30 (obesity)

Table No. 5: Female Body Mass Index (BMI)

BMI Chart	Normal Values	Female	Percentage
Underweight	Less than 18.5	03	06%
Healthy	18.5 to 24.9	09	18%
Over Weight	25 to 29.9	27	54%
Obesity	Above 30	11	22%
Total		50	100%

In this study 34 men had normal sperm followed by 7 had mild oligospermia (10-15million sperm/ml) followed by 4 had moderate oligospermia(5-10 million sperm/ml)followed by 3 had severe oligospermia(0-5 million sperm/ml)followed by 2 had Azoospermia.

In this study 34 men had normal sperm followed by 7 had mild oligospermia (10-15million sperm/ml) followed by 4 had moderate oligospermia(5-10 million sperm/ml)followed by 3 had severe oligospermia(0-5 million sperm/ml)followed by 2 had Azoospermia.

Table No. 6: Semen Analysis

Semen	Cases	Percentage
Normal Sperm	34	68%
Mild Oligospermia	07	14%
Moderate Oligospermia	04	08%
Seveve Oligospermia	03	06%
Azospermia	02	04%
Total	50	100%

In this study 1 case had varicocele followed by 16 had others (mild moderate severe oligospermia) followed by 2 had cryptorchidism.

Discussion

A descriptive approach is used to ASSESS AND EVALUATE ETIOLOGICAL FACTORS IN CASES OF FEMALE PRIMARY INFERTILITY. The study was conducted at Sree Balaji Medical College and Hospital in Chrompet. After taking informed consent, a structured questionnaire is prepared to find out the etiological factors

The sample size for this study is 50 couples

Age: The prevalence of infertility in the age group 21–29 years were about 76% in women The prevalence was observed 24% of the women from age group 31 to 34 years . This showed that increase in age is an important risk factor for infertility

Menarche: In our study, the mean age of attaining menarche is12.5 years. The 40% age group of females at tainedmenarche at age group of (12-14 years) and 16% attained atthe age of 11 years and the remaining 4% attained at the age group of (15-17 years). This showed that maximum numberof female attain menarche at the age group of 12 to 14years.

Menstrual Cycle: In the present study, 44% of the women has history of irregular menstrual cycle, 56% had regular cycle.

Duration of Infertility: In our study, duration of infertility is 1 to 3 years in 27% of the couples, 4 to 6 years in 36% couples, 7 to 9 years in 22% of couples and above 10 years in 15% couples.

BMI: In our study, it is observed that there is a strong relation of infertility with BMI, the prevalence of infertility increases as BMI Increases in population. 22% of the women has BMI above 30 (obese). 54% of the women are with BMI 25–29.9 (over weight), 18% are with 18.5–24.9 (normal) and 6% are with BMI <18.5 (underweight)

Female Structural Abnormalities: In our study, 8% of the women hashydrosalpinx, 4% of the women had fibroids and 6% of the women has polyps.

Base Line Scan: In the present study, base line scan showed 5 to 15 antral follicles in 46% of the women of age group (20-29) and in 14% of the women of age

group (30-35). Base line scan showed less than 5 antral follicles in 34% of the women (20-29) age group and in 6% of thewomen (30-35) age group.

Hysterosalpingogram: In our study, we observed that 4% of the women had unilateral fallopian tubal block and 2% had bilateral fallopian tubal block.

Conclusion

The present study assessed and evaluated etiological factors of primary infertility in couple at Sree Balaji Medical College and Hospital and we have concluded that the prevalence of infertility is about 76% in women of age group 21-29 year. We have observed the age of attaining menarche in all the women who has included in the present study. 40%of the women has attained menarche at 12-14 years. We have observed the relation of infertility with menstrual cycle irregularities we have observed that44% of the women has regular menstrual cycle and56% of the women has irregular menstrual history. We have observed the relation of BMI to infertility and concluded that 54% of the women has 25-29.9 (over weight) and 22% of the women has BMI above 30 (obesity). We have evaluated all the women who were included in the study for structural abnormalities and we have observed hydrosalpinx in 8%, polyps in 6% and fibroids in 4%. We have taken base line scan for all the women who were included in the study on day 2 of the menstrual cycle and observed 34% has less than 5 antral follicles in the age group (20-29 year). We have done hysterosalpingogram for all the women and observed unilateral tubal block in 2 women and bilateral tubal block in 1 women in age group 20-34years.

To Study the Mobidity and Mortality of Primary Cesarean Section in Multigravida

M. Prasanthi[1], T.G. Revathy[2]

[1]Post Graduate Student, [2]Professor, Department of Obstetrics and Gynecology, Shree Balaji Medical College and Hospital, Chrompet, Chennai-44, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Aim: To study the mobidity and mortality of primary cesarean section in multigravida.

Method: In this study 58 cases of primary caesarean in multigravida over a period of two Years i.e. from August 2016 to April 2018 at the obstetric department of Sree Balaji Medical College And hospital, Chennai-44 were taken. Before surgery, indications for the cesarean section were observed. All problems have been observed and noted until the patient's release. For primigravida and multigravida, calculations were produced individually and the outcomes were contrasted. Statistical analysis was performed by meaningful chi square test.

Results: During this era, the main cesarean segment supplied 58 multigravida. The most prevalent signs in multigravida were fetal distress and misrepresentation. Primary PPH was commonest intraoperative complication (17.34%) followed by extension of uterine incision (3.44%) in multigravida women. In multigravida women Maternal morbidity was seen in 20 cases and Perinatal morbidity seen in 45 babies. Major causes for perinatal morbidity are birthasphyxia 22 cases(38%), Prematurity 6 cases(10.34%). Perinatal Mortality seen in 2 cases with incidence of 3.44%.There were no maternal deaths in the present study.

Conclusion: Women's first labour requires to be handled well to decrease the prices of cesarean section. Good antenatal check-ups can reduce the incidence of APE. Multigravida carries a greater danger of morbidity that highlights the need to improve women's health status in the reproductive age category and to better implement family planning facilities.

Keywords: *Cephalopelvic disproportion (CPD), Antepartum eclampsia (APE).*

Introduction

The rate of cesarean area has multiplied or significantly increased everywhere throughout the world over the most recent 15 years [(1).] In spite of the fact that cutting edge innovation and offices have made this activity amazingly sheltered, yet cesarean segment is related with expanded danger of maternal horribleness and mortality when contrasted with vaginal conveyance just as it additionally confuses the administration of consequent pregnancies. Additionally this expansion in cesarean rate has not contributed essentially to the synchronous watched decrease in perinatal mortality [(2).] Henceforth the essential cesarean segment performed on a lady is of much obstetric essentialness and requirements a top to bottom examination. The reason for this examination is to assess the inconvenience of essential cesarean segment in multigravida with the goal that the perspectives which need due consideration could be separated and better obstetric administration could be given to them.[3-8]

Materials and Method

In this study 58 cases of primary caesarean in multigravida and primigravida done over a period of two Years i.e. from August 2016 to April 2018 at the obstetric department of Sree Balaji Medical College And hospital, Chennai-44 were taken.

Inclusion Criteria:

1. Multigravida with pregnancy of >28 weeks gestation (gravida 2 and above), with previous one or more vaginal deliveries.
2. Multiple pregnancy
3. Pregnancy with medical disorders.
4. Previous instrumental, assisted breech deliveries, still births and IUD.

Exclusion Criteria:

1. Previous one or more caesarean.
2. Previous h/o hysterotomy

Findings: Around 1857 caesarean sections were made 5161 shipments during this era, representing 36 percent of all shipments. The incidence of main caesarean section in females with multigravida is 1.12 percent of all shipments and accounted for 3.10 of all segments.

Table 1: Booking Status

	No of Cases Inmultigravida
NO OF BOOKED CASES	22(38%)
NO OF UNBOOKED CASES	25(43%)
NO OF REFERRED CASES	11(19%)

Table 2: Indications of Caesarean Section in Multigravida and Primigravida

Sl. No.	Indication	No of Cases in Multigravida	Percentage
1	Fetal Indications		
	a) Fetal distress	16	27.6
	b) Malpresentation	10	17.2
	c) Cord prolapse	-	-
	d) Macrosomia	-	-
2	Obstetric Indications		
	a) Antepartum haemorrage	7	12.1
	i) Placenta previa	4	7
	ii) Abruptio placenta	3	5.1
	b) CPD	9	15.6
	c) Labour disorders	5	8.6
3	**Maternal Indications**		
	a) Medical Disorders	7	12.1
	i) Hypertensive disorders	5	8.6
	ii) Heart disease	1	1.7
	iii) renal causes	-	-
	iv) Infections to the mother (HIV,HPV,HSV)	1	1.7
	b) Maternal request	-	-
	c) Previous VVF Repair/iv degree perineal laceration	-	-
	d) Neoplasm	2	3.4
	e) Previous uterine surgery	2	3.4

The Indications of caesarean section in multigravida the most common are fetal distress accounting for 27.6% cases and second common was malpresentation with 17.2%, CPD accounting for 15.6%, Antepartum haemorrage accounting for 12.1% amond this Placenta previa was 7% and abruption placenta was 5.1%.Labour disorders accounting for 8.6% and in medical disorders, hypertensive disorders accounting for 8.6%.

Table 3: Showing Various Intraoperative Complications.

Intraoperative Complications	No: of Cases in Emergency CS	Percentage	No: of Cases In Elective CS	Percentage
PPH (Atonic)	6	10.34	4	7
Extension of uterine incision	2	3.44	-	-
INJURY(bowel, bladder, ureteric injury, broad ligament haematoma	1	1.72	-	

Around 9 patients had intra operative complications with incidence of 22.5%. The incidence of complications is more with emergency section(15.5%) than with elective section(7%). The most common complication is PPH with incidence of 17.34%. In 2 cases extension of uterine incision and was sutured. In 1 case broad ligament haematoma and it was resolved after a course of antibiotics.

Table 4: Post-Operative Complications

Postoperative Complications	Incidence	Percentage
Wound infections	6	10.34
Pyrexia	5	8.62
Sub involution of uterus	2	3.44
Secondary suturing	2	3.44
Urinary tract infections	2	3.44
Respiratory tract infections	1	1.72
Endometritis	1	1.72
Paralytic ileus	1	1.72

In present study, 20 patients had morbidity after caesarean with incidence of 24%.Wound infection with gaping was the most commonest with incidence of 10.34% followed by febrilemorbidity in 8.62% followed by sub involution of uterus, secondary Suturing, UTI, endometritis, paralytic ileus shows incidence of 1.72%.

Table 5: NICU ADMISSION RATES

NICU admission	No of cases in multigravida	Percentage in multigravida
Admitted	45	77.58
Not admitted	13	22.41

NICU admission rates are significant in multigravida accounting for 77.58% and in primigravida 17.8% with p value <0.0001.

Table 6: Perinatal Morbidity

	No of Cases	Percentage
Birth asphyxia	22	38
TTNB	5	8.62
Hypoglycaemia	3	5.17
Prematurity	6	10.34
Sepsis	4	6.89
RDS (HMD, Pneumonia, MAS, Pneumothorax)	4	6.89
Anomalies	1	1.72

45 babies had perinatal morbidity and requiring NICU admission. Birth asphyxia

Accounting for 22 cases and prematurity 6 cases are the leading cause.

Transient tachpnoea of newborn 5 cases, sepsis 4 cases, respiratory distress

Syndrome4 cases, hypoglycaemia 3 cases, anomalies 1 case.

Neonatal Mortality: In our study there were two still births accounting for 3.44% due to abruptio placenta and transverse lie with hand prolapse.

Intrapartum monitoring with CTG, availability of USG and NST have been also took part in reducing neonatal morbidity. Recent improvement of neonatal care,neonatal setup, preterm Care and availability of medications may be contributing factor for absent neonatal deaths.

Discussion

This research highlights the need for labor leadership through antenatal care and vigilance. Negligence in which operational measures are needed most of the moment for both mom and baby's healthy issues. Above all, there is a huge need for multigravida councils to report to the hospital as soon as feasible as many of them travel to the hospital during the active labor stage.

The most prevalent signs for caesarean segments were fetal distress (27.6%), misrepresentation (17.2%), CPD (15.6), APH (12%), medical illnesses (12%) and labor diseases (8.6%). Cases obtained immediately rather than referenced were higher in figures (48.84%) and also unbooked patients were higher (43%) than booked instances (38%) implying that even multigravida patients do not go to antenatal visits.

Due to excellent antepartum and intrapartum care, mortality rates in tertiary care hospitals are lower. Unrecognized cephalopelvic disproportion (in mentioned instances) resulting to obstructed labor is a contributing factor in growing maternal morbidity. A multigravida female in labor therefore needs the same attention as the primigravida female. Good intrapartum and antenatal care and premature referral can decrease multigravida mortality and parental and perinatal morbidity.

There is no Maternal Mortality in the Present Study.

Neonatal Mortality Following Caesarean Section in Different Series

- In our study number of still births which is accounting for 3.44% and it is correlating with all the other studies where there is more percentage of still born as in Rao Jyothi[7] H (2013) it is 7%, Sethi Pruthwiraj[6] (2014) it is 3% and in Sharmila[8] (2016) it is 1.5%.
- There were two still births in the present study due to abruptio placenta and transverse lie with hand prolapse.

Perinatal Mortality	Rao, Jyothi	Sethi Pruthwiraj	Sharmila	Present Study
STILL BIRTH	7%	3%	3(1.5%)	2(3.44%)
EARLY NEONATAL DEATH	-	-	-	-

Conclusion

In this manner, to close, the pace of essential cesarean area in primigravida is expanding as somewhere else and is higher than multigravida. So to decrease the pace of cesarean segment, first work of lady is to be very much overseen.

Most normal signs for cesarean area are fetal trouble and CPD. Electronic fetal observing, fetal scalp blood inspecting and intrapartum fetal heartbeat oximetry for fetal reconnaissance would diminish some superfluous activities. An all around applied arrangement on dynamic administration of work and careful utilization of partograph will lessen the occurrence of dystocia. Wellbeing mindfulness will build the antenatal visits and diminish the rate of inconveniences like APE.

Essential cesarean segments in multigravida comprise just a little level of all out conveyances however run a more serious hazard during pregnancy and work. This hazard can be adequately decreased by giving great antenatal consideration, compelling family arranging measures and wellbeing instruction to patient and intensive consideration and cautiousness in the administration of work. Likewise terrific multigravida is a condition to be averted. Further, measures ought to be taken to lessen youth unhealthiness and to energize instruction of the young lady kid. This will eventually improve the degree of use of wellbeing offices by ladies during their regenerative age and therefore would improve the obstetric result. There is requirement for solid and speedy systems administration with fringe medical clinics and empowering brief referral of high hazard and troublesome cases so obstetric crises arrive at a specific organization prior and an appropriate administration should be possible before the results turned out to be grave.

Summary: This study was conducted at Sree Balaji Medical College and Hospital, Chennai.

Over a period of 2 years i.e., from August 2016 to April 2018. There were 5161 deliveries during this period, which included 1853 deliveries by caesarean section. Among them 58 were primary caesarean sections in multigravida, an incidence of 1.12% of all deliveries.

The common indications for caesarean section in multigravida women are fetal distress(27.6%),M alpresentation(17.2%),CPD(15.6%), APH(12.1%), Hypertensive disorders and Labour disorders (8.6%).In Primigravida the common indications are CPD(36%), Labour disorders(18%), fetal distress(17%).

Primary PPH was commonest intraoperative complication (17.34%) followed by extension of uterine incision (3.44%) in multigravida women. In multigravida women Maternal morbidity was seen in 20 cases and Perinatal morbidity seen in 45 babies. Major causes for perinatal morbidityarebirthasphyxia 22 cases(38%), Prematurity 6 cases(10.34%).Perinatal Mortality seen in 2 cases with incidence of 3.44%.There were no maternal deaths in the present study.

To Evaluate the Anti Inflammatory Effect of Metformin on C Reactive Protein in Newly Diagnosed Type 2 Diabetes Mellitus Patients: A Open Label Prospective Study Conducted in a Tertiary Care Hospital for 6 Months Period

Manivel T.[1], R. Vedamanickam[2]

[1]Professor, [2]Associate Professor, Department of General medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Aim: To evalaute the pleiotropic effects of metfromin by measuring the Hs-CRP in newly diagnosed type 2 diabetes mellitus patients.

Materials and Method: A total of 70 patients were enrolled in the study, and out of that 50 patients who fulfilled the eligibility criteria were included in the study. And after randomization and obtaining the informed consent,50 patients were subjected to the trial drug-tablet Metformin 500mg twice daily for a period of 6 months and the patients were advised to follow at 3 and 6 months and hs-crp levels were measured at baseline and followup and patients were monitored for adverse drug events.

Results: hs-CRP baseline value expressed as Mean±SD was 3.4±1.16 mg/L . After 3 months of metformin therapy, hs-CRP reduced to 2.93±0.9 mg/L. After 6 months of metformin therapy, hs-CRP effectively reduced to 1.7±0.81 mg/L. hs-CRP levels were lowered after 6 months of treatment. Treatment with Metformin showed effective reduction in hs-CRP values comparatively between hs-CRP baseline values and hs-CRP values at sixth month were significant ($P<0.05$).

Conclusion: To conclude with the above findings shows that there was significant reduction in hs-CRP after six of therapy with metformin and hence proving its pleiotropic effects and hence apart from it's a antidiabetic agent it proves its beneficial cardioprotective role in patients with newly diagnosed type 2 diabetes mellitus patients.

Keywords: *Metformin, diabetes mellitus, anti diabetic, pleiotropic.*

Introduction

Diabetes mellitus (DM), speak to a huge worldwide wellbeing problem[1]. Type 2 DM (once in the past known as non-insulin subordinate DM) is the most widely recognized type of DM described by Insulin inadequacy, Insulin obstruction and expanded hepatic glucose creation (HGP) prompting glucotoxicity, beta cell fatigue lastly beta cell failure[2]. The objective of treatment for DM is to avoid mortality and complexities by normalizing blood glucose level. Recent proof proposes that poor glycemic control is altogether connected with the improvement of Microvascular Complications like diabetic nephropathy, neuropathy and retinopathy by means of a few systems, for example, the generation of cutting edge glycation final results (AGEs), the production of a proinflammatory microenvironment, and the acceptance of oxidative pressure and along these lines to macrovascular intricacies. [3]

Poor quality constant aggravation, reflected in raised degrees of serum C-responsive protein (CRP), has as of

Corresponding Author:
Manivel T.
Professor, Department of General medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

late been connected to corpulence, insulin obstruction disorders, for example, polycystic ovary disorder (PCOS), and an expanded danger of cardiovascular infection. Studies have shown that C-receptive protein (CRP) a marker of fundamental aggravation is rising as a significant autonomous hazard factor for cardiovascular complications[3,4].High CRP levels have been connected to an expanded danger of thrombotic occasions like myocardial infarction[4]. Raised CRP levels have likewise been connected to an expanded danger of later advancement of diabetes[5]. Moreover, CRP levels are higher in individuals with diabetes contrasted and non diabetics[6,7].Insulin resistance therapies can profit people by decreasing inflammation, atherogenesis, and thus problems of the macrovascular system.

To achieve glycemic control in diabetes, oral hypoglycemic agents (OHAs) stay a key factor. Studies indicate that OHAs in Type-2 DM patients decrease some amount of CRP. Given the above-mentioned connection between oral hypoglycemic agents and the amount of CRP, it is complicated[8].

Poor quality constant aggravation, reflected in raised degrees of serum C-responsive protein (CRP), has as of late been connected to corpulence, insulin obstruction disorders, for example, polycystic ovary disorder (PCOS), and an expanded danger of cardiovascular infection. Studies have shown that C-receptive protein (CRP) a marker of fundamental aggravation is rising as a significant autonomous hazard factor for cardiovascular complications[3,4]. High CRP levels have been connected to an expanded danger of thrombotic occasions like myocardial infarction[4]. Raised CRP levels have likewise been connected to an expanded danger of later advancement of diabetes[5]. Moreover, CRP levels are higher in individuals with diabetes contrasted and non diabetics

Materials and Method

Study Design: This is an Open Label, Prospective Study, of 6 months duration evaluating the effect of Metformin on C reactive protein in patients of newly diagnosed Type 2 Diabetes mellitus.

This study was conducted in Sree Balaji Medical College and Hospital, Chennai during the period from November 2017 to April 2018 in accordance with the declaration of the Helsinki and ICH GCP guidelines. The study protocol was reviewed and approved by the Committee on Institutional Ethics and all participants in the trial were informed of the study procedures and received written informed consent.

Withdrawal Criteria:

- Adverse event which warrants withdrawal of subject.
- Non-compliance with procedures.
- Withdrawal of consent for participation in the study by the subject.
- Failure of the study drug to produce the desired effect

Study Procedure: The study " Effect of Metformin On C-Reactive Protein in Type 2 Diabetes Mellitus Patients" Open Label, Prospective Study was started after obtaining approval from the Institutional Ethics Committee of Sree Balaji Medical College and Hospital. Voluntary written informed consent was taken from all the study participants after explaining the clinical study protocol in detail about the risk and benefit. They were given adequate time to decide for their participation. Confidentiality was maintained and patient's identity was not revealed in the source document. The informed consent was available in English as well as local language (Tamil).

All the 50 patients who fulfilled the Eligibility criteria was advised to take the study drug Tablet Metformin 500mg twice daily one in the morning and one in night. The study Drug was given free of cost to the patients and they were given assurance that any withdrawal from the study would not affect their future treatment in the same hospital.

Baseline laboratory investigations were done before study and repeated after 3 months and 6 months of treatment.The baseline features like demographic data, general, systemic and local examination were carefully noted in the case report form. Contact numbers of the investigators and emergency physician were provided to all the study participants for any queries during the study period and for reporting of any adverse events.There were three scheduled visits during the study-baseline visit, 3rd month and 6th month (end of the study visit).

Study Population: A total of 50 patients with newly diagnosed type 2 DM were included in the study. Both sexes were included in study . Study data was documented and patients were assessed periodically.

Drug Dosage: Tablet Metformin 500 mg twice daily, one in the morning and one in the night were advised to the study participants**.**

Adverse Event Reporting: All the adverse events observed/complained by the study participants were reported in the case report form along with the other information about the severity such as mild, moderate or severe and any relation to the study medication.

Laboratory Investigations: A baseline investigation protocol was followed before starting the study, the following investigations were performed at the beginning of the study:

Blood Biochemistry: High-sensitivity (hs) C-Reactive protein (CRP) level were done at baseline and repeated at 3 and 6 months of follow up.

Findings:

Primary endpoints: To evaluate the effect of metformin on C-reactive protein levels in patients with newly diagnosed type 2 diabetes mellitus.

Secondary endpoints: To evaluate the tolerability of metformin in type 2 diabetes mellitus.

Statistical analysis: All values are expressed as mean ± standard deviation. Comparison hs-CRP, values before and after the study was performed by paired t-test using SPSS software 16.0 version. Comparsion of blood parameters at baseline, 3month and 6month were found to be statistically significant. And also comparsion of blood parameters at 3 month and 6 month were found to be statistically significant ($p<0.05$ value).

Discussion

Effect of Metformin on hs-CRP: hs-CRP baseline value expressed as Mean±SD was 3.4±1.16 mg/L . After 3 months of metformin therapy, hs-CRP reduced to 2.93±0.9 mg/L. After 6 months of metformin therapy, hs-CRP effectively reduced to 1.7±0.81 mg/L. hs-CRP levels were lowered after 6 months of treatment. Treatment with Metformin showed effective reduction in hs-CRP values comparatively between hs-CRP baseline values and hs-CRP values at sixth month were significant ($P<0.05$).

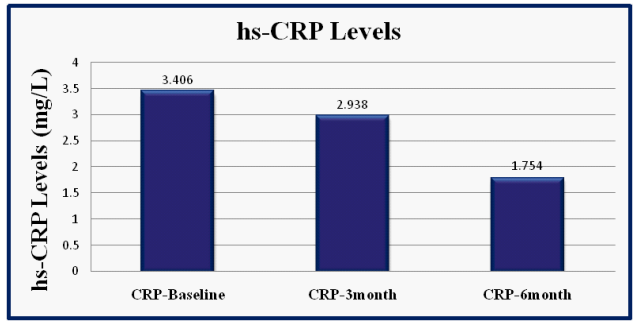

Figure 1: Comparison of hs-CRP levels between Baseline and at the end of the study

Table 1: Comparison of hs-CRP levels between Baseline and at the end of the study

S.No	Parameter	N	Metformin (n=50)	
			Baseline (1month)	End of the Study(6month)
	CRP	50	3.406 ± 1.16	1.754 ± 0.81 *

Values Expressed in Mean ± STD. Deviation, * Represents P < 0.05.

Conclusion

The results of the present study proves that metormin in newly diagnosed type 2 diabetes mellitus patients significantly improves CRP level (inflammatory marker) after six months of treatment. So this study emphasizes the intitaion of metformin as monotherpay in diabetic patients that apart from its effective gylcemic control it also reduces CRP level which prove its additional pleotropic effect (anti inflammatory effect), and hence thereby in diabetes patients by decreasing the long term macrovascular complications.

To Evalaute the Efficacy of Metformin Monotherapy in Newly Diagnosed Type 2 Diabetes Mellitus Patients by Assesing the HBA1C Percentage Reduction as a Single Diagnostic Tool for Glycemic Control and its Incidence in Preventing Macrovascular Complications: A Prospective Open Label Study for a Period of 6 Months Duration

Manivel T.[1], G. Jagan[1]

[1]*Professor, Department of General medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73*

Abstract

Aim: To evaluate the efficacy of metformin monotherapy in newly diagnosed type 2 mellitus patients by assessing the hba1c reduction percentage and thereby preventing the incidence of macrovascular complications.

Materials and Method: A total of 50 type 2 diabetes mellitus patients were included in the study.and after obtaining the informed consent the patients were advised to take Tablet metformin 500mg twice daily and hba1c were done at baseline, 3 and 6 months of the study period and the patients were assessed periodically and if any adverse events were reported it was recorded and manged promptly.

Results: HBA1C baseline value expressed as Mean±SD was 7.966±0.85 %. After 3 months of metformin therapy, HBA1C mean obtained was 7.53±0.83 %. After 6 months of metformin therapy, HBA1C improved to 6.8±0.93. Treatment with Metformin showed effective reduction in HBA1C values comparatively between HBA1C baseline values and HBA1C values at sixth month were statistically significant($P<0.05$).

Conclusion: From the above results the current study shows significant reduction in hba1c values after six months of metformin therapy and this proves that metformin is a sole antidiabetic agent started as monotherapy in newly diagnosed diabetic patients the incidence of macrovascular complications can be prevented at the intial stage of the disease.

Keywords: *Metformin, macrovascular, type 2 diabetes mellitus.*

Introduction

Diabetes mellitus is a complex endocrinology disease which requires a meticulous understanding of its pathogenesis and its complications to subdue it. It has been riddled with extensive micro and macrovascular complications which by itself has its own set of pathogenesis. There is a near connection between DM and cardiac illness (CVD), which in diabetic patients is the most common source of morbidity and mortality. In people with DM, cardiovascular (CV) risk variables such as obesity, hypertension, and dyslipidemia are prevalent, putting them at enhanced danger for heart incidents.

The goal of prescribing medication to decrease glucose among individuals with type 2 diabetes is to decrease hyperglycaemia signs and the possibility of

microvascular and macrovascular problems. A variety of therapies have been efficient since old times to alleviate the polydipsia and polyuria involved with increased concentrations of blood glucose. Twenty years earlier, trial proof lastly appeared that reducing blood glucose lowered the risk of microvascular problems among individuals with type 2 diabetes.

The glycated hemoglobin (HbA1c) and fructosamine is additionally still valuable for deciding glucose authority after some time. In July 2009, the International Expert Committee (IEC) suggested the extra analytic criteria of a HbA1c result ≥6.5% for DM. This board of trustees recommended that the utilization of the term pre-diabetes might be eliminated yet recognized the scope of HbA1c levels ≥6.0% and <6.5% to distinguish those at high danger of creating DM [1,2]. Similarly as with the glucose-based tests, there is no positive limit of HbA1c at which typicality finishes and DM begins[3, 4]. The IEC has chosen to suggest a cut-off point for DM analysis that underlines explicitness, remarking this reasonable the shame and cost of erroneously distinguishing people as diabetic against the insignificant clinical results of deferring the finding in a patient with a HbA1c level <6.5%.

Metformin, other than hypoglycemic movement, has been taken with eating routine and exercise changes to avoid diabetes in individuals who are at high hazard for getting to be diabetic. Metformin (a biguanide subsidiary), by controlling blood glucose level abatements these entanglements. Metformin works by reestablishing the body's reaction to insulin. It diminishes hepatic glucose creation (HGP) and intestinal glucose assimilation [5,6]

Recent proof indicates that bad glycemic regulation is substantially correlated with the growth of microvascular problems such as diabetic nephropathy, neuropathy and retinopathy through several processes such as the manufacturing of sophisticated glycation end goods (AGEs), the creation of a proinflammatory microenvironment, and oxidative stress induction and consequently macrovascular[7].

Materials and Method

To evalaute the efficacy of metformin monotherapy in newly diagnosed type 2 diabetes mellitus patients by assesing the hba1c percentage reduction as a single diagnostic tool for glycemic control and its incidence in preventing macrovascular complications-a prospective open label study for a period of 6 months duration.

This study was conducted in Sree Balaji Medical College and Hospital, Chennai during the period from November 2017 to April 2018 in accordance with declaration of Helsinki and ICH GCP guidelines. The study protocol was reviewed and approved by the Institutional Ethics Committee and all trial participants have been informed about the study procedures and written informed consent was obtained.

Inclusion Criteria:

a. Newly diagnosed Type-2 DM

b. Patients started on metformin monotherapy.

Exclusion Criteria:

a. Patients on insulin/other oral hypoglycemic agents

b. Any infective, inflammatory, allergic disorders, cardiovascular disorders, malignancy

c. Patients with trauma due to surgery, burns, fractures

d. History of alcohol and/or smoking

e. Pregnant/lactating women

Withdrawal Criteria:

- Adverse event which warrants withdrawal of subject.
- Non-compliance with procedures.
- Withdrawal of consent for participation in the study by the subject.
- Failure of the study drug to produce the desired effect.

Study Procedure: The study " Effect of Metformin On C-Reactive Protein in Type 2 Diabetes Mellitus Patients" Open Label, Prospective Study was started after obtaining approval from the Institutional Ethics Committee of Sree Balaji Medical College and Hospital. Voluntary written informed consent was taken from all the study participants after explaining the clinical study protocol in detail about the risk and benefit. They were given adequate time to decide for their participation. Confidentiality was maintained and patient's identity was not revealed in the source document. The informed consent was available in English as well as local language (Tamil).

All the 50 patients who fulfilled the Eligibility criteria was advised to take the study drug Tablet Metformin 500mg twice daily one in the morning and

one in night. The study Drug was given free of cost to the patients and they were given assurance that any withdrawal from the study would not affect their future treatment in the same hospital.

Baseline laboratory investigations were done before study and repeated after 3 months and 6 months of treatment. The baseline features like demographic data, general, systemic and local examination were carefully noted in the case report form. Contact numbers of the investigators and emergency physician were provided to all the study participants for any queries during the study period and for reporting of any adverse events. There were three scheduled visits during the study-baseline visit, 3rd month and 6th month (end of the study visit).

Study population: A total of 50 patients with newly diagnosed type 2 DM were included in the study. Both sexes were included in study . Study data was documented and patients were assessed periodically.

Drug dosage: Tablet Metformin 500 mg twice daily, one in the morning and one in the night were advised to the study participants.

Laboratory Investigations: A baseline investigation protocol was followed before starting the study, the following investigations were performed at the beginning of the study:

Blood Biochemistry: Hemoglobin A1c (hbA1c) were assed at baseline, 3 months and 6 months of study period

End points

Primary endpoints: To evaluate the efficacy of metformin montherapy in patients with newly diagnosed type 2 diabetes mellitusby assessing the hba1c percentage reduction as a single diagnostic tool

Secondary endpoints: To evaluate the tolerability of metformin in type 2 diabetes mellitus.

Findings:

Effect of Metformin on HBA1C: HBA1C baseline value expressed as Mean±SD was 7.966±0.85 %. After 3 months of metformin therapy, HBA1C mean obtained was 7.53±0.83 %. After 6 months of metformin therapy, HBA1C improved to 6.8±0.93. Treatment with Metformin showed effective reduction in HBA1C values comparatively between HBA1C baseline values and HBA1C values at sixth month were statistically significant (P<0.05).

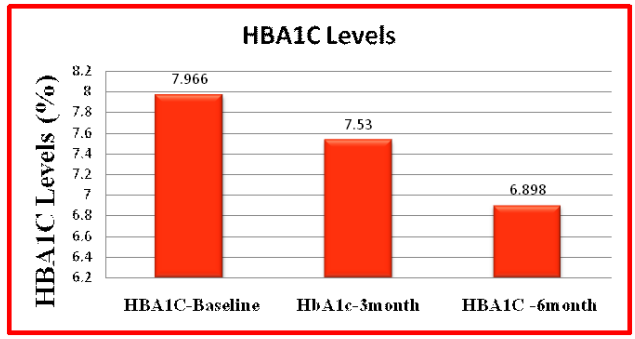

Figure 1: Comparison of HBA1C levels during study period

S.No	Parameter	N	Metformin (n=50)	
			Baseline (1month)	End of the Study(6month)
1	HBA1C	50	7.966 ± 0.85	6.898 ± 0.94 *

Values Expressed in Mean ± STD. Deviation, * Represents P<0.05.

Discussion

Metformin brings down glucose and, subsequently, lessens indications of hyperglycaemia. It has a decent security profile, even among patients with disabled renal capacity, is generally very much endured. While recognizing that metformin has pleiotropic impacts, in the event that it was demonstrated to be viable in numerous preliminaries, the close direct connection between HbA1c decrease rate and danger of cardiovascular ailment and demise, and the to some degree self-assertive analytic limit for diabetes, may likewise fortify the notoriety of metformin for treating diabetes.

Conclusion

Fresher operators that could possibly be utilized right off the bat throughout the infection are presently accessible, and are sponsored by information from later thorough cardiovascular endpoint preliminaries. Maybe regardless of, as opposed to in light of, the proof, metformin monotherapy is probably going to remain the primary line treatment for the hyperglycaemia related with sort 2 diabetes for a long time to come and subsequently our present examination infers that metformin monotherapy is profoundly helpful in averting the frequency of macrovascular intricacies by accomplishing the glycemic control by following the hba1c inside objective control.

Prevalence of ESBL Producing Escherichia Coli in Urine Samples in a Tertiary Care Hospital

V. Naveen Kumar[1], Chitralekhasai Kumar[2]

[1]Final Year Postgraduate,Deptarment of Microbiology, Sree Balaji Medical College and Hospital,
[2]Professor and Head Department of Microbiology, Sree Balaji Medical College and Hospital, Chennai

Abstract

The assessment was driven at Sree Balaji Medical College and Hospital, Chrompet, Chennai, Central Laboratory Department of Microbiology for a period of one year from August 2017 to August 2018. An entirety of 3580 pee tests were obtained in the Central Lab during the examination timespan and tests were read for the pace of Escherichia coli and its antimicrobial inadequacy structure. Of the 3580 urine samples obtained, the bulk of the samples were taken. from inpatient departments (2800) while 780 samples were from outpatient. 150 random Escherichia coli samples isolated from urine were tested further for ESBL and antibiotic sensitivity pattern.

Prevalence of ESBL production

In India, event of ESBLs has been recorded since the 1990s[1-8]. The Phenotypic substantiating test and the E test revealed that 56 detaches (37.3 percent) of 150 breaking points from E. coli were viewed as ESBL creators and 94 pulls back were non-ESBL producers (62.7 percent). A latest research in Chennai revealed that ESBL age among E. coli was 47% in tertiary thought workplaces[20]. Various nations, in assessment with India, have exhibited a lessened pace of ESBL creators. Studies have shown that the pace of E. coli-generation ESBL is 13.3 percent in Lebanon, 9.2 percent in Korea, 10.3 percent in Saudi Arabia and 17 percent in Turkey[21]. Notwithstanding, there is a steady rising in the measure of occupants in strain-generation ESBL in the social requesting of various nations [22-25]

The move in strains made by ESBL could be ascribed to the usage of cures with no past control or affectability tests, got together with misery and mass nonappearance of planning. This has achieved askew dosing, a nonattendance of completing of the proposed course and the utilization of additional cures [26]. An evaluation attempted in Mangalore by [27] exhibited a rehash of 70% ESBL among E. coli pulls back.

Affectability of USG Guided FNAC of Axillary LYMPH Nodes in Breast Cancer Patients with Clinically Node Negative Axilla

Shreya Rajkumar[1], P. Darwin[2], C.T. Karthikeyan[1]

[1]Post Graduate, [2]Associate Professor, Department of General Surgery, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

This is a prospective study undertaken at Sree Balaji Medical College and Hospital between August 2016 and August 2018 to evaluate the sensitivity of USG-guided axillary node FNAC in breast cancer females. 40 patients with biopsy have been shown to have breast cancer but clinically adverse axilla. Sensitivity and specificity were calculated by comparing the FNAC report to the postoperative histopathological report.

In this study US-FNAC showed the accuracy of 90.9% .USG of axilla in correlation with US-FNAC showed the sensitivity, specificity, PPV and NPV of 97.77%, 25%, 92.01%, and 50% respectively.

Keywords: *Lymph Nodes, Axilla.*

Introduction

Chest infirmity is the most overpowering explanation for dangerous improvement related going among females. As the size of essential chest sullying rises, explicit danger cells are discharged into the cell spaces and experienced the lymphatic structure. These perilous cells may then extension through the instance of the lymph center point and join to the depicting structures of the axilla, including the chest divider. Axillary lymph center point get-togethers are routinely progressively associated with from the most unassuming (level I) to the basic (level II) to the apical (level III) lymph center point parties[1-3]. Around 95 percent of all females who pass on from chest clever have remote metastatic malady and is commonly the most key sullying free acknowledgment factor and all around affirmation was the axillary lymph center status. The females with negative nodal ailment had less a 30% danger of rehash, separated and as high as a 75% threat for women with positive nodal sullying[4]. The status of the axillary lymph center metastasis, regardless of being the most principal prognostic gadget in this social event of patients, has a key spot in the relationship of this undermining progress.

Sree Balaji Medical college is located in Chrompet, one of the socioeconomically backward areas of Chennai, Tamil Nadu. Breast malignancies are considered a major problem in Western countries, and are the leading cancer in the female population. In India, this has been our major problem,as it has overtaken even cancer of the cervix. All breast malignancies with clinically negative axilla,seen during the period from August 2016 to August 2018, were taken up for study. The study was taken up to assess the sensitivity of ultrasound guided FNAC of axillary nodes in detecting metastasis, the presence or absence of which dramatically changes the prognosis of the patient.

Materials and Method

This study (prospective type) was performed in 40 female patients who had a clinically node-negative axilla tested breast cancer biopsy submitted to the OPD or IPD of our General Surgery Department during the period from August 2016 to August 2018. All these patients underwent surgery (altered radical mastectomy). The establishment's ethics driving get-together of trustees was comprehended and patients went into the evaluation show up after their informed consent structure had been

Corresponding Author:
Shreya Rajkumar
Post Graduate, Department of General Surgery, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Agharam Road, Selaiyur, Chennai-73

settled upon. The patients encountered a blue clinical evaluation and standard hematological appraisals. A proforma was made,and all the participants were asked to fill the proforma. Ultrasound guided FNAC was performed by the pathologists, and this report was compared to the post operative histopathological report[5,6].

Inclusion Criteria:

- All females above the age of 40 years diagnosed with breast carcinoma
- Any T stage of malignancy, with N 0 and M 0

Exclusion Criteria:

- Males
- Females below the age of 40 years
- Patients with palpable axillary nodes

Ultrasound Guided FNA procedure: In the Supine position, fine needle aspiration guided ultrasound was performed with a 22G needle which was attached to a 10 ml syringe. Smears were then prepared from the aspirated material and air-dried.

Cytology findings were reported to be satisfactory for assessment, categorized as: adverse for metastases; positive for metastases; or inadequate for definitive reporting. In the wake of looking check center centers, axilla evaluation was done close to medicinal viewpoint for the focal tumor. The nodes dissected from the axilla were then subjected to pathological and histological examination of the metastatic deposits. Following the correlation of sonological and pathological results, the precision of this operation was calculated.

Findings:

Number of true positive =35 (87.5%)

No of False Positive =3 (7.5%)

Number of true negative =1 (2.5%)

No of False Negative =1 (2.5%)

Statistics: In solid end, “affectability” is the most far away motivation driving the test to suitably watch those with the torment (real flawless rate), while “expressness” is the cutoff of the test to sensibly watch those without the dirtying (veritable negative rate).

Positive and negative sensible characteristics (PPV and NPV) are the degrees of positive and negative results in bits of data and unequivocal tests, which are real positive and veritable negative results, self-governingly[7]. PPV and NPV delineate the credibility of an obvious test or other genuine estimation.

Using statistical equations and the final diagnoses from histopathological examination, the following statistics were generated for the study:

Sensitivity of the study = 35/(35+1) x 100 = 97.77%

Specificity of the study = 1/(1+3)x100= 25%

Positive predictive value (PPV) of the study = 35/(35+3)x100=92.01%

Negative predictive value (NPV) of the study = 1/(1+1)x100=50%

Diagnostic accuracy of the study = (35+1)/(35+1+3+1)x100=90%

Discussion

The closeness structures of the lymphatic methodology of the mammary organ has been looked into for a few different years. The head wide delineation was given by Haagensen1. At the fulfillment of the eighteenth century, Cruikshank and Mascagni depicted two principal lymphatic courses: the nternal and inside plan. In 1830, Sappey found that all chest tissue had a centripetal discharge into the subareolar plexus2. Assessment of the twentieth century by then solidified extra ways. Camper was the first to delineate lymphatic spillage to lymph centers along the internal mammary vessels in 1770. Autoradiographic system with isotopes in twentieth century included helpful information. One outlined by Grossman and Rotter called the interpectoral center obsessions and the unmistakable center individual and paramedian centers wereseen by Cruikshank3. Gerota and Turner-Warwick passed on that the ipsilateralinternal mammary nodes receive more than 75% of lymph drainage from the breast[4].Mornard first described the occasional direct drainage from breast parenchyma tosupraclavicular nodes[5]. Retro-sternal lymphatic drainage to contra lateral internal mammary chain of lymph nodes occurs sporadically.

There are 5 sets of axillary nodes draining the breast:

1. Anterior group (Pectoral group): these are situated along the lateral thoracic vein under the anterior axillary fold mainly in the 3rd rib. From here the lymph drains primarily into the central group.

2. Posterior group (Subscapular group): these lie along the posterior axillary fold in relation to the subscapular vessels. Lymph drains from here mainly into central and supraclavicular nodes.
3. Lateral group (Axillary vein group): they lie along the upper part of humerous in relation to axillary vein.
4. Central group: These are situated in the fat of the upper part of the axilla. Lymph drains from here into the supraclavicular nodes. This nodal group is often palpable in metastatic disease.
5. Apical group (Subclavicular group): They are constant in position bounded below by 1st intercostal space, behind by the axillary vein and in front by the costocorocoid membrane.

These sets of lymph nodes and the area of breast from where they receive the lymph is of paramount importance, since it is now proved that the first lymph node to get involved in breast cancers are these nodes and this is known as sentinel node, it being the most important factor deciding the stage, likelihood of recurrence and response to treatment.

Sentinel Lymph Node Biopsy: Current research is directed towards the sentinel node. Forward and in turn around progress research is stimulated towards the sentinel center. A cognizance get-together at work of sentinel center point biopsy in chest carcinoma was held in 2001 at Philadelphia, Pennsylvania from April nineteenth to 22nd. Current isotope structures using radiopharmaceutical, technetium sulfur colloid or then again egg whites and isosulfane blue stowing endlessly or patent blue veiling, are prompt being reliably used to see the sentinel centers. These can be managed by systems for various courses checking peritumoral, intratumoral and subcutaneous, intradermal and subareolar implantations. Most clear experience has been with peritumoral mix to discover

Lymphatics: Axillary center spotlights are in like manner dispensed subject to their relationship with level and customary edges of pectoralis minor muscle. There are three remarkable levels:

Level I: Nodes parallel to level edge of pectoralis minor

Level II: Nodes among ordinary and parallel edges of pectoralis minor, checking interpectoral centers.

Level III: Nodes customary to average edge of pectoralis minor, including apical moreover, supraclavicular centers.

Lymphatics of overlying skin: Lymphatics of overlying skin: They go an expansive course and in checking centers. Those from outside side go to the axillary center obsessions and those structure upper part channel into the supraclavicular center focus interests. Auchincloss changed radical mastectomy is the helpful method all things considered got all through the world. This has begun to be emptied by Breast Conservation Therapy (BCT) containing wide neighborhood extraction of tumors (segmental mastectomy), axillary lymph center dismantling, trailed by post usable radiation to the remainder of the tissue in the included chest. The National Attentive Adjuvant Breast Project (NSABP) B 06 starter began in 1976 found no separate in the consistency results between patients who experienced BCT and MRM6. Less observable systems to the affiliation and organizing of axilla are in like manner grabbing more thought.

The ability of ultrasonogram to detect more suspicious lymph nodes increased with increasing tumour size. In conclusion, only those patients who showed benign or indeterminate features of lymph nodes on ultrasound and had negative US-FNAC of suspicious lymph node will require SLNB as the staging procedure.

Rest of the patients who show definite features of lymph node involvement on ultrasound and positive US-FNAC may undergo ALND directly as a part of primary breast surgery, thus saving time and expense and also avoiding the morbidities associated with SLNB[7].

Ultrasound guided axillary center point throbbing has a high pace of trademark exactness and could change into an obliging mechanical social gathering for the evaluation of axillary metastasis in early chest torment in low resource settings. Unequivocally when center centers are not seen using all frameworks, by then the chances of metastasis are irrelevant. Higher getting together with the structure may help ruin the pace of dissatisfaction. Openness of Intra-employable ultrasound for assessment of lymph centers may show to be a valuable gadget for testing of suspicious center focus interests.

Conclusion

Convincingly, using axillary ultrasound and express US-FNAC is a splendid, non-terrible structure for planning the axilla in beginning late inquired about chest ghastly improvement patients and may particularly change into a standard bit of patient thought as it can spare various patients a purposeless procedure, particularly the people who are encountering axillary evaluational.

Assessment of the Complication and Radiological Outcome of Proximal Femoral Nailing in Unstable Trochanteric Fractures

Mohammed Irshad Basha[1], A. Venkatachalam K.[2]

[1]Post Graduate, [2]Professor, Department of Orthopaedics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

The demographics of world population are changing. More of the elderly people are living in the developing countries. Presently about three-fifths of the hip fracture occur in Asia which, it is predicted that will become almost one-half by the year 2050. Inter-trochanteric fractures are one of the most common fractures of the hip occurring both in the young adults, as a result of high energy trauma and in the elderly, as a result of low energy trauma due to osteoporosis. Problems with these fractures are: (a) they are associated with significant morbidity and mortality; (b) malunion is prevalent; (c) implant failure such as head cuts and hip penetration is a complication; (d) they are a major economic burden on the family; and (e) they are most frequently linked with medical comorbidities such as diabetes and hypertension. The objective of this research is to evaluate the complications and radiological outcome of proximal femoral nailing in patients who have sustained an unstable trochanteric fracture.

Keywords: *Proximal, Femoral, Nailing, Orthopaedics, Fractures, Trochanteric failure.*

Introduction

Both male and female patients aged 46 to 65 years with an unstable trochanteric fracture (AO-OTA 2.2, 2.3, 3.1, 3.2 and 3.3) were included in the studies. Patients with displaced trochanteric fractures, open and pathological fractures, have been excluded. Patients have been tracked for a minimum period of 7 months (mean 12.6; range 7 to 19 months). Cases were investigated on the basis of injury mechanism, classification and treatment with Proximal femoral nail and assessed using Harris Hip Score for their functional outcomes. In our study which included 42 patients, intra-operatively, we experienced difficulty in achieving anatomical reduction of the fracture (n=1) in 2.38%, difficulty in passing de-rotation screw (n=2) in 4.76%, distraction at the fracture site occurred during nail insertion (n=2) in 4.76%, breakage of the guide wire (n=1) in 2.38% and a varus angulation (n=2) in 4.76%. Post-operative complications included superficial infection (n=1) in 2.38%, deep infection (n=1) in 2.38%, limb shortening (n=2) in 4.76%. Complete radiological union was observed in 90.4%. Lateral slide of the proximal screws occurred (n=1) in 2.38% and varuscollapse (n=1) in 2.38%, 'Z' effect was seen (n=1) in 2.38% and failure of the implant (n=1) in 2.38% .[1-4]

It is essential to differentiate between unstable and stable versions of these fractures in the treatment of trochanteric fractures. With cortical instability on one side of the fracture due to cortical overlap or destruction, the fracture would tend to collapse in the direction of instability. Thus, by definition, a truly stable inter-trochanteric fracture is one that, when lowered, has a cortical contact without a gap in the back and in the middle.

The proximal femoral nail (PFN) launched by the AO/ASIF group in 1998 has become common in the treatment of trochanteric fractures in latest years [7,8.]

Materials and Method

The present study has been a prospective study, involving patients who had sustained unstable inter-trochanteric fractures. The study began in March 2017

Corresponding Author:
Mohammed Irshad Basha A.
Post Graduate, Department of Radiodiagnosis, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

and went on till February 2018 (a total recruitment period of 12 months). The study concluded in September 2018, so that there was a minimum follow-up of 7 months (mean 12.6; range 7 to 19 months).[9-12]

Inclusion Criteria:

- Only unstable trochanteric fractures were included (AO-OTA 2.2, 2.3, 3.1, 3.2 and 3.3).
- Only fractures seen within 15 days of injury were included.
- Both male and female patients, in the age group of 46 to 65 years were included in the study.

Exclusion Criteria:

- Patients with displaced trochanteric fracture not conforming to the above parameters were excluded.
- Open and pathological fractures were excluded.
- Inability to walk independently, prior to fracture due to pre-existing stroke or CVA were excluded.

Follow Up Period: Minimum period of 7 months (mean 12.6; range 7 to 19 months).Cases were investigated on the basis of injury mechanism, classification and treatment with Proximal femoral nail along with complications and radiological outcome.[13-16]

Pre-Operative Protocol: All the routine investigations were done as follows,

- CBC.
- Blood sugar and urine routine with sugar and acetone check.
- Serum urea, creatinine.
- Bleeding time and clotting time.
- Serum electrolytes.
- Blood grouping and Rh typing.
- HIV ELISA and HbsAg.
- Chest X-ray PA view and ECG in all leads in deep inspiration.
- Echo-cardiogram and cardiologist opinion in warranted cases was sought.

Surgical Technique:

Positioning: The patient is positioned supine on the traction table. The ipsi-lateral arm was placed in an arm sling. The trunk was angled 15 degrees towards the unaffected side. The unaffected limb was flexed, abducted and externally rotated for providing enough space for positioning of the image intensifier. The affected lower limb was held in traction and adduction in the foot piece. Reduction was achieved by traction (disengaging the fracture fragments) and internally rotating the limb while maintaining traction and confirming with the image-intensifier view.[17-19]

Approach: A 3 cm incision is made proximal to the tip of greater trochanter slightly bent dorsally. Skin with subcutaneous tissue and deep fascia are incised. Gluteus maximus was split by blunt dissection. The tip of trochanter is then felt with finger

Entry Point: Reduction of the fracture was essential before making the entry point. After confirming the anatomical reduction, entry point is made with a bone awl over the tip of greater trochanter. If the reduction is not anatomical, we manipulated the fragments by percutaneously passing the Steinmann pin in the proximal fragment and temporarily holding the reduction with 'k' wires driven along the anterior cortex such a way that it shall not interfere with the path of nail. After confirming the position in AP and lateral views, the awl was driven just proximal to the level of lesser trochanter.[20-23]

Guide Wire Insertion and Reaming: A 3.2mm guide wire was inserted and driven into the distal fragment. Proximal reaming was done with a 15 mm cannulated awl upto 7 cm distally in order to accommodate the proximal portion of the nail. Distal reaming was done with an increment of 1 mm more than the predicted diameter of the nail planned to be used.[24-26]

Post-Operative Protocol:

- Parenteral third generation cephalosporin and aminoglycosides were given for 72 hours. Oral antibiotics started from POD 4 (Linezolid with Dalacin C) and continued till suture removal.
- Parenteral NSAIDS given for the first two days and changed to oral there-after.
- Drain was removed on POD 2.
- Static and dynamic quadriceps exercises from POD 2 were initiated.

Follow-Up:

- Patients were evaluated clinically and radiologically bi-weekly for the first 2 months and then, once monthly there-after until signs of radiological and clinical union appear.

- Clinical union was assessed as being absence of pain and tenderness upon full weight-bearing.[27-28]

Clinical Assessment Included the Folowing Parameters: 1. Gait, 2. Pain, 3. Deformity, 4. Shortening, 5. Range of movements,6. Ability to sit cross-legged, 7. Ability to squat, 8. Be able to return to pre-injury occupational status.

Radiological Assessment Included: 1. Signs of union, 2. Varus collapse, 3. Amount of lateral slide, 4. Screw cut-out, 5. 'Z' effect, 6. Implant failure and loss of fixation.

Table 1: Sex Distribution

Sex	No. of Patients 'n'	% age
Male	16	38.10

Table 3: Intra-Operating Time: (Incision to Closure)

Operating Time (in min)	No. of Patients 'n'	% age
< 45	16	33.33
45–60	7	16.66
61–75	9	21.42
76–90	10	23.80
Total	42	100

Table 4: Intra-Operative Complications

Nature of complication	No. of Patients 'n'	% age
Fracture displacement upon nail insertion	2	4.76
Failure to get anatomical reduction	1	2.38
Difficulty to engage a de-rotation screw	2	4.76
Breakage of guide wire	1	2.38
Breakage of drill bit	0	0.00
Varus angulation	2	4.76
Total	**8**	**19.04**

Table 5: Post-Operative Complications & Radiological Outcome

S. No.	Nature of complication	No of Patients 'n'	% age
1.	Shortening	2	4.76
2.	Superficial infection	1	2.38
3.	Deep infection	1	2.38
4.	Varus collapse	1	2.38
5.	Lateral slide of proximal screws	1	2.38
6.	Non-union	0	0.00
7.	'Z' effect	1	2.38
8.	Implant failure	1	2.38
9.	Mortality	0	0.00
	Total	8	19.04

As per our inclusion criteria, 42 patients were recruited for surgical fixation of unstable trochanteric fractures. Of these 42 patients, approximately 28% of the patients were of the age group of 46 to 50 years, 26% of the patients were between 51 to 55 years, 26% were between 56 to 60 years and 19% were between the age of 61 to 65 years. We had a total of 38.10% (n=16) male and 61.90% (n=26)female patients, with a male to female ratio of 2 : 3.2, thus indicating a female preponderance.[23-25]

Among the 42 cases treated surgically, 49.99 % were of A2 type and 50.01 % were of the A3 type. Thus in our series, the fracture pattern distribution was found to be equal. The average operating time was 58 minutes (range 45 to 90 minutes).Intraoperatively, we experienced difficulty in achieving anatomical reduction of the fracture in one patient, difficulty in passing de-rotation screw in two patients, distraction at the fracture site occurred during nail insertion in two patients, breakage of the guide wire in one patient and a varus angulation in two patients.

Discussion

Successful treatment of inter-trochanteric fractures relies on many factors10; the age of the patient, the overall health of the patient, the time elapsed from trauma to therapy, the concomitant medical procedure and the stability of fixation11. The suitable technique and perfect implant used for these fractures are still being discussed with the advocates of the different method, each claiming their benefits over the others. Many inner fixing systems, including extra-medullar and intra-medullar implants, have been suggested for the therapy of these fractures.[33]

The dynamic hip screw stayed the preferred implant for more than four centuries due to its favourable outcomes and a comparatively small rate of non-union and failure. It ensures controlled compression at the fracture site. The use of DHS was backed by their biomechanical characteristics, which were assumed to enhance the healing of fractures12. However, DHS needs comparatively higher exposure, more tissue handling and near anatomical decrease, all of which increase morbidity, the likelihood of infection and a substantial loss of blood. The chance of a varus collapsing and the failure of the implant to survive until the fracture union was its primary drawbacks.[26-29]

The side-plate and the screws mechanically weaken the bone. The prevalent causes of this fixing failure were unstable trochanteric fractures, osteoporosis, absence of anatomical decrease, failure of the fixing device and inaccurate positioning of the lag screw in the femoral head [13,14].

Conclusion

With the demographics of the world population changing, more and more elderly persons are sustaining osteoporotic fractures. Among them, displaced and unstable trochanteric fractures are in significant numbers. The development of implant designs to address these unstable fractures of the proximal femur, have got refined. This has significantly improved the surgical outcomes in managing these problematic fractures. The proximal femoral nail, which was the implant used in this study, has established its distinct superiority in the instances of surgically managing displaced and unstable trochanteric fractures. Its unique advantages are that it is amenable to closed reduction which preserves the fracture hematoma. There's less of a surgical insult. It allows early rehabilitation and early return to pre-injury activity status. We hereby conclude that PFN osteosynthesis used in unstable trochanteric fractures provides outstanding stability, fewer mechanical problems and satisfactory functional outcomes. It is therefore an optimal implant for the surgical management of unstable inter-trochanteric fractures.[30-32]

Recent Trend in Rise of Caesarean Section in Multigravida and Primigravida

M. Prasanthi[1], T.G. Revathy[1]

[1]Post Graduate Student, [2]Professor Department of Obstetrics & Gynaecology, Bharath Institute of Higher Education and Research, Shree Balaji Medical College and Hospital, Chrompet, Chennai

Abstract

There is a trend towards an rise in the rate of the Caesarian section globally. With enhanced safety following the advent of contemporary anaesthesia, blood transfusion equipment and greater antibiotics, the signs for the cesarean section are liberalized to include dystocia, placenta previa, fetal distress, BOH, and others.

Keywords: *Multigravida, Primigravida.*

Introduction

Caesarian section is regarded a safer alternative to extended and hard vaginal surgery to decrease maternal and perinatal morbidity and mortality[1-8]. With the advent of contemporary technology in the workplace, such as cardiotopography, color doppler, biophysical profile, the rate of cesarean section has increased further with countless other medical societies.

Other accountable considerations for the increase in the frequency of cesarean section in the multipara are the identification of high-risk pregnancies with enhanced antennatal care and antipartum fetal surveillance method[9-13], enhanced rates of elective induction of labor, decreased operative vaginal delivery and vaginal delivery, enhanced number of pregnant females after 30 years with related medical com.[6]

Materials and Method

In this study 58 cases of primary caesarean inmultigravida done over a period of two Years i.e. from August 2016 to April 2018 at the obstetric department of Sree Balaji Medical College and Hospital, Chennai-44 were taken.

Inclusion Criteria:

1. Multigravida with pregnancy of >28 weeks gestation (gravida 2 and above), with previous one or more vaginal deliveries.
2. Multiple pregnancy
3. Pregnancy with medical disorders.
4. Previous instrumental, assisted breech deliveries, still births and IUD.

Exclusion Criteria:

1. Previous one or more caesarean.
2. Previous h/o hysterotomy

Observation and Results:

Table 1: Incidence of Caesarean Section

	No of Cases	Percentage
Total Number of Primary C.S in Multigravida	58	3.10
Total Number of C.S. in Primi	995	53.56
Total No of Repeat C.S.	805	43.34

During this era, 5,161 shipments were made to approximately 1,857 Caesarean segments, representing 36% of all deliveries. The incidence of main caesarean in parous females is 1.12 per cent of all deliveries and 3.10 of all segments.

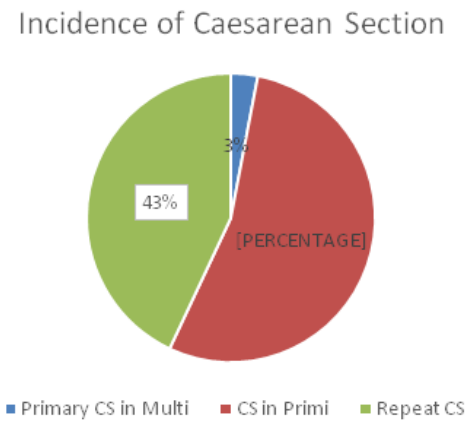

Figure 1: Incidence of caesarean section

Table: 2 Distribution of Cases According to Age in Multigravida and Primigravida

Age Interval	No of Cases in Multigravida	Percentage	No of Cases in Primipara	Percentage
<20 Yrs	5	8.2	139	13.97
21-25 Yrs	15	25.87	348	34.98
26-30 Yrs	21	36.21	294	29.55
31-35 Yrs	12	20.68	179	17.98
36-40 Yrs	5	8.62	35	3.52

Findings: Maximum number of women undergoing primary caesarean section in multigravida were in the group of 26-30 yrs with incidence of 36.21% and lowest were in the group of <20 yrs and 36 to 40 yrs and in primigravida it is 21 to 25 yrs age group with incidence of 34.98%.

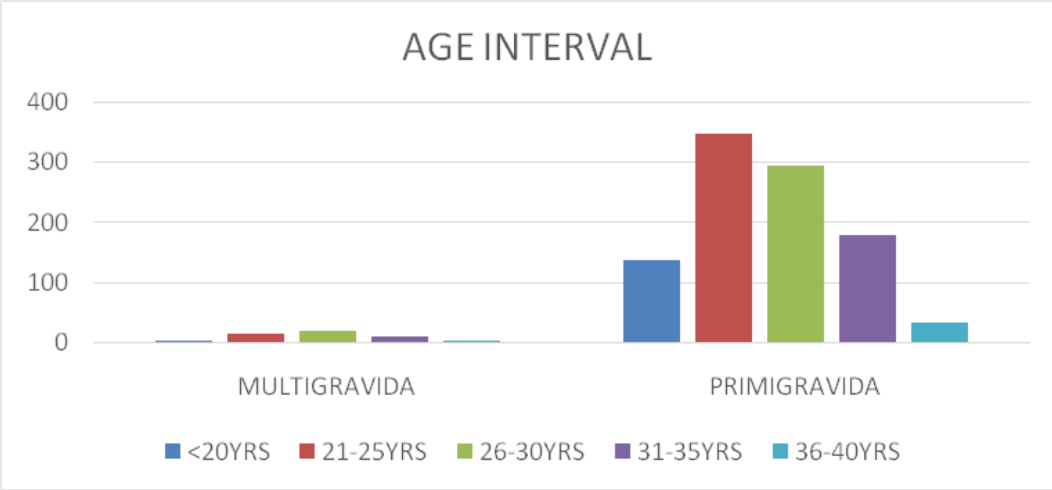

Figure 2: Distribution of cases according to age in multigravida and primigravida

Table 3: Gravida And Frequency of Caesarean Section

Gravida	No of Cases	Percentage
I.	24	41.3
II.	20	34.2
III.	9	16.5
IV.	3	5
V.	2	3

In this study majority of patients belonged to gravida-2 with incidence of 34.2%. There were 2 grand multigravida in the present study, incidence is 3%.

TABLE 4: Indications of Caesarean Section In Multigravida And Primigravida

SL.NO	Indication	No of Cases In Multigravida	Percentage	No of Cases In Primi	Percentage	P Valve (One Side Test)
1	Fetal Indications					
	a. Fetal distress	16	27.6	170	17	<0.05
	b. Malpresentation	10	17.2	92	9.2	<0.05
	c. Cord prolapse	-	-	-	-	
	d. Macrosomia	-	-	40	4	
2	Obstetric Indications					
	a. Antepartum haemorrage	7	12.1	79	8	>0.05
	i. Placenta previa	4	7	19	2	<0.05
	ii. Abruptio placenta	3	5.1	60	6	>0.05
	b. CPD	9	15.6	358	36	>0.05
	c. Labour disorders	5	8.6	178	18	>0.05
3	Maternal Indications					
	a. Medical Disorders	7	12.1	55	5.5	<0.05
	i. Hypertensive disorders	5	8.6	35	3.5	<0.05
	ii. Heart disease	1	1.7	6	0.6	>0.05
	iii. renal causes	-	-	-	-	
	iv. Infections to the mother (HIV, HPV, HSV.	1	1.7	14	1.4	>0.05
	b. Maternal request	-	-	12	1.2	
	c. Previous VVF repair/iv degree perineal laceration	-	-	-	-	
	d. Neoplasm	2	3.4	8	0.8	<0.05
	e. Previous uterine surgery	2	3.4	3	0.3	<0.001

On comparing the indications of caesarean section in multi and primigravida table), the most common was fetal distress accounting for 27.6% cases in multi, 17% in primi (p value <0.05) and second common was malpresentation with 17.2% in multi and 9.2% in primi (p value<0.05). CPD in patients in 15.6% multi and 36% in primi(p value>0.05). Antepartum haemorrage accounting for 12.1% in multi and 8% in primi (p value>0.05) although not significant. Placenta previa was 7% in multi and 2% in primi with significant p value <0.05. labour disorders accounting for 8.6% in multi with no significant difference between multi and primi. In multi medical disorders are common than primi leading to hypertensive disorders as a significant indication for primary caesarean section 8.6% in multi and 3.5% in primi.

Discussion

The changing trends in caesarean deliveries There has been a steady increase in the rates of CS in both developed and developing countries. The reasons for the increased caesarean are multifaceted.Commonly cited causes are Increased institutional deliveries • Avoiding difficult manipulative or instrumental vaginal deliveries. • Foetal distress detected especially with the use continuous electronic foetal monitoring • Liberal use of caesarean in high risk cases like Breech presentation, previous caesarean delivery, growth retarded foetus, multiple pregnancy, preterm baby. • Improved safety of C-section with better surgical techniques, anaesthesia, better availability of blood and its products, advanced antibiotics. • Fear of the patient for labour pain. • Busy schedule of the obstetrician specially those working in private sector and also an apprehension of the obstetrician

regarding the fear of poor neonatal outcome. • Increased incidence of IVF and other high risk pregnancies.

Table 5: Incidence of Total Caesarean Section

Authour	Totalcaesarean Section Percentage
Present study	36
Shanti sri (2013)	38.5
Sherinsams(2014)	33.5
Sharmila (2015)	29.3
Himabindu (2015)	40.55

The incidence of total caesarean section is 36% and it is proportional compared to the rise in other studies.

Table 6: Incidence of Primary Caesarean in Multigravida

Author	Percentage (%)	P Value
Present study (n=58)	1.12	
Rao,Jyothi (n=200)	10.28	0.0253
Sherinsams(n=211)	2.59	0.5059
J.K.Saluja (n=50)	3.82	0.4268
P.Himabindu (n=186)	2.80	0.3577
Sharmila (n=196)	3.00	0.4655
G.Parthasarathy (n=436)	1.73	0.7325

Incidence of total caesarean section in this present study is 1.12 among all deliveries. The incidence is correlating with other studies except Rao, Jyothi the incidence is higher 10.28 and is significant.

More over increase in incidence of primary caesarean in primigravida in the recent years can be attributed to greater incidence of repeat caesarean. In a uterus with previous scar there is always a risk to the mother and fetus and also risk of uterine scar rupture, which will increase maternal and fetal morbidity.

Conclusion

The greatest emphasis on fetal welfare in today's tiny family norm has altered shipping method in favor of the C-Section. There is no empirical evidence of an optimum proportion. What is most important is that all females in need of caesarean sections receive them (WHO Statement 2010). A safe decrease in the frequency of main caesarean deliveries will involve distinct method for each indication. Customization of the indication and thorough assessment, following standardized rules, the practice of evidence-based obstetrics and audits at the organization, can assist us reduce CSR.

Suicidal Behavior in Adolescents: A Tertiary Hospital Based Study

Heigrujam Jina[1], Lakshmi Prabha[2], Nambi S.[3]

[1]Post Graduate, Department of Psychiatry, [2]Assistant Professor, [3]Professor and HOD, Department of Radiodiagnosis, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

In adolescent it is the second most common mode of death after accident. Suicide is now the second most cause of death in young adults ranging 15-35 year world over. There has been a dramatic rise in suicide in last 40 years. Every 2 hours a youth commit suicide. (1)However, in spite of the dramatic rise, suicide is still unrecognized & under reported due to stigma attached to it. There has been a dramatic rise in adolescent suicide & it not only affects individuals but also has devastating effect on family friends & community as a whole. Suicide attempts occur 30-100 times more frequently than completed suicide.

Keywords: *Suicide, adolescents, Dramatic rise.*

Introduction

Suicidal behavior in adolescent is dissimilar to that of adult population. Girls attempt three times more than boys.

Causes of adolescent can be :

Biological

Psychosocial

Emotional

Intellectual

Substance abuse.

Biology: In biological causes depression, physical illness and psychological changes due to puberty.

Psychosocial: Psychosocial changes includes-Isolation, Withdrawn behavior, Lack of social skills,Lack of social integration, Peer problems, Unpopularity.

Corresponding Author:
Heigrujam Jina
Post Graduate, Department of Radiodiagnosis, Sree Balaji Medicalcollege, Bharath Institute of Higher Education and Research, Chennai-73

Emotional: Emotional causes includes-Sadness of mood, Lack of self esteem, Feeling helplessness/ hopelessness/worthlessness. Impulsivity, Anger, Identity crisis, Loneliness, Anxiety.

Intellectual Causes: Intellectual causes are those who are shy, who has pressure to achieve, self criticism, inability to communicate feelings and those who see a lot of fault in themselves and in others.

Substance Abuse: The most important cause to contribute to impulsivity in adolescent is substance use. Adolescent tend to use substance of abuse when they are neglected, when there is a loss and when the family is not supportive [(2).]

One has to look out for the danger in adolescent suicide. It includes-

Depression, Abuse of substance, Negativity, Giving away positions, Estrangement[(3,4)], Rebellious nature.

Four personality characteristics among adolescent suiciders:

- Irritable and over sensitive to criticism.
- Impulsive and volatile,
- Withdrawn and Uncommunicative and perfectionist and
- Self-critical

Aims: To find out the suicidal behavior in adolescent

Methodology:

- The study was conducted at the outpatient department of Psychiatry at Sree Balaji Medical College and Hospital, Chennai-44.
- Includes 30 adolescent (13-18 years)
- Patient who comes to SBMCH psychiatry opd
- Scales used-GHQ, HAM-D, Beck's suicidal intent scale.

Findings: Out of the 30 adolescents, 1 had history of deliberate self harm in the past. The frequency of deliberate self harm in present is more. 11 out of 30 patients who reports to psychiatry opd.

Deliberate self harm past:

1 (3.3%)

Deliberate self harm present:

11 (36.7%)

Prevalence of depression:

Mild depression	16 (53.3%)
Moderate depression	13 (43.3%)
Severe depression	1 (3.3%)

General health Questionnaire:

15 (50%)	Normal
14 (46.7%)	Evidence of distress
1 (3.3%)	Severe Psychological distress

Conclusion

Deliberate self harm in adolescents as per the study suggest more of an impulsive act rather than a well planned out activity. Mild depression is noted in 53.3% of the study population. With the GHQ of majority normal followed by evidence of distress accounting for 50% and 46.7% respectively.

Breast Carcinoma: A Review

Shreya Rajkumar P.[1], Darwin C.T.[1], Karthikeyan[2]

[1]Post Graduate, [2]Associate Professor, Department of General Surgery, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Breast malignancy has fast overtaken ovarian malignancy as the leading cause of death in women. A number of factors attribute to the rise in breast cancer,including obesity, food habits and carcinogen exposure.

This article is a review of breast malignancy, and its pathological nature,and highlights the significance of axillary staging as a prognostic factor,and hence the importance of axillary investigation.

Keywords: *Malignancy, prognostic.*

Introduction

Breast cancer is the most common cause of cancer-related deaths among women. As size of primary breast cancer increases, a number of cancer cells are shed into the cellular spaces and these are transported through the lymphatic network. These malignant cells may then proliferate through the lymph node capsule and fix to contiguous structures in the axilla, including the chest wall. Around 95% of all women who die of breast malignancy[1] have distant metastatic disease and traditionally the most important prognostic coefficient of disease-free and overall survival was the axillary lymph node status.

History: Female breast carcinoma was the first tumor reported as far back in historyas the time of the Egyptian civilization. In ancient Greece, Hippocrates, who was one of the fathers of modern medicine[2], advocated surgery as the only treatment option in these patients.

During the time of Celsus, the prototype of radical mastectomy was performed. The metastatic nature of the disease was recognized by LeDran (1685-1790),[3] who advocated the removal of primary and axillary lymph nodes in continuity. Breast cancer is a major issue of all women, regardless of race,socioeconomic status or country of origin. It is one of the top ten killers of adult population in our country. However, this incidence is not the same in all populations. Thus in 1982, the incidence in Madras was 15.8% while at Manipurwas only 7.2%. The same is true in western countries as well. It is not only the occurrence that varies,but also the prognosis. For example though the incidence ofbreast cancer in African-American women is lower than in Caucasian women[4] is, they have a higher mortality from breast cancer, and are less likely to survive 5 years after diagnosis.

A number of factors are attributed to this-like the younger age atdiagnosis, later stage of detection, different incidence of negative tumor receptors and lesser degree of response to treatment in African-American women. The endogenous hormones play a complex role in this respect as well. Surgery has been the main treatment modality for the last 75 years. All patientsare subjected to surgery unless they are unfit due to other reasons. The detailed description of radical mastectomy by Halstead of Baltimore was given in 1894[5]. Varioussurgical procedures have evolved during the ensuing years. Modifications and improvisations have been made by extensive research on various method. Now Auchincloss's Modified Radical Mastectomy and Breast Conservation Surgery have become the mainstay of modern surgical treatment[6]. Hence greatest importance is to be given towards its prevention and early detection.

Role of Axillary Metastasis and Required Investigations:

Findings: Breast cancer is the most common cause of cancer-related deaths among women. As size of primary breast cancer increases, a number of cancer cells are shed into the cellular spaces and these are transported through the lymphatic network. These malignant cells may then proliferate through the lymph node capsule and fix to contiguous structures in the axilla, including the chest wall. Usually, the axillary lymph node groups are involved sequentially from the lowest (the level I) to the central (the level II) to the apical (the level III)groups of the lymph nodes.

Around 95% of all women who die of breast malignancy have distant metastatic disease and traditionally the most important prognostic coefficient of disease-free and overall survival was the axillary lymph node status. The females with negative nodal disease had less than a 30% risk of recurrence, compared with as high as a 75% risk for women with positive nodal disease[7]. The status of the axillary lymph node metastasis, in addition to being the most important prognostic tool in this group of patients, has a critical place in the management of this cancer. For many many years,the axillary lymph node dissection (ALND) was amethod of choice for the axillary nodal evaluation to stage and treat effectively the metastatic lymph node involvement. However, for the cases that had no node involvement, axillary dissection gave no advantages and it was also sometimes associated with certain significant complications such as lymphoedema, infection of wound, stiffening, weakness of shoulder, numbness and pain of the affected arm. Later, the method of biopsy of sentinel lymph node (SLNB) was developed.

This method has proven to be a valuable tool in determining whether the malignancy has spread from its site of origin and for the staging of the axilla. It has been proven to be a very effective alternative to ALND[9]. Those patients whose SLNB is disease-free require no more treatment and are thus spared from unnecessary surgery for the axilla.

Discussion

Despite the general acceptance of this method in practice, sentinel node biopsy has certain drawbacks; it is a meticulous and slow procedure for surgeons in the theatre, needs the administering of radioisotopes to patients, and requires many microscopic sections for the final pathological examination. Also this method is not freely available in all centres and it is quite expensive. A sonological examination is recommended by the previously done studies in order to find suspicious involved lymph nodes in the axilla. High resolution sonology, which can help to establish the structural features of the axillary lymph nodes and the structural changes which may suggest metastasis, is now being accepted as an important non-invasive method increasingly.

Conclusion

Breast cancer is on the rise,and claims more victims every minute. Axillary metastasis indicates advancement of the disease, and indicates a poorer prognosis than non metastatic disease. Hence,investigations like sonology of the axilla,and sentinel lymph node biopsy play significant roles in predicting the prognosis of the patient as well as guiding surgeons in the appropriate treatment.

Abstract

A Community based cross sectional descriptive study done in Anakaputhur, an Urban area of Kancheepuram district, Tamil Nadu. Depression among adolescent age groups has an effect on teen socialization, academic achievement, family relationships. They are at danger of gambling addiction, social media, electronic gadgets, smoking, alcohol, antisocial behaviour, and also psychosocial impairment. Suicide, the third major cause of death among elderly adolescents (Centre for Diseases Control, Atlanta), is the most disastrous result of adolescent depression. In India, more than six kids commit suicide every day due to failure of examinations in 2011.10 Thus, it can be seen that today's adolescents are confronted with multiple types of physical, psychological and social issues.

Keywords: *Depression, Adolescents, electronic gadgets, Depression.*

Introduction

Major depressive disorder is estimated to be the second most vulnerable human disease in 2020.1,2 Globally, most of them are shielded under the Convention on the Rights of the Child. However, their demands and vulnerabilities often stay unnoticed. They lack fundamental facilities on the basis of their particular requirements. National programs concentrate primarily on newborns, under-five, adults but adolescents are not covered by any programs. 3,4 According to the World Health Organization, depressive disorders are the primary mental health disorders of adolescents owing to their elevated incidence and associated complications and other health-related consequences.[5] The incidence of depression among adolescents varies from 15 to 20 per cent with a recurrence rate of approximately 60 to 70 per cent.[6,7] This often results in suicide, college dropout, substance abuse, adolescent pregnancy, overeating and obesity, and in the long run leads to adult depression.[8,9] Mental health problems create socio-economic burdens by contributing to the growth of more disabled people.

Materials and Method

Study Design: A Community based cross sectional descriptive study done in Anakaputhur, an Urban area of Kancheepuram district, Tamil Nadu.

Study Area: The study was conducted in the Urban Field Practice Region of the Urban Health Training and Center linked to our organization located in Anakaputhur, Kancheepuram, Tamil Nadu District. Kancheepuram is one of the 32 districts of Tamil Nadu. According to the 2011 Indian census, the Kanchipuram county covers an area of 4433 sq.km with a population of 39.98 lakhs, comprising 20.12 male lakhs and 19.8 female lakhs. Kancheepuram, the town of the temple is the headquarters of the district for administrative purposes, the district has been divided into 4 revenue divisions composed of 11 taluks with 1137 revenue villages.

Anakaputhur is a town in the Kancheepuram district of Tamil Nadu. It's split into 18 rooms. The research was performed in Anakaputhur, an urban field practice region of the Department of Community Medicine of

Sree Balaji Medical College and Hospital (SBMCH), situated at a distance of 7 kilometers from the institution with an region of roughly 16 square metres. It's miles.

Study Period: The study was conducted between June 2017 to July 2018.

Study Participants: According to the 2011 census, Anakaputhur urban field practice area had a total population of 48,050 of which 24,158 were males, 23,892 were females with 8890 adolescent (Individuals aged 10-19 years) . Total number of houses in Anakaputhur is 12,146. The study was done among adolescent who are residing in the study area permanently at the time of the study.

Inclusion Criteria: The inclusion criteria for the study were adolescent people of both the genders of age group (13-18) residing in the study area, who were willing to participate in the study were included.

Exclusion Criteria: The exclusion criteria for the study were adolescents who have any physical illness, severely ill and those who were not willing to participate in the study were excluded.

Sample size: Sample size was calculated from the earlier research undertaken by Kunal Kishore et al among school-going adolescents in the urban area of Bihar in 2016, the incidence of depression reported in this research was 49.2 percent. This was taken as the reference value for the calculation of sample size. The size of the sample was calculated using the formula. $N=Z\ a^2pq/[L]^2$

Where, Z = 1.96 at 95% confidence interval

p= Expected prevalence rate,

q=100-p,

L =Relative precision, which is assigned as 10% of p (10% of 49.2% = 4.92) for this study.

Substituting in the formula,

Z = 1.96, p =49.2 %, Q=50.8% [100–49.2], precision=10 % of prevalence

= 1.96* 1.96 *49.2*50.8/24.20

= 396

= 396 which was rounded off to 400. [N = 400]

Sampling method: Anakaputhur had a total population of 48,050 as per 2011 census. As per census data, the adolescent age group (10–19) were identified and there were 8890 adolescent residing in the study area . The sampling technique followed for this study was Systematic randomsampling technique. Sampling interval K= (N/n) is calculated as follows, where K is the sampling interval

K = Total adolescent in Anakaputhur/sample size

K = N/n = 8890/400 = 22^{nd}. Every 22^{nd} adolescent were selected.

The name and address of the person was noted and was visited for the data collection. If the person corresponding to the number did not give informed consent or absent,the next number was chosen and the next person was selected and interviewed. Likewise, 400 adolescents who gave informed consent and willingly participated in the study were identified.[10-13]

Study tools: A pretested structured questionnaire was used as a study tool to interview the study participants. The questionnaire was drawn up in English and translated into Tamil. It was conducted by face to face interview by the investigator herself and the responses were recorded in the questionnaire.

Ethical approval: The research was endorsed by the Institutional Ethical Review Committee of the Sree Balaji Medical College and the Chennai Hospital. **Ref No : 002/SBMC/IHEC/2017/954 (ANNEXURE I)**

Informed consent: The details and purpose of the research and the confidentiality of their identity have been clarified to each participant, and those ready to engage in the research have been required to sign informed permission, after which they have been included in the research. The informed consent was given in Tamil, the local language of the research respondents.

Pilot study: A pilot study was conducted among 40 adolescent residing in urban area of Pammal which is the adjacent area to the study area and also located in Kancheepuram district. It was done for a period of one month during the month of July 2017. Based on the results of the pilot study, the necessary changes were incorporated in the questionnaire and the study was conducted. The samples included in the pilot study were not included in the present study.

Data collection period: Data was collected from the study participants for a period of one year from June 2017 to July 2018.

Data collection Method: Using systematic random sampling study subjects were identified. The adolescents of both the genders were identified after obtaining their written consent in the informed consent form. The interview was conducted by the investigator herself. The pilot study questionnaire was used to interview each participant by one to one individual method on socio-demographic details, family history, questions regarding depression etc.PHQ–9 depression scale, questionnaire was used for ascertaining the prevalence of depression. Anthropometric measurements such as height, weight were measured among the study participants.

Data Analysis: The information was entered in Microsoft Excel 2007 and analyzed using the Windows Social Sciences Statistical Package (SPSS) version 20.0. Prevalence information was provided in the form of numbers, percentages, tables and figures. The analytical statistics used were chi-square, odds ratio and confidence intervals. Binary logistic regression has been used to calculate the adjusted odds ratio. $P < 0.05$ was regarded to be a statistically significant value.

Findings: Distribution of family history of mental disorder research respondents

Table 1 demonstrates the allocation of research respondents by family history of mental disorders. Of the 400 survey population, most of them had no family history of mental disorder 365 (98.8 per cent), only 5 (1.3 per cent) had a family history of mental disorder.

Table 1: Distribution of family history of mental illness (N=400) research participants

Family history of mental disorder	Frequency (N)	Percent (%)
Yes	5	1.3
No	395	98.8
Total	**400**	**100.0**

Distribution of study respondents based on the smoking/alcohol status of the father Figure 1 demonstrates the allocation of study respondents on the basis of the smoking/alcohol status of the dad. Among the study participants, 69.80 % did not had the habit of alcohol intake and smoking,13.30% had habit of intake of alcohol and smoking, 9.30% had habit of smoking alone and 7.80% had the habit of smoking alone.

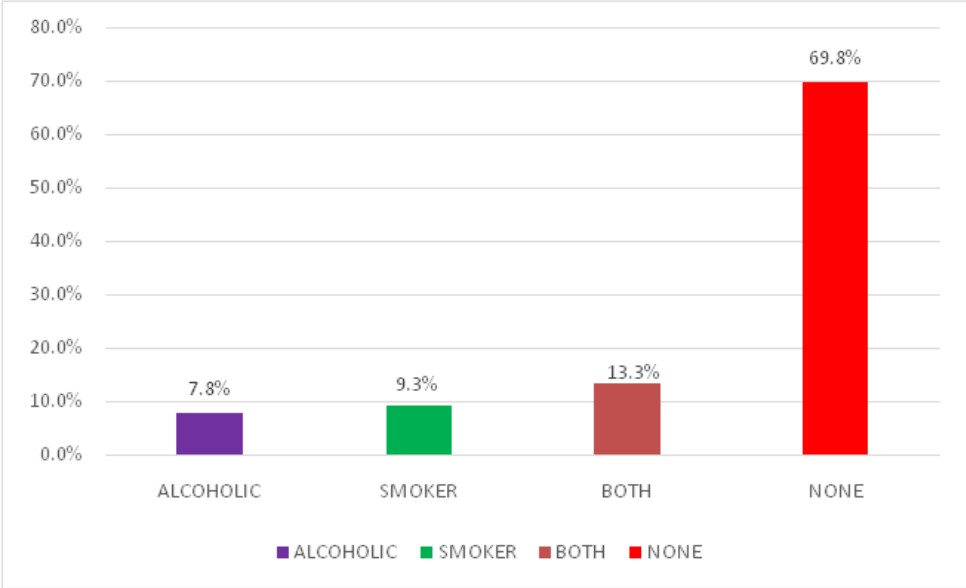

Figure 1: Distribution of research respondents on the basis of father's smoking/alcohol status (N = 400)

Distribution of research respondents on the basis of whether the research becomes burdensome: Table 2 Shows the allocation of study respondents based on whether the research has become burden some. Out of the 400 study population, only 101 (25.3%) told study became burden but most of them 299 (74.8%) told that study not became a burden.

Table 2: Distribution of research respondents on the basis of whether the research becomes burdensome (N = 400)

Study becoming burden	Frequency (N)	Percent (%)
Yes	101	25.3
No	299	74.8
Total	400	100.0

Distribution of study members on the basis of study burden: Table 3 demonstrates the distribution of study respondents on the basis of study burden, out of the 400 study inhabitants, 98 (24.5%) of the study population reported. problems related to parents, 94(23.5%) of them told problems related to teachers,45(11.3%) of them told problems related to friends, 29(11.3) of them told due to physical ill-health and 124(31%) of them told other reasons.

Table 3: Distribution of study respondents on the basis of the study burden (N=400)

Reason for study burden	Frequency (N)	Percent (%)
Not interested in study	10	2.5
Physical ill-health	29	7.3
Problems related to classmate/friends	45	11.3
Problems related to teachers	94	23.5
Problems related to parents	98	24.5

Discussion

Academic Performance: The connection between academic performance and depression was discovered to be statistically important (p<0.005) in this research. This may be due to the experience of school-related stress, such as bad academic performance, negative feedback from parents and educators about school work, daily problems in the school setting, stressful life activities, and adverse effects during school work. 11

Similarly, a research undertaken by Jayanthi p et al among teenagers discovered that the study population with academic pressure was 2.4 times (95% CI-0.9-2.4) (p<0.001) greater risk of depression than teenagers without academic pressure. 12 Similarly, a study by Man Mohan Singh et al discovered that there was a statistically significant connection between academic performance and depression. 13 Another research by Bit Na Kim et al on the impacts of academic stress on depression discovered that both boys and girls had higher rates of academic stress than depression. This could be due to poor academic degrees, which usually predict elevated psychology.

Alcoholic/Smoking Status of Father: Alcohol and smoking status of the dad and depression were discovered to be statistically important with depression p(<0.005). In a multivariate assessment, depression was substantially correlated with the alcoholic/smoking status of the dad (P value–0.016) OR–1.540; CI–(1.083–2.191).

Similarly, a research by Jacob t et al on psychosocial functioning in children of alcoholic father found that the association between parental alcohol intake and depression was higher and it was statistically significant (p <0.005).

Conclusion

Teachers should be made aware of the issue at an previous point so that the risk of advancement to other severe issues, such as substance abuse, etc., can be minimized. Health education for parents as well as for the society as a whole should be encouraged in order to eliminate the stigma connected to these illnesses.

To Compare the Efficacy of Azithromycin Pulse Therapy with Doxycycline in Acne Vulgaris Treatment: An Open Labelled, Randomised, Parallel Group, Hospital Based Study

A. Muzamil Ahmed[1], Chinni Vikram[1], R.G. Santhaseelan[2]

[1]PG Student, [2]Professor, Dept. of General Surgery, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai, India

Abstract

Skin break out vulgaris is a typical dermatological issue with multifactorial etiology . There exists both topical and fundamental treatment for skin break out This investigation was led to think about the viability of oral azithromycin beat treatment with oral doxycycline in the treatment of skin break out vulgaris . Strategies: This randomized controlled preliminary was directed in the Dermatology branch of Sreebalaji therapeutic school and medical clinic from March 2016 to March 2017. Patients of age (15–40 years) having any evaluation of skin inflammation vulgaris were incorporated into the study.200 patients were arbitrarily isolated into two gatherings. Patients in first gathering were given azithromycin 500 mg day by day before feast for 3 back to back days in seven days for 3 months while patients in second gathering were given doxycycline 100 mg every day after dinners for 2 months. Patients were followed up in the wake of taking treatment for 2 months to see the adequacy of each medication. Results: Both the medications are effective in lessening skin break out. Anyway, towards the finish of the examination less number of evaluation III and grade IV cases in the doxycycline bunch than azithromycin gathering involves doxycycline is better then azithromycin .Conclusion: Doxycycline is a superior choice for treatment of skin inflammation vulgaris when contrasted with azithromycin as far as symptoms.

Keywords: *Acne vulgaris,acne therapy***,** *Doxycycline, Azithromycin.*

Introduction

Acne vulgaris is defined as a chronic, inflammatory disease of pilosebaceous unit, manifesting generally in adolescents with pleomorphic lesions like comedones, papules, nodules and cysts and these may lead to scaring[1]. It is a multifactorial disease influenzed by hormonal, genetic, microbiological and immunological factors. Though, it is highly prevalent among adolescent age group, it can affect all age groups [2]

Acne normally affects people during the onset of puberty[1]. It's severity generally increases with age and time. The inflammatory changes of acne may be quite chronic and may lead to severe residual scarring. It is more common and severe in males than in females. The age of incidence is between 14 to 17 years in women and 16 to 19 years in men [1][2].

Genetic factors influence the susceptibility to acne[1]. The role of diet as a cause is unclear. Hormonal activity such as menstrual cycles and puberty, may contribute to the formation of acne. Increase in sex hormone called androgen causes follicular gland to grow larger and make more sebum[3]. Similar condition is seen in pregnancy, leading to increased sebum production. Cigarette smoking does increase the risk of developing acne and worsens its severity[1][4].Acne mostly affects skin with a greater number of oil glands including the face, upper part of the chest and back .

If not treated properly, acne might lead to complications such as inflammatory lesions and nodules,

Corresponding Author:
Dr. R.G. Santhaseelan
Dept. of General Surgery, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

cystic lesions, post inflammatory hyperpigmentation (PIH), nodular hypertrophic scars, exudative or hemorrhagic nodules and rarely sinus tract formation between the nodules . Lesions in severe acne vulgaris might be very painful, chronic and refractory to treatment and even cause psychological complications.(1-2)

Successful management of acne needs careful selection of anti-acne agents according to clinical presentation and individual patient needs. . Systemic antibiotics, hormonal therapy or retinoids are used in moderate to severe acne [6]. Antibiotic selection may be driven by its efficacy, side effect profiles and patterns of Propionibacterium acnes resistance.

From the mid-1950s through the early 1970s, the predominant oral antibiotics that were utilized in acne were tetracycline and erythromycin . Over time, as the sensitivity of many strains of *P.acnes* to erythromycin and tetracycline decreased, the therapeutic utility of these two agents also diminished, leading to increased use of " newer generation " tetracyclines-doxycycline, released in 1967. However tetracyclines may be associated with a fairly large number of adverse effects . Azithromycin is a macrolide and a methyl derivative of erythromycin that has been recently prescribed for the treatment of acne. It is as effective as doxycycline [7]. Its extensive distribution in the tissue allow pulse dose regimen recommendation for increased compliance[8]. Due to its improved pharmacokinetic properties, high tolerability profile and efficacy against P.acnes, its rationale use in acne has been examined and it has been found to be effective in a few clinical studies [7][9][10]Various doses and regimens of azithromycin have been studied for acne treatment but still data about the optimum dose of azithromycin is lacking . On this basis, the present study is specifically undertaken to compare the efficacy of azithromycin pulse therapy-5oo mg once daily for three consecutive days in a week with doxycycline 200 mg daily for 2 months.

Material and Method

This is an open label, prospective, single centred, randomized, comparative study conducted to evaluate the efficacy of oral Azithromycin Pulse Therapy-5oo mg once daily for three consecutive days in a week with oral doxycycline 100mg once daily for 8 weeks in patients with acne vulgaris. This study enrolled 200 patients. Patients who visited the Department of Dermatology, at Sree Balaji Medical College and Hospital, Chennai Tamil Nadu, with the complaints of pimples (acne), were the source of samples in the present study. The study duration was for 2 months and study period was from March 2016 to March 2017. The study protocol was reviewed and approved by the Institutional Ethics Committee and all trial participants have been informed about the study procedures and written informed consent was obtained.(3-5)

Subjects:

Inclusion criteria:

- Both male and female patients
- Age between 15 to 40 years
- Patient with all grades of acne (Grade I to IV according to Indian author acne classification)

Exclusion criteria:

- Patients age less than 15 and age above 40 years of age
- Patients with history of drug sensitivity
- Patients with history of taking any topical and systemic treatment for acne during the past two and four weeks respectively
- Patients received oral isotretinoin for the past 6 months
- Patients with other dermatological disorders
- Presence of any other skin disorder that would interfere with diagnosis or assessment of acne
- Presence of hepatic or renal derangement
- Patients with history of psychiatric disorders
- Pregnant and lactating women
- Patients with any medical diseases including endocrine or gastrointestinal, and hyperandrogenism manifestations in girls

With Drawal Criteria:

- Adverse events which warrant withdrawal of subject
- Non-compliance with procedures
- Withdrawal of consent, for participation in the study by the subject
- Failure of the study drug to produce the desired effect

Sample size for this study was calculated using power and sample size calculation program software (version 2.1.31). The calculated requisite total sample size was 200.

Methodology: All 200 study subjects, who fulfilled the study criteria were selected from 248 patients . They were then randomized into two groups in 1:1 ratio with the help of a statistical software SPSS version 23 . Each study group consists of 100 participants.

Initial assessment of acne vulgaris was carried out based on the simple grading system followed by Indian dermatologists in their routine clinical practice[1]

Drug Dosage: Group I (100 patients): Drug–Azithromycin-500 mg Azithromycin is given orally once daily for three consecutive days in a week for 2 monthsGroup II (100 patients) :Drug-Doxycycline-100 mg Doxycycline is given orally once daily for 2 months

Study subjects were also instructed not to apply any topical medicaments or to undergo any beauty procedures such as chemical peels, facials, bleaches etc during the study period. Parallel assignment of drug was used in both groups. Three scheduled visits were carried out during the study period–Baseline visit, visit at the end 4th week and visit at the end of 8th week (end of study). The response to treatment was evaluated during each follow up visit . (15)

Laboratory Investigations: The following laboratory investigations were done during screening i.e. baseline visit ('0'weeks), at 4th week and at 8th week. Blood Biochemistry :Complete blood count,Random blood sugar,Renal function test,Liver function test.

Primary outcome measure : To compare the safety and side effect profile of oral azithromycin and oral doxycycline by marking the adverse effects during the treatment phase.

Statistical Analysis: Data analysis was done using Statistical Package for the Social Sciences (SPSS) version 23 .

- All continuous variables were compared using t-test.
- Qualitative variables were compared using chi-2 test. (12)

Findings: A total of 248 patients were screened for this study, out of which 48 patients were excluded . Among the 48 patients, 10 patients refused to participate and 38 patients didn't meet the inclusion criteria of our study. The selected 200 patients were randomised into two groups and the treatment was started as and when they reported to the hospital. All of them continued the study, and there was no discontinuation or withdrawl due to adverse events. All statistical analysis was done in SPSS version 23 and intent to treat principle is employed for analysis . Results were distributed in age, sex, treatment comparison and adverse event profile. The overall results of this study is shown below :p value (Probability that the result is true) of < 0.05 was considered as statistically significant after assuming all the rules of statistical tests. Regarding demographic characteristics there is no significant difference between the two treatment groups.

Table 1: Distribution of participants based on age

Characteristics	Group 1 Azithromycin (n=100) Mean ± SD	Group 2 Doxycycline (n=100) Mean ± SD	p value
Age	26.5 ± 5.6 yrs	26.9 ± 6.8 yrs	0.557

The mean age of the study subjects is 26.7 ± 6.2 yrs.

Figure 1: Distribution of age groups in Azithromycin and Doxycyclin treatment groups

Treatment efficacy

Table 2: Comparison clinical grade of patient at baseline, first and second month

	Azithromycin			Doxycycline		
	Baseline	4th week	8th week	Baseline	4th week	8th week
Grade 1	20	23	10(10%)	20	37	17(17%)
Grade 2	26	47	49(49%)	24	50	71(71%)
Grade 3	27	20	34(34%)	33	9	10(10%)
Grade 4	27	10	7(7%)	23	4	2(2%)

Distribution of different grades of disease at baseline and at the end of first and second month for both Azithromycin and doxycycline is documented in Table-2. At the follow up visits the acne grades were significantly reduced in both the groups compared to the baseline indicating that both drugs could able to reduce acne vulgaris . Towards the end of the study, presence of more grade III and grade IV patients in Azithromycin group compared to the doxycycline group indicates that doxycycline is more efficient in reducing the severity of the acne compared to azithromycin.[10,11]

Table 3: Comparison of Azithromycin and Doxycycline treatment response

Response	Azithromycin (100 patients)	Doxycycline (100 patients)	p value
No response	12	6	0.004*
Mild response	21	10	
Moderate response	29	19	
Good response	28	52	
Excellent response	10	13	

*p value-clinically significant

Further comparison of response in both Azithromycin and doxycycline groups also showed that the doxycycline more efficient in achieving good improvement (Table-5 & Figure-9). The difference in the response of these treatments is statistically significant (p value = 0.004).

Discussion

Acne vulgaris is a common dermatological problem. The choice of proper treatment is determined by the severity and extent of acne . Systemic antibiotics have been the mainstay of treatment for moderate to severe acne vulgaris. The anti propionibacterium property found in antibiotics are able to inhibit the bacterial colonisation of pilosebaceous glands and prevent further inflammation. The efficacy and possible side effects of various oral antibiotics has been the subject of numerous studies for atleast the last twenty years in an effort to understand, which products are likely to produce better efficacy with least possible side effects. The new emerging problem is antibiotics resistance to propionibacterium . There has been a constant increase in search of safe medications to overcome the side effects and resistance of existing formulations for the treatment of acne vulgaris. [6,7]

The tetracycline class of antibiotics should be considered first-line therapy in moderate to severe acne, except when contraindicated. Macrolides like azithromycin are effective alternatives for the treatment of acne. Its extensive distribution in the tissues allows pulse–dose regimen recommendation for increased compliance.Various dose regimens of azithromycin has been compared with doxycycline with variable results. Therefore, this study was being conducted to assess the efficacy of oral azithromycin pulse therapy for three consecutive days in a week with doxycycline therapy in the treatment of acne vulgaris.

Doxycycline is a long acting tetracycline derivative. In contrast to tetracycline, the absorption of doxycycline is less affected by food and it has better efficacy. Doxycycline is effective in reducing both inflammatory and non–inflammatory lesions. 50 to 100 mg doxycycline daily for three months treatment could able to reduce 14% and 50% for non-inflammatory lesions, and between 30% and 75% for inflammatory lesions. Its drawbacks are adverse effects and its prolonged use is associated with the resistance. Therefore comparison of the results of efficacy between these two drugs may help in optimizing the dosage of the drugs .Azithromycin is a macrolide antibiotic. It has a long half-life of 68 hours and therefore can be given three times a week to have better patient compliance. Various oral azithromycin regimens were found to be effective in reducing both inflammatory and non-inflammatory lesions in patients with moderate to severe acne . The results of previous studies indicated that both drugs has good therapeutic efficacy.[1-3]

Conclusion

Our study shows that both azithromycin and doxycycline are efficient in reducing acne . However towards the end of the study, presence of less grade III and grade IV patients treated with doxycycline compared to the azithromycin clearly indicates that doxycycline is more efficient in reducing the severity of the acne compared to azithromycin. Percentage of good and excellent responses are also higher with doxycycline. Hence for the treatment of acne vulgaris, doxycycline 100 mg daily for 2 months is better than azithromycin pulse therapy-500 mg daily for three consecutive days in a week for 2 month in terms of efficacy.

Prevalence of Hypertension and its Correlation with Diet in School Going Adolescent Girls in an Urban Setting

A. Priya Margaret[1], Shanthi Ramesh[2], S. Sundari[3]

[1]Asst. Professor, [2]Associate Professor, [3]Head of the Department of Paediatrics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research , Chennai, Tamil Nadu, India

Abstract

Background: Hypertension in children is a frequently overlooked problem and an important cardiovascular risk factor of adulthood. This study was conducted to determine the prevalence of hypertension among school aged urban children and find out the association of diet with hypertension.

Method: The study included 100 children aged 15–17 years. The weight, height, and BP were measured using standardized instruments following standard guidelines.(7) Details regarding food habits were obtained. Blood pressure measurements were taken by an electronic BP monitor–Omron. Hypertension was considered when blood pressure was more than the 95th percentile for age and sex as per the NHLBI, NIH (National heart lung blood institute) standards. In children having hypertension a repeat measurement was done to confirm hypertension.

Results: In this study the prevalence of hypertension was found to be 9%.

Conclusion: High Blood pressure in children and adolescents is on the rise. These new findings have implications for the cardiovascular disease public health burden. They reinforce the urgent call for early prevention of obesity and High blood pressure in adolescents

Keywords: *Hypertension, Adolescents, Urban, school, diet.*

Introduction

Risk factors for cardiovascular disease such as hypertension have been increasingly prevalent among adolescents[1]. The causes for increase in blood pressure are attributed to obesity(2) change in dietary habits, decreased physical activity and increasing stress. Data is lacking from India regarding the prevalence of hypertension in adolescent children and its association with diet. So this study was conducted to determine the prevalence of hypertension among school aged urban children(3) and find out the association of diet with hypertension(1)

Method

The study included 100 children aged 15–17 years. The weight, height, and BP(5) were measured using standardized instruments following standard guidelines. Details regarding food habits were obtained. Blood pressure measurements were taken by an electronic BP monitor–Omron. Hypertension was considered when blood pressure was more than the 95th percentile for age and sex as per the NHLBI, NIH(National heart lung blood institute) standards. In children having hypertension a repeat measurement was done to confirm hypertension(2).Overweight is defined as a BMI at or above the 85 th percentile and belowthe 95th percentile for children and adolescents of the same age and sex(9). Obesity is defined as a BMI at or above the 95th percentile for children and adolescents of the same age and sex(6-8). Weight was measured using anelectronic weighing machine Omron and height was measured with astadiometer. The children were questioned about their food habits whether they took vegetarian or non vegetarian food.(3)

Results

A cross sectional study on hypertension among adolescent girls wasdone in an affluent school in Chennai.[9] A total of 100 adolescent girlswere included in the study. The mean age of the children was 16.4 years. The mean weight of the children was found to be 56.8 Kg (SD 11.3 Kg).The mean height of the children was found to be 159.8 cm (SD 6 cm).80 children were non vegetarian while 20 children took vegetarian food.12 children were found to be obese while 88 children had a normal weight. 9 children were found to be hypertensive while 91 children had normal blood pressure[4].

In this study, the prevalence of obesity was found to be 12%[10]. The chance of an adolescent girl to have hypertension was 11.7 times higher for those adolescents who were obese comparedto those with normal weight. It was found that 5 of theadolescent girls who were obese and 4 of the adolescent girlswho had normal weight had hypertension and this was found to bestatistically significant (p=0.000).[5]

Discussion

India is undergoing an epidemiological transition where non-communicable diseases (NCDs) are on rise. According to World Health Report 2002,cardiovascular diseases (CVDs) will be the largest cause of death and disability by 2020 in India.[6]The growing burden of CVDs is being contributed largely due to multitude of risk factors with hypertension being one of them

Hypertension is one of the diseases which is diagnosed and treated in 25%of the cases only making it largely an under-diagnosed problem. There isplenty of evidence to suggest that hypertension begins in childhood andadolescence. The asymptomatic nature of hypertension in early phases ofits onset during adolescence increases the chances of developingcomplications during adulthood.[4] Therefore, detection of hypertensionduring childhood is of potential value in identifying those, who are atincreased risk of primary hypertension as adults, and who might benefitfrom earlier intervention and follow-up[8].

Several studies in India have reported the prevalence of hypertension to be ranging between 0.46% and 11.7% amongst children and adolescents. Further, a number of environmental factors have been found to be associated with hypertension in children and adolescents. Thus, early detection of hypertension and its aggravating factors becomes imperative. The data on blood pressure (BP) profile of school adolescents is scanty in India. Considering the detection of hypertension in adolescence as the best possible preventive intervention to avoid complication later in life, the present study was undertaken to determine the prevalence of hypertension amongst urban school adolescents and its correlation with diet.

High Blood pressure in children and adolescents is on the rise. These new findings have implications for the cardiovascular disease public health burden. They reinforce the urgent call for early prevention of obesity and High blood pressure. Cardiovascular diseases are a leading cause of death. Systematically assessing and quantifying modifiable CVD risk factors is therefore crucial. Better understanding and awareness of CVD risk factors may help clinicians and public health professionals develop culturally sensitive interventions, prevention programs, and services specifically targeted toward risk burdens in each of these populations.

Conclusion

Hypertension is increasing in adolescent urban children[10]. Our present study estimated the prevalence of hypertension in adolescent school going children as 9%. Non vegetarian diet is more associated with hypertension. Sedentary habits, lack of exersice, intake of junk food and increasing screen time is associated with increasing hypertension in adolescent children. More data on the prevalence of hypertension in adolescent urban children is required to form public health preventive policies.

Limitations of the study: A large sample size is needed to study the association between weight, food habit, and hypertension in adolescents.

Epidemiology of Breast Cancer: A Case Series

Ar. Anjanaa[1], Gayathri Devi T.[2], Hemalatha Ganapathy[3]

[1]Post Graduate, [2]Assistant Professor, [3]Professor and HOD, Department of Pathology, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Background: Breast cancer is the most frequent cancer in women and represents the second leading cause of cancer death among women (after lung cancer).The proportion of breast cancer is rising in India. Incidence rates are high in more developed countries, whereas rates are lower in less developed countries but increasing.

Aim: This is a retrospective study of 90 breast cancer patients less than 70 years of age treated in a single center from April 2018 to April 2019. The aim is to assess the known risk factors that modulate the development of breast cancer.

Materials and Method: Data were collected from medical records. Variables such as age, parity, breast feeding, body mass index (BMI), family history and usage of oral contraceptive pills (OCP) were analyzed in relation to outcome. All data were recorded in MS Excel sheet.

Results: Maximum number of cases (58.8.4%) belonged to age group of ≥50 yrs. Maximum number of cases falls under lower parity/nulliparity. There was no data in the records on duration of breast feeding, to determine its association with breast cancer. Postmenopausal women (37 cases) with increased BMI is evident to show its risk. Most of the cases (80%) didn't have positive family history. 93.3% of cases not associated with intake of OCP.

Conclusion: Increase in age contributes to maximum number of cases. Parity & Breast feeding is inversely proportional to breast cancer. In postmenopausal age group, BMI is increased. Positive family history is present in few cases, which shown familial breast cancer accounts less than of all breast cancer cases. Intake of OCP shows no association with breast cancer. This study has several limitations of being a descriptive study & it described only the collected data.

Keywords: *Breast cancer; epidemiology; risk factors.*

Introduction

Breast cancer is the leading cause of death among cancer patients worldwide. More than 100,000 patients are estimated to be newly diagnosed in India which depicts the disease burden. This neoplasm is probably the most feared by women, especially by the negative stigma brought by its diagnosis and due to its psychological effects, which affect the perception of sexuality and their own personal image(1).

As compared to the western countries breast cancer in Indian women presents at a younger age, almost a decade earlier. Hence, a significant breast cancer burden in India occurs in younger women(2).

This study was conducted to determine and explore the association of breast cancer with age, socio-demographic details, body mass index, duration of breast feeding and the usage of oral contraceptive pills in a tertiary care center in India.

AIMS and Objectives: To determine the association of breast carcinoma with age, socio-demographic details, body mass index, duration of breast feeding and the usage of external hormones pathologic among women.

Materials and Method

This study has been done retrospective, descriptive study on ninety proven patients of carcinoma breast with regard to histopathology in the Department of Pathology, Sree Balaji Medical College and Hospital, Chennai. Data was collected from the hospital medical records department.

The study included a convenience sample of 90 women in the period between April 2018 and April 2019, diagnosed with breast cancer at any stage of disease.

Patients with incomplete data were excluded from the study. All data were recorded in MS Excel sheet.

Discussion

Age: The proportion of breast cancer is increasing in urban India. It presents approximately a decade earlier than the West. It is yet to be proved whether this reflects the younger population in India, or a true biological difference. At present, breast cancer in women below 40 years occurs in approximately 5-7.5% of the total number of cases diagnosed every year in Western Europe and US[3] In Asian studies, the incidence is two-folds higher[2]

As there is no effective screening strategy for this age group, the presentation is almost always with a palpable lump. McAree *et al*., have reported a symptomatic presentation in 98.2%,[4] while Foxcroft *et al*., have reported a symptomatic presentation in 93%[5] of all breast cancer patients less than 40 years of age.

Current literature supports the hypothesis that breast cancer is generally more aggressive in younger women than older women due to larger tumor size, higher grade, higher lymph node positivity, hormone receptor negativity with associated lymphovascular emboli[6].

The incidence of breast cancer increases rapidly with age during the reproductive years and then increases at a slower rate[7].

Our study showed that most of the cases i.e 39 cases(43%) falls between 50-59yrs of age, followed by 24 cases(26.6%), 15 cases(16.6%) and 12 cases(13%) falls between age group of 40-49yrs, 30-39yrs and 60-69 yrs respectively Fig. 1.

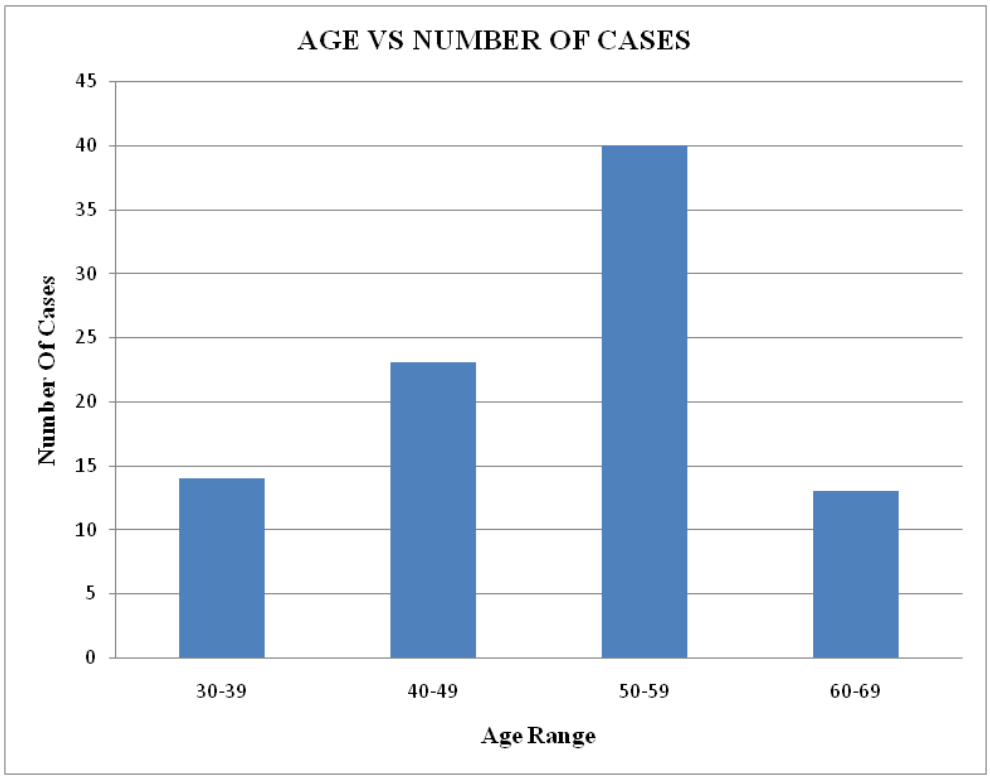

Fig. 1: Distribution of cases based on age.

In conclusion, this study has shown most of the cases presented at older age group and significant proportion of young females (those less than 40 years) with breast cancer. Breast cancer education, free breast cancer detection camps can help in creating awareness on this disease. Proper awareness and screening programs can promote early access to the treatment.

Findings: The high incidence of triple negative breast cancer may be partly explained by the fact that the risk factors for triple negativity are commonly seen in Indian population, like-high parity, young age at the time of first birth[8,9] younger age at diagnosis, i.e., <50 years[10,11] and lower socio-economic status[12].

Higher parity decrease breast cancer risk to half of the risk of nulliparous women. Early age at second pregnancy further reduces the risk of breast cancer [13]. In contrast, nulliparity and late age at first birth contribute towards an increased risk of developing breast cancer. Interestingly, women with their first birth after age of 35 are even at higher risk than nulliparous women [13,14,15].

Our study shown less number of cases in higher parity compared to lower parity Fig. 2.

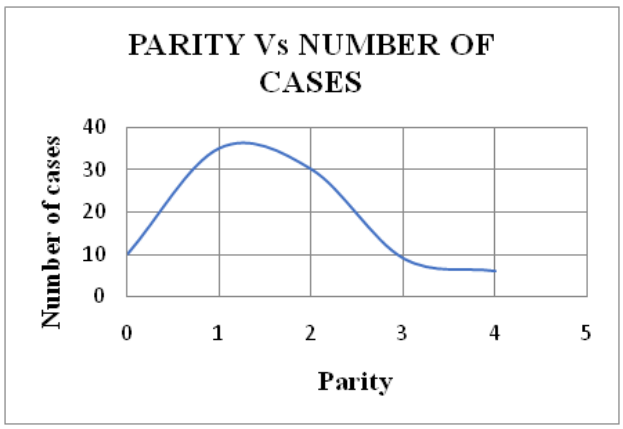

Fig. 2: Distribution of cases based on parity.

Breast Feeding: Prolonged lactation has been demonstrated to be protective, as well [16]. There is a 4.3% decrease in the relative risk of breast cancer for every 12 months of breast feeding. The decrease of breast cancer risk due to prolonged lactation may be explained in part by the reduction of total number of ovulatory menstrual cycles and consequently reduced cumulative ovarian hormone exposure [15].

Studies in less developed countries, where the total duration of breast feeding can be very long, have reported substantial protective effects[16]. Protection has also been seen in some, but not all, studies in more developed countries. For example, the US Cancer and Steroid Hormone Study examined the relation between breastfeeding and breast cancer in over 4500 women with the disease and found that women who had breastfed for a total of 25 months or more had a 33% lower risk of breast cancer than those who had never breastfed [17].

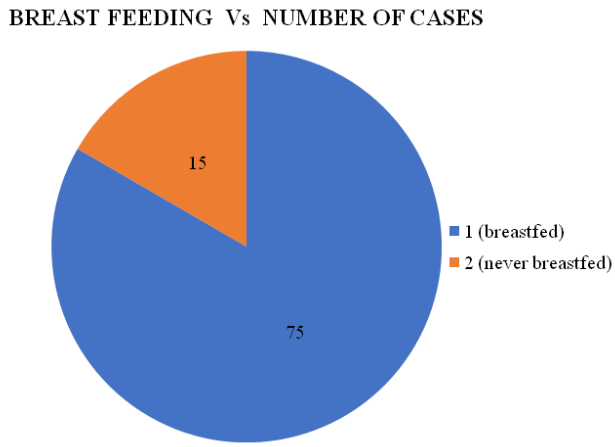

Fig. 3: Distribution of cases based on breast feeding

In our study, there is no data on duration of breast feeding so the study of this association is incomplete.

Obesity: Higher adiposity has opposing effects on breast cancer risk, depending on a woman's menopausal status. Among premenopausal women, higher adiposity, in childhood or during adult life, is associated with decreased risk of breast cancer, while among postmenopausal women obesity increases risk.

Interestingly, greater adiposity during childhood and adolescence is inversely associated with both hormone receptor-positive disease (i.e., tumors expressing estrogen (ER) and progesterone (PR) receptors) and receptor-negative disease. In contrast, obesity in adulthood has been found to be associated predominantly with ER+/PR+ breast cancer, and, in the case of postmenopausal obesity, with increased risk of ER+/PR+ disease only among women not using HRT.

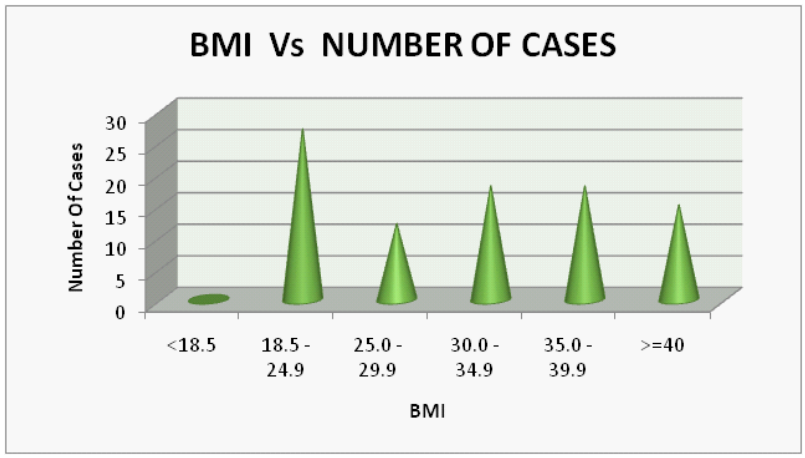

Fig. 4: Distribution of cases based on BMI.

Of note, while the relationship between body size in pre-and postmenopausal women and subsequent breast cancer risk has been extensively investigated, it still remains somewhat uncertain until what point in the premenopausal period obesity is protective, and, similarly, from what point in the postmenopausal period obesity begins to show a deleterious effect[18].

Our study shown 51 cases has BMI of ≥30.0 Table. 2, which indicates most of them are obese according to WHO classification of BMI. Particularly in postmenopausal age group women ≥45yrs, 37 caseshas increased BMI ≥30.0. Fig. 5.

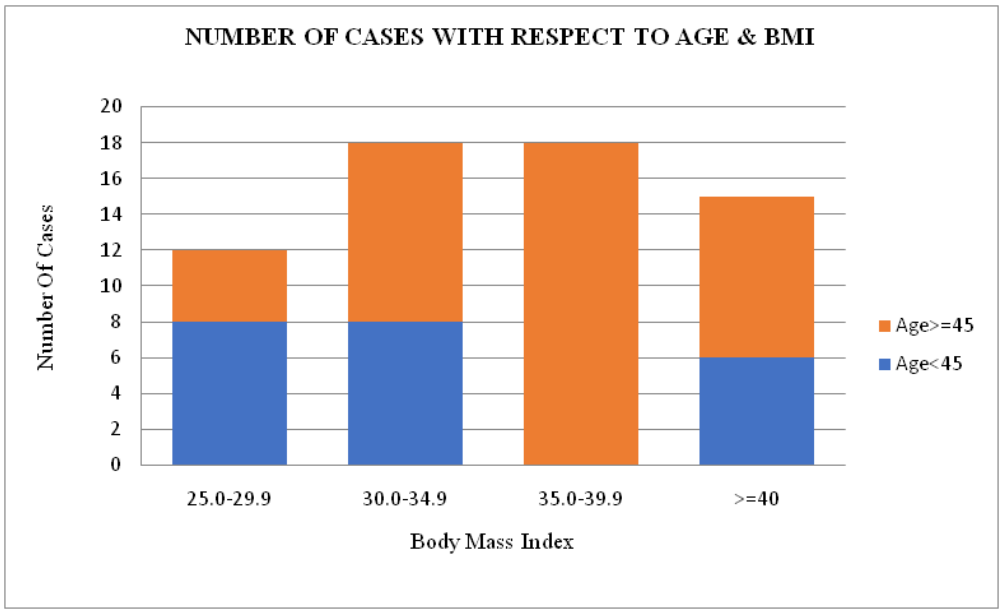

Fig. 5: Distribution of BMI in age groups.

Family History:

Discussion

Family history of breast cancer increases a woman's risk of developing the disease. A meta-analysis of 52 individual epidemiological studies showed that 12% of women with breast cancer have one affected family member and 1% have one or more relatives affected [19]. Women with one, two, and there or more first-degree affected relatives have an increased breast cancer

risk when compared with women who do not have an affected relative.

Most studies on familial risk of breast cancer have found about two-fold relative risks for first-degree relatives (mothers, sisters, daughters) of affected patients[28]. With affected second-degree relatives (grandmothers, aunts, grand-daughters), there is a lesser increase in risk.

Two genes, *BRCA1* and *BRCA2,* have been implicated in familial breast cancer but account for less than 10% of all breast cancer cases[20]. In our study, there is no data on genes associated with breast cancer. Most womeni.e 72 cases(80%) Fig.6 with the disease do not have a family history of it. Environmental and lifestyle factors rather than inherited genetic factors account for most cases of breast cancer.

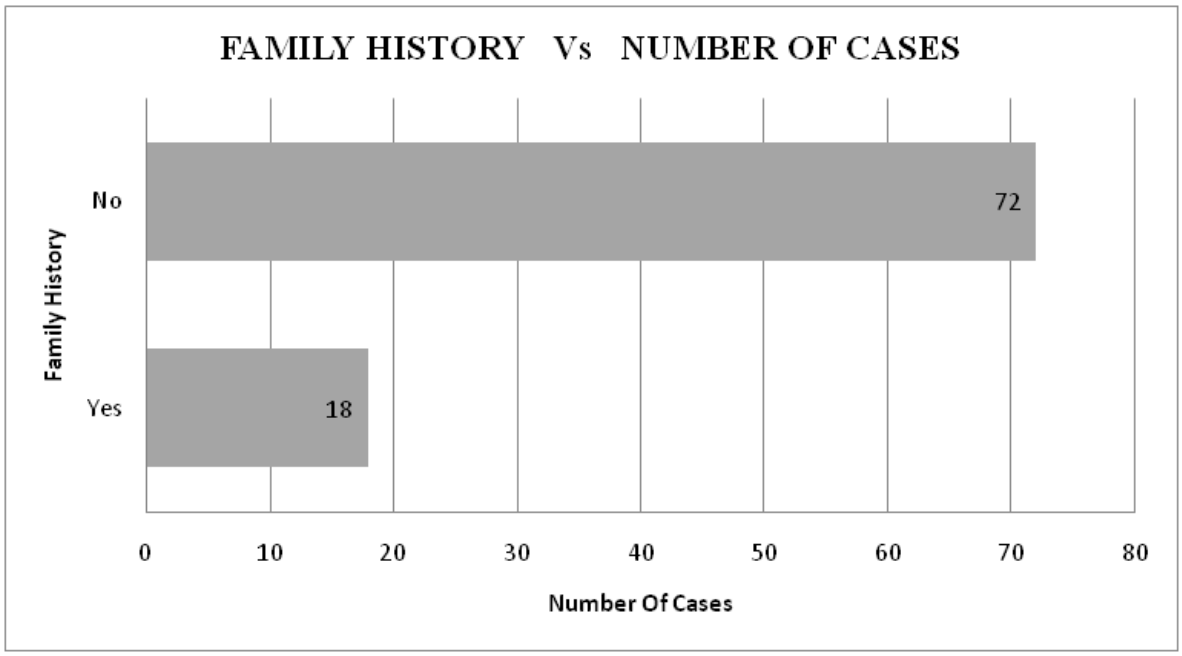

Fig. 6: Distribution of cases based on family history.

OCP: A meta-analysis study by Kahlenborn et al.[21] on 34 case/control studies showed that Odds Ratio (OR) of breast cancer increased by 1.19 times in the women who used contraceptive pills. In addition, results of the present study indicated that using contraceptive pills for more than 4 years increased OR of breast cancer by 1.52 times. Consistently, Nelson et al.[22] conducted a meta-analysis study on 61 studies and examined 8 factors. The 12 studies showed that using the pills increased the risk of breast cancer by 30% times (relative risk = 1.30, CI = 1.13–1.49).

Some studies show that there is no relationship between the use of oral contraceptives and breast cancer. Marchbanks et al.[23] carried out a meta-analysis in 2002 and reviewed 54 studies that represented 4,574 and 4,682 case and control subjects among women from 35 to 64 years of age, including white and black races. They concluded that current or former oral-contraceptive use was not associated with a significantly increased risk of breast cancer.

Conclusion

Increase in age contributes to maximum number of cases. Parity & Breast feeding is inversely proportional to breast cancer. In postmenopausal age group, increase in BMI has a significant association. Positive family history is present in few cases, which shown familial breast cancer accounts less than of all breast cancer cases. Intake of OCP shows no association with breast cancer.

Manyof the established risk factors are linked to oestrogens. Risk is increased by obesity in postmenopausal women. Childbearing reduces risk, with greater protection for early first birth and a larger number of births; breast feeding probably has a protective effect.

Oral contraceptives are not associated with the risk of developing breast cancer. Mutations in certain genes greatly increase breast cancer risk, but these account for a minority of cases.

Breast cancer is a complex disease and a variety of risk factors are involved in the etiology and development of breast cancer. The decline in breast cancer mortality has been attributed to both improvements in breast cancer treatment and early detection. However, not all segments of the population have benefited equally from these advances. This mortality difference reflects a combination of factors, including differences in stage at diagnosis, obesity and comorbidities, and tumor characteristics, as well as access, adherence, and response to treatment.

Feasible changes in risk factors, such as obesity, breastfeeding, and physicalactivity, could yield important reductions in breast cancer risk. Further progress may come fromthe identification of new, modifiable lifestyle (especially dietary) risk factors.

This study has several limitations of being a retrospective descriptive study with a small sample size from a single center. However, it does give an idea about the disease profile of breast cancer in the relatively lesser studied population in India. It described only the collected data and its characteristics.

Mobile Phone Use and Possible Cancer Risk: A Review

Aman Singla[1], S. Gopalakrishnan[2]

[1]Student, [2]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research , Chennai-73

Abstract

Versatile correspondence is presently basically controlling our every day survives better availability and shrewd cell phone administrations. This survey discussions talks about colossal development in Indian correspondence industry alongside developing concerns with respect to wellbeing impacts of portable radiation introduction. Concerns presented are particularly with respect to carcinogenesis and other health related impacts of portable radiation presentation. In the push to set up or invalidate any such concerns, numerous examinations have been embraced in the previous three decades, for the most part casecontrol structures or cross-sectional reviews. In any case, the vast majority of them significantly neglected to set up causal affiliation principally inferable from potential inclinations and blunders in their lead and examination. Past accomplice studies have given conflicting outcomes prompting proceeded with vulnerability in regards to tumorigenic capability of portable radiation presentation. In India, there remains a tremendous information hole relating to this specific subject and just couples of studies are by and by in progress, for example, the Indian Council of Medical Research (ICMR) mobile phones consider in the National capital area (NCR). Global Agency for Research on Cancer (IARC) has arranged radio frequency electromagnetic fields related with remote telephone use as potentially cancer-causing to people (Group 2B), causing significant concerns worldwide among versatile organizations and supporters ambiguously. The World Health Organization (WHO) is by and by conveying formal hazard evaluation of all considered wellbeing results from radio recurrence field's exposures.

Keywords: *Radio Waves, Carcinogen, Non ionizing radiation.*

Introduction

"Make tracks in an opposite direction from you."That's something everybody's parents says simply regarding each time they see their kids with a cell phone squeezed against their ear. They are voicing something numerous cell phone clients, or guardians of cell phone clients, naturally feel: that these gadgets are by one way or another creation them wiped out. Though they have never been especially worried about cell phone radiation and malignant growth, there telephone makes them uneasy. It directions a lot of their consideration. It takes up a lot of their time. Also, it isn't shrewd to have its warmth so near there cerebrum.

Cell phones are a necessary piece of current media transmission frameworks and are generally utilized around the world. In numerous nations, over a large portion of the populace utilizes cell phones. The expense of cell phone innovation has fallen, prompting expanded number of endorsers in the nation (725 million). There is a developing open concern with respect to conceivable antagonistic wellbeing impact because of versatile radiation exposures, which, keeping in view colossal number of portable supporters appears justified[1]. Therefore, today is essential to deliberately research, comprehend, and screen any potential general wellbeing effect of expanding cell phone use in India. Cell phones impart by transmitting radio recurrence waves through a system of fixed reception apparatuses. Such radiations are delivered by cell phones and other family unit gadgets, for example, Wi-Fi, (TV), and

Bharath Institute of Higher Education and Research , Chennai-73

radio transmitters and so forth. Radio frequency waves are electromagnetic fields, and not at all like ionizing radiation, for example, X-beams or gamma beams, can neither break synthetic bonds nor are incredible enough to harm our deoxyribonucleic corrosive (DNA). Be that as it may, they are probably going to be consumed by tissues nearest to gadget presentation site and produce mellow nearby warm impact. Among studies directed to evaluate exposures to cell phone radiations, an investigation close schools and medical clinics in Chandigarh, Punjab found the most noteworthy thickness of 11.48mW/mm, which is 1,148% of as far as possible. The examination reasoned that presentation level in the city were much about the organic wellbeing limit above which the natural arrangement of people and creatures begins getting affected[2]. The measure of radio recurrence vitality introduction relies upon portable set innovation, the degree kind of utilization, telephones reception apparatus, and phone towers remove from the client. Physicists have examined each other possible connection between versatile radiation and natural procedures, for e.g., physical misshapenness of proteins, initiation of flagging pathways, and docking with receptors on cell films. For each situation, the determined quality of portable radiation has been immaterial to influence any neurotic transformation[3].

What is radio recurrence radiation?

Materials and Method

Radio frequency radiation is a type of electromagnetic radiation. Electromagnetic radiation can be classified into two sorts: ionizing (e.g., x-beams, radon, and grandiose beams) and non-ionizing (e.g., radio frequency and very low recurrence, or power recurrence). Electromagnetic radiation is characterized by its wavelength and recurrence, which is the quantity of cycles of a wave that pass a reference point for each second. Electromagnetic frequencies are depicted in units called hertz (Hz).The vitality of electromagnetic radiation is dictated by its recurrence; ionizing radiation is high recurrence, and in this way high vitality, while non-ionizing radiation is low recurrence, and along these lines low vitality. The recurrence of radiofrequency electromagnetic radiation ranges from 30 kilohertz (30 kHz, or 30,000 Hz) to 300 gigahertz (300 GHz, or 300 billion Hz). Electromagnetic fields in the radiofrequency range are utilized for media communications applications, including PDAs, TVs, and radio transmissions.

Momentary Effects: Various examinations have explored the impacts of radiofrequency fields on mind electrical movement, intellectual capacity, rest, pulse, and circulatory strain and so on. In an examination directed on male understudies of National Institute of Technology (NIT), Kerala, India. Migraine, discombobulating, deadness in the thigh, and largeness in the chest were accounted for among successive cell phone clients. The examination revealed an expansion in pulse changeability when the cell phone is held near the chest and a decline when held near the head. Nonetheless, these perceptions were not discovered any progressively noteworthy in contrast with conditions without versatile phone[6]. To date looks into haven't proposed any steady proof of unfriendly wellbeing impacts from introduction to radiofrequency fields aside from the tissue warming impact. Further, looks into haven't had the option to offer help for a circumstances and logical results connection between presentation to electromagnetic fields and any self reported symptoms such as electromagnetic touchiness among versatile users[7].

Long Haul Effects: Epidemiological inquires about analyzing potential long term risks from radiofrequency introduction have for the most part searched for an association between cerebrum tumors and cell phone use. In any case, the same number of malignancies stays imperceptible until numerous years after the communications that prompted the tumor, and in light of the fact that cell phones were not broadly utilized until the mid 1990s; epidemiological investigations were confined distinctly to those diseases that become clear inside shorter time spans. Consequences of creature studies have reliably demonstrated no critical increment in the disease chance because of long haul presentation to radiofrequency fields[8]. Few examinations have attempted to search for any other possiblelong term wellbeing impacts of introduction to portable radiation. In an investigation led in Amritsar, Punjab, India, a relationship between's cell phone use (introduction to radio recurrence radiations) and DNA and chromosomal harm in lymphocytes of cell phones clients was watched. Such harms can have long term results regarding expanded danger of neoplasia or other age related changes. Indian test creature studies directed on rodents have furthermore demonstrated that cell phone radiations may influence cerebrum work and can make a few neurological issue and unending introduction no ionizing microwave (MW) radiation can prompt fruitlessness by means of free radical/oxidative species mediated pathway[9,10].

In an investigation led on occupants living close cell phone towers, higher hazard for creating neuropsychiatric issues and a few changes in neurobehavioral capacities was watched, hence, upholding alert in such regard[11].

Findings:

Malignancy in Humans: Since mobile phones typically are held close to the head when being utilized, the fundamental concern has been whether they may cause or add to tumors around there, including[12].

- Malignant (malignant) mind tumors, for example, gliomas
- Non-malignant tumors of the mind, for example, meningiomas
- Non-malignant tumors of the nerve interfacing the mind to the ear (vestibular schwannomas, otherwise called acoustic neuronal)
- Non-malignant tumors of the salivary organs.

The Interphone Study is the greatest of all the investigation discoveries into mobile phone radiation and the wellbeing of cell phones for people. At an expense of 25 million dollars, this is the biggest investigation of PDA use and tumor hazard led to date. It found that "standard utilization of a wireless by grown-ups can altogether expand the danger of gliomas by 40% with 1640 hours or a greater amount of utilization"[13.]

Broad proof audits have been directed to comprehend conceivable cancer-causing dangers presented by versatile radiation in the previous decade. In a metaanalysis of concentrates on intracranial tumors and cell phone use which was distributed before the finish of 2012, high heterogeneity was recognized acrosson individuals withestimation of glioma and acoustic neuronal hazard in long term utilization of cell phone because of methodological contrasts installed in the variable investigation gatherings. By and large, the outcomes from the speculation are that cell phone use influences the event of intracranial tumors[14].

The largest review case control ponder INTERPHONE, directed by a consortium of scientists from 14 nations and composed by the International Agency for Research on Cancer (IARC), demonstrated no measurably critical increment in mind or focal sensory system malignant growths identified with higher measures of cell phone use[15]. However, the workgroup didn't disregard the restricted proof in people for the cancer-causing nature of radiofrequency radiation as constructive affiliations. The investigation gathering watched an association between introduction to radiofrequency radiation from remote telephones and glioma and acoustic neuroma[16].

The Handel group directed two case controls contemplates on mind tumors during 1997–2003 with cases being accounted for from the Swedish Cancer Registries. Steady example of the expanded danger of glioma and acoustic neuroma related was seen with utilization of cell phones and cordless telephones. Steady proof originated from anatomical limitation of the tumor to the most uncovered territory of the mind, amount of introduction, and inactivity time that all add to the organic pertinence of an expanded hazard. In light of on information which suggests expanded hazard for glioma, a threatening sort of mind cancer. The IARC in May 2011 ordered radiofrequency electromagnetic fields as conceivably cancer-causing to humans[17].

Notwithstanding cerebrum malignant growth, these examinations connect mobile phone radiation presentation to numerous different sorts of disease, including[18, 19] .

- Cancer of the Pituitary Gland
- Thyroid Cancer
- Melanoma Risk
- Stem Cell Cancer
- Parotid Malignant Tumors
- Leukemia
- Lymph Node Cancer
- Multifocal Breast Cancer
- Eye Cancer

Discussion

Suggestions by Expert Agencies: WHO expresses that "countless investigations have been performed in the course of the most recent two decades to survey whether cell phones represent a potential wellbeing hazard. Until this point in time, no unfriendly wellbeing impacts have been built up as being brought about by cell phone use. WHO will lead a formal hazard appraisal of all considered wellbeing results from radiofrequency field's introduction by 2016" [22].

Indian Council of Medical Research (ICMR) states

that "In various investigations it has been accounted for that introduction to radiation from cell phones can cause unfavorable wellbeing impacts. Yet, there is no decisive information accessible so far on this issue, in any case, the developing group of logical confirmations demonstrates some bioeffects and conceivable antagonistic wellbeing impacts of Radio Frequency Radiation (RFR) which require further investigations"[23].

The American Cancer Society (ACS) expresses that "The IARC order implies that there could be some hazard related with malignant growth, yet the proof isn't sufficiently able to be viewed as causal and should be researched further. People who are worried about radiofrequency introduction can restrict their presentation, including utilizing an ear piece and constraining cell phone use, especially among children"[24, 25].

Proposals on Mobile Use: In the current circumstance, we can't be totally certain about the long term impacts of versatile radiation introduction. Moreover, there have not been sufficient investigations to take a gander at how the utilization cell phones could influence the wellbeing of kids. In the present situation, preventive methodology remains the best alternative to cell phones clients, who could be prescribed to limit their presentation by keeping their calls short. Individuals ought to guarantee that their cell phone has low explicit ingestion rate (SAR) of radio recurrence and kids, immature, and pregnant ladies playing it safe. Cell phones ought to be avoided the body (head) by utilizing content informing, or utilizing a "hands free" gadgets bringing presentation down to radiofrequency fields and, consequently, better protection[26].

Conclusion

Generally speaking assessments demonstrate that the present proof for a causal relationship among malignancy and presentation to portable radiation is weak and not totally persuading. A portion of the examinations building up affiliation had constraints and shortcomings and, stay inconsistent. Studies have featured that utilizing these telephones for around 10 years isn't probably going to cause malignant growth. Yet, as cell phones are as yet another innovation and there is a little proof about impacts of longer term use. Anticipation is the best methodology. Individuals are exceedingly concerned with respect to conceivable wellbeing impacts of cell phones, particularly on the grounds that they are broadly utilized and conveyed for longer lengths by the clients. There is a pressing need of advancing further research and better innovative mediations in field of portable innovation for guaranteeing wellbeing and security of endorsers around the world.

Prevalence of Gastroesophageal Reflux Disease and Gastritis in Chennai and Kanchipuram District

Swetha A.[1], Anantha Eashwar V.M.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: To think about the commonness GERD and Gastritis among Kanchipuram and Tamil Nadu locale and to bring mindfulness among the populace the causes and forestall the sickness.

Point and Objectives: To explore the pervasiveness of gastritis and GERD among fiery sustenance and caffeine consumption people and to bring mindfulness among people about the way of life changes in GERD and gastritis.

Materials and Method: This graphic arbitrary examining strategy was completed among 100 people among Chennai and Kanchipuram locale between age gatherings of 15-45 years. The information was gathered utilizing a semi organized questionnaire was gathered through online in web.

Conclusion: The commonness of GERD and gastritis of the examination populace was observed to be low. Awareness of the malady and the avoidance must be made to diminish the frequency of the ailment.

Keywords: *Gastroesophageal Reflux, GERD, Gastritis, Esophagus.*

Introduction

GERD and gastritis is the regular gastrointestinal issues in western nations and Asia and now it is getting to be normal issue in eastern nations too. This is because of expanding current way of life with expanded fast-food admission, smoking and liquor consumption and so on. This causes antagonistic impacts like spewing forth of nourishment and acid reflux and henceforth this examination is imperative to know the predominance among people and bring mindfulness among them. Reflux infection is considered as a typical reason for alluding patients to restorative care[1]. Risk factors for reflux esophagi is incorporate the nearness of hiatal hernia, transient unwinding of the lower esophageal sphincter, and debilitated freedom of disgorged gastric substance in the esophagus[2]. Despite these actualities, the basic component of reflux illness has not been totally defined[3,4]. It was proposed that Helicobacter pylori (H. pylori) could be a causative factor for some gastrointestinal illnesses, for example, gastritis. In any case, the connection between H. pylori contamination and gastro esophageal reflux illness (GERD) is as yet disputable.

During the most recent decades H. pylori treatment was generally controlled to patients with dyspepsia. In this specific situation, examines on patients with non-ulcer dyspepsia demonstrated that H. pylori destruction probably won't have a useful job for patients with reflux disease[5-7]. Even a few analysts recommended that nearness of H. pylori disease may have a defensive job against GERD[8]. Although it isn't affirmed in all studies[9]. Thus the relationship between H. pylori, gastritis, and GERD is considered as a point of enthusiasm for studies. In view of past investigations ceaseless dynamic H. pylori gastritis is related with milder types of reflux illness and annihilation of H. pylori expanded the danger of creating GERD[5, 9]. Moreover there is little data about the example of gastritis in dyspeptic patients with creating GERD. The point of this examination was to decide the

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

relationship between the nearness of GERD and gastritis designs in patients with H. pylori contamination.

Materials and Method

Kind of study: This is a Descriptive cross sectional examination

Study populace: All subjects were between the age group of 15 to 40 years .

Study Area: Urban region of Kancheepuram locale.

Study test: An example of 100 people were taken

Study strategy: Convenient examining technique. Study period: During the long stretch of April 2019.

Incorporation criteria: Individuals between 15 to 40 years and taking an interest willfully in the examination

Avoidance criteria: people beneath 15 or more 40 years and the individuals who did not give educated assent.

Information accumulation: An organized poll was utilized for information accumulation which incorporate all information of zesty sustenance intake, caffeine consumption, information identified with tobacco use and liquor admission and information is gathered with their willful educated assent

Measurable examination: Information section was done in Microsoft exceed expectations and dissected by SPSS adaptation 22.

Findings:

Table 1: Sociodemographic details of the study population

Demographic Variables	Groups	Percentage
Age in years	<20	52%
	20-30	46%
	30-40	2%
	>40	0%
Sex	Male	30%
	Female	70%
Do you consume alcohol	Yes	10%
	No	90%
Do you consume tobacco in any form	Yes	5%
	No	95%

Among the study participants, most of them (52%) were below the age group of 20 years and 70% were males. Most of them did not consume tobacco and alcohol. [Table 1].

Table 2: Dietary habits of study population

Dietary Habits	Groups	Percentage
Do you drink coffee	Yes	75%
	No	25%
If yes,how many glasses per day	1-2	70%
	>2	5%
How many times do you eat per day	<3	20%
	3	75%
	>3	5%
Do you skip meals	Yes	45%
	No	55%
If yes, which one do you skip (n = 45)	Breakfast	35%
	Lunch	8%
	dinner	2%
Do you eat spicy food very often?	Yes	60%
	No	40%
Do you eat in fast food restaurants?	Yes	80%
	No	20%
If yes,how often do you eat fastfood? (n = 80)	Daily	5%
	Weekly	45%
	Monthly	15%
	Very rarely	15%
Some interested food you prefer	Fast food	38%
	Packeted chips	15%
	Carbonated drinks	12%
	Chat items	35%

Table 2 shows the dietary habits followed by the study participants. Around 75% of them drank coffee, 45% of them had a practice of skipping meals, 35% skipped breakfast. Regarding consumption of spicy food, 60% consumed those and 80% had a habit of eating in fast food establishments with 45% of them having a weekly habit of going too fast food restaurants. Most of the study participants preferred to eat in fast food and consume chat items.

Table 3: Symptoms related to gastritis and GERD among population

Symptoms	Groups	Percentage
When do you go to bed after eating	Immediately After few minutes After few hours	0% 30% 70%
Do you get regurgitation of food	Yes No	13% 87%
Do you have pain in epigastrium	Yes No	15% 85%%
If yes,is it relieved or aggravated after eating	Relieved Aggravated	9% 6%
Any change/hoarseness in voice	Yes No	10% 90%
Do you get blood in stools?	Yes No	2% 98%
Are you a diabetic	Yes No	2% 98%
Do you take pain killers too often?	Yes No	5% 95%

Table 3 shows the symptoms experienced by the study participants related to gastritis and GERD. Around 30% of the study participants had a habit of going to bed after few minutes of having food, 13% had symptoms of regurgitation, 15% had pain in epigastrium occasionally and 9% of them had relief of pain after eating. Among the participants, 10% had a change in voice, 2% passed blood in stools and 5% take painkillers often.

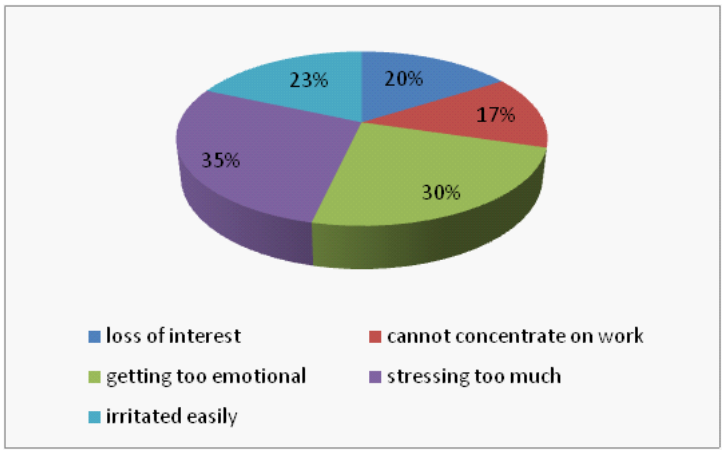

Figure 1: Psychosocial problems among study population

Among the study participants 35% suffered from stress, 30% got emotional too often on petty things, 23% got irritated too easily and 17% had difficulty in concentrating on their work.

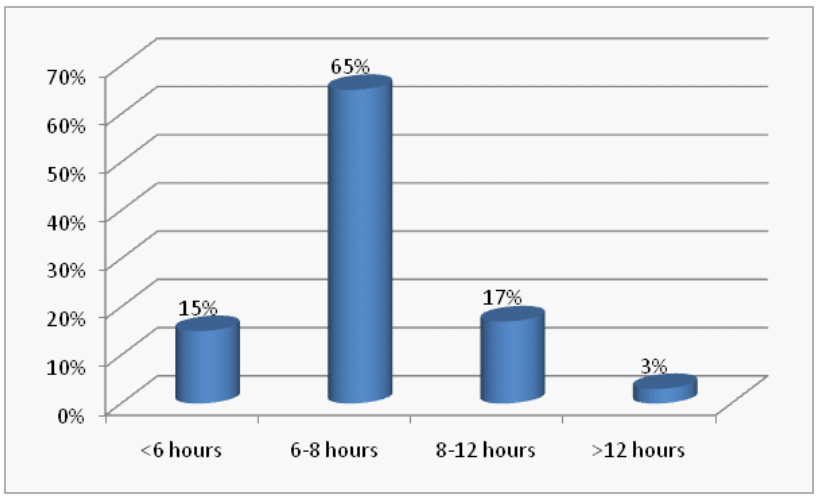

Figure 2: Sleeping pattern of the study population

Among the study participants, 65% of them had night sleep duration of 6-8 hours, 17% slept for 8-12 hours and 15% of them slept for less than 6 hours.

Discussion

In the present investigation, we found that the commonness of H. pylori among patients with reflux infection and GERD were 74.4% and 75.3%, individually. Additionally we demonstrated that the seriousness of antral gastritis was related with reflux disease. H. pylori could add to numerous gastrointestinal infections including GERD. The job of H. pylori in creating GERD still remains a disputable issue[9, 10]. Based on past reports, the rate of H. pyloriinfectionin patients with GERD, fiercely fluctuates from 30-90% and it appears that about 40% of patients with GERD are tainted by this bacterium[5, 11]. Furthermore, most preliminaries on the relationship between's H. pylori infection and GERD have demonstrated no causal relationship Acid contact to throat mucosa is considered as the fundamental driver of esophagitis[2, 5, 12]. H. pylori itself produces corrosive inhibitory proteins, while the disease instigates restraint of corrosive emission.

In certain patients H. pylori is basically colonized in the antrum, bringing about an antral transcendent gastritis, which thusly incites gastrin and corrosive discharge. In the remainder of patients H. pylori disease spreads from the antrum towards different pieces of the stomach[5, 13]. When the corpus (as the fundamental corrosive creating area) is tainted, the emission of corrosive is influenced by aggravation procedure and diminishes. In this perspective on point the annihilation of H. pylori may build corrosive emission and thusly actuate esophagitis as uncovered by past reports.

Conclusion

The predominance of GERD and gastritis of the examination populace was observed to be low. Awareness of the infection and the counteractive action must be made to diminish the rate of the illness. As indicated by the investigation we have discovered that in excess of 50 percent of populace eat fiery sustenance and inexpensive food and henceforth mindfulness must be spread about the irritating elements and avert the infection.

Abstract

Lead is a substantial metal. It is utilized in lead-corrosive battery, as a shading specialist, paints, and metal alloyed as protecting materials, smelters, printing press, etc. It is a lethal metal influencing different organs, and creating hatchling and youthful youngsters are progressively helpless against harmfulness of lead. This outline depends on the data of poisonous capability of lead to human multiplication and conceptive result. Introduction to lead may influence drive, semen quality by declining sperm tally, motility, feasibility, honesty, height in morphological variations from the norm, and sperm DNA respectability. These adjustments prompted decreasing fruitfulness potential and odds of unsuccessful labors, preterm birth, etc in an accomplice. Lead introduction impedes hormonal combination and guidelines in both genders. Lead introduction additionally influences female proliferation by impeding monthly cycles, decreasing ripeness potential, deferring origination time, modifying the hormonal generation, dissemination, influencing pregnancy and its result, etc.

Keywords: *Follicle-animating hormone, lead, moxie, luteinizing hormone, pregnancy result, semen quality, sperm DNA honesty, testosterone.*

Introduction

Lead is a normally happening component found in earth peak and is generally joined with different components. Lead is a substantial metal and dangerous to human and creature wellbeing. Lead harming happens in people when they are presented to higher dosages of lead or its ceaseless introduction which once in a while winds up lethal when lead develops in the body step by step through nonstop constant exposures to little amounts of lead through various sources. It influences practically every one of the organs of the human body and furthermore causes physical and mental hindrances. Youngsters are progressively helpless against introduction to lead when contrasted and same greatness of dosages of lead presentation in grown-up as their sensory systems are as yet creating. Lead still remains a critical ecological, word related, and general medical issue internationally. As of late, the World Health Organization (WHO) (2017) cited the information of Institute for Health Metrics and Evaluation that lead presentation represented 494,550 passing's and loss of 9.3 million inabilities balanced life years because of long haul impacts on wellbeing. They additionally evaluated that lead presentation represented 12.4% of the worldwide weight of idiopathic formative scholarly handicap, 2.5% ischemic coronary illness, and 2.4% of stroke[1]. Adequate quantities of distributed reports are accessible on lead and human generation alongside controlled test examines regarding lead conceptive lethality. Agarwal detailed that overwhelming metals, for example, lead, mercury, cadmium, arsenic, and chromium may cause birth abandons. Despite the fact that the mother might be unaffected or unconscious to such low-level introduction, their off springs may be influenced unfavorably with presentation to such specialists in utero[2]. Winder referenced that from the view purpose of human propagation, lead is known to cause various unfriendly conceptive results in

Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

the two people. Revealed impacts of lead in men incorporate decreased charisma, consequences for spermatogenesis (diminished motility and numbers, expanded irregular morphology), chromosomal harm, barrenness, anomalous prostatic capacity, changes in serum testosterone, and impacts in ladies which include fruitlessness, unnatural birth cycle, early layer break, preeclampsia, pregnancy hypertension, and furthermore preterm birth[3].

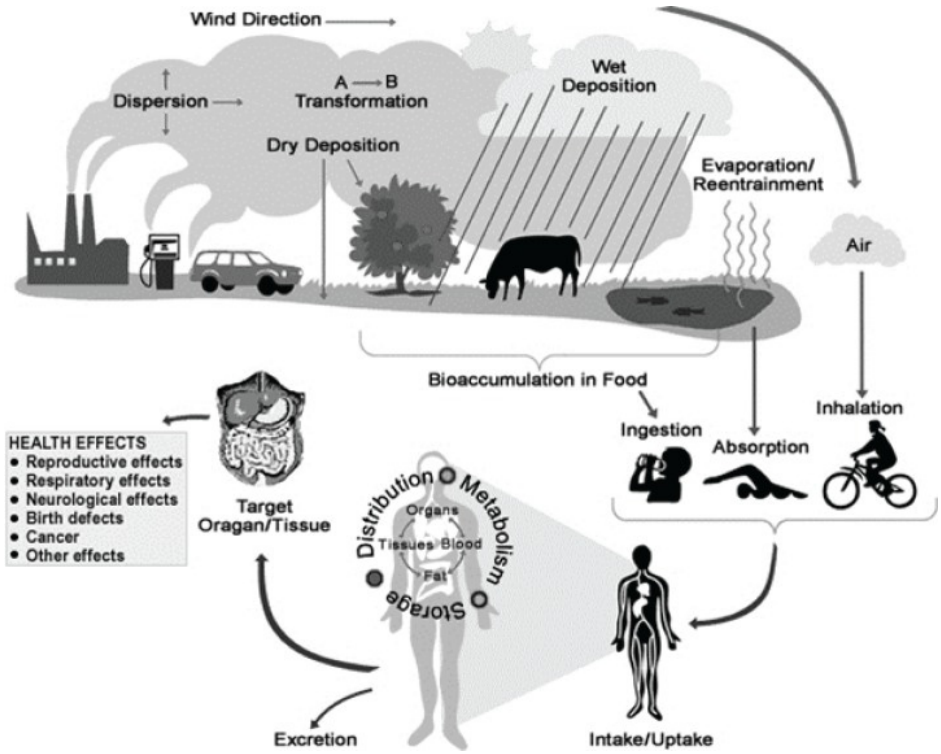

Figure 1: Illustration how people are exposed to chemicals in the environment and the effect of such chemicals on human health

Occupational Expose: Word related presentation is a noteworthy hotspot for lead harming in grown-ups. As per evaluations made by the National Institute of Occupational Safety and Health (NIOSH), in excess of 3 million laborers in the United States are possibly presented to lead in the work environment (Staudinger and Roth, 1998). Word related presentation as the significant concern and furthermore the primary driver of lead harming was accounted for by Needleman (2004). The basic working offices that include lead containing items are radiation shields, ammo, and certain careful gear, creating dental X-beam films before computerized X-beams, fetal screens, plumbing, circuit sheets, stream motors, and fired coatings. All these expansion the odds of danger with expanding presentation. Moreover, numerous other word related laborers like lead excavators and smelters, handymen and fitters, vehicle mechanicals, glass makers, development specialists, battery producers and recyclers, terminating range teachers, and plastic makers are in danger for lead presentation.

Lead is a typical natural contamination. Presentation to lead happens for the most part at word related destinations, creation of lead-corrosive batteries or funnels, metal reusing and foundries. Kids living close such places are additionally in danger of raised blood lead levels. In August of 2009, 2000 kids living close zinc and manganese smelters were observed to be harmed with lead, an occurrence which brought about uproars. Other basic things which cause lead introduction are lead noticeable all around, family unit dust, soil, water, and business items.

Signs and manifestations: Lead harming causes an assortment of manifestations, including unusual conduct which changes from individual to individual, while time of presentation assumes a significant job. There

are additionally thinks about which demonstrate no side effects of lead harming even with raised degrees of lead in the body. The inquiry what makes such contrasts in the human body is an issue of real concern. For what reason are there such contrasts in achieving harmfulness of lead or other lethal substance? Why for one gathering of individuals any expansion in the fixation gives poisonous quality and for another a similar level has no impact. As of now there is no proof from the writing about such contrasts, anyway it is trusted that future research could investigate this region and make sense of the potential reasons.

Materials and Method

The writing on introduction to lead and human male and female propagation just as on pregnancy, fetal advancement, and its result were gathered through looking through different sites, for example, Google, Pub Med, and TOXNET and furthermore counseling different books and diaries identified with word related, natural, and regenerative wellbeing. The article is isolated into various areas dependent on male and female concerning word related and natural introduction to lead. Information are condensed and delineated in [Table 1], [Table 2].

Table 1: Word related and natural introduction to lead and human male multiplication

Exposure to lead	Observed effects	References
Exposure to inorganic lead >40 µg/dL of blood	Reduced sperm count, volume, density, changing sperm motility, and morphology	Apostoli *et al.* (1998)
Reproductive endocrine function in healthy male industrial workers	Moderate exposure to Pb (BPb <400 µg/L) and Cd (BCd <10 µg/L) reduces semen quality without conclusive evidence of impairment of male reproductive endocrine function	Telisman *et al.* (2000)
Reproductive effects were observed at low-level Pb environmental exposure (BPb median 49 µg/L, range 11-149 µg/L)	A significant association of BPb, delta-aminolevulinic acid dehydratase, and/or erythrocyte protoporphyrin with reproductive parameters indicated a lead-related elevation in immature, pathologic, wide, round, and short sperm, serum testosterone and estradiol level, and a decline in seminal plasma zinc and serum prolactin	Telisman *et al.* (2007)
BLL ≥20 µg/dL and subjects with BLL <20 µg/dL	A nonsignificant reduction in count, motility, higher impaired sperm morphology with BLL ≥20 µg/dL compared with <20 µg/dL subjects; chromatin condensation negatively correlated with BLL	Awadalla *et al.* (2011)
Semen quality and endocrinal function in infertile painter	A significant negative correlation between BPb and sperm count, motility, whereas no significant correlation between BPb and endocrinal parameters PbB ≥20 µg/dL showed a significant decrease in sperm motility, increase in testosterone level	Hosni *et al.* (2013)
Seminal Pb and Cd at environmental level and semen quality	A negative association between seminal Pb or Cd and sperm concentration, motility, and % abnormal morphology; exposure to Pb (5.29-7.25 µg/dL) and Cd (4.07-5.92 µg/dL) might affect semen quality	Pant *et al.* (2015)
Accumulation of lead	Affects hypothalamic-pituitary axis causing blunted TSH, GH, and FSH/LH responses to TRH, GHRH, and GnRH stimulation, respectively; higher levels of PRL in Pb intoxication In short-term Pb exposure, higher LH and FSH associated with normal testosterone, whereas long-term exposure low testosterone levels do not induce high LH and FSH	Doumoucht-sis *et al.* (2009)
Lead-exposed male workers and serum sex hormone	Testosterone lower, whereas inhibin B significantly higher; Pb exposure alters male sexual hormone, which might harm endocrine function and Sertoli cells	Yu *et al.* (2010)
Role of Pb and Cd on sex hormones and molecules of steroid biosynthesis pathway	After adjustment for age, race, BMI, smoking, diabetes, and alcohol, BPb was positively associated with testosterone and SHBG, whereas BCd positively associated with SHBG	Kresovich *et al.* (2015)

BLL: Blood lead level; TSH: Thyroid-stimulating hormone; GH: Growth hormone; FSH: Follicle-stimulating hormone; LH: Luteinizing hormone; TRH: Thyrotropin-releasing hormone; GnRH: Gonadotropin-releasing hormone; BMI: Body mass index; SHBG: Sex-hormone binding globulin; PRL: Prolactin

Table 2: Occupational and environmental exposure to lead and human female reproduction

Exposure to lead	Observed effects	References
Low-level cumulative lead exposure	An association found between low-level cumulative Pb exposure and an earlier age at menopause may contribute to menopause-related health outcomes in older women	Eum *et al.* (2014)
Female workers of lead battery plants	Incidence of poly-menorrhea, prolonged and abnormal menstruations, hypermenorrhea; spontaneous abortion noticed in few workers; poor working conditions and workload may also be additional factors	Tang and Zhu (2003)
Geometric mean of Cd, Pb, and Hg levels was 0.29 (0.19-0.43) µg/L, 0.93 (0.68-1.20) µg/dL, and 1.03 (0.58-2.10) µg/L, respectively	Decreases in FSH with increasing Cd and elevation in progesterone with increasing Pb level; environmentally relevant levels of metals are associated with modest changes in reproductive hormone levels in premenopausal women	Pollack *et al.* (2011)
BPb levels and serum FSH and LH in 35- to 60-year-old women; BPb levels of women ranged from 0.2 to 17.0 µg/dL	As BPb increased, the concentration of serum FSH increased in postmenopausal women, women with both ovaries removed, and premenopausal women; LH increased as BPb level increased in postmenopausal women and women with both ovaries removed; lowest concentrations of BPb at which a relationship detected were 0.9 µg/dL for FSH and 3.2 µg/dL for LH	Krieg Jr and Feng (2011)
Low level of Pb	BPb in infertile women was significantly higher than controls (3.55 vs. 2.78 µg/dL); compared with women with BLL ≤2.5 µg/dL, and BLL >2.5 µg/dL associated with a threefold increased risk for infertility	Chang *et al.* (2006)
Effect of Pb and Cd on hormone production throughout sensitive developmental period	High Pb (≥5 µg/dL) inversely associated with inhibin B >35 pg/mL (odds ratio=0.26 compared with Pb <1 µg/dL); at 10 and 11 years, girls with low Pb (<1 µg/dL) had significantly higher inhibin B than girls with moderate (1-4.99 µg/dL) or high Pb (≥5 µg/dL); inhibin B levels lower among girls with both high Pb and high Cd than with high Pb, relative to girls with low Pb and low Cd	Gollenberg *et al.* (2010)

BLL: Blood lead level; FSH: Follicle-stimulating hormone; LH: Luteinizing hormone

Findings: There are a few reports on introduction to lead and disintegration of human conceptive wellbeing, and unfavorable impact on pregnancy and its result are accessible since long and endeavors are in progress to decrease/confine/stop human presentation to lead by different partners everywhere throughout the world. These reports showed that lead can instigate barrenness and hormonal awkwardness in the genders, decrease moxie, influence spermatogenesis and interruption in ovarian cycle in ladies, influence fertility and unfavorable pregnancy result, etc. Be that as it may, people are presented to lead as well as presented to a few different toxicants during their everyday exercises. In this manner, it is hard to pinpoint a solitary operator/ factor in charge of unfriendly regenerative impacts. These variables at some point may act synergistically to deliver such unfavorable impacts or even a few factors, for example, diet may likewise effect on unfriendly impacts. Be that as it may, the positive finding of these toxicants supports taking up preventive measures to stop introduction to such conceptive toxicants.

Male Propagation and Lead Presentation: People are presented to various toxicants including overwhelming metal lead during their occupations and through condition. Toxic substances in work environment may likewise add to barrenness among specialists. There are a few reports which demonstrated that lead effectsly affects human male propagation by declining charisma, spermatogenesis, semen quality, hormonal generation and guideline, etc. A mix of hereditary, have, natural, word related, and way of life elements adds to unfavorable consequences for the conceptive strength of men. A large portion of the examinations have commonly affirmed that even moderate-to low-level introduction to lead influences certain regenerative parameters[8]. Various prior reports proposed that word related presentation to lead influences the semen quality at a degree of >40 µg/dL in blood of uncovered individual. As ahead of schedule as 1975, Lancranjan et al. announced that raised degrees of Pb were related with diminished moxie and an expansion in semen variations from the norm in laborers presented to lead in workplace[9]. Earlier, Apostolic et al. revealed that introduction to inorganic lead >40 µg/dL in blood disabled male conceptive capacity by decreasing sperm tally, volume, and thickness, or changing sperm motility and morphology[10]. Alexander et al. additionally found a decrease in absolute sperm tally with expanding blood lead level (BLL), and semen Pb fixation was conversely connected with complete sperm check, discharge volume, and serum testosterone, yet not to sperm concentration[11]. Later, Telisman et al. researched blood lead (BPb), action of delta-aminolevulinic corrosive dehydratase (ALAD), erythrocyte protoporphyrin (EP), blood cadmium (BCd), serum zinc (SZn), fundamental liquid zinc (SfZn), serum copper (SCu), and semen quality and regenerative endocrine capacity in solid mechanical specialists. They found that moderate exposures to Pb (BPb <400 µg/L) and Cd (BCd <10 µg/L) can essentially lessen semen quality without convincing proof of disability of male conceptive endocrine function[12].

Discussion

Various pathways may be associated with lead-initiated weaknesses of male regenerative wellbeing. Vigeh et al. detailed that regenerative impacts of lead are intricate. In spite of the fact that lead can conceivably lessen male ripeness by diminishing sperm quality and influencing useful parameters, not the sum total of what concentrates have had the option to exhibit such discoveries. They additionally referenced that blood-testis obstruction can shield testicular cells from direct introduction to high BLLs. For these and thinking about the wide range of lead lethality on regenerative hormones, they recommended that lead's principle impact on male propagation perhaps happens by changing the conceptive hormonal pivot and hormonal control on spermatogenesis[28]. Furthermore, as of late Gandhi et al. referenced that natural and word related presentation of lead may unfavorably influence hypothalamic–pituitary–testicular hub, debilitating spermatogenesis. Brokenness at the regenerative pivot, specifically testosterone concealment, is most defenseless and irreversible during pubertal improvement.

Female Multiplication and Lead Introduction: Various examinations are likewise accessible on female multiplication and on pregnancy and its result as for lead introduction. Tang and Zhu announced that the occurrence of poly-menorrhea, drawn out and anomalous monthly cycles, and hyper menorrhea was essentially higher in female laborers of lead battery plants than control. The rate of unconstrained premature birth was likewise seen in couple of laborers when contrasted and none in charge. They presumed that word related Pb introduction could prompt impedance of the capacity of conceptive frameworks; in any case, poor working conditions and remaining task at hand may likewise be extra explanations behind such effects[30]. Eum et al. likewise found a relationship between low-level total lead introduction and a previous age at menopause. These information propose that low-level lead introduction may add to menopause-related wellbeing outcomes in more established women[31].

Usage and Perceptions of Anabolic-androgenic Steroids among Male Fitness Centre Attendees in Urban Area of Kancheepuram District in Tamil Nadu

Prudhvi Balaji S.[1], Mohan Kumar P.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Background: Thinking about the ongoing ubiquity of weight training and the clear spread of anabolic androgenic steroid (AAS) use among working out devotees in Kancheepuram locale, there is an overall absence of logical examination concerning the utilization, learning and frames of mind towards AAS among the populace in danger of manhandling it. In this manner, this examination intends to explore the recurrence, learning, dispositions and routine with regards to AAS use among male wellness focus participants in Kancheepuram region in Tamil Nadu.

Strategies: A cross sectional review using a self-directed poll was utilized. Data on socioeconomics just as information and mentality about and towards the utilization of AAS was incorporated into the survey. Ten wellness focuses in Kancheepuram area were arbitrarily chosen and surveys were disseminated to all people leaving each inside on haphazardly chosen days and time frames for each middle. Generally n = 100 surveys were circulated.

Results: An aggregate of n = 80 polls were returned finished. Of the responders, 28.7 % utilized AAS. About 48.8% of responders accept that ideally solid body must be accomplished by utilizing AAS, and greater part of non-AAS clients (67.9%) accept that AAS use would have huge damages to wellbeing. There is blended reaction with respect to the information of symptoms of AAS.

Conclusion: The utilization of AAS is high among male exercise center clients in Kuwait and is probably going to introduce an extra weight to the wellbeing administration. A powerful activity to limit the weight of AAS misuse should concentrate on changing the demeanours towards AAS as opposed to spreading consciousness of their symptoms.

Keywords: *Sports medication, androgenic anabolic steroids, general wellbeing.*

Introduction

Anabolic androgenic steroids (AAS) are engineered subsidiaries of testosterone having articulated anabolic properties and generally powerless androgenic properties. They are utilized clinically for the treatment of conditions portrayed by strangely low generation of testosterone, or muscle squandering. In any case, since the 1950s, AAS have been utilized by expert muscle heads and progressively by youthful grown-ups to improve physical appearance. These non-medicinal employments of AAS are related with noteworthy wellbeing dangers, for example, cardiovascular, hepatic, endocrine, psychosocial and mental issue just as death[1-3].

In the course of the most recent decade various examinations have analyzed the commonness of exercise center clients' utilization of execution upgrading medications, for example, anabolic steroids, clenbuterol

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

and development hormones just as why teenagers utilize these medications. AAS are utilized to improve athletic execution, physical engaging quality, increment body weight, sans fat mass, muscle size, and quality when joined with quality preparing. Various investigations have distinguished hazard factors for AAS use, including negative self-perception, more youthful age, knowing different AAS clients, more noteworthy time spent on weight lifting, more prominent familiarity with the impacts of AAS use, and other illegal medication use.

The most widely recognized discussions against AAS use start with the contentions on symptoms of AAS that dangers young people. A considerable lot of the substances utilized by competitors and youths to upgrade execution convey noteworthy basic dangers, including a danger of death. Also; AAS use has been related with a wide scope of physical and mental inconveniences including atrial fibrillation, skin sores, for example, extreme skin break out and canker at site of infusion, edema, heart palpitations, diminished richness, and sexual brokenness, changes in lipoprotein part, expanded triglyceride levels, expanded convergences of a few thickening variables, changes in the myocardium, for example, expanded left ventricular mass and enlarged cardiomyopathy and hyperinsulinism and reduced glucose resistance . Mental symptoms, for example, hypomania, craziness, or real gloom have likewise been related with AASs. Notwithstanding expanded forcefulness, there have additionally been reports of fierce conduct and there are confirmations recommending an upgraded danger of unnatural demise by ending it all or being the casualty of crime. Moreover, AAS have likewise been connected to the maltreatment of liquor, morphine, and other addictive substances[4, 5].

Avocation of Study: This examination intends to research the recurrence, information, frames of mind and routine with regards to AAS use among male wellness focus participants in urban zone of Kancheepuram area in Tamil Nadu. Also in regards to the learning about the solid nourishment propensity. It likewise centers on the information of symptoms of AAS[6].

Members: This was a cross-sectional study of guys going to wellness focuses in Kancheepuram region. These wellness focuses were haphazardly chosen from the national phone registry. Self-managed polls were then circulated to all people leaving each inside on an arbitrarily chosen day and timeframe which was distinctive for each middle. Generally speaking n = 100 polls were disseminated. A sum of n = 80 were returned finished.

Examining type: cross sectional overview.

Testing size: Reactions from 80 subjects have been gathered.

Testing outline: Testing edge incorporates male wellness focus participants.

Consideration criteria: The individuals who were available and complete noting the survey.

Rejection criteria: The individuals who neither were absent nor did not finish noting the poll[7,8].

Findings:

Utilization and socioeconomics: The age conveyance of the example incorporate 53.7% were matured between 19-25, 18.8% were between 26-34 years, 23.8% were between 14-18 years and 3.7% were over 34 years. People from a wide range of occupation were considered for the examination.

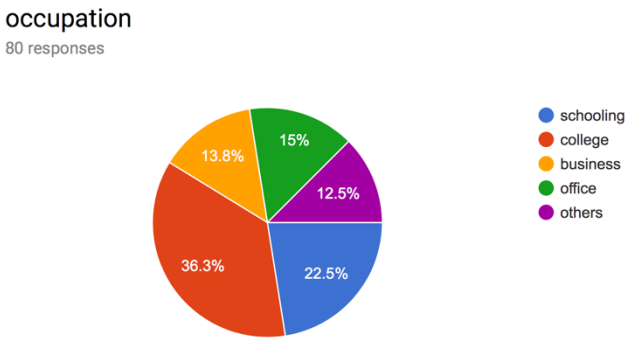

Figure 1: Occupation

The questionnaire dealt with 5 main areas of interest which includes:

i. Demographic

ii. AAS usage

iii. Knowledge and attitude toward AAS

iv. AAS practise habits

v. Healthy lifestyle

The percentage of people who've used AAS in our sample was 28.7% of the responders, 31.3 % with intentions to use, 41.3 % with no intentions to use, and 27.5 % with undetermined intentions.

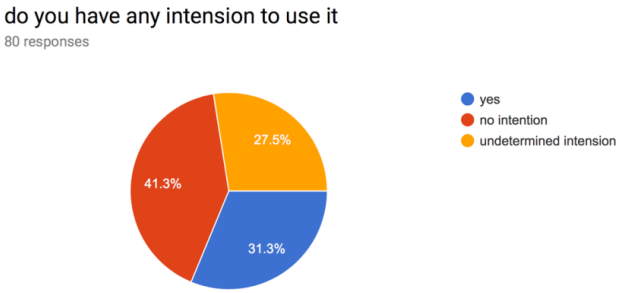

Figure 2: Intention of Users

Attitude to AAS: A high percentage of users and non-users with intentions to use agreed with the statement that having an optimally muscular body can only be achieved by using AAS.

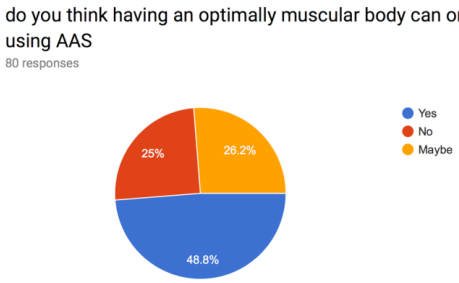

Figure 3: Attitude to AAS

Several reasons for not using AAS were reported. When analysed, being harmful to health was the most important single reason for not using AAS and having not felt the need to use AAS was the second. Amongst non-users only 67.9 % reported that being harmful to health was their primary reason for not using AAS, and 32.1 % reported that it was not their reason at all

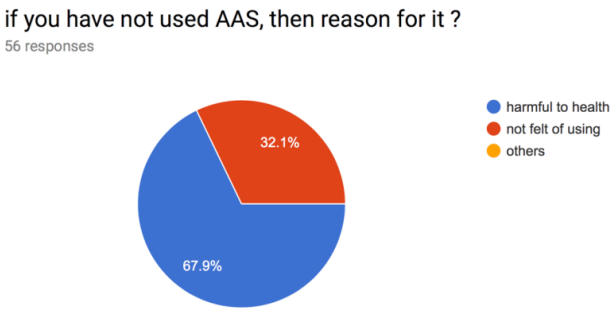

Figure 4: Reason for not using AAS

Practise of AAS use: Injectable forms of AAS were used in high frequency at about 75%, and a combination of oral and injectable AAS was the least common practice whereas oral form of AAS were at about 25%.

The frequency of intake of many (≥3) other ergogenic aids and supplements (e.g. growth hormone, Nitric Oxide-containing supplements, creatine-containing supplements, etc.) was highest amongst AAS users 55% whereas the response for not required is 45%.

Source of AAS: Users obtained AAS from a variety of sources as follows: gym coach (56.6 %), individual supplier (30.4%), (pharmacy or physician (13%).

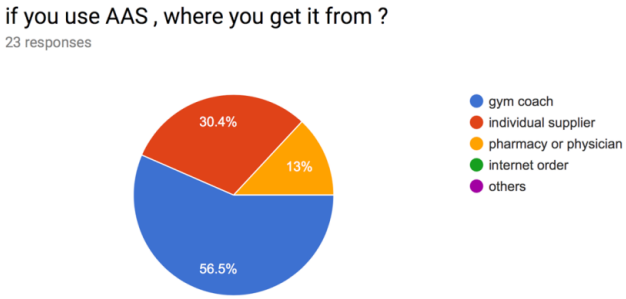

Figure 5: Source of AAS

Healthy lifestyle: About 57.5% responders consume 3 meals a day whereas 42.5%of responders consume more than 3 meals a day. When asked regarding the diet the following responses is been obtained.

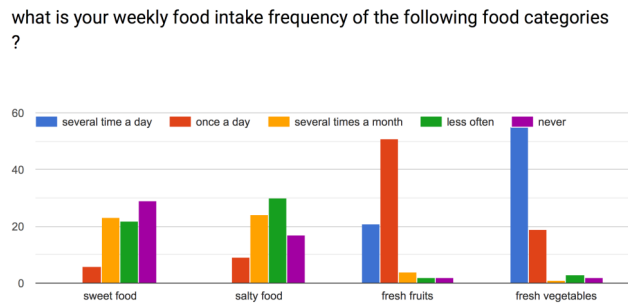

Figure 6: Healthy lifestyle

Discussion

This examination explored the recurrence, information, frames of mind and routine with regards to AAS use in Kancheepuram locale among male wellness focus participants. The recurrence of AAS clients was 23%considering that AAS clients were as taught as non-clients, it doesn't create the impression that the degree of training was a factor in the choice to utilize AAS in this examination. Both the conviction that AAS are critical to ideal solid bulk.AAS clients and non-clients with goals to utilize accepted all the more unequivocally in the advantages of AAS and were less stressed over the dangers related with their utilization. In general, clients saw that the advantages to muscle mass exceeded the dangers of negative symptoms.

It is fascinating that lone 67.9% of non-clients announced that being hurtful to wellbeing was their essential explanation behind not utilizing AAS. The vast majority of non-clients without any aims to utilize AAS have joined the exercise center for reasons other than lifting weights, and the greater part of them detailed they have not wanted to utilize AAS to accomplish their ideal objective in the rec center. This demonstrate the primary reason exercise center individuals did not utilize AAS was that they didn't think or feel they required them, and not as a result of their symptoms. This snippet of data could be pivotal for any exertion toward controlling the spread of AAS misuse. The utilization of AAS was connected with the utilization of other substances; AAS use was obviously connected with an a lot higher recurrence of admission of many (≥3) ergogenic helps and different substances (for example development hormone, Nitric Oxide-containing supplements, creatine-containing supplements, and so on.)[9].

Lacking information about entanglements of AAS was likewise detailed in past investigations. Curiously, non-clients were as much clueless as clients about the reactions of AAS, despite the fact that a fundamentally bigger level of them thought they are hurtful to wellbeing. Supporting the end that spreading mindfulness about the symptoms of AAS may not be the best system for restricting their maltreatment. These outcomes demonstrate that the dispositions towards AAS don't relate with information about their damages, and the demeanors towards AAS are more firmly connected with their utilization than is learning of the potential damages[10].

Conclusion

Anabolic androgenic steroids (AAS) are engineered subsidiaries of testosterone having articulated anabolic properties and generally frail androgenic properties. They are utilized clinically for the treatment of conditions described by unusually low creation of testosterone, or muscle squandering. In any case, since the 1950s, AAS have been utilized by expert muscle heads and progressively by youthful grown-ups to improve physical appearance. These non-therapeutic employments of AAS are related with noteworthy wellbeing dangers, for example, cardiovascular, hepatic, endocrine, psychosocial and mental issue just as death.

The Incidence and Health Burden of Earaches Attributable to Recreational Swimming in Natural Waters: A Prospective Cohort Study (Swimmer's Ear)

Aravind R.[1], Mohan Kumar P.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Otitis externa is thought to influence 10% of individuals at some stage, and can display in intense, unending, or necrotizing frames. Otitis externa might be related with skin inflammation of the ear waterway, and is increasingly normal in swimmers, in moist situations, in individuals with tight ear trenches, in portable amplifier clients, and after mechanical injury. Intense Otitis externa (AOE) is the irritation of external ear and ear channel. Four classifications of otitis externa that incorporate intense limited otitis externa, diffuse otitis externa, chronic otitis externa, and harmful otitis externa.

Incidence of otitis externa is high in Europe and most likely higher in the creating nations. Inclining factors for AOE is swimming and swimming in the dirtied water. Bacterial development and impedance of the skin of the ear trench that allows the advancement of infection. Chronic skin conditions atopic dermatitis, psoriasis or variations from the norm of keratin generation may cause contamination and outside otitis. Frequently related pathogens include, Pseudomonas Aeruginosa, Staphylococcusepidermidis, Staphylococcus Aureus, fungi, and yeast. Treatment of decision utilized are anti-toxin ear drops with or without corticosteroid Fungal or otomycosis require debridement and nearby treatment.

Keywords: *Otitis Externa, outer soundrelated trench, Pathophysiology, Clinical presentation,Treatment.*

Introduction

Otitis externa, outside otitis or swimmer's ear is an irritation of the external ear and ear trench. Alongside otitis media, outer otitis is one of the two human conditions usually called "earache"[1].Infection of the outside sound-related canal(EAC),[1](otitis externa) is like contamination of skin and delicate tissue somewhere else. Disease of the outside ear channel might be sub divided into four categories:(a)acute confined otitis externa (b)diffuse otitis externa(c) interminable otitis externa, and (d) dangerous otitis externa[2-4]. The occurrence of otitis externa is high. In the Netherlands,it has been assessed at 12-14 for every 1000 populace for each year, and has been appeared to influence over 1% of the example populace in the United Kingdom over an a year term[5]. Of the inclining factors for intense otitis externa,only swimming has been appeared to expand the risk[6]. Swimming in contaminated water is a typical method to get swimmer's ear, yet it is additionally conceivable to get swimmer's ear from water caught in the ear waterway after shower, particularly in a muggy climate[7]. Constriction of the ear channel from bone growth(surfer's ear) can trap flotsam and jetsam prompting infection[8] Saturation jumpers have announced otitis externa during word related exposure[9]. Even without presentation to water, the utilization of articles, for example, cotton swabs or other little items to clear the ear trench is sufficient to cause breaks in the skin, and enable the condition to develop[10]. Once the skin of the ear channel is aroused, outer otitis can be definitely improved by either scratching the ear channel with an item, or by enabling water to stay for any delayed length of time[10]. Two factors that are required for outside otitis

Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

to create are (1) the nearness of microorganisms that can taint the ear and (2) hindrances in the respectability of the skin of the ear waterway that enables disease to happen. On the off chance that the skin is sound and unharmed, just presentation to high centralizations of pathogens, for example, submersion in a lake tainted by sewage, is probably going to set off a scene. Be that as it may, if there are ceaseless skin conditions that influence the ear trench skin, for example, atopic dermatitis seborrheic dermatitis, psoriasis or anomalies of keratin creation, or if there has been a break in the skin from injury, even the typical microbes found in the ear channel may cause disease and out and out manifestations of outer otitis[11]. Prophylactic measures, for example, drying the ears with a hair dryer and staying away from control of the outside waterway may help recurrence[12]. Pathogens generally connected with intense otitis externa are Pseudomonas aeruginosa, Staphylococcus epidermidis, Staphyococcusaureus,,and Streptococcus Pyogenes[13]. Organisms and yeast are normally found in patients with unending otitis externa or those are immunocompromised[14]. Current the executives incorporates debridement pursued by dressing and topical treatment with acidifying or antibacterial specialists, with or without corticosteroids[15]. Frequently utilized are anti-infection ear drops with or without steroids. The paper surveys the present writing, pathophysiology, diagnosis, and treatment of otitis externa

Pathophysiology:

Sound-related Canal: The one of a kind structure of sound-related channel adds to the advancement of otitis externa. It is the main skin-lined circular drive in the human body. The outer sound-related channel is warm, dull and inclined to end up sodden, making it a magnificent situation for bacterial and parasitic growth. The skin is dainty and the sidelong third overlies ligament, while the rest has a base of bone. The waterway is effectively traumatized. The exit of trash, emissions and outside bodies is actuated by a bend at the intersection of the ligament and bone. The nearness of hair, particularly the thicker hair basic in more seasoned men, can be a further impediment. The outer sound-related has some unique protections. Cerumen makes an acidic coat containing lysozymes and different substances that likely hinder bacterial and parasitic development. The lipid-rich cerumen is hydrophobic and keeps water from infiltrating to the skin and causing maceration too little cerumen can incline the ear to contamination, yet cerumen that is over the top or too gooey can prompt obstacle, maintenance of water and flotsam and jetsam, and infection Additionally, the trench is guarded by one of a kind epithelial movement that happens from the tympanic layer outward, conveying and garbage[16,17]. When these protections come up short or when the epithelium of the outer sound-related channel is harmed, otitis externa results. There are numerous precipitants of this contamination however the most widely recognized is unnecessary dampness that raises the pH and expels the cerumen. Once the defensive cerumen is evacuated, keratin garbage assimilates the water, which creates a nourishing medium for bacterial growth[12]. The outside sound-related channel is roughly 2.5 cm long from the concha of the auricle to the Tympanic layer. The horizontal portion of the trench is cartilaginous; the average; half passages through the transient bone. Choking, theism thus, present at the intersection of the rigid and cartilaginous bits, restrains the passage of wax and remote bodies to the tympanic layer. The skin of the channel is thicker in the cartilaginous segment and incorporates a well-created dermis and subcutaneous layer. The skin coating of the rigid part is more slender and solidly joined to the periosteum and does not have a subcutaneous layer. Hair follicles are various in the external third space in the inward 66% of waterway[18]. The microbial vegetation of the outside trench are like the greenery of skin somewhere else. There is transcendence of Staphylococcus epidermidis, Staphylococcus Aureus, Corynebacterium and, to lesser degree anaerobic microbes, for example, Propina Bacterium Acnes. Pathogens in charge of contamination of the center ear (Streptococcus pneumonia, Haemophilus Influenzaeand Moraxella catarrhalis) are extraordinarily found in the way of life of the outside sound-related channel when the tympanic film is intact[19, 20].

Clinical Presentation and Management: Intense limited otitis media externa may happen as pustule or furuncle related with hair follicles; the outer ear channel is erythematous, edematous and might be loaded up with discharge and chips of skin trash. Staphylococcus Aureus is the most incessant pathogen. Erysipelas caused a gathering A Streptococcus may include the concha and the canal. Pain might be severe. Bluish-red hemorrhagic bullae might be available on the rigid trench dividers and furthermore on the tympanic layer. Adenopathy in the lymphatic waste zones is frequently present. Neighborhood and fundamental are normally healing. Entry point might be important to ease serious agony[18]. Intense diffuse otitis externa (swimmer's ear) happens for the most part in sweltering muggy climate. The ear tingles and turns out to be progressively painful.

The skin of waterway edematous and red. Gram-negative bacilli, basically P. pseudomonas may assume a critical job. A serious discharge outer otitis brought about by P.pseudomonas was related with portable redwood hot tub frameworks[26]. Gentle purifying to expel flotsam and jetsam, incorporating water system with hypertonic saline (3%) and purging with blend of liquor (70% to 95%) and acidic corrosive ought to be utilized initially. Hydrophilic arrangements, for example, half Burow's answer might be utilized for 1 to 2 days to diminish irritation .A cotton wick might be of an incentive in upgrading dispersion of the ototopical operator when trench is swollen. A ten-day routine of fluoroquinolone otic arrangement, for example, ofloxacin or ciprofloxacine-dexamethasone otic or ear drops of neomycin alone or with polymyxin joined with hydrocortisone are successful in decreasing neighborhood irritation and infection[27, 28].

Incessant otitis externa is brought about by aggravation from waste through a punctured tympanic film. The fundamental reason is endless suppurative otitis media. Tingling might be extreme. The board is coordinated to center ear issue. Uncommon reasons for interminable otitis externa incorporate tuberculosis, syphilis, yaws, uncleanliness, and sarcoidosis[18]. Intrusive threatening otitis externa is an extreme necrotizing contamination that spreads from the squamous epithelium of the ear channel to nearby regions of delicate tissue, veins, ligament and bone[4,29].

Treatment: Powerful answers for ear waterway incorporate acidifying and drying specialists, utilized either separately or in blend. At the point when the ear trench skin is aroused from the intense otitis externa, the utilization of weaken acidic corrosive might be difficult. Burow's answer is an extremely viable cure against both bacterial and parasitic outer otitis. This is a cushioned blend of aluminum sulfate and acidic corrosive, and is accessible without medicine in the United States .Topical arrangements or suspensions as ear drops are the backbones of treatment for outside otitis. Some contains anti-infection agents, either antibacterial or antifungal, and others are basically intended to gently ferment the ear channel condition to dishearten bacterial development. Some solution drops additionally contain mitigating steroids, which help to determine swelling and itching. Although there is proof that steroids are powerful at diminishing the length of treatment time required, fungal otitis externa (likewise called otomycosis) might be caused or disturbed by excessively delayed utilization of steroid containing drops .Oral anti-microbials ought not be utilized to treat uncomplicated intense otitis externa .Oral anti-infection agents are not an adequate reaction to microscopic organisms which cause this condition and have a huge symptoms including expanded danger of artful infection. In differentiate; topical items can treat this condition.

In contagious or otomycosis otitis externa, purging of the ear channel by suctioning is head treatment. Acidifying drops, offered three to multiple times day by day for five to seven days are typically sufficient to finish treatment[12]. Because the contamination can endure asymptomatically, the patient ought to be assessed toward the finish of the course of the treatment. As of now any further purging can be executed as required. On the off chance that the contamination isn't settling over-the counter clotrimazole 1 percent arrangement (Lotrimin), which likewise has some antibacterial movement can be utilized. In vitro examinations demonstrate that topical arrangements of thimerosal (Merthiolate) and M-cresyl acetate(Cresylate) are increasingly powerful specialists yet are messier. If the tympanic film is punctured, tolnaftate 1 percent solution(Tinactin) ought to be utilized so as to counteract ototoxicity. All of these topical operators topically utilized at a dose of three or four drops day by day for seven days. Aspergillus contaminations might be impervious to clotrimazole and may require the utilization of oral itraconazole (Sporanox).

Prevention: Counteractive action of repeat of otitis externa essentially comprises of staying away from the numerous precipitants and dermatologic issue. This especially significant for patients with surprisingly gooey cerumen, a limited outside sound-related channel or fundamental allergies[17].After washing or swimming, the outer sound-related waterway ought to be dried utilizing a hair dryer on the most minimal warmth setting. Acidifying drops would then be able to be ingrained .Some creators prescribe consolidating acidifying specialist with liquor drops (Swim Ear) to go about as an astringent, yet numerous doctors feel this excessively bothering and favor utilizing Burow's answer as the astringent (Star-0tic).0bviously and control of the skin of the outer sound-related canal(such as scratching or enthusiastic purging) ought to be kept away from. Whenever the outside sound-related waterway is cleaned and cerumen is evacuated, the trench turns out to be progressively powerless against disease. In this manner, if there has been any injury and syringing has left the outer sound-related channel wet, utilization of

an acidifying operator with hydrocortisone is a decent prophylactic measure .If the cerumen is hard to expel, ceruminolytic specialist such as Cerumenex or even a straightforward 4 percent heating soft drink arrangement ought to be utilized in the workplace to mellow the cerumen first to abstain from damaging the outside sound-related canal. Persons who swim every now and again should utilize an obstruction to shield their ears from water. In any case, impermeable ear attachments go about as a neighborhood aggravation and have been appeared to incline the ear channel to otitis externa. A tight-fitting top offers better protection[17]. Patients with intense otitis externa ought to ideally refrain from water sports for in any event seven to 10 days, although a few creators would enable focused swimmers to return following three days of treatment as long as all agony has resolved. Other would permit come back with the utilization of well-fitting ear plugs[17].

Conclusion

Otitis externa is an aggravation of the external ear and ear canal. Frequently utilized treatment is anti-toxin ear drops, with or without corticosteroid. In parasitic or otomycosis otitis externa purging by suctioning, and with acidifying drops given a few times every day is the treatment of decision .Malignant otitis externa (MOE) may result in genuine confusions

Study on Immunization Knowledge, Attitude and Practice among the Parents having Children Less than 16 Years of Age

Sandhya M.[1], Mohan Kumar P.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: A standout amongst the most financially savvy wellbeing intercessions is vaccination. The principle goal of the investigation is to create and approve a poll to watch the learning, frame of mind, routine with regards to immunization among guardians having youngsters under 16 years old. This examination likewise assesses the familiarity with guardians towards more up to date antibodies present today.

Strategies: A Cross-sectional investigation was done among 100 guardians utilizing helpful inspecting procedure and a survey was made to gather the Parents information and the information accumulation is made in MS-EXCEL. Educated assent and moral board of trustees endorsement is acquired.

Result: 84% of the guardians inoculate their youngster routinely 16% don't immunize normally. Among 100, 68% of guardians don't know about the more up to date antibody. Specialists were the primary wellspring of data. 65% of the guardians accept that immunization that doesn't anticipate the illness.

Conclusion: There is a restricted information among guardians with respect to more current immunization. Inoculation mindfulness by specialists and wellbeing training by the open are significant for the network acknowledgment of the new antibody and furthermore for keeping up their trust in the current immunization. Mindfulness in regards to NATIONAL Immunization SCHEDULE ought to be actualized all over India.

Keywords: *Awareness program, Health instruction, Parental training.*

Introduction

Childs wellbeing incorporates physical, mental and social prosperity. After the presentation of extended program on vaccination by world wellbeing association (WHO) in 1974, Global inclusion with routine antibodies has expanded from <5% to >=84%, inclusion of the third portion of diphtheria, lockjaw, pertussis immunization (DTP) before 12 months' over of age is a noteworthy pointer of inoculation program performance[1]. One of the significant hindrance for less inoculation inclusion in India are gigantic populace and poor mindfulness among general society. Infections can be forestalled somewhat by the usage of National Immunization timetable as per the truism "Avoidance is superior to fix". In 2016, almost 1 out of 10 youngsters did not get any immunization. WHO says an extra 1.5 million passing's could be stayed away from if worldwide inoculation normal improves? In 2017, no of kids inoculated are 116.2 million and it was the most astounding record ever. Since 2010,113 nations have presented new immunizations in excess of 20 million extra youngsters have been inoculated. Polio has been totally destroyed from India, where as measles, rubella, maternal and monatal lock jaw are behind the timetable. The greater part of the youngsters passing up a great opportunity is those living in the least fortunate, underestimated networks. Inoculation counteracts sickness, handicap and demise from immunization preventable infections including cervical malignant growth, diphtheria, hepatitis-B, measles, mumps, pertusis, pneumonia, polio, rotavirus, rubella

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

and lockjaw. 169 million youngsters passed up a major opportunity first portion of measles immunization somewhere in the range of 2010 and 2017, UNICEF said.

Materials and Method

The survey was created based on Parents learning and practice towards the inoculation. An example space of 100 Parents were taken by arbitrary testing strategy. Guardians who came to visit the medical clinic for inoculation and guardians of in patient in Chennai are chosen. Cross sectional examination is done. It is the easiest type of an observational investigation. It depends on single examination of a cross area of populace. It is otherwise called pervasiveness ponder. Cross sectional investigations are more helpful for unending than fleeting diseases[2]. The deliberate assent is acquired from the guardians in the wake of advising in insight concerning the system and insights about the examination. Moral advisory group endorsement is gotten. Created survey was restricted to sixteen inquiries that was viewed as plausible and concentrated on learning, mentality and routine with regards to guardians about the antibody in the national vaccination plan.

Findings: Aggregate of 100 guardians were incorporated into the investigation of inoculation information, frame of mind and practice. Out of 100, 84% of the guardians inoculate their tyke normally, though, 16% doesn't immunize

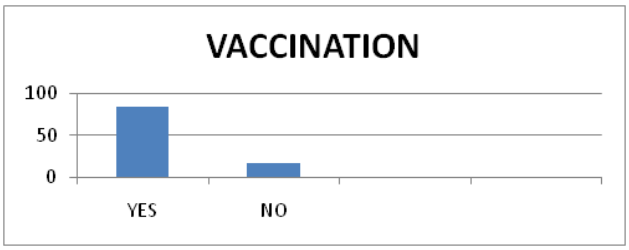

Figure 1: Awareness about vaccination

Yes-Regular

No-Irregular

Immunization knowledge of the parents are mostly acquired from the doctors and rest from relatives, mass media, and Internet.

Table 1: Sources of knowledge regarding immunization from various sources

Choices	%	Count
Doctor	65%	65
Relatives	27%	27
Internet	5%	5
Mass Media	3%	3

As a result of decreased awareness among the public regarding vaccination many aren't aware of the newer vaccines.

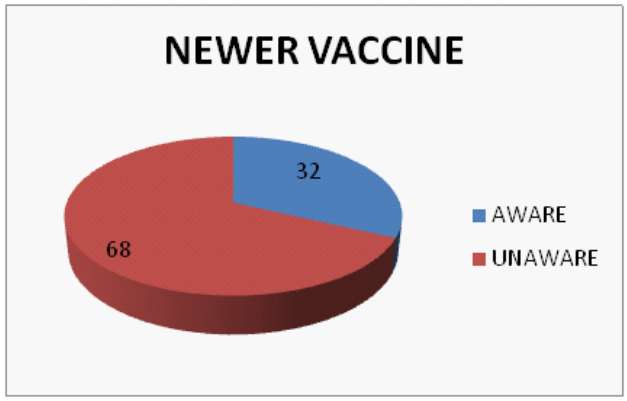

Figure 2: Awareness about latest trend in vaccination

Parents knowledge regarding maximu.m age vaccine can be administered is described

Under the following bar diagram

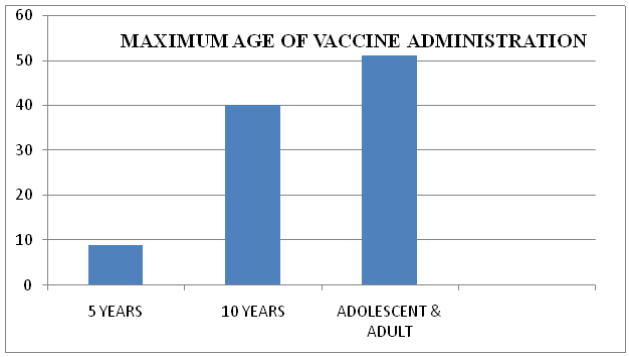

Figure 3: Maximum Age of Vaccine Administration

People have a false belief that autism can be caused due to vaccine administration. Among the 100 parents, certain think vaccination is harmful.

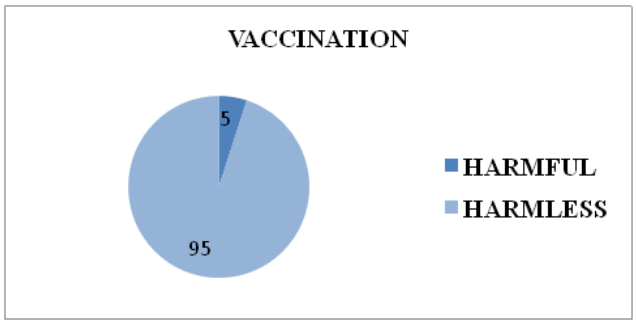

Figure 4: Distribution of people thinking vaccine as harmful

Discussion

80% of the parents are unaware that not all vaccines are administered under the national program and there are few vaccines which are in the recommended immunization schedule and need to be taken in addition to routine vaccines[3]. Another finding in the study was limited knowledge of the mothers regarding immunization through, a vast majority of respondents agreed on the fact that immunization was important to protect their children from diseases and most of them could not even name one disease that immunization provided protection against.

2019 campaign objectives: The main goal of campaign is to raise awareness about the critical importance of full immunization throughout the life[4].

As part of 2019 campaign WHO aims to:

1. Demonstrate the value of vaccine for the health of children, community and the world.
2. Highlight the need to be built on immunization progress while addressing gaps, including through increased investment.
3. Show how routine immunization is the foundation for strong, resilient health systems and universal health coverage.

Table 2: Knowledge about vaccination for different dieseases

Knowledge Assessment Questions	Yes (%)	No (%)	Don't Know (%)
Child with common cold be vaccinated	5%	82%	13%
Child with fever be vaccinated	4%	87%	9%
Child with diarrhea be vaccinated	5%	76%	19%
Vaccination available after 20 years of Age	33%	67%	-

Conclusion

Among the sample space collected, only 45% of the parents have the knowledge that, 3 vaccines are administered at birth, whereas 51% say as 2 vaccines, 4% say 4 vaccines respectively."Compliance to immunization is important", "Child immunization is important", and it is important for children to get all doctor-recommended vaccines.

World immunization week celebrated in the last week of April aims to promote use of vaccines to protect people of all ages against various diseases. Immunization saves millions of lives every year and it is recognized as one of the worlds successful and cost effective health intervention.

A Study of the Knowledge and Attitude towards Pulsepolio in Urban areas of South India

Muppalla Niteesh Kumar[1], Thatiparthi Stephen[2]

[1]UG Student, [2]Associate Professor, Department of Community Medicine,
Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Polio infection transmission has been hindered in many pieces of the world with the exception of couple of foci in ten nations situated in South Asia and Central/Western Africa[2]. The Government of India propelled the beat polio inoculation (PPI) program on a nationwide premise in 1995. The expression "beat" portrays the concurrent, mass organization of oral polio antibody (OPV) on a solitary day to all kids matured underneath 5 years[3]. PPI comprises of inoculation of kids at fixed stalls on two national vaccination days (NID), isolated by about a month and a half, throughout the winter season. The primary point of PPI is to intrude on the transmission of wild polio infection by presenting kids to the antibody virus[3]. However, 5–6% of kids were being missed in the PPI. In this manner, during 1999–2000, notwithstanding stall inoculation, a house-to-house search of missed youngsters was embraced to immunize them over the 2–3 days following each NID.

Keywords: *Pulsepolio, beat polio inoculation (PPI), oral polio antibody (OPV).*

Introduction

Poliomyelitis is a dreaded ailment in certain nations of the world because of its lamentable inheritance of loss of motion and disfigurement. In 1988, the World Health Assembly and its individuals focused on the objective of annihilation of poliomyelitis continuously 2000[1]. This worldwide activity to kill polio was the biggest global illness control exertion ever. Polio infection transmission has been hindered in many pieces of the world with the exception of couple of foci in ten nations situated in South Asia and Central/Western Africa[2].

The Government of India propelled the beat polio inoculation (PPI) program on a nationwide premise in 1995. The expression "beat" portrays the concurrent, mass organization of oral polio antibody (OPV) on a solitary day to all kids matured underneath 5 years[3]. PPI comprises of inoculation of kids at fixed stalls on two national vaccination days (NID), isolated by about a month and a half, throughout the winter season. The primary point of PPI is to intrude on the transmission of wild polio infection by presenting kids to the antibody virus[3]. However, 5–6% of kids were being missed in the PPI. In this manner, during 1999–2000, notwithstanding stall inoculation, a house-to-house search of missed youngsters was embraced to immunize them over the 2–3 days following each NID.

Despite the broad PPI presented by the legislature, the point of making India a 'polio free state' still stays fantastical with 733 youngsters with polio detailed in 2009[4]. This makes India the biggest polio endemic nation in the world[2]. Resistance by the all inclusive community seems to anticipate acknowledgment of this program. Confusions and legends with respect to the immunization worry about its evil impacts and absence of mindfulness about poliomyelitis and PPI are the major obstacles[5]. Our examination means to distinguish these misinterpretations to all the more likely illuminate future usage regarding this program. This investigation was accordingly directed to evaluate the consciousness of the objective populace about polio and PPI, and to

survey their frame of mind and practice towards PPI.

Materials and Method

This cross-sectional examination was attempted in june 2019 in urban regions, in Kancheepuram area in Tamil Nadu territory of South India. The moral endorsement for directing this investigation was acquired from the institutional moral freedom board of trustees. The example size was determined utilizing 95% certainty breaking points and 90% power. Accepting a mindfulness level of poliomyelitis and PPI among individuals as being about 56% from a past study,[6] the example size was determined as roughly 100 individuals. An aggregate of 100 such were secured by comfort examining during the investigation time frame. Information was gathered by talking any part inside age gathering of 50 years utilizing a pretested, semi-organized survey subsequent to taking their educated assent.

Members were gotten some information about signs and manifestations of poliomyelitis, the age bunches most vulnerable to this infection, the method of sickness transmission, the wellsprings of data about PPI, the quantity of and seasons in which the PPI rounds are held, the advantages of PPI and purposes behind non-inoculation during PPI rounds. Each answer given to the poll was allocated focuses which empowered the estimation of total scores and resulting classification of the degree of familiarity with members into well, modestly and ineffectively. Every one of the information gathered were dissected utilizing rendition 11.5 of the Statistical Package for Social Sciences programming bundle was utilized for testing measurable centrality and P esteem <0.05 was considered as noteworthy.

Findings: The reaction rate was 100 % as all the 100 members consented to be met by our group. Of the absolute 100 members, 69% were guys. Proficiency rate among members was close aggregate at 100% with77% taught up to secondary school

Table 1: Socioeconomic distribution of study participants. (n = 100)

Educational status	No.	Percentage
Illiterate	0	0
Primary school (1–5 std)	0	0
Secondary school (6–10)	8	8
Pre University (11–12)	15	15
Graduation & above	77	77

Awareness about The Disease: All of the participants had heard about poliomyelitis. Although 90 (90%) knew that poliomyelitis is a preventable disease, 48(48%) were under the misconception that it is curable. (See Table 2).

Table 2: Awareness of participants about poliomyelitis (n = 100)

Total	**15**	**34**	**51**	**100**

Discussion

PPI has been intended to annihilate polio. In the event that this can be accomplished it will likewise establish tone for the annihilation of different ailments, for example, measles. Such a noteworthy activity requires participation from all areas, especially individuals from the all inclusive community. In this manner their discernment and acknowledgment of PPI turns out to be exceptionally fundamental for its prosperity.

This examination uncovered that every one of the members had caught wind of polio and PPI. As to of the illness, most of members realized that youngsters are most defenseless to polio, that loss of motion is a significant continuation and that the malady is preventable. These discoveries were like an examination done by Singh et al where 70.3% of the members realized that polio prompts loss of motion of legs and 86.2% realized that polio is preventable by vaccination[7]. However, an investigation done by Chincholikar et al demonstrated that regardless of a decent education status just 60% of the respondents thought about polio[8]. Similar discoveries were accounted for by Misra et al where just 56% thought about polio and just 63% realized that it is preventable[6]. The contrasts between studies might be on the grounds that the last two examinations were embraced in a provincial and ghetto region individually while the previous investigation and our own were done in urban territories. This could show that degree of learning about polio contrasts relying on the territory of home.

Disregarding decent information with respect to most parts of the ailment, more than quarter of members in our examination had the misguided judgment that polio is treatable and 89% did not know the correct method of sickness transmission. Indeed, even in the investigation done by Singh et al 30.7% of respondents believed polio to be a treatable disease[7]. The essential wellspring of data about PPI in this examination was for the most part from the TV. In a few different examinations too TV was observed to be the commonest wellspring of data for participants[7-10]. This demonstrates TV is a distinct advantage to utilize when wishing to spread data of general wellbeing significance.

The job of wellbeing laborers as suppliers of essential data about PPI was constrained (19%) in our examination. This was as opposed to consequences of concentrates done in West Bengal and Agra where wellbeing specialists were the principle wellspring of data in about 70% participants.[11-13] Wellbeing laborers are evidently the best way to improve the accomplishment of the program. This is on the grounds that they are browsed the network and are known to impact the learning of neighborhood individuals by relational methodology during entryway to-entryway battle as likewise saw in an investigation done by Manjunath et al[14].

Sixty five to 75% members in our examination knew the objective populace, number of rounds of PPI and the season during which PPI is held. This was like perception of Bhasin et al where 75% respondents

realized the objective gathering correctly[15]. Whereas in an investigation done among Delhi ghetto populace, 82% of respondents realized the right target bunch for PPI which was more than our examination results[6]. This could be on the grounds that the fundamental wellspring of data on PPI among members in their investigation was wellbeing specialists (67.2%). As examined before between close to home correspondence is the most effective method for data spread. In another investigation done in Delhi just 18.1% of respondents knew the PPI day's correctly[7].

In our investigation, practically 19% members had a misinterpretation that OPV can anticipate different illnesses too. This conviction could prompt poor take-up of vaccinations for sicknesses. A further misinterpretation was recognized in 15% members in our investigation, as they accepted that rehashed immunization under PPI results in over dose. This was equivalent to the finding of Dobe et al where 2.2 to 6.3% respondents in different locale did not inoculate their kids because of the dread of over dosage[12, 16].

Instructive status was observed to be essentially connected with level of mindfulness about the PPI program in our investigation; this is like the discoveries of Chincholikar et al and Rasania et al where likewise noteworthy affiliation was seen[8, 12]. These discoveries uncover that disregarding a high proficiency rate and moderately great learning about the illness and the program, misguided judgments still exist in the brains of the general population. These issues should be routed to improve the achievement of this program.

Conclusion

The instructive degree of the considerable number of members in the examination regions was great however their mindfulness level as for the ailment and the program was inadmissible in the greater part of them. Not many members realized that polio is transmitted by debased nourishment and water.

Confusion that it is a treatable infection was found in excess of a fourth of them. Likewise as for the program various misguided judgments were featured. A fourth of our members did not know the recipients of PPI or said it wrongly. A couple of members felt that rehashed inoculation in PPI causes over measurements and is in this way destructive for youngsters. Confusions like routine inoculation under national inoculation program can substitute for immunization under PPI program are not many different reasons which can decrease the inclusion of PPI. Hazardous misguided judgments like OPV can counteract different illnesses notwithstanding poliomyelitis can decrease the inclusion of inoculation against different sicknesses. TV which was the most mainstream essential wellspring of data needs be used to create mindfulness about the significance of PPI. Notwithstanding this a system of wellbeing laborers ought to be successfully prepared and activated to evacuate the misguided judgments and falsehood about poliomyelitis and PPI through guiding of guardians and parental figures just before vaccination rounds. The best methodology would be relational correspondence by house to house visits in family units having under-fives. For hesitant families center gathering talk can be masterminded including Medical Officer, nearby pioneers and agents from ladies self improvement gatherings. This will further improve the acknowledgment of PPI in the network.

A Study to Assess Depression among Patients with Non-Communicable Diseases Attending a Tertiary Care Hospital

Vidhyalakshmi S.[1], Anantha Eashwar V.M.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73.

Abstract

Background: Misery influences individuals paying little mind to their experience and all ages too. As per the World Health Organization, 300 million individuals have melancholy around the globe. Somewhere in the range of 18 and 25 is most noteworthy among people with the predominance of significant burdensome scenes among grown-ups.

Technique: The unmistakable cross sectional investigation was done on 120 patients with non-transmittable ailment going to a tertiary consideration emergency clinic by arbitrary testing system. . Data would be assembled from patient, relative and guardian about statistic, clinical information utilizing a semi organized proforma. Melancholy will be affirmed by Patient Health Questionnaire (PHQ-2) and seriousness deciphered utilizing Patient Health Questionnaire (PHQ-9).

Results: The predominance of misery among patients with non-transferable malady is observed to be 77%. Wretchedness was for the most part because of weakening of wellbeing and their dread of compounding of disease and passing. There were likewise related elements which further declined the condition like family issues.

Conclusion: The pervasiveness of sadness has been observed to be increasingly regular in patients in extreme type of illness. Subsequently many helped directing and mental trainings should be possible to control or lessen despondency because of horribleness.

Keywords: *PHQ-9, PHQ-2, morbities, mental health, counselling.*

Introduction

Misery is one of the normal mental issues worldwide. It influences individuals of all age bunch with/without co-morbities. It most generally shows as bitterness or loss of enthusiasm for things which were once favored. The basic side effects are low disposition, loss of interests and joys, low vitality, weariness, aloofness, cynicism towards the future, irritated rest, poor craving, poor fixation, low confidence, blame or self-fault, self-destructive thoughts. The current demonstrative criteria for discouragement is to indicate that 2 out of 10 manifestations enduring at any rate 2 weeks should be resolved for conclusion[1]. Some other ailments like cerebrum tumors, vitamind eficiency, etc may take after depression, hence it is important to discount such conditions. As per American mental association, one in 15 grown-ups have discouragement in any given year, and it is more typical in females than male. It is additionally observed to be increasingly pervasive in age gathering of 18-25 years. Non-transferable interminable maladies like diabetes, hypertension, osteoarthritis, malignancy, and so on expand the danger of creating extreme burdensome illness. High rates of melancholy have been noted in patients with neurological issue, especially epilepsy (20%-55%), numerous sclerosis (40%-60%) and stroke (14%-19%) Other generally included morbities are cardiovascular ailments, pneumonic ailments, stroke, skin issue, parkinsonism[2].

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Misery is regularly treated with prescriptions or psychotherapy or both. if these medicines don't diminish symptoms, electro convulsive treatment or some other cerebrum incitement treatment can be done. commonly utilized meds are energizer. Discouragement is one of the need conditions secured by WHO's emotional well-being Gap Action Program (mhGAP). The Program intends to enable nations to expand administrations for individuals with mental, neurological and substance use issue, through consideration given by wellbeing laborers who are not masters in emotional wellness. WHO, among different offices, has created brief mental intercession manuals for melancholy that might be conveyed by lay laborers. A model is, Problem Management Plus, which portrays the utilization of conduct enactment, unwinding preparing, critical thinking treatment and reinforcing social help. Also, the manual Group Interpersonal Therapy (IPT) for Depression depicts bunch treatment of melancholy. At long last, Thinking Healthy spreads the utilization of intellectual social treatment for perinatal depression[3].

Philosophy: Setting of study-Patients of different age bunch in different offices in a tertiary consideration medical clinic.

Test measure 120 subjects. Kind of study-Cross sectional investigation.

Incorporation

- Patients with non-transferable maladies.
- Clinically steady for meeting

Avoidance

- Patients with transferable maladies and mental issues.
- Clinically temperamental or uncooperative.
- Persons with serious tactile (hearing and visual imperfections) and informative hindrances.
- Persons who is experiencing ridiculousness, schizophrenia, different psychoses or major emotional issue and mental hindrance.
- Those not satisfying the consideration criteria. Instruments utilized
- Modified BG Prasad scale (2018)
- Patient Health Questionnaire-2 (PHQ-2)
- Patient Health Questionnaire-9 (PHQ-9)

Altered BG Prasad scale (2018)-Modified BG Prasad financial scale has been being used for deciding the financial status of study subjects in network based wellbeing contemplates in India.

Persistent Health Questionnaire-2(PHQ-2)-The motivation behind the PHQ-2 is to screen for misery in an "initial step" approach. It asks about how much an individual has encountered discouraged state of mind over recent weeks.

Tolerant Health Questionnaire-9 (PHQ-9)-The PHQ-9 is the downturn module, which is utilized to screen the seriousness of gloom. Patients who screen positive for PQ-2 ought to be additionally assessed with the PHQ-9 to decide if they meet criteria for a burdensome issue or not. Information accumulation strategy

People who satisfy the incorporation and the rejection criteria subsequent to acquiring composed educated assent in various offices were incorporated into the investigation. Data was accumulated from patient, relative and guardian about statistic, clinical information utilizing a semi organized proforma. Despondency was affirmed by Patient Health Questionnaire (PHQ-2) and seriousness deciphered utilizing Patient Health Questionnaire (PHQ-9). There would be no intercession as a piece of study and normal treatment would not be changed as a feature of the investigation. The information will be assembled in Microsoft Excel and fitting factual investigation will be finished utilizing SPSS adaptation 22.

Results

By and large 120 patients finished the questionnaire. Out of this, 92 patients (77%) have been in mellow to extreme depression. Among this, 53(57%) were females and 40(43%) were guys.

Table 1: Shows the socio-demographic details and prevalence of depression among the study participants Prevalence of Depression

Variables	Yes	No
Age group		
<20	27(23%)	6(5%)
21-35	31(26%)	7(6%)
36-50	24(20%)	11(9%)
>51	10(8%)	4(3%)
Sex of the participant		

Male	39(32%)	14(12%)
Female	53(44%)	14(12%)
Profession		
Student	43(36%)	4(3%)
Working	30(25%)	15(12)
Housewife	19(16%)	9(8%)
Marital status		
Single	46(38%)	9(8%)
Married	45(37%)	18(15%)
Divorced/widow	1(1%)	1(1%)
Type of family		
Jointfamily	24(20%)	16(13%)
Nuclearfamily	68(57%)	12(10%)
Consumption of tobacco		
Yes	7(6%)	1(1%)
No	85(71%)	27(22%)
Consumption of alcohol		
Yes	12(10%)	2(2%)
No	80(67%)	26(21%)
Socioeconomic status		
I	63(53%)	13(11%)
II	17(14%)	10(8%)
III	10(8%)	3(2%)
IV	2(2%)	1(1%)
V	-	1(1%)

Depression was more common in the age group of 21-35 years. Females were more depressed. Participants who were students were found more to be suffering from depression. Those who were unmarried and those belonging to nuclear family and those belonging to upper socioeconomic status were more depressed.

Table 2: Severity of depression among the study participants.

Depression Severity (PHQ–9)	Male	Female
No depression	14(12%)	14(12%)
Minimal depression(1-4)	20(16%)	27(22%)
Mild depression(5-9)	7(6%)	7(6%)
Moderate depression(10-14)	9(7%)	13(11%)
Moderately severe depression(15-19)	1(1%)	6(5%)
Severe depression(20-27)	2(2%)	-

Minimal depression was present more in females when compared to males. Mild depression was present in 6% among male and female respectively. Moderate depression was present in 24% of study participants.

Discussion

Patients with non-transmittable maladies being one of the hazard factor for depression,It is seen to be increasingly regular among patients with differing severity. Our concentrate appeared about 77% (92 out of 120) of patients endure gloom with different ailments. Comparative examinations done by Brygidakwiatkowska among patients with rheumatoid joint pain demonstrated 91(76%) patients including 79(87%) female and 12(13%) guys have manifestations of depression[4]. It is discovered that downturn is more typical in females than guys while certain examinations appears there is no sex differences[5].

Melancholy, paying little respect to the seriousness of disease,is seen in grim people. This shows the dread of being sick or practical imapairment or perished. Studies led in different populace gatherings demonstrates that downturn is all the more regularly happening during endless ailments and could result in inability if the comorbid melancholy isn't treated[6-9]. A partner think about by American school of rheumatology on rheumatoid joint inflammation patients which connects with financial status indicated higher pervasiveness of gentle to direct wretchedness among low financial status[10].

Conclusion

Physical ailment generally went with burdensome side effects. This comorbidity has some administration problems. The first hindrance to treatment is acknowledgment of wretchedness in restoratively sick patients, and mental indications ought to likewise be organized when making the diagnosis. Several intercessions for sadness can be made and have been demonstrated to be successful in this patient gathering, including handicap of the medicinal ailment being limited, general steady measures, CBT, and stimulant prescriptions in patients with moderate to extreme symptoms. Patient's wellbeing criteria ought to be considered while endorsing antidepressants.

Appendicular Adenocarcinoma with Pseudomyxoma: A Case Report

Anagha V.K.[1], S. Gopalakrishnan[2]

[1]MBBS Student, [2]Professor and HOD, Department of Community Medicine,
Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Essential adenocarcinoma of the informative supplement is an uncommon illness as contrasted and malignant growth of the colon. It is normal in patients in the middle age. Mucinous adenocarcinoma is one of the histological kinds seen. The typical introduction of patients is intense an infected appendix or peri–attached boil. Finding is generally made after the careful example has been sent for histopathological survey. It is imperative to discount synchronous and metachronous tumor during medical procedure

Harmful mucinous neoplasms of the informative supplement is an inconsistently experienced substance. Extra appendiceal spread of these tumor is one of the commonest etiology of pseudomyxoma peritonei, which requests an uplifted carefulness in their initial conclusion. Albeit second rate appendiceal mucinous neoplasms (LAMNs) to a great extent remain restricted to the index, however they can spread to the peritoneum as pseudomyxoma peritonei prompting a flighty result. Because of the uncommon event of poor quality appendiceal neoplasm constrained data is available in the medicinal writing. This investigation exhibits an instance of a 50 years of age female who was given grievances of right lower stomach torment, loss of weight and repetitive fever for a month. CECT Abdomen and colonoscopy recommended occasional ulcer optional to affixed aperture. Medical procedure was done and histological report was that of mucinous adenocarcinoma.

Keywords: *Supplement, Mucinous neoplasm, Pseudomyxoma peritonei, Adenocarcinoma*

Introduction

Essential adenocarcinoma of the supplement when contrasted and malignant growth of the colon is an uncommon illness. It establish < 0.5% of gastrointestinal neoplasm[1,2]. As at 2002, under 250 cases had been accounted for. It is regularly found in patients over the age of 50 years and exhibits as intense a ruptured appendix or peri-attached abscess[3]. The histological sorts seen incorporates mucinous adenocarcinoma, cystadenocarcinoma, adenocarcinoids, adenosquamous,seal ring type adenocarcinoma and colonic sort non mucin creating adenocarcinoma of the reference section . Mucinous adenocarcinoma is a troublesome infection to analyze preoperatively and in many patients are not recognized till the ailment is progressed . Niteck et al saw that in just 32% of cases examined were the analysis made intraoperatively . Determination is regularly made after the histopathological examination of the careful example . Once in a while, solidified areas are additionally utilized in the determination . Dangerous tumors of the index take after colonic adenocarcinoma[4]. Henceforth, there ought to be reconnaissance for synchronous or metachronous tumors of the gastro-intestinal and extra intestinal tract during medical procedure. The degree of the infection as at the season of medical procedure is a more significant indicator of survival than the histological sort. It has likewise been accounted for that mucinous adenocarcinoma and nonattendance of carcinomatosis are great prognostic elements.

Poor quality appendiceal mucinous neoplasms (LAMNs) are uncommon condition with the revealed

Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

predominance of less than 1% of all appendectomies[1]. Low-grade mucinproducing tumors of the index that incorporates adenomas and mucinous tumors of obscure harmful potential (MTUMP) may give pseudomyxoma peritonei because of their capability to spread to the peritoneal hole and viscera as mucinous stores. Peritoneal mucinous carcinomas with middle of the road and incongruent highlights are watched frequentlyand in this manner another divaricate grouping has been prescribed, ordering the pseudomyxoma peritonei of appendiceal starting point into mucinous carcinoma peritonei–second rate and mucinous carcinoma peritonei–high level[5, 6].

Materials and Method

A multi year old female instructor from Koyilandy,with no comorbidities exhibited to gastro-specialist with right lower stomach torment related with looseness of the bowels, spewing and reccurent fever of one month span. She additionally had protests of loss of hunger and loss of weight .she was assessed with routine blood examinations, CECT stomach area and colonoscopy which were suggestive of occasional canker auxiliary to affixed puncturing.

Findings: She at first experienced CT guided ponytail inclusion into the intra stomach collection(sub-hepatic space).since the braid catheter was depleting inadequately she was planned for medical procedure, was done on 31st walk 2018 solidified biopsy announced as adenocarcinoma with pseudomyxoma peritonii. She experienced adjuvant chemotherapy with CAPEOX based routine. She endured the treatment with no intense dismalness and was released in stable condition. Figure 1 & 2: Colonoscopy reports of the patient:

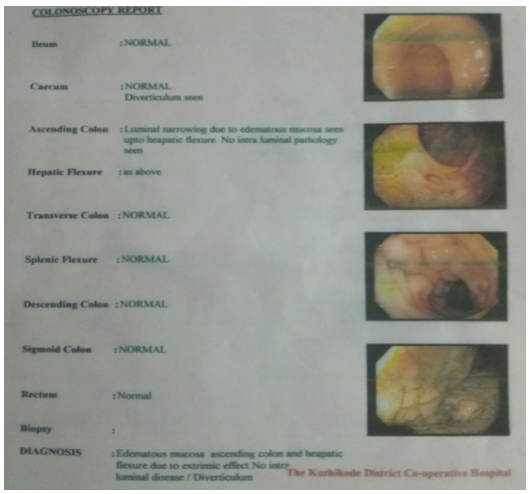

Figure: 1

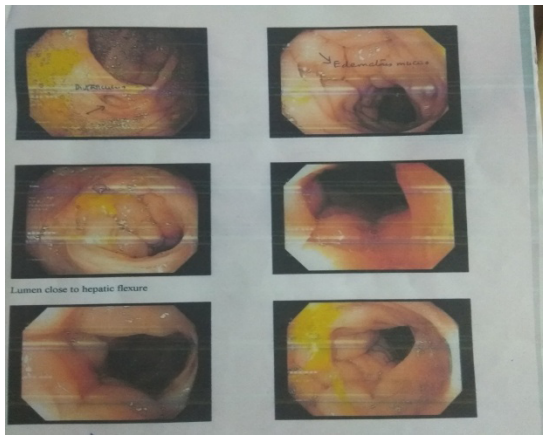

Figure: 2

Discussion

Mucinous adenocarcinoma of the index is an uncommon illness. It is a malady of the gastrointestinal tract that normally displays in patients over the center age[1]. The discoveries of a bulbous and firm informative supplement (4 cm in distance across) without inclusion of its base and caecum, nonappearance of lymphadenopathy and metastatic sores in other piece of the inside and the clinical condition of the patient educated the choice to play out an appendectomy. There is debate with regards to the predominance of right hemicolectomy over appendectomy .Some creators are of the sentiment that a privilege hemicolectomy is the suitable careful treatment in patients analyzed for mucinous adenocarcinoma of the reference section[4, 2]. The favored surgery and result are ineffectively gotten[1]. The intra employable conclusion was that of carcinoid tumor, which brace the way that mucinous adenocarcinoma isn't speculated most occasions; both previously and during activities .However, the utilization of solidified area would have enabled the finding of mucinous adenocarcinoma to be made intraoperatively[7]. Moreover, since female patients present with gynecological signs and indications it is fitting to prohibit metachronous tumors, for example, metastatic adenocarcinoma from the ovary during medical procedure [1]. This was carefully done at medical procedure.

Pseudomyxoma peritonei is a pathologic element having a variable clinical outcomes; if this condition is brought about by a high-grade appendiceal tumors, it is generally connected with a more awful prognosis[5, 6]. Pseudomyxoma peritonei is particularly characterized element portrayed by the nearness of intraperitoneal mucin, with or without related mucin-creating epithelium. Not inconsistently this condition is joined

by fibrosis and granulation tissue arrangement. It is estimated that the mucin may spread to the peritoneal cavity causing pseudomyxoma peritonei[5],either by bodily fluid following all through the expanded, diminished appendiceal divider or through the appendiceal diverticulum. Pseudomyxoma peritonei with inadequate, poor quality epithelium on microscopy has a decent visualization, while pseudomyxoma peritonei with bottomless, high-grade (carcinomatous) epithelium has been found to have an awful prognostic result.

Conclusion

Taking everything into account, mucinous adenocarcinoma of the reference section is a determination made on histopathological evaluation and is an uncommon tumor. doctors and specialists ought to engage a conclusion of the illness in moderately aged patients to such an extent that investigation of the gut ought to be performed with careful reconnaissance for synchronous and metachronous tumors. Also, intraoperative analysis can be made utilizing solidified areas. Reviewing of epithelium in psuedomyxoma is significant for the executives and visualization. Clear correspondence between the pathologist and clinicians and their collective exertion is in this manner pre imperative so as to reach to a corroborative conclusion.

Dyslipidemia on Type 2 Diabetes Mellitus

Jaishree P.[1], Krishnakumar J.[2], Gopalakrishnan S.[2]

[1]UG Medical Student, [2]Professor, Department of Community Medicine,
Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: In spite of the fact that diabetes keeps on being the significant way of life condition in India, there is absence of concentrates on whether Dyslipidemia in diabetics are sufficiently controlled early recognition.

Techniques: A cross sectional examination was performed on the back to back patients of sort 2 diabetes mellitus with helpful testing strategy. Fundamental information was gathered from a gathering of individuals of 100 patients matured over 45 years with diabetes mellitus in Chennai were chosen.

Results: An aggregate of 100 patients were chosen in Chennai matured over 40 years with sort 2 diabetes mellitus with and without dyslipidemia. Out of all out populace 56% were guys and 44% were females and 68% were dyslipidemic and 32% were non-dyslipidemic. Aftereffects of serum lipid profile demonstrated that the mean qualities for absolute cholesterol levels, triglyceride levels, high thickness lipid levels, low thickness lipid levels, low thickness lipid levels were 221.82 mg/dl, 159.7 mg/dl, 39.25 mg/dl, and 142.50 mg/dl, 36.92 mg/dl. Among all patients 68 people had hypercholesterolemia.

Ends: The investigation indicated regular lipid variations from the norm during Diabetes prompted Dyslipidemia i.e., Hypercholesterolemia, Hypertriglyceridemia and raised Low thickness lipid cholesterol (LDL-C) levels. This examination demonstrates Dyslipidemia control in sort 2 Diabetes Mellitus patients is poor.

Keywords: *Catchphrases–glucose levels, hypercholesterolemia.*

Goals:

I. To think about the predominance of dyslipidemia in sort 2 diabetes mellitus in Chennai

II. To explore the subjects of diabetic dyslipidemia who are at a danger of cardiovascular illness

Introduction

Diabetes mellitus is a standout amongst the most widely recognized perpetual ailments all inclusive and keeps on expanding in numbers.[1] It is among top five reasons for mortality. It is characterized as a metabolic issue of various aetiologies, portrayed by unending Hyperglycemia with unsettling influences of sugar, fat and protein digestion.

Corresponding Author:
Prof. Krishnakumar J.
Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

The recurrence of diabetes mellitus is expanding numerous folds in South Asian populace because of high level of hereditary inclination and high vulnerability to natural insulin, described by high BMI, high chest area adiposity, a high muscle versus fat ratio and an abnormal state of insulin resistence. The incessant Hyperglycemia of diabetes is related with long haul harm, brokenness, and disappointment of different organs like eyes, kidneys, nerves, heart and veins.

In this manner, present investigation was done to discover relationship between serum lipid profile and glucose, in perspective on speculation that early recognition and treatment of lipid variations from the norm can limit the danger of atherogenic cardiovascular

issue and cerebrovascular mishap in sort 2 Diabetes Mellitus patients. Consequently, the method of reasoning of this examination was to recognize Dyslipidemia in patients with sort 2 Diabetes Mellitus.[2, 3]

Materials and Method

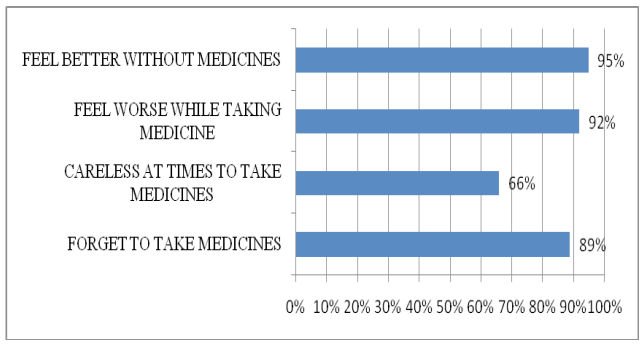
A cross sectional investigation was performed on the continuous patients of sort 2 diabetes mellitus. This examination was embraced to survey dyslipidemia in sort 2 DM was finished. The investigation was endorsed by the Institutional Ethics Committee, SBMC & H. The investigation was directed in the year-2019. 100 subjects of sort II DM were chosen, with term of 3-15 years, matured above 45yrs. Both male and female were chosen from patients going to diabetic OP at Sree Balaji Medical College and Hospital.

Educated assent was acquired from all subjects preceding enrolment into the examination. A proforma with itemized history of the subjects were filled. Tallness, weight, BMI was estimated. The predominance study are surveyed utilizing a poll, the members of the examination are assembled into diabetes dyslipidemic and diabetic non-dyslipidemic by evaluating their Fasting Blood Sugar levels, Postprandial glucose levels, Total cholesterol levels, LDL-C levels, HDL-C levels, VLDL-C levels, Triglyceride levels. The subsequent information was broke down measurably.

Consideration Criteria: All the individuals who consent to take an interest in the investigation will be incorporated.

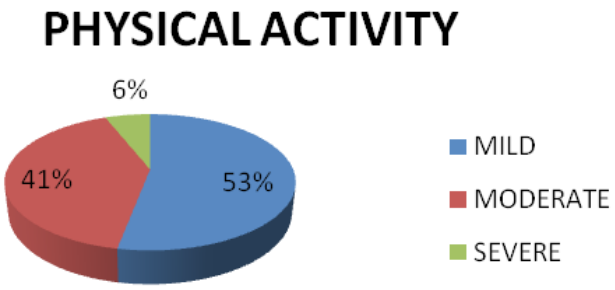
Rejection Criteria: Those who don't give assent will be prohibited.

Findings: An aggregate of 100 patients were chosen in Chennai matured over 40 years with sort 2 diabetes mellitus with and without dyslipidemia. Out of absolute populace 56% were guys and 44% were females and 68% were dyslipidemic and 32% were non-dyslipidemic. The mean age of the investigation populace was 53.08 years and mean weight record was 26.43.



The range and mean estimation of fasting glucose levels were 110-240 mg/dl and 173.24 mg/dl, while the range and mean estimation of postprandial glucose levels were 145–400 mg/dl and 248.51 mg/dl. It was seen that a few patients have controlled fasting glucose levels however their postprandial glucose levels was uncontrolled.

Blood Sugar Parameter	Normal Range	Calculated Range	Mean Value
Fasting Blood Sugar	70–100 mg/dl	110-240 mg/dl	173.24 mg/dl
Postprandial Blood Sugar	Less than 140 mg/dl	145–400 mg/dl	248.51 mg/dl



Results of serum lipid profile showed that the mean values for total cholesterol levels, triglyceride levels, high density lipid levels, low density lipid levels, very low density lipid levels were 221.82 mg/dl, 159.7 mg/dl, 39.25 mg/dl, and 142.50 mg/dl, 36.92 mg/dl. Among all patients 68 individuals had hypercholesterolemia.

Lipid Parameter	Normal Range	Mean Value
Total Cholesterol (Tc)	< 200 mg/dl	221.82 mg/dl
High Density Lipid Cholesterol (Hdl-C)	> 60 mg/dl	39.25 mg/dl
Triglycerides	50–150 mg/dl	159.70 mg/dl
Low Density Lipid Cholesterol (Ldl-C)	< 130 mg/dl	142.50 mg/dl
Very Low Density Lipid Cholesterol (Vldl-C)	15–30 mg/dl	36.92 mg/dl

Out of total subjects 56% subjects had a family history of type diabetes mellitus and 49% had dyslipidemia. And 46% of subjects were only on regular monitoring of blood sugar levels and lipid profile. And only 47% and 39% subjects were on regular medications for Diabetes Mellitus and Dyslipidemia. Rest of the subjects did not take medications due to some reasons as follows: forgetting to take medicines regularly, being careless at times to take medicines, feeling worse while medicines, feeling better without medicines.

The mean value of waist circumference for females and males were 39.5 inches and 46.5 inches. The subjects having abdominal obesity were of 58%. In the study, 44% were smokers and alcoholic and 56% were non-smokers and non-alcoholic. The levels of physical activity of the subjects are depicted below:

The patients had following symptoms of diabetes mellitus–fatigue, hunger, and intense thirst, frequent desire to urinate and trouble focusing vision.

Discussion

The connection between diabetes mellitus and serum lipid profile had been tremendously talked about during the previous decades. Both lipid profile and diabetes have been demonstrated to be significant indicators for metabolic unsettling influences including dyslipidemia, hypertension, cardiovascular infections, hyperinsulinemia, and so on.[4]

An investigation by Packard et al., reports that decreased HDL-C as an amazing indicator for untimely coronary heart sicknesses. Goldberg announced that hyperglycemia logically builds the exchange of cholesterol esters from HDL-C to VLDL-C particles, subsequently denser LDL particles gain a huge extent of these HDL esters, further lessening the HDL-C levels.

HDL is a prepared substrate for hepatic lipase which changes over it into littler particles, which are promptly cleared from the plasma. Likewise with the triglycerides, improvement in glycaemic control prompts the expansion in the degrees of HDL-C and proposes the proof for the job for poor glycemia in diminishing the degree of this lipoprotein.[5]

Conclusion

Present investigation demonstrates normal lipid anomalies during diabetes initiated dyslipidemia are hypercholesterolemia, hypertriglyceridemia and raised LDL-C. Results recommend a high pervasiveness of dyslipidemia, which may assume a noteworthy job in the advancement of cardiovascular ailments among diabetic patients

Effect of Caffeine Consumption on Mood and Alertness of Medical Students of Urban Area of Kanchipuram

Shreya Rohra[1], Swetha N.B.[2], Gopalakrishnan S.[3]

[1]Undergraduate Student, [2]Assistant Professor, [3]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: Caffeine is expended in various structures, for example, tea, espresso, soda pops and caffeinated drinks. It is a typical fixing in prescription to treat or oversee laziness, cerebral pains and headaches. Caffeine improves the state of mind by expanding the sentiment of prosperity. Some espresso contains about 90% of caffeine and it needs 20 minutes to clear from the stomach after utilization. Stimulated drinks are being devoured by medicinal understudies more when contrasted with different understudies to deal with the pressure and outstanding task at hand.

Point: This examination is intended to discover the impact of caffeine utilization on state of mind and sharpness of therapeutic understudies among medicinal understudies.

Technique: A cross sectional enlightening examination was directed at Sree Balaji Medical College and Hospital, Chromepet, Chennai. 200 understudies (100 male and 100 female) took an interest from first year to definite year based on helpful examining technique. Information has been gathered from April 2019 to June 2019 through self-tried survey and examined utilizing distinctive factual apparatuses.

Results: Caffeine more often than not as espresso (40.6%), tea (16.75%), Carbonated drinks(11.16%) and not vitality drinks(3.55%) is devoured by the vast majority of the therapeutic understudies. Understudies give numerous reasons, for example, To help vitality (33.5%), To lessen sleepiness or cerebral pain (20.3%), To remain conscious particularly before tests (18.78%) and other reasons(15.22%, for example, for taste, to extinguish thirst or for refreshment, and so on.

End: The principle reasons regarding why medicinal understudies expend a lot of caffeine is to support vitality, diminish tiredness and to remain conscious particularly before test. Despite the fact that it is sheltered, a high admission client ought to limit their utilization.

Keywords: *Carbonated Drinks, Energy Drinks, Coffee, cerebral pain.*

Introduction

When we get up in the first part of the day, a large number of us go after an espresso to kick-begin our day. As per global espresso association, roughly 1.4 billion cups of espresso are expended worldwide each day.[1] The greater part of Indians begin their day by expending caffeine in different structures particularly espresso and tea. Espresso utilization is for the most part amassed in the southern states like Tamil Nadu (60%) and Karnataka (25%). [2] It has turned into an essential part in everybody's life. Some are mentally and physically subject to caffeine to carry on their day by day exercises. As per numerous investigations moderate caffeine admission can advance an assortment of medical advantages. Caffeine is a socially adequate 'Psychoactive drug'.[3]

Corresponding Author:
Dr. N.B. Swetha
Assistant Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Caffeine is a focal sensory system stimulant that influences human body from multiple points of view. It is expended in various structures, for example, tea, espresso, soda pops and caffeinated drinks. It is a typical fixing in medicine to treat or oversee laziness, cerebral pains and headaches. When it comes to in the cerebrum it brings sharpness and fills freshness in one's brain. Caffeine improves the disposition by expanding the sentiment of prosperity. It builds the general movement of the person.

Some espresso contains about 90% of caffeine and it needs 20 minutes to clear from the stomach after utilization. The impact begins from an hour and stays for 3-4 hours. The pinnacle plasma focus is come to following 40 to an hour. The half-existence of caffeine is around six hours in sound adult 4. Being a restorative understudy the remaining burden is more contrasted with different understudies. It incorporates Regular tests, Exam arrangement and more which incorporates intemperate pressure, significantly working without appropriate rest.

Caffeine admission is most normally credits to the utilization of espresso (± 137 mg/cup of stimulated espresso and ± 2 mg/cup of decaffeinated espresso; the volume of one cup is roughly 240 ml), tea (± 47 mg/cup), juiced soda pops (± 46 mg/340 ml can or container of cola refreshment) and caffeinated drinks (up to 80 mg/can)5. In spite of the fact that it has its reactions and withdrawal side effects, for example, Headache, Confusion, Palpitation, Depression and Anxieties, and so on.

It is currently broadly accepted that routine day by day utilization of caffeine for example 4-7 cups of espresso or 7-9 cups of tea (>500–600 mg) speaks to a critical wellbeing hazard and may consequently be viewed as 'misuse'. Supported maltreatment alludes to a disorder results in 'caffeinism', which is portrayed by a scope of antagonistic responses, for example, fretfulness, tension, crabbiness, muscle tremor, a sleeping disorder, cerebral pain, tactile unsettling influences (for example tinnitus), cardiovascular indications (for example tachycardia, arrhythmia) and gastrointestinal objections (for example sickness, heaving, diarrhea)6. To deal with their scholarly pressure jazzed drinks are being devoured by medicinal understudies. Henceforth this examination was directed to evaluate the effect of caffeine on temperament and sharpness of restorative understudies.

Materials and Method

System: A cross sectional enlightening investigation was done among the medicinal understudies in a therapeutic school of Chennai. Helpful testing technique was pursued for determination of members. Therapeutic understudies from first year to definite year have been given the pre-tried semi-organized poll and information have been gathered from April 2019 to June 2019. The investigation comprises all out number of 200 respondents.

Information Collection: Primary information was gathered through poll. Educated assent was gotten before starting the investigation. The poll contained dichotomous inquiries (yes/no), various decision questions and scaled inquiries. 5 point Likert scale type articulations were utilized in poll. The survey established inquiries in regards to their refreshment utilization propensities, amount and purpose behind utilization and so on.

Information Analysis Tool: The information have been examined utilizing distinctive measurable apparatuses, for example, Descriptive Statistics (Frequency and Percentage) to decipher the outcomes. The information was dissected by utilizing Statistical Package for Social Sciences (SPSS) 21.0. What's more, Microsoft-Excel.

The examination was endorsed by the Institutional Ethics Committee, Sree Balaji Medical College and Hospital.

Findings: An aggregate of 200 respondents (100 guys and 100 females) from first year to definite year took an interest in this investigation. Lion's share of respondents were of age bunch 18-20 years (58%) trailed by 21-23 years (38%) and 24-26 years(4%). Around 197 out of 200 respondents were caffeine customers and 3 were non purchasers.

Table 1 demonstrates the example of caffeine utilization among restorative understudies. It demonstrates that most favored refreshment is espresso (65%) and generally during morning and night. The majority of them were devouring 1-2 times each day (32%).

Figure 1 delineates the reasons of utilization of energized refreshments which demonstrates that most basic reason is to support vitality and to remain wakeful particularly during tests. Practically 15%students chose

different reasons, for example, for taste, to extinguish thirst or for refreshment, and so on.

Figure 2 portrays the reviewing given by respondents for state of mind and readiness increase after caffeine utilization. Larger part of them concurred that it causes expanded vitality, diminishes weakness and cerebral pain.

Table 1 : Pattern Of Caffeine Consumption Among Medical Students

Variable	Classification	Frequency (n=200)	Percentage (%)
Consumption of caffeine in any form	Yes	197	98.5
	No	3	1.5
	Less than once in a week	37	18.5

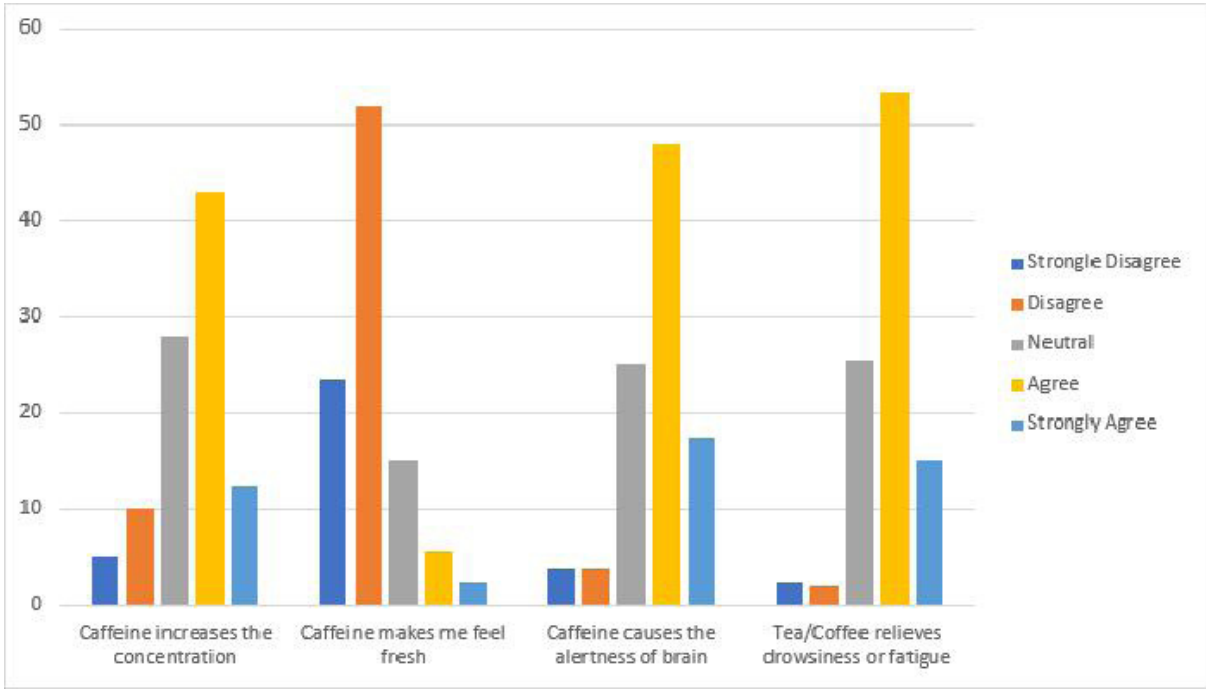

Figure 2: Reasons For Consumption Of Caffeinated Drinks

Discussion

The principle motivation behind the examination was to discover the impact of caffeine utilization on disposition and readiness of medicinal understudies of tertiary social insurance focus. The utilization of caffeine by college understudies utilizing an information from helpful examining of 200 understudies (100male and 100 female) of Sree Balaji Medical College and Hospital, Chrompet, Chennai. Out of which 98.5% of respondents devour charged beverages.

A greater part of respondents who are in age bunch 18-20 years were accounted for the utilization of

caffeine in various structures, for example, tea (16.75%), coffee(40.6%), carbonated drinks(11.16%) and vitality drinks(3.55%). Most broadly utilized refreshment among medicinal understudies are espresso trailed by tea and carbonated beverages which is devoured for 1-2 times day by day.

In our examination most basic motivation to drink charged refreshments is to help vitality and to remain wakeful particularly during tests. Dominant part of the understudies apparent that utilization of caffeine expands fixation, it is utilized for refreshment and readiness of cerebrum and to ease sleepiness and exhaustion. An examination directed by University Puerto Rico Medical Sciences Campus on first year and second year understudies demonstrated that in excess of two third of understudies expended charged refreshments and the report demonstrated that it encourages them alert during test, diminishes pressure and remaining task at hand yet none of the factor was found essentially connected with scholarly pressure or load.[4]

The blend of sugar with caffeine uncovers that Caffeine ingestion does not modify starch or fat digestion. In spite of the fact that the theme of connection between espresso utilization and glucose resilience has been disputable for a long time. In our investigation just 3.55% understudies devour caffeinated drinks which are a decent sign since restorative understudies thinks about the symptoms of caffeinated drinks. As opposed to a few different investigations which show high measure of caffeinated drink utilization. In 2018, 33.85% of respondents of age bunch 18 to 29 years expressed they drink Energy Drinks consistently in United States.[7]

An examination was finished by Datta SS et.al. On Medical understudies during planning of their examination which demonstrates that the enslavement level during test increments among understudies and utilization of tea, espresso, tobacco and smoking expanded particularly among the individuals who concentrated late night.[8] In our examination, just about 36 (18%) respondents couldn't abandon 48-72 hours which shows the reliance of caffeine on understudies. The withdrawal indications of caffeine are felt anyplace between 12 to 20 hours in the wake of stopping and can keep going for up to 1week.[9]

For the all inclusive community of sound grown-ups, moderate caffeine consumption at a portion level of 400mgday-1 isn't related with unfriendly impacts, for example, general poisonous quality, cardiovascular impacts, changes in conduct, expanded occurrence of disease and impact on male ripeness issues. Nor are moderate admissions of caffeine related with unfavorable impacts on bone status or potentially calcium balance if satisfactory admissions of calcium are being consumed.[6]

The investigation had couple of constraints, for example, the portion reaction relationship couldn't be resolved.

Conclusion

It was seen from this examination that the vast majority of the understudies devoured either types of caffeine. The purposes behind caffeine utilization are that it builds focus, it is utilized for the refreshment and readiness of cerebrum and to calm laziness and exhaustion. A few buyers announced that it improves mind-set and physical execution. The majority of the caffeine expended in type of espresso pursued by tea and starch drinks, not caffeinated drinks. It is prescribed to screen the every day admission of caffeine. In spite of the fact that couple of buyers speak to reliance on caffeine, others likewise should attempt to limit it. The container specialist of school must give caffeine free refreshments or point of confinement stimulated beverages so understudies would embrace a sound way of life.

Effect of Electronic Gadget Usage on Sleep Quality among Medical Students in Chennai

Shanmugasundaram S.[1], Swetha N.B.[2], Gopalakrishnan S.[3]

[1]Undergraduate Student, [2]Assistant Professor, [3]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background**:** Electronic device gadget which was once considered as an extravagance of the prosperous has now turned into an imperative one. To begin with, it was the radio, at that point the phone, and the TV, pursued rapidly by the web. The current-day interest with the electronic contraption (e.g., cell phones) is the most recent innovation that seems, by all accounts, to be urging individuals to invest moderately more energy with innovation and less with individual people. Cell phone dependence is a quickly expanding variable that effects physical, mental and social wellbeing. Cell phone fixation may prompt less and less fortunate rest. Point: To evaluate the electronic device utilization design among the restorative understudies and furthermore to decide its impacts on nature of rest accomplished by them. Techniques: Subjects of age gathering of 18-25 years in a restorative school of Chennai were chosen. An example space of 200 youthful grown-ups is taken by helpful inspecting technique during the investigation term.. The inquiries were arranged for the most part to comprehend the connection between the cell phone utilization and rest. Results: In this examination, it was discovered that about 52% of the members dozed not exactly the required least of 6 hours out of each day. Practically 58% of the members have the propensity for utilizing an electronic contraption directly before resting. Upto 67% of the members had the propensity for utilizing an electronic device in obscurity. Conclusion: Students ought to be urged to accomplish ordinary rest and maintain a strategic distance from the utilization of any sort of electronic gadget before rest. Individuals ought to be instructed to utilize blue light channel which was demonstrated to be successful in improving rest quality as blue light incites melatonin arrangement which thus animates the cerebrum to remain conscious prompting poor rest quality.

Keywords: *Cell phones, rest aggravations, blue light channel.*

Introduction

Electronic contraption gadgets which were once considered as extravagance of the princely, have now turned into an indispensable.[1] First, it was the radio, at that point the phone, and the TV, pursued rapidly by the web. The current-day enthusiasm with the electronic device (e.g., cell phones) features that the most recent innovation has urged individuals to invest moderately more energy with innovation and lesser with individual humans.[2] Due to innovation progression, numerous improvement is found in devices like camera, web, cell phones, which has made life increasingly less difficult and imaginative, which draws in the general population to utilize the contraptions routinely and frequently.

It is discovered that young people are more dependent on cell phones than grown-ups, this is on the grounds that youngsters have a lower level of discretion, and they might be powerless against cell phone addiction. Several elements affect the quality and length of rest and one quickly developing variable might be the expanded utilization of innovation, all the more explicitly cell phone use. A few examinations demonstrate that the utilization of cell phones is related with lacking rest duration. Poor rest quality and inadequate rest span are perceived as significant wellbeing concerns internationally.

Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

In young people, deficient rest may cause poor scholarly execution or contrarily influence development and development. Poor rest around evening time is expands daytime dysfunction. It has likewise ensnared in a progression of weakness behavior. Proliferation of electronic gadgets, for example, PDAs has been involved in the poor rest of youngsters all day, every day association with innovation is really undesirable when you're attempting to nod off. 71 percent of individuals rest either holding their cell phone, having it in bed with them, or having it on their end table. Such huge numbers of individuals utilize their cell phones as their morning timers, it bodes well that many would need their telephones inside an arm's scope. Cell phones–like PCs, tablets, and TVs–produce something many refer to as blue light, which is a kind of light that the cerebrum translates as sunshine. The blue light really smothers melatonin (a hormone that influences circadian beat and should increment when you are getting ready for sleep time). This prompts lack of sleep because of incitement of the brain

Exorbitant utilization of cell phones is known to be related with cerebral pain, ear throb, warmth sensations and furthermore seen focus troubles. There are additionally different investigations which have demonstrated that most of portable uses experience the ill effects of lack of sleep and expanded pressure influencing their subjective and learning capacities. The cell phone subordinate understudies likewise become scholastically worried. In any case, there are not very many examinations directed among restorative understudies with respect to cell phone use and their impact on rest aggravation. Henceforth, this examination was endeavored with a goal to evaluate the impact of cell phone use on rest among restorative understudies.

Materials and Method

Subjects of age bunch over 18-25 years were chosen from a restorative school in Chennai . An example of 200 youthful grown-ups were selected to the investigation during the examination time frame from April 2019 to June 2019. The inquiries were organized and arranged basically to comprehend the connection between the cell phone utilization and rest. The overview was begun in the wake of getting endorsement from the Institutional Ethics Committee of Sree Balaji Medical College and Hospital. In the wake of acquiring educated assent the survey was self-directed. Questions in regards to the members cell phone use, the measure of time they spend in cell phones, and the recurrence of utilizing cell phones every day. They were additionally gotten some information about the time at which they would for the most part utilize their cell phones and in the event that they would utilize it directly before resting. The recurrence and the planning of the cell phone utilization directly before resting were enquired. The information gathered was entered in an exceed expectations sheet and investigated utilizing SPSS programming.

Findings: Table 1 portrays the various sorts of electronic gadgets utilized by the understudies. It was discovered that greater part (181,92%) of them utilized cell phones. Table 2 exhibits the time contrast between screen time and time of resting. It was seen that larger part (115,58%) of then had a distinction of <1 hour. Figure 1 portrays the understudies who utilized blue light channel (116) in their electronic gadget. 80 of them utilized the electronic gadget to visit via web-based networking media. (figure 2).

In this investigation, it was discovered that about 52% of the members dozed not exactly the required least of 6 hours of the day. Practically 58% of the members have the propensity for utilizing an electronic device directly before resting. Upto 67% of the members had the propensity for utilizing an electronic device in obscurity. Practically 21% of the members marathon watch atleast once every week and upto 40% of them experienced incessant cerebral pains.

Table 1: Types of Electronic Device Used

Type of device	No. of participants (197)	Percentage (%)
Mobile	181	92
PC	8	4
Console	4	2
Others	4	2

Table 2 : Duration Between Screen Time and Sleep

Time (Hour)	No. of participants (197)	Percentage (%)
<1 hour	115	58.3
1 hour	62	31.4
2 hour	12	6
3 hour	6	3
>3 hour	2	1.3

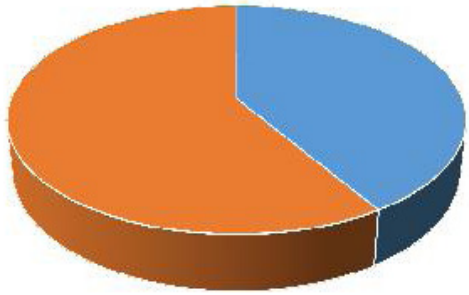

Figure 1: Utilization Of Blue Light Filter In Electronic Device

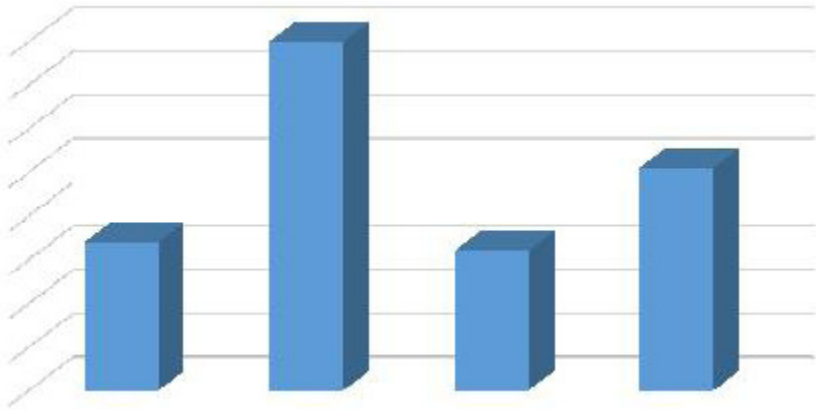

Figure 2: Purpose Of Usage Of Electronic Device

A significant amount of participants,64.5%, belonged to the age group of 16-20 while 31.5% of the participants belonged to the age group of 21-24. The rest 4% of the participants belonged to the age group above 25 years. Also in this research, 50.3% of the participants were females while 49.7% of the participants were males which showed an equal gender distribution.

Discussion

It was observed that most of them had very less time gap between screen time and time of sleep. Mobiles were the most common gadget used apart from console, laptops etc. It was found that most of the participants slept less than 6 hours per day. Almost 58% of the participants have the habit of using an electronic gadget right before going to sleep. Majority of them had the habit of using an electronic gadget in the dark. Most of them were also involved in binge watch at least once a week and upto 40% of them suffered from frequent headaches. It's been found that about 55.3% of the participants do not silence their mobile phone will going to sleep. 51.3% of the participants had morning fatigue due to poor sleep quality. 40.3% of the participants suffered from some form of ocular abnormalities. 48% of the participants used an electronic gadget for more than 5 hours per day. Also, 39% of the participants had nightmares during sleep.

Conclusion

The long standing effects of lack of sleep are well known and there is a need to insist on adequate sleep among students. The effects could be avoided by proper education about the adverse effects due to lack of sleep. People could be educated to use blue light filter which was proven to be effective in improving sleep quality in comparison to those who did not use blue light filter as blue light induces melatonin formation which in turn stimulates the brain to stay awake leading to poor sleep quality. Promotion of health by attaining quality and adequate sleep has to be encouraged among young students.

Effects of Cosmetics on the Aetiology of Acne Vulgaris

Pooja Mohan[1], Thatiparthi Stephen[2], Gopalakrishnan S.[3]

[1]UG Medical Student, [2]Associate Professor, [3]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: Skin inflammation, otherwise called skin break out vulgaris, is a long haul skin sickness that happens when hair follicles are stopped up with dead skin cells and oil from the skin. The primary goal of the investigation was to examine the relationship between the incessant presentation of beautifying agents and the improvement of skin break out.

Techniques: Subjects of arbitrary age gathering and sexual orientation were chosen. An example space of 105 people was taken by irregular examining technique. An organized survey was utilized to examine the connection between the use of beautifiers and the improvement of skin inflammation which incorporated the socio statistic subtleties, history of skin break out, family ancestry of skin break out, use of beauty care products, and the fundamental treatment for the equivalent. The subsequent information was investigated measurably. Result: The investigation demonstrated that out of 105 people 27.6% of them had skin break out vulgaris and 44.8% of the all out members use beauty care products while 4.76% of the people created skin break out vulgaris due to the use of beautifying agents. Along these lines, beauty care products alone isn't in charge of the causation of skin inflammation vulgaris and skin break out can be caused because of different elements. conclusion: We found that the utilization of beautifying agents alone was not in charge of causing skin inflammation, and the improvement of skin break out is multifactorial.

Keywords: *Skin infection, obstructed skin, multifactorial.*

Introduction

Skin break out, otherwise called skin break out vulgaris, is a long haul skin ailment that happens when hair follicles are stopped up with dead skin cells and oil from the skin.[1] It fundamentally influences regions of the skin with a generally high number of oil organs, including the face, upper piece of the chest, and back.[2] The subsequent appearance can prompt nervousness, diminished confidence and in outrageous cases, discouragement or contemplations of suicide. Hereditary qualities are believed to be the essential driver of skin break out in 80% of cases. Different causative variables, including corrective introduction, have been ascribed towards acne.[3] Therefore, it is imperative to dissect the connection between the utilization of beautifiers and the improvement of skin break out.

Materials and Method

A cross-sectional investigation was led in Chennai, Tamil Nadu, India. The institutional moral panel affirmed the investigation. Subjects of age bunch 13-60 years were chosen. An example space of 105 people was chosen. All the included members were talked with utilizing a self-controlled survey to evaluate the examples of restorative use and the improvement of skin inflammation. It comprised of inquiries on socio-statistic subtleties, history of skin break out, utilization of beauty care products and the vital treatment for the equivalent. The information gathered was organized in Microsoft exceed expectations worksheet and PC based investigation was performed utilizing the measurable item and administration arrangements (SPSS) 16.0 programming. The clear cut factors were outlined as extents and rates.

Findings: A cross-sectional investigation was led. 105 people finished the poll. There were 65(61.9%) females and 40 (38.1%) guys. The age scope of the people was from 13-60 years. Table 1 and 2 delineates the socio-statistic qualities of the members. Table 3 demonstrates the different causes and worsening variables of skin break out vulgaris among the examination populace. Table 4 demonstrates the level of people utilizing makeup and experiencing skin break out. We saw that beautifiers don't really cause skin inflammation, and people in whom skin break out is brought about by the utilization of beauty care products demonstrated that long haul utilization of beautifying agents might be a potential disturbing element for their facial skin break out.

Table 1: Socio-demographic characteristics of the participants

Total Responses (105)	Gender (%)
Females	61.90%
Males	38.10%

Table 2: Age

Total	
Responses	105
Age	**%**
13 ~ 20	21%
21 ~ 30	26%
31 ~ 40	29%
41 ~ 50	18%
51 ~ 60	6%
61 ~ 70	1%

Table 3: Causes and exacerbating factors among the participants (n=105)

Causes	Yes	No
Family history	19	86

Table 4: Individuals having acne using cosmetics

	Yes	No
Acne	29	76
	(27.6%)	(72.4%)
Using	9	20
cosmetics	(31%)	(69%)

Discussion

The present examination was led to discover the connection between the use of beauty care products and skin break out and to investigate the relationship between the continuous presentation of makeup and the advancement of skin break out. Skin break out is a standout amongst the most widely recognized issue treated by dermatologists and other human services suppliers. In excess of 90 percent of total populace is influenced by skin break out sooner or later in their life. In spite of the fact that skin break out is a skin malady, it can prompt noticeable enthusiastic and mental issues.[2] In 2010, skin break out positioned eighth in the rundown of most predominant infections on the planet, with a worldwide pervasiveness of 645 million. Around 80 percent of individuals are influenced by skin break out between the beginning of pubescence and 30 years old.

Skin break out cosmetica is currently a consuming issue looked by a large portion of the populace. It is a skin express that most adolescents experience from most fragile occasions of their regular lives.[4] They will in general put most spotlight on their appearance and look and when they experience the ill effects of skin inflammation flare-ups, they pick it rather difficult to manage the issue. It is along these lines pivotal to work at treating skin inflammation assaults. On the off chance that it is left untreated, it just prompts burdensome issues, instructive drops, material maltreatment, and social detachment. Skin inflammation isn't a perilous issue, and the mental impacts principally comprise scarring which may keep going forever. The seriousness of Acne is fundamentally estimated by the skin inflammation sufferer's passionate and public activity. Corrective actuated pimples influence huge gathering of populace independent of their age gatherings. Unmethodical utilization of beautifying agents ought to be dodged. Severe individual cleanliness ought to be kept up to avoid the repeat of the pimples.[5]

Skin inflammation vulgaris is an almost all inclusive skin illness distressing 79-95% of the juvenile populace in westernized societies.[1] This anticipates approval and acknowledgment by the dermatological network. Skin break out influences 80% of people among pubescence and 30 years of age.[6] It was likewise recorded in 54% of ladies and 40% of men more than 25 years old.[3] Other examinations have detailed skin inflammation in 28-61% of younger students in the age bunch 10-12 years; 79-95% in the age bunch 16-18 years; and

even in kids in the age bunch 4-7 years.[4,5, 7] In India, commonness information from a dermatology center in a showing emergency clinic in Varanasi detailed skin break out in 50.6% of young men and 38.13% of young ladies in the age bunch 12-17 years.[6] There are accepted to be no sexual orientation contrasts in skin break out predominance, albeit such distinction is frequently revealed and, all around likely, speak to social predispositions. In centers in the urban regions, there is a reasonable prevalence of young ladies looking for treatment.[8]there is additionally an observation that skin inflammation is less predominant in rustic populace.

The general pervasiveness of skin inflammation in our investigation populace was 27.6% with 31% of the skin break out populace use beauty care products. This empowers us to realize that there is no critical relationship between's corrective utilization and improvement of skin break out vulgaris.

Conclusion

Skin break out is a standout amongst the most irksome and regular healthy skin issues for individuals around the globe, and sincerely a standout amongst the most thinking and humiliating skin issue to involvement. Albeit frequently connected with adolescents and the beginning of adolescence, in all actuality you can get skin break out at any age, which makes it all the more disappointing. Comprehending what causes Acne, is the initial phase in figuring out how to control it. Corrective initiated Acne is a present consuming issue. Skin inflammation cosmetica will create a gathering of manifestations like, pimples, redness, comedones, tingling, and staining. Basically eight of every ten individual's experience the ill effects of skin break out, every one of them must fight with Acne and its negative impacts. This investigation reasons that beauty care products isn't the main source for the improvement of skin break out and that skin break out has multifactorial causation.

Gallstone Ileus: A Rare Presentation of Cholecystoduodenal Fistula in a Female

Ameya Arjun Arumugam[1], S. Gopalakrishnan[2]

[1]UG Medical Student, [2]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Gallstone ileus is an uncommon type of little gut hindrance brought about by an impaction of gallstone inside the lumen of small digestive system. The regular side effects are sickness, regurgitating, clogging, stomach agony and distension. Starting administration includes liquid revival and conceivably nasogastric suctioning. Since gallstone ileus is a mechanical little entrail deterrent, it tends to be a careful crisis and requires open or laproscopic medical procedure to evacuate an affected stone. We present an instance of Gallstone ileus in a 75-year-old female who had a 2-day history of intense spewing which bothered after sustenance consumption. Patient was determined to have intestinal hindrance. Enterotomy was finished. The stone was found and recovered. The post-usable stage was uneventful.

Keywords: *Enterotomy, little inside check, jejunal gallstones, Rigler's set of three.*

Introduction

The gallbladder is a little, pear-molded organ that is a piece of the stomach related framework. It is situated on the correct side of the stomach area beneath your liver. The gallbladder stores and secretes bile, which is made by the liver, into the small digestive tract during absorption. Bile, a yellow-caramel liquid, helps condensation fats in nourishment. Gallstone ileus is an uncommon type of little inside impediment brought about by an impaction of gallstone inside the lumen of small digestive tract. It represents 1-4% of intestinal checks only in the more seasoned female population.[2] A jejunal area of gallstone ileus has been once in a while depicted in the writing. Gallstone ileus is a mechanical intestinal check because of gallstone impaction inside the gastrointestinal tract. Under 1% of instances of intestinal deterrent are gotten from this etiology. The name "gallstone ileus" is a misnomer in light of the fact that an ileus is, by definition, a non-mechanical inside motility disappointment.

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Materials and Method

A multi year elderly person was admitted to the emergency clinic with a multi day history of intense spewing which exasperated after nourishment consumption and was bilious in nature. She had a background marked by stomach torment that was colicky in nature. Anyway there was no history of stomach distension or fever or then again some other explicit protests. Before, there were no comorbidities, no past careful history yet the lady had a propensity for tobacco biting for as far back as 25 years. On clinical examination the patient seemed, by all accounts, to be got dried out, paleness (anicteric) and had low pee yield. Follow up of which CT ABDOMEN was done and uncovered proximal jejunum expanded and fallen ileum. Patient was additionally screened under USG uncovering intense intestinal obstacle. Examinations uncovered that, Hb-8.3 g%, S.Creatinine-2.0 mg%, Blood urea–65mg/dl, LFT ordinary, S.potassium–3.0 mEq/L. X-beam erect guts demonstrated numerous air liquid level, indications of intestinal hindrance.

Laparotomy discoveries uncovered a gallstone 3.5 cm X 2 cm blocking the jejunum 100 cm from the DJ flexure, Proximal dilatated inside circles, Multiple 1.5 cm calculi found in the digestive tract proximal to the deterrent, Gallbladder thickly disciple to duodenum and

containing stones. A 3 cm longitudinal entry point made only proximal to the deterrent drained out the stone. The various stones in the proximal small digestive tract were drained out. The entry point shut transversely in two layers. DT put and twisted shut in layers. Considering the age, drying out, ARF and poor general state of the patient, separation of cholecystoduodenal fistula and subtotal cholecystectomy was arranged later as an elective medical procedure. The patient was doing admirably post task.

Findings: Patient was determined to have intense little inside impediment and in this way crisis laparotomy was arranged and the surgical technique pursued with restorative administration. Following which Enterotomy was done in the ileum for 4cm, proximal to affected site. Stone was found and recovered. Around five littler stones additionally recovered proximally. Enterotomy shut in opposite way to stay away from hindrance in two layers. The post-usable stage was uneventful.

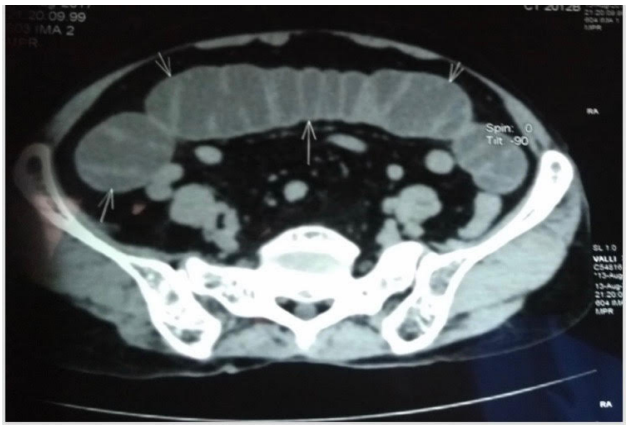

Figure 1: abdominal radiograph shows dilated jejunum & abdominal radiograph shows collapsed ileum.

Figure 2: Shows stone of size 3.5x2cms and multiple 1.5cm calculi.

Discussion

Gallstone ileus is a mechanical intestinal obstacle because of gallstone impaction inside the gastrointestinal tract. Under 1% of instances of intestinal block are gotten from this etiology. The name "gallstone ileus" is a misnomer in light of the fact that an ileus is, by definition, a non-mechanical gut motility failure.[1] Gallstone ileus is an unprecedented difficulty of cholelithiasis with a high grimness and mortality rate.[2] Gallstone ileus is an uncommon ailment and records for around 1-3% of specialist ileus of the little inside, however for 25% of all little entrail blocks in patients more seasoned than 65 years. Associative cardiorespiratory maladies or diabetes are visit in more established patients and in charge of the high death rate.

The traditional X-beam portrayal of gallstone ileus is RIGLER'S TRIAD (ectopic gallstone, halfway or complete entrail deterrent and gas in the gallbladder or biliary tree) Riglers Traid is a mix of discoveries on a stomach radiograph of individuals with gallstone ileus.[3] Pneumobilia is seen in just 33% of cases likely because of impediment of the cystic pipe from the inflammed gallbladder. Radiological highlights of little inside deterrents might be missing when in the sub intense stage, as found for this situation. One investigation has exhibited 96% affectability in analysis when stomach X-beam is joined with a stomach ultra sound scan.[4]

Conclusion

Gallstone ileusis an uncommon reason for little gut impediment (1-4%). Jejunum as a site of check is seen uniquely in 15% of gallstone ileus(70% in ileum).10% have extra stones in small digestive tract like our case.[4] Jejunum gallstones represent a specific indicative test and request a high file of doubt. The administration of the stone seems to fluctuate contingent upon the method of introduction. A high record of doubt is required on deciphering plane x-beam films. Stomach ultra sound, differentiate considers and a stomach CT output are on the whole complimentary and may help in achieving a pre usable finding. The perfect treatment for jejunum gallstones is a solitary stage laparotomy, cholecystectomy and fistula repair.[5]

Metabolic Syndrome: A Short Review

Ambati Lakshmi Vaishali[1], S. Gopalakrishnan[2]

[1]UG Medical Student, [2]Professor,Department of Community Medicine,
Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Critical intrigue exists in understanding the common metabolic dysregulation prompting heftiness, diabetes, and cardiovascular sickness (CVD). Henceforth came the idea of the "metabolic disorder" (MetS). Reaven first depicted MetS in his 1988 Banting address as "Disorder X". Reaven recommended that the disorder depended on the presence of insulin opposition and brought about glucose narrow mindedness, hypertension and dyslipidemia. The World Health Organization (WHO) created the main formalized meaning of the MetS in 1998. From that point forward numerous meanings of the disorder have been proposed, the latest being the Harmonized Definition where 3 of the 5 hazard variables are available: amplified abdomen outline with populace explicit and nation explicit criteria; triglycerides ≥ 150 mg/dL, HDL-C < 40 mg/dL in men and < 50 mg/dL in ladies, systolic circulatory strain ≥ 130 mm Hg or diastolic pulse ≥ 85 mm Hg and fasting glucose > 100 mg/dL, with the consideration of patients taking drug to oversee hypertriglyceridemia, low HDL-C, hypertension, and hyperglycemia. The National Health and Nutrition Examination Survey (NHANES) assessed the general predominance of MetS in grown-ups (matured ≥ 20 years) in the United States as 33% from 2003 to 2012. The high commonness is especially disturbing given that MetS likewise inclines to various genuine conditions past diabetes and CVD including non-alcoholic greasy liver illness (NAFLD), non-alcoholic steatohepatitis (NASH), polycystic ovarian disorder (PCOS), obstructive rest apnea (OSA), malignancy, and numerous different genuine ailment states.A study directed in urban zones of Karachi and Pakistan,showed high predominance of MetS-34.8 and 49% as per International Diabetes Federation (IDF) definition and altered National Cholesterol Education Program,Adult Treatment Panel III (NCEP ATPIII) criteria,respectively.Hence, early distinguishing proof and intercession are justified. Way of life change is the central intercession in treatment of MetS.

Keywords: *Metabolic Syndrome, CVD, non-alcoholic greasy liver illness (NAFLD), polycystic ovarian disorder (PCOS).*

Introduction

The metabolic disorder (MetS) is depicted by the bunching of a few hazard factors for cardiovascular infection (CVD, for example, hypertension, dyslipidaemia, weight (especially focal stoutness), insulin opposition and high fasting plasma glucose.[1] In 2001, The Third Report of National Cholesterol Education Program Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III) (ATP III) underlined the significance of the metabolic disorder and gave a working meaning of this disorder for the first time.[2] Contrasts in hereditary foundation, diet, levels of physical movement, age and sex structure all impact the pervasiveness of both metabolic disorder and its components.[3] Cardiovascular sickness is one of the fundamental reasons of death among ladies on the planet.[4]

Meaning of Metabolic Syndrome: There are a few meanings of Metabolic Syndrome in the World. World Health Organization's (WHO) settled on a choice in 1988 to institutionalize the criteria. The WHO was characterized as one of the accompanying: Type 2

diabetes debilitated fasting glucose, hindered glucose resilience and for those with typical fasting glucose (< 110 mg/dL). The hazard components incorporate antihypertensive prescription or potentially hypertension (≥ 140 mmHg systolic or ≥ 90 mmHg diastolic), plasma triglycerides ≥ 150 mg/dL, HDL cholesterol < 35 mg/dL in men or < 39 mg/dL in ladies, BMI > 30 kg/m2 and additionally midriff: hip proportion > 0.9 in men and > 0.85 in ladies.[5]

Met S is characterized by a group of stars of an interconnected physiological, biochemical, clinical, and metabolic elements that straightforwardly builds the danger of atherosclerotic cardiovascular illness (ASCVD), (T2DM), and all reason mortality.[6]

The three most broadly perceived ongoing endeavors to characterize the metabolic disorder incorporate the WHO report from 1999[7], the European Group for the Study of Insulin Resistance (EGIR), additionally in 1999[8], and the meaning of the National Cholesterol Education Program Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults–also called the Adult Treatment Panel III (ATPIII)–in 2001.[9] The first 352 A.J. Cameron et al/Endocrinol Metab Clin N Am 33 (2004) 351–375 WHO proposals were not intended to be an accurate definition; rather, they were planned as a working rule, to be enhanced later on, that would empower likeness between studies. Following the distribution of the WHO meaning of the metabolic disorder in 1999, the EGIR proposed an adjusted form to be utilized in nondiabetic subjects just, that would be more straightforward to use in epidemiologic examinations since it didn't require an euglycemic clip to quantify insulin opposition, and with marginally changed cut-focuses for hypertension, triglycerides, high-thickness lipoprotein (HDL) cholesterol, and modified measures and cut-focuses for obesity. [8]

Epidemology: Overall commonness of MetS ranges from <10% to as much as 84%, contingent upon the area, urban or provincial condition, piece (sex, age, race, and ethnicity) of the populace considered, and the meaning of the disorder used. [10,11]

The predominance of MetS shifts the world over and regularly relates with the pervasiveness of weight. There is a wide variety in predominance dependent on age, sexual orientation, race/ethnicity, and the criteria utilized for determination. MetS influences a fifth or a greater amount of the number of inhabitants in the USA and about a fourth of the number of inhabitants in Europe. South-east Asia has a lower pervasiveness of MetS yet is quickly moving towards rates like the western world. Beltrán-Sánchez and partners announced a lessening in the age-balanced commonness of MetS in the USA, from 25% in 2000 to 22.9% between 1999/2000 and 2009/2010 dependent on National Health and Nutrition Examination Survey (NHANES) data.[12]

Higher financial status, inactive way of life, and high weight file (BMI) were altogether connected with MetS. Cameron et al. have inferred that the distinctions in hereditary foundation, diet, levels of physical action, smoking, family ancestry of diabetes, and instruction all impact the commonness of the MetS and its components.[13] The watched pervasiveness of the MetS in National Health and Nutrition Examination Survey (NHANES) was 5% among the subjects of ordinary weight, 22% among the overweight, and 60% among the obese.[14] It further increments with age (10% in people matured 20–29, 20% in people matured 40–49, and 45% in people matured 60–69)15. The predominance of MetS (in view of NCEP-ATP III criteria, 2001) fluctuated from 8% to 43% in men and from 7% to 56% in ladies around the world. Park et all seen that there is an expansion in the pervasiveness of MetS from 20 years of age through the 6th and seventh decade of life for guys and females, individually. Ponholzer et al. detailed that there is high predominance of MetS among postmenopausal ladies, which changes from 32.6% to 41.5%16.

Pathogenesis of MetS: job of irritation: The pathogenic instruments of MetS are intricate and stay to be completely explained. Regardless of whether the individual segments of MetS speak to unmistakable pathologies or signs of a typical pathogenic component is still discussed. The wide variety in geographic dispersion of MetS and the ongoing ‘make up for lost time’ in the creating scene underscore the significance of ecological and way of life factors, for example, the utilization of abundance calories and absence of physical action as being real supporters. Instinctive adiposity has been shown to be an essential trigger for the greater part of the pathways associated with MetS, in this manner focusing on the significance of a high caloric admission as a noteworthy causative factor.[17] Of all the proposed components, insulin obstruction, neurohormonal enactment, and interminable aggravation have all the earmarks of being the principle players in the inception, movement, and change of MetS to CVD (Figure1).

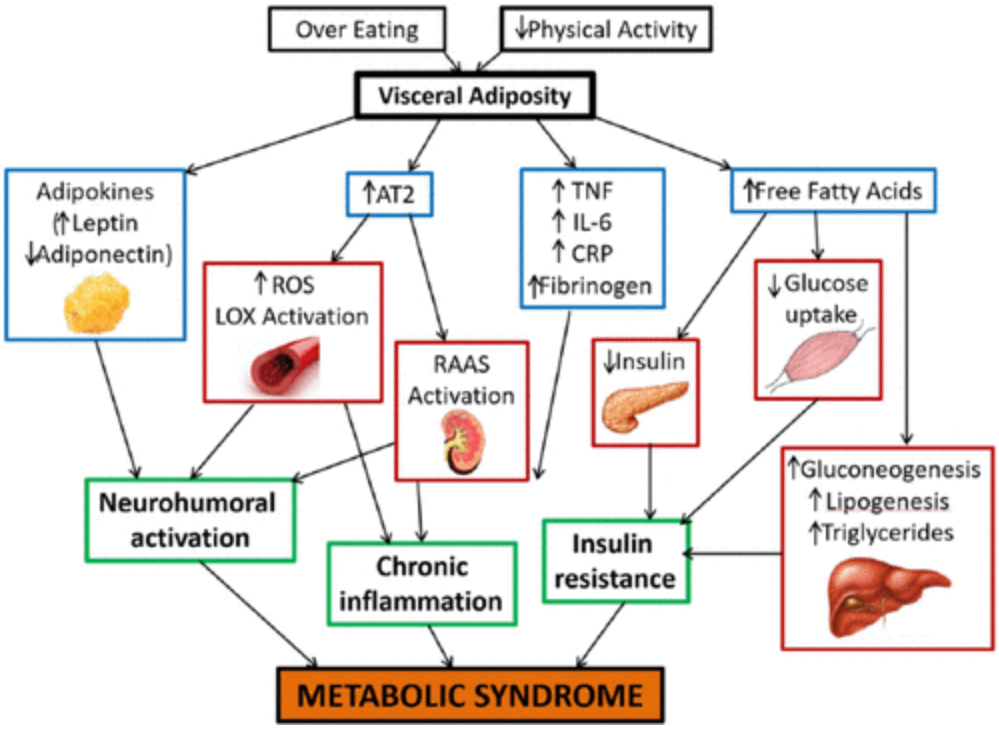

Figure 1. Pathophysiological systems in metabolic disorder. AT2, angiotensin II type 2 receptor; CRP, C-responsive protein; IL-6, interleukin 6; LOX, lectin-like oxidized low-thickness lipoprotein; RAAS, renin-angiotensin-aldosterone framework; ROS, receptive oxygen species; TNF, tumor rot factor. Metabolic disorder: pathophysiology, the board, and balance by normal mixes. The board of MetS.

MetS is related with an expanded danger of both atherosclerotic and nonatherosclerotic CVD. Regardless of whether the hazard is a whole of its individual parts or the bunching of these segments instigates a synergistic hazard is still under discussion. Results from an ongoing meta-investigation by Motillo and partners showed that MetS copies the danger of CVD results and expands all-cause mortality by 1.5 occasions. The executives of MetS includes a double methodology that joins way of life changes and pharmacological intercessions with an end goal to diminish CVD.[18]

Way of life change: As depicted before, MetS results from expanded calorie utilization lopsided to metabolic necessities. Way of life adjustment is basic in the administration of basic hazard factors. Weight decrease and support of perfect body weight are fundamental preventive and the board techniques. The objective of weight decrease is lost 7–10% in gauge body weight over a time of 6 a year just as a decrease of caloric admission by 500–1000 calories/day. Dietary change can likewise control different MetS segments: low admission of soaked fats, trans fats, cholesterol, sodium, and basic sugars is known to help with dyslipidemia, hyperglycemia and hypertension, for instance. Diets high or low in fat substance fuel atherogenic dyslipidemia, all things considered, 25–35% of every day caloric admission as fat is typically suggested. Reasonable utilization of bariatric medical procedure has indicated advantage in the butterball shaped. Weight decrease assists with progress in all segments of activity. Exercise builds calorie utilization, helping weight reduction and diminishing generally speaking CVD hazard: around 30–60 min of moderate power practice and cognizant endeavors to adjust a stationary way of life can be useful for the administration of MetS.[18]

Pharmacotherapy: Alongside altering the hidden hazard factors, pharmacotherapy is another alternative for the counteractive action of CVD. Major pharmacological intercessions incorporate administration of dyslipidemia with statins, diminishing prothrombotic hazard with antiplatelet drugs, and the utilization of insulin sensitizers to diminish the danger of diabetes. There is no single medication treatment for MetS and as of now accessible pharmacotherapy and related comorbidities require delayed utilization of different drugs, which is trying for patients because of

polypharmacy and diminished consistence. Therefore, there is developing enthusiasm for the utilization of normally happening mixes in bringing down the hazard and movement of MetS however their impact on long haul cardiovascular results and long haul consistence is unknown.[18]

Treatment: MetS is a condition of endless second rate irritation with the significant fundamental impacts (Table1). Clinical recognizable proof and the board of patients with the MetS are essential to start endeavors to satisfactorily actualize the medications to lessen their danger of resulting diseases.[19] Successful preventive methodologies incorporate way of life changes, basically weight reduction, diet, and work out, and the treatment contains the suitable utilization of pharmacological operators to decrease the particular hazard factors. Pharmacological treatment ought to be considered for those whose hazard elements are not sufficiently decreased with the preventive measures and way of life changes.[20] The clinical administration of MetS is troublesome in light of the fact that there is no perceived technique to counteract or improve the entire disorder, the foundation of which is basically insulin resistance.[21] In this manner, most doctors treat every segment of MetS independently, laying a specific accentuation on those parts that are effectively agreeable to the medication treatment. Truth be told, it is simpler to endorse a medication to lower circulatory strain, blood glucose, or triglycerides instead of starting a long haul system to change individuals' way of life (practice more and eat better) with the expectation that they will eventually shed pounds and will in general have a lower pulse, blood glucose, and triglycerides. For the treatment of hazard components of MetS, the doctor ought to pursue the present treatment rules of the National Cholesterol Education Program (NCEP)[22], the American Heart Association (AHA) 23.

Table 1: Fundamental impacts of MetS.

Renal	Microalbuminuria, hypofiltration, hyperfiltration, glomerulomegaly, central segmental glomerulosclerosis, and endless kidney disease.[24]
Hepatic	Increased serum transaminase, nonalcoholic steatohepatitis (NASH), nonalcoholic greasy liver sickness (NAFLD), hepatic fibrosis, and cirrhosis.[25]
Skin	Acanthosis nigricans, lichen planus, fundamental lupus erythematosus, consume instigated insulin obstruction, psoriasis, androgenetic alopecia, skin labels, skin malignancy, and skin inflammation inversa.[26]
Ocular	Nondiabetic retinopathy, age related waterfall atomic, cortical, back subcapsular; focal retinal supply route impediment, essential open point glaucoma, oculomotor nerve paralysis, and lower cover Entropion.[27]
Sleep	Obstructive rest apnea (OSA)[28]
Regenerative system	Hypogonadism, polycystic ovarian disorder (PCOS), and erectile dysfunction[29]
Cardiovascular system	Coronary coronary illness (CHD), myocardial localized necrosis (MI), and stroke[30]
Cancers	Breast, pancreas, and prostrate[31]

Hazard Assessment: The objectives of treatment are to decrease both a present moment and lifetime chance. The nearness of the MetS per seindicates a higher lifetime chance. A commonsense way to deal with gauge supreme, present moment CHD/CVD hazard in patients with the MetS without ASCVD or diabetes is to utilize the standard Framingham calculation to appraise a 10-year danger of the coronary illness (CHD).[22]

Conclusion

MetS is a worldwide pandemic and built up hazard factor for atherosclerotic and non atherosclerotic CVD.Insulin resistance, visceraladiposity, atherogenic dyslipidemia, endothelial dysfunction, geneticsusceptibility, elevated blood pressure, hypercoagulable state,chronic stress are a few elements of MetS. Lifestyle alteration stays as the underlying intercession of choice. Existing treatments to handle different parts of MetS are constrained by different elements. Right off the bat, the presence of just a bunch of prescriptions that have been appeared to convincingly affect long haul results settles on the decision of treatment testing. Also, the ceaseless idea of the segments of MetS warrant delayed and regularly uncertain utilization

of different meds, for example, statins, prompting an expanded weight of medication related antagonistic impacts and patient rebelliousness. In this specific circumstance, the improvement of nutraceuticals that are promptly accessible and with negligible reactions may speak to a region of guarantee in the advancement of novel treatments.

Parenteral Breastfeeding Practices in Rural Population of Kancheepuram District

Venkata NagaPoojitha L.[1], V.M. Anantha Eashwar[2], S. Gopalakrishnan[3]

[1]UG Medical Student, [2]Assistant Professor [3]Professor,Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Breast sustaining assumes a significant job in the advancement of the child. The greater parts of the moms in our general public are uninformed of its significance. Thus, this examination is being led to know the commonness of breastfeeding rehearses in the urban zone of kancheepuram local. Materials and Method: The unmistakable cross sectional examination was completed among 100 ladies having kids between the age gathering of 0 months to 1 year going to urban Health preparing focal point of a private restorative school. Helpful examining strategy was pursued, and a semi-organized poll was utilized to gather socio statistic subtleties and breastfeeding rehearses. Result: The commonness of parenteral breastfeeding practices is observed to be 67%. There found to a misguided judgment among the moms that the other weaning items give a superior wellbeing and advancement to their infants. End: The predominance of parenteral bosom nourishing practices in our examination is has been observed to be low. Consequently, instructive projects and mindfulness camps must be made and taken to the mother and other relatives.

Keywords: *Parenteral Breastfeeding, semi-organized poll, parenteral bosom.*

Introduction

Breastfeeding has been definitively exhibited as a standout amongst the most significant determinants for development and survival of newborn children, youngster and lactating moms. For any neonate, 'Bosom is ideal' is currently an all inclusive idea. It contains abnormal amounts of counter acting agent rich proteins, particularly secretory immunoglobulin an and lactoferrin, which offers security to the new conceived from disease. The antibodies found in human bosom milk secure the infant against respiratory contaminations. Increment in breastfeeding practice has decreased the occurrence of intrusive bosom malignant growth by 4.3 percent while 30 rate decreases in ovarian disease can be seen related with longer times of breastfeeding.

World Health Organization (WHO) suggests early commencement of breastfeeding solely for a half year. And furthermore included that breastfeeding till 1 year is progressively effective to build the invulnerability of the tyke. It is can be noticed that youngsters breastfed for under 1 year are at extraordinary danger of being underweight and squandering as the bosom milk supplements Vitamin A. In any case, an all-inclusive breastfeeding without the presentation of suitable reciprocal nourishments following a half year can prompt hunger. All around, just 40 percent of newborn children under a half year of age are only breastfed.[1] About 67% of newborn children in India are only breastfed.

The breastfeeding project endeavors to rejuvenates the endeavors towards advancement, security and backing of breastfeeding rehearses through wellbeing frameworks to improve breastfeeding rates.[2] Under any conditions bosom milk is the perfect nourishment for the newborn child. No other sustenance is required by the child until a half year after birth. Under typical conditions, Indian mother emit 450-600ml of milk day by day with 1.1gm protein per 100ml. The vitality estimation of human milk is 70 Kcals per 100ml.[3] Bosom milk is the characteristic first nourishment for children, it gives all the vitality and supplements that the baby

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

requirements for the main long stretches of life, and it keeps on giving up to half or even more a kid's dietary needs during the second 50% of the primary year, and up to 33% during the second year of life.[4]

The Government of India just because had included explicit objectives to improve newborn child bolstering rehearses for decreasing the Infant Mortality Rate (IMR), hunger and advancing coordinated early tyke advancement in the 10 th Five-Year Plan. It likewise intended to build the rate of commencement of breastfeeding inside 1 h to half from the present degree of 15.8%, and to expand the selective breastfeeding rate to 80% during the initial a half year from the present level. Despite the fact that there have been worldwide developments towards ensuring, advancing and supporting bosom milk as a piece of ideal bolstering rehearses among infants, there exist numerous disparities between what has been prescribed and what is being polished in actuality. "Poor newborn child bolstering rehearses and their results are one of the world's serious issues and a genuine obstruction to social and financial improvement. It isn't just an issue of the creating scene, it happens in numerous pieces of the created world also". As indicated by National Family Health Survey–4, which were discharged in 2016, the predominance of select breastfeeding in India was 55% and in Tamil Nadu, it was 48.3 %. Youngsters under 3 years old, breastfed inside one hour of birth was observed to be 41.6% in India and 54.7% in Tamil Nadu. All inclusive (90%) inclusion of breastfeeding can forestall 13% of passings of youngsters under 5 years of age.[5]

Materials and Method

Study plan: This was network based clear cross sectional investigation did in a urban zone of Kancheepuram. Study territory and test estimate: The investigation was done among ladies having youngsters matured 0 months to 1 year going to as outpatients in a private therapeutic school. The example size is 100. Study Period: The investigation was completed in April 2019. Moral endorsement and Informed Consent: Ethical freedom was gotten from the Institutional Ethical Committee and educated assent was acquired from every single member. Study Tool: A semi-organized survey was utilized information gathering by eye to eye meet. The survey incorporated the socio-statistic subtleties, term of selective breastfeeding, inception of breastfeeding, other weaning items utilized. They were enquired and noted.

Findings: Table. 1 demonstrates the sociodemographic profile of the example individuals. It demonstrates that the example has a larger number of moms of age over 31 years and the per capita salary of them is in excess of 10,000 rupees and furthermore they all have the instructive capability of auxiliary training and the vast majority of them are non-working lastly the financial status of them is medium.

Table 1: Sociodemographic profile of the study participants

Demographic Variables	Groups	Percentage
Age in years	<19	0%
	20-25	30%
	26-30	41%
	>31	29%
Income per month	<2500	0%
	2500-5000	0%
	5000-10000	5%
	>10000	95%
Marital status	Married	100%
Formal education	None	13%
	Primary	15%
	Secondary	72%
Mothers employment	Working	56%
	Non-working	44%
Socio economic status	Low	16%
	Medium	73%
	High	11%

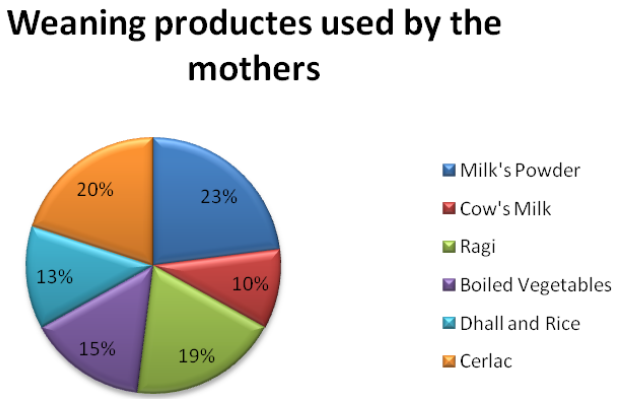

Figure 1: Weaning productes used by the mothers.

Figure.1 shows the other weaning products that has been used along with or other than the breast milk. Of all these milk powder tops the list next comes the

supplementary food cerelac and it is followed by ragi, boiled vegetables, dhal and rice and finally then cow's milk.

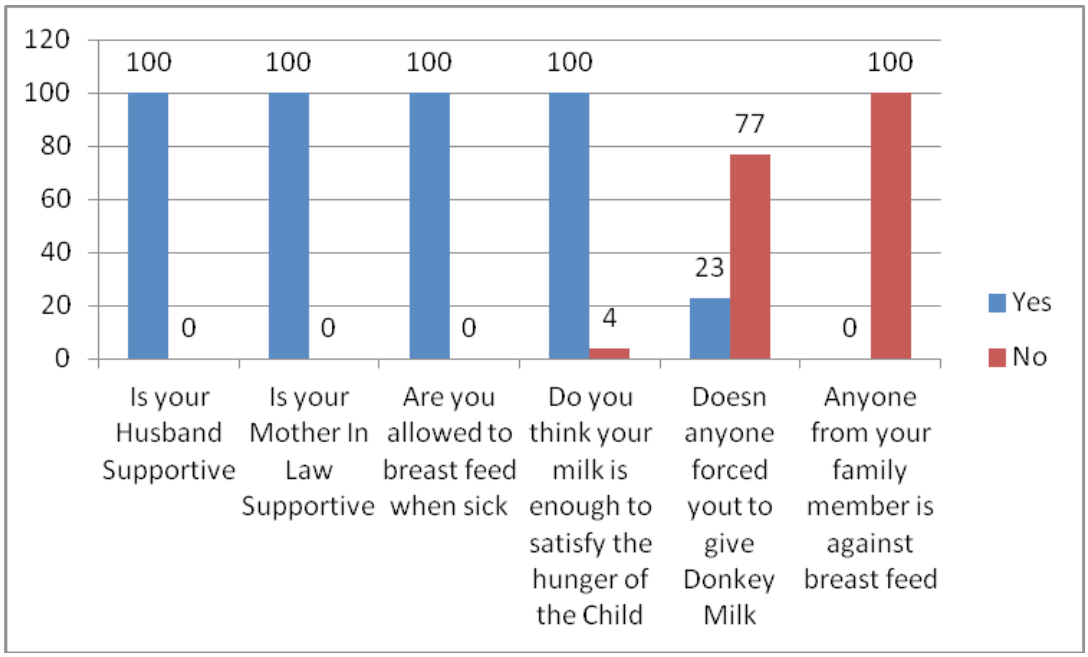

Figure 2: Breastfeeding support among family members

Figure 2 demonstrates the level of answers to the inquiries that has been posed during the review. It speaks to that every one of the spouses and mother in laws are strong in breastfeeding and none of the relatives are against the breastfeed. Also, about 77% have addressed that they were told by few of their relatives and companions to give jackass' milk as it builds the vocal limit of the infant. What's more, nearly everyone were to permitted breastfeed notwithstanding when they wiped out. What's more, 96% of the moms feel that their milk is adequate to fulfill the craving of the kid.

Discussion

Because of modernization and uncontrolled publicizing of equation sustains, the act of restrictive breastfeeding is gradually vanishing from our locale. Our investigation done in urban region of kancheepuram, demonstrated the predominance of select breastfeeding to be 67%. Comparable outcomes were found in an investigation done by S. Radhakrishnan et al in Salem (34%) and by Joshi PC et al in Bangladesh (36%).[6, 7] This demonstrates the qualities are lower than our national predominance of selective breastfeeding.

It is discovered that lone 33% of kids are breastfed inside 60 minutes. As per NFHS–4 reviews held in 2015-16, broadly 41.6% of babies were breastfed 1 hour after birth. Additionally in our examination, 21% of the youngsters were not breastfed even following 24 hours after birth. This demonstrates the absence of familiarity with breastfeeding rehearses that will be started following birth.[5]]

Numerous confusions about breastfeeding practices are rehearsed all over our nation. At the point when approached about the purpose behind not rehearsing, the most widely recognized answer was that there are other weaning items superior to anything bosom milk in giving better improvement and expanding body weight and a decent vocal limit. The other weaning items utilized by a large portion of them are ragi, jackass milk, cerelac, bovine's milk, vegetables, dhall, ect.

Conclusion

This examination demonstrates that the restrictive breastfeeding practices are being brought down in our locale. Also, there is a need to make mindfulness among the ladies' of tyke bearing age with respect to the breastfeeding practices like select breastfeeding for a half year and to begin nourishing following birth. This training ought to likewise be given to the next relatives. This would bring the change and make it a triumph.

Funding source: No financing sources

Conflict of intrigue: None announced

Ethical endorsement: The investigation was affirmed by the Institutional Ethics Committee, Sree Balaji Medical College and Hospital.

Prevalance of Obesity among Urban Population in Thiruvallur District

Tejal H.[1], V.M. Anantha Eshwar[2], S. Gopala Krishnan[3]

[1]UG Medical Student, [2]Assistant Professor, [3]Professor Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: Stoutness and overweight are quickly expanding in nations like India. Weight prompts different conditions like expanded dangers of Cardiovascular infections, angina, diabetes mellitus. There is additionally a connection among obesity and atherosclerosis. Because of the utilization of unfortunate nourishment, stationary way of life, absence of social insurance administrations, and money related help, the creating nations are confronting high danger of corpulence and their unfriendly outcomes like ischemic heart ailments, diabetes mellitus, and so on.

Techniques: This is a cross sectional examination led in Thiruvallur region among urban populace. Every one of the general population having a place with either sexual orientation in the gathering of 20-50 years, who were obviously sound were incorporated into the examination.

Results: A sum of 100 individuals was incorporated into the investigation, 11 people were observed to be stout.

Conclusion: BMI is fundamentally identified with dietary propensities. Dietary propensities are of the significant determinants of stoutness and its related outcomes, and other related issues like hair fall, stomach throb, obstruction and so forth.

Keywords: *Weight, Overweight, Bmi, Cardiovascular Diseases.*

Introduction

Weight and overweight are quickly expanding in nations like India. Weight prompts different conditions like expanded dangers of Cardiovascular ailments, angina, diabetes mellitus.[1] The rising weight of corpulence is the significant risk for the creating nations. Heftiness is the way of life executioner illness. Heftiness is ordinarily characterized calm basically as abundance body weight for tallness, however this basic definition gives a false representation of an etiologically mind boggling phenotype essentially connected with adiposity, or body bloatedness, that can show metabolically[2] and not simply as far as body measure. Corpulence extraordinarily builds danger of unending ailment horribleness–specifically inability, wretchedness[3], type 2 diabetes cardiovascular infections, and mortality. Weight is influencing a large number of individuals in our country[4]. Obesity was viewed as a created world issue. Anyway these days the pervasiveness of stoutness is definitely expanding in creating nations too.[5] Different parts of neighborhood condition assume a key job in the improvement of heftiness. Weight and overweight is the fundamental driver for the improvement of non-transferable malady dreariness and mortality. BMI is the proportion of weight in kilogram isolate by stature in meters squared (kg/m2).[6] Neighborhood retailing of fatty unfortunate sustenance had been involved in influencing the commonness rate of weight and overweight. As per the world wellbeing association, heftiness is a standout

Corresponding Author:
Dr. M. Anantha Eshwar
Assistant Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

amongst the most widely recognized, yet among the most dismissed, general medical issues in both created and the creating nation. The danger of death was most minimal when BMI was 30 kg/m2.[7] Individuals with heftiness have higher mortality than non-hefty people. Corpulence is numerous, complex, and to a great extent preventable infection, influencing more than 33% of the number of inhabitants on the planet.[8]

Materials and Method

This was a spellbinding cross sectional examination done to discover the predominance of heftiness among urban populace in Thiruvallur region between the time of April 2019-July 2019. The example size was 100.

Educated composed assent was taken from the examination members before they were incorporated into the investigation. Data was gotten utilizing a self-regulated poll. Weight file was evaluated by estimating their and weight and were arranged into whether they were hefty or not.

Findings: A sum of 100 people were engaged with the investigation. Around 45% of them were between the age gathering of 20-30 years. 59% of them were of them were females. With respect to, 25% were overweight and 11% were hefty.

Category	Criteria	Percentage
Age group	20-30	45%
	30-40	20%
	40-50	35%
Sex	Male	41%
	Female	59%
Occupation	House wife	29%
	Teacher	3%
	Student	22%
	Business	31%
	Tailor	2%
	Government staff	13%
BMI	Under weight (<18.5)	2%
	Ideal weight (18.5-24.9)	62%
	Over weight (25-29.9)	25%
	Obese (>29.9)	11%
Consumption of tobacco in some form	Yes	14%
	No	81%
	Occationally	5%
Drinking	Yes	8.2%
	No	81.6%
	Occationally	10.2%
Ever tried to quit smoking & drinking	Yes	9.1%
	No	30.3%
	Not applicable	60.6%
Hypothyroidism	Yes	4%
	No	96%
Sleep duration	>6-8 hours	34%
	<6-8 hours	49%
	>12 hours	27%
Stress	Yes	63%
	No	37%

Mobility	No problem	84%
	Some problem	16%
	Confined to bed	0%
Medical problems preventing you from doing exercises	Yes	15%
	No	81%
	Don't know	4%
Have you ever tried to lose weight	Many times	15%
	Occationally	24%
	Never	61%

Discussion

The ICMR-INDIAB study is the principal think about from India to appraise the predominance of corpulence (summed up and stomach) among urban and rustic inhabitants of States of India. This investigation demonstrated the accompanying outcomes: the most astounding commonness of the two kinds of heftiness (GO and AO) was found in Chandigarh pursued by Tamil Nadu, Maharashtra and Jharkhand. This isn't amazing as Chandigarh has the most elevated per capita pay among all the four areas considered and is profoundly urbanized, comprising essentially of the city of Chandigarh and a couple of peri-urban clusters.[9]

In the present examination pervasiveness of summed up, stomach and joined stoutness was observed to be 56%, 71.2% and 51.3% separately. Andhra Pradesh, 44.4 percent urban men experienced stoutness, while the rate in provincial parts was 28 percent. Correspondingly, 45.6 percent of the urban ladies in the state were stout against the 27.6 percent ladies in rustic Andhra Pradesh. In an investigation led in urban north India (New Delhi), the general commonness of summed up weight was 50.1 percent, while that of stomach corpulence was 68.9 per cent.[10]

In nations like India, the ascent in heftiness predominance could be ascribed to the expanding urbanization, utilization of automated vehicle, expanding accessibility of handled and quick nourishments, expanded TV seeing, reception of less physically dynamic ways of life and utilization of more "vitality thick, supplement poor" diet. Higher predominance of obesiety in young ladies is likewise troubling in light of the fact that it might build the prevalanvce of gestational diabetes, type 2 diabetes, hypertension and cardiovascular maladies in later life. They may experience the ill effects of significant outcomes like polycystic ovary disorder, barrenness, etc..with further urbanization, changing way of life and conduct we may expect further increment in the occurrence and the predominance of obesiety in india.

Conclusion

BMI is essentially identified with stationary way of life and dietary propensities. Dietary propensities and absence of activity and inactive way of life are the real determinants of weight and other wellbeing related issues like heart ailments, diabetes, and so on heftiness can likewise be brought about by the propensity for skirting breakfast being particular about sustenance. Different propensities like taking desserts routinely and so forth turns into a significant reason for creating corpulence. So measures should take at school levels, kids, ought to be instructed about the outcomes of weight and its preventive measures. And furthermore they ought to be guided for ordinary little exercise which can keep them from weight. Legitimate sound eating regimen ought to be prompted. An activity of around 30 min is exhorted.

Prevalence of Gaming and its Psychological Effects among Young Adults in an Urban Area of Chennai

Siva Sankarasekaran V.[1], Swetha N.B.[2], Gopalakrishnan S.[3]

[1]Student, [2]Assistant Professor, [3]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: Video gaming has turned into a most well known relaxation action in numerous pieces of the world, which seems to create issues because of unreasonable gaming, most ordinarily among understudies. The gaming standard of conduct is of adequate seriousness to result in huge disability in close to home, family, social, instructive, word related or other significant regions of working. In this setting present examination was directed to survey the predominance of dependence on online computer games among young people. Techniques: This is a cross-sectional investigation led among 100 youthful grown-ups (18-25 years) chose from a urban territory of Chennai by advantageous examining. The greater part of them were chosen from the schools arranged close to the urban zone. The parts of gaming and its belongings were evaluated utilizing a pre-tried organized poll. Results: In our examination, the normal length of gaming was 2 hours. The members conceded about irregular rest practices like dozing late around evening time, awakening amidst night for scoring higher levels in the game. Because of expanded preoccupancy with gaming, they conceded to having lesser focus during classes in this way indicated terrible showing in their examinations. As 26% of understudies were making diversions in the class hours with their companions their examinations and scholastic execution was influenced the most. In this investigation, understudies who were having high scores grumbled of state of mind issue like uneasiness, discouragement, impulsivity and compulsivity. Conclusion: Gaming issue are on an ascent, which has lead understudies to psychosocial unsettling influences, tension, wretchedness, state of mind issue, rest aggravations, cerebral pain, absence of social exercises, and debilitation in instruction. In this way, the time has come to manage the utilization of Electronic gadgets, Internet and computer games.

Keywords: *Video gaming, rest, scholastic execution.*

Introduction

Gaming issue is portrayed by longing for of the individual to play computer games. This may influence every day schedule exercises of the individual, alongside horrible showing in studies, not ready to satisfy the needs in occupation, different regions of significant working and aggravations in family connections. As indicated by world Health association, gaming issue is analyzed after time of at any rate a year, however from the get-go in instances of seriousness of signs and symptoms.[1] It has perceived as serious issue and has included under International Classification of Diseases 11, for example scatters because of substance utilize or addictive practices.

An examination led by Caplan et al, uncovered that there was psychological debilitation among computer game addicts.[2] Physical ailments like repetitive incessant cerebral pains, queasiness, cervical spondylitis because of inappropriate adjusting of neck, obscuring of vision, dry eyes, early advancement of waterfalls, torment in wrist and bury phalangeal joints were credited to gaming addicts.[3] Psychiatric diseases like mind-set issue, tension, longings for gaming, propensity for stealing, loss of intrigue and so on were additionally

Corresponding Author:
Dr. NB. Swetha
Assistant Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

noted in numerous studies.[4,5] The American Psychiatric Association (APA), while expressing there is lacking proof for the consideration of web gaming issue in the Diagnostic and Statistical Manual of Mental Disorders in 2013, thought of it as a condition for further study.[6] Some scholars center around assumed inherent reward frameworks of the recreations to clarify their possibly addictive nature.[7,8] Many computer games, especially greatly multiplayer online job playinggames and informal organization and versatile games,[9] depend on an "impulse circle" or "center circle"-a cycle of exercises that include remunerating the player and driving them to proceed through another cycle, holding them in the game. The expectation of such rewards can make a neurological response that discharges dopamine into the body, so that once the reward is acquired, the individual will recall it as a pleasurable inclination.

A few understudies make web based amusements utilizing cell phone, and some favor PC and x box as well. People who have gaming entrances at their home will play for longer term of hours. People playing over cell phones are for the most part playing web recreations, they will play with this present reality and will contend to win and accomplish greatest rewards in the game. This is conceivable just when additional time is apportioned for playing. Also, with cell phones which are convenient this turns out to be progressively simpler. Henceforth cell phone gamers are influenced in a progressively extreme manner when contrasted and different gamers. The gaming issue may introduce itself as impulse, social separation, forceful conduct, temperament swings, decreased creative mind, and hyper center around in-game accomplishments, at the expense of other significant occasions in life.[2, 3] Gaming issue can be analyzed when an individual takes part in gaming exercises at the expense of satisfying day by day obligations and without respect for the negative consequences.[10,11]

As of late, understudies are dependent on live gushing recreations like "Conflict of Clans" "Conflict Royale" "Smaller than expected Militia" and "Players obscure Battle ground [PUBG]", while certain Computer games like "Blue Whale", "Pokémon" and "MomoChallenge" and so forth have guaranteed lives of individuals who were playing them. Along these lines, in this unique circumstance, this investigation was led to know the pervasiveness of gaming and its belongings among youthful grown-ups.

Materials and Method

This is a cross-sectional clear investigation. Youthful grown-ups of age bunch 18 to 25 years were chosen from a urban territory of Chennai. This investigation was led between April to July 2019. An example of 100 youthful grown-ups was chosen from an urban region of Chennai by advantageous examining. The vast majority of them were chosen from the schools arranged close to the urban region. The parts of gaming and its belongings were surveyed utilizing a pre-tried organized poll.

The information gathering was started in the wake of getting freedom from Institutional Ethical board of trustees and in the wake of acquiring educated assent from the members . An organized poll was self-managed. Gathered information was gone into Microsoft Excel sheet and after that examined utilizing SPSS programming

Findings: The mean time of understudies took an interest in the investigation is22±4 and the normal time of Play was 3 hours. Be that as it may, the majority of the understudies were gaming for over 2 hours. Male members were 73% and female members were 27%.

Table 1 delineates the qualities of the gaming among the members. Larger part were playing disconnected gushing recreations (60%). In spite of the fact that the greater part (61%) of members gaming span was under 1 hour yet at the same time 39% had higher gaming length.

Table 2 delineates the impacts of gaming. Albeit every one of the outcomes demonstrate that lion's share of them were not influenced by gaming but rather still a noteworthy number were observed to be influenced with eagerness, crabbiness, playing during class hours and restless.

Figure 1 shows the assortment of gaming entries utilized. Versatile was the most much of the time utilized entrance. What's more, Figure 2 portrays the commonest kind of game played was Pubg.

Table 1 : Characteristics of the Games Played By The Participants

Sl No	Characteristics of gaming	Frequency (Percentage)
1	Game Streaming	
	Online gaming	40 (40%)
	Offline gaming	60 (60%)
2	Duration of gaming	

Sl No	Characteristics of gaming	Frequency (Percentage)
	<1 hour	61 (61%)
	1-3 hours	28 (28%)
	>3 hours	11 (11%)
3	Preoccupied with gaming	
	Yes	24 (24%)
	No	76 (76%)

Table 2: Effects of Gaming among Participants

Sl No	Effects of gaming	Frequency (Percentage)
1	Game has replaced hobby	
	Yes	32 (32%)
	No	68 (68%)
2	Playing during class hours	
	Yes	26 (26%)
	No	74 (74%)
3	Sleep Deprivation due to gaming	
	Yes	43 (43%)
	No	57 (57%)
4	Restlessness/irritability due to gaming	
	Present	27 (27%)
	Absent	73 (73%)

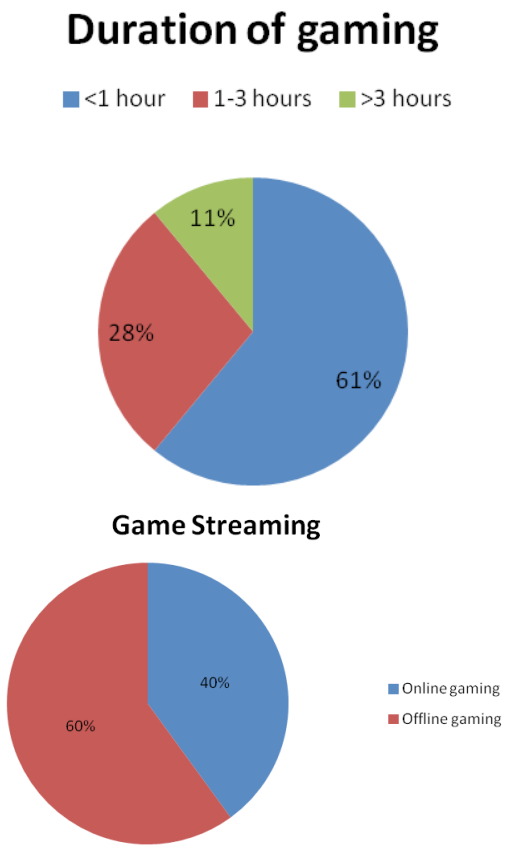

Figure 1: Characteristics of gaming

Discussion

This investigation was embraced to examine the gaming patters and its persuasions throughout the everyday existence of members. The members conceded about unusual rest practices like dozing late around evening time, awakening amidst night for scoring higher levels in the game. Because of expanded preoccupancy with gaming, they conceded to having lesser fixation during classes along these lines indicated terrible showing in their investigations. As 26% of understudies were making recreations in the class hours with their companions their examinations and scholarly execution was influenced the most .It was found in the reactions that 53% conceded that they were visit gamers and 47% as non-visit gamers. Due to expanded preoccupancy of understudies with gaming, they whined of having lesser fixation during classes in this manner indicated lackluster showing in their examinations.

Comparable discoveries were found in concentrates done by Hawi et al, Rehbein et al and KO et al.[7,12,13] Hawi et al, Bartel et al and Satghare et al, which was because generally dozing, awakening amidst night for scoring higher levels.[7,14,15] In this examination, understudies who were having high scores grumbled of state of mind issue like tension, sorrow, impulsivity and compulsivity, which was like the examination directed by Savvidou et al and Zhou et al.[16,17]

Contrasting and the examination done by pradeep yarsani 18, the individual gaming normal of 7 hours were making them game issue like eye issue and different issues like eagerness. 23 % have incidental rest unsettling influences and 6 % had extreme rest aggravation and anomalous rest design, In our investigation 43%of them free their ordinary rest example and 11% of understudies play over three hours and with lion's share having a normal of 2 hours gaming span. In the majority of the investigations guys were prevalently engaged with playing computer games which was likewise found in our examination.

Conclusion

Gaming issue are on an ascent, which had lead understudies to psychosocial aggravations, nervousness, discouragement, state of mind issue, rest unsettling influences, cerebral pain, absence of social exercises, and debilitation in instruction. These understudies felt trouble in adapting up in their investigations, since they invested more energy in gaming and less time on studies,

rest and different exercises. The understudies who are dependent on online video gaming conceded that, they are investing less energy with their families and are neglecting to control feelings with other relatives. Just as, these understudies may create conditions like dry eyes, early waterfalls and weakening of cerebrum. In this way, the time has come to control the use of electronic gadgets, web and computer games.

Evaluation of Urinary Iodine and Thyroid Hormone in Hypothyroidism of South Indian Population

Sathya V.[1,2], Bupesh G.[3], Vasanth S.[4], Somasekar R.[5], Ramadevi K.[6], Vijayanandh A.[7]

[1]Research Scholar, [3]Associate Director, [4]Junoir Research Scientist, Research & Development Wing, [5]Professor, Department of Pediatrics, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India, [2]Research Scholar, [6]Professor, Institute of Biochemistry, Madras Medical College & RGH, Chennai, Tamil Nadu, India, [7]Assistant Professor, Department of Human Genetics and Molecular Biology, Bharathiyar University, Coimbatore, Tamil Nadu, India

Abstract

Aim and objective: The present study was conducted to assess the Urinary iodine excretion levels among hypothyroid patients based on Thyroid profile and to correlate the Urinary iodine excretion with various disorders associated with hypothyroidism.

Method: The study group includes 50 control subjects and 100 clinically proven hypothyroidism patients. Histopathological investigations and thyroid scan were taken for all the patients. They were analyzed for Thyroid hormone profile and the Urinary iodine excretion level was determined by Ammonium persulfate method in spot urine sample.

Results: Free T_4, TSH and Urinary iodine concentration (UIC) were measured for both the control and study group (P = 0.00).The mean Free T4, TSH & UIC for control group was 1.71 ng/dl, 1.41µIU/ml & 150.28µg/L and the mean Free T4, TSH & UIC for test group was 0.85ng/dl, 48.38µIU/ml & 233.74µg/L respectively. A significant positive correlation between Free T_4, TSH and UIC was found. Increased Urinary iodine excretion (UIE) was observed in patients with Papillary Carcinoma, Thyroiditis and Multinodular goiter.

Conclusion: The findings of the present study reveals that increased excretion of urinary iodine reflects under utilization or impaired iodination by the thyroid gland.

Keywords: *Hypothyroidism, Urinary iodine, Iodine deficiency disorders, Goitre.*

Introduction

Iodine deficiency damages human health in several ways, most importantly by interfering with normal development of the brain. Iodine deficiency is a major health problem in India. Surveys conducted in 275 districts of 25 states and 4 union territories in India had identified that 235 districts are endemic for Iodine deficiency disorders (IDDs) [1].

Corresponding Author:
Dr. G. Bupesh
Associate Director, R & D Wing, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73,
e-mail: bupeshgiri55@gmail.com, Mobile: 8012405965

Out of 29 districts in Tamil Nadu, 24 have been surveyed and all have been found to be endemic to IDD. Iodine Deficiency Disorders (IDD) is the most common cause of preventable brain damage and mental retardation affecting 118 countries worldwide.[1] Government of India in 1997 imposed ban on the storage and sale of the non-iodized salt[2,3]. Monitoring Urinary Iodine excretion(UIE) level is an essential part of measuring a country's thyroid health[4].

Clinical and subclinical manifestations of Iodine deficiency is collectively denoted by the term Iodine deficiency disorders (IDD), affects all stages of human life and encompass a variety of conditions including Goitre, Cretinism, Dwarfism, Mental retardation, Muscular disorders, Spontaneous abortions and

Stillbirths[5,6]. India is one of the major endemic areas of IDD where 167 million people are at risk, 54 million people have Goitre, 6.6 million have mild neurological defects and 2.2 million are cretins[2,7].

Disorders associated with altered thyroid hormone secretion are common and affect about 5% women and 0.5% men[7]. Normal levels of thyroid hormones are required for Neuronal migration and Myelination of fetal brain and lack of Iodine irreversibly impairs brain development. Severe Iodine deficiency during pregnancy increases risk for Stillbirths, Abortion and Congenital abnormalities[8].

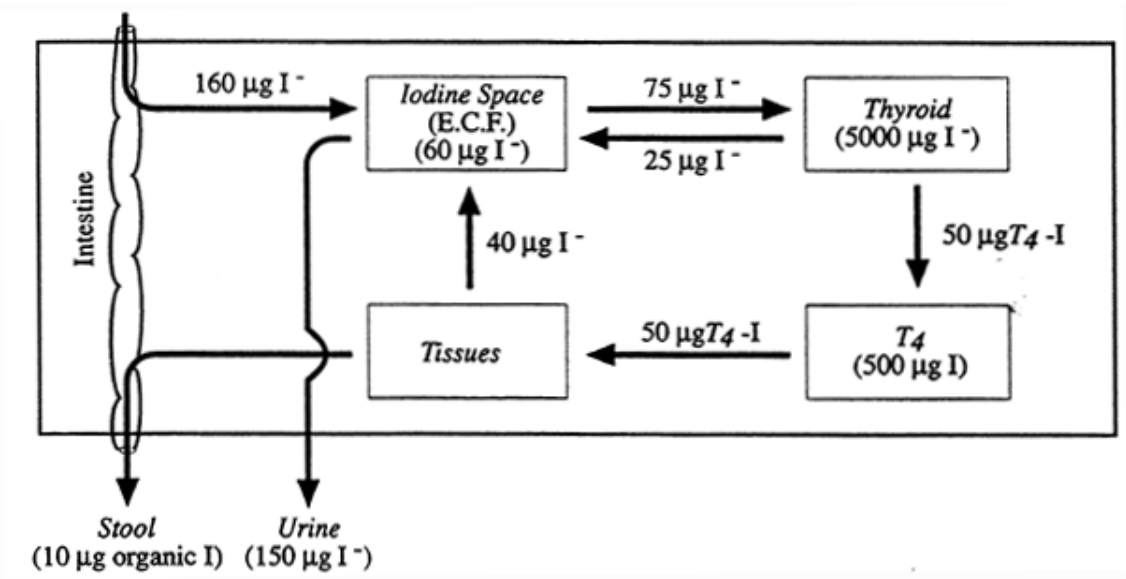
Hypothyroidism is a condition characterized by abnormally low thyroid hormone production. There are many disorders that result in hypothyroidism. These disorders may directly or indirectly involve the thyroid gland, because thyroid hormone affects growth, development, and many cellular processes, inadequate thyroid hormone has widespread consequences for the body[9].

The hypothyroid patients were classified into five sub groups according to their disorders. They were as follows 1. Thyroiditis 2. Dishormonogenetic goiter (DHGG) 3. Multinodular goiter (MNG) 4. Papillary carcinoma(pap ca) 5. Ectopic thyroid.

The main objective of the present study is

1. To evaluate the Iodine status in patients with proven Hypothyroidism.
2. To identify the various factors that leads to hypothyroidism by studying the thyroid profile and by measuring the Urinary Iodine excretion level.

Normal requirement of Iodine in the diet: In 2000, the Institute of Medicine at the National Academy of Sciences developed new Dietary Reference intakes for iodine. Adequate intakes were established for children up to one year old, and RDA was determined for all people over one year. These recommendations appear as follows: 0-6 months-110 µg; 7-12 months-130 µg; 1-8 years-90 µg; 9-13 years-120 µg, 14-18 years-150 µg, Women 19 years and older-150 µg; Pregnant women-220 µg; Lactating women 14 years and older-290µg.



Foetal Thyroid Hormones: Thyrotropin Releasing Hormone (TRH) and Thyroid Stimulating Hormone (TSH) start being secreted from the fetal hypothalamus and pituitary at 18-20 weeks of gestation, and fetal production of Thyroxine (T4) reach a clinically significant level at 18–20 weeks. Fetal Triiodothyronine (T3) remains low (less than 15 ng/dl) until 30 weeks of gestation, and increases to 50 ng/dl at term. Fetal selfsufficiency of thyroid hormones protects the fetus against brain development abnormalities caused by maternal hypothyroidism. However, Preterm births can suffer from neuro developmental disorders due to lack of maternal thyroid hormones, due to their own thyroid being insufficiently developed to meet their postnatal needs[10, 11].

Toxicity of Iodide Ion: Excess iodine has symptoms similar to those of iodine deficiency. Commonly encountered symptoms are abnormal growth of the thyroid gland and disorders in functioning and growth of the organism as a whole. Iodides are similar in toxicity to bromides. Excess iodine can be more Cytotoxic in the presence of selenium deficiency[12, 13].

Iodide Leak: Iodide has several actions on the synthesis and secretion of the thyroid hormones. Administration of small amounts of iodide results in the increased synthesis without increased secretion. Acute administration of large amount iodide causes a progressive decrease in iodination of TG. This phenomenon is called the Wolff-Chaikoff effect. It is dependent on the concentration of iodide in the thyroid cells. The effect is transient and is overcome by an adjustment of the iodide transport system, which lowers intracellular iodide concentration. Chronic administration of large amounts of iodide results in an increase in iodide uptake and binding to TG while secretion of T4 remains normal. This is accompanied by release of non hormonal iodide from the gland, termed as **Iodide leak.** Failure of this adaptive mechanism may be the cause of goiter and hypothyroidism, which are occasionally observed in patients who have a chronically excessive iodide intake. Large amounts of iodide also inhibit release of thyroid hormones, probably by a direct effect on proteolytic enzymes[14].

Fate of Ingested Iodides: Iodides ingested orally are absorbed from the gastrointestinal tract into the blood in about the same manner as chlorides. In the small intestine, facilitated diffusion enables organic iodine absorption to occur across the intestinal cells. The more common inorganic iodide form requires a specific transport protein called the Sodium-Iodide Symporter (NIS). Once iodine absorption is complete and the iodine is in the blood stream both forms are concentrated into

various tissues including the thyroid, mammary glands, the eyes, salivary glands, cervix, thymus, choroid plexus, kidneys, arteries, and bones. These tissues also contain the sodium-iodide symporter, so they can absorb the inorganic form. Normally, most of the iodides are rapidly excreted by the kidneys, but only after about one fifth are selectively removed from the circulating blood by the cells of the thyroid gland and used for the thyroid hormones. Iodine is an indispensable component of the thyroid hormones, comprising 65% of T4's weight, and 58% of T3's weight. Tyrosine is also consumed through diet and is absorbed from the GIT. For the synthesis of normal quantities of thyroid hormones, approximately 1 mg of Iodine is required per week or about 50 mg per year. To prevent Iodine deficiency common table salt is iodized with one part of Sodium Iodide to every 1,00,000 parts of Sodium Chloride[15].

Courtesy: Iodine metabolism and balance in humans. Dr. Noel sturm 2010

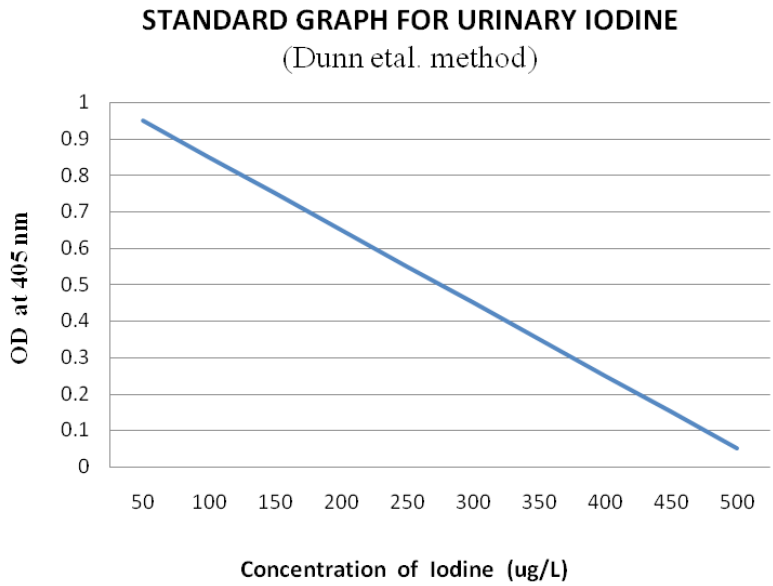
Goitre: Iodine deficiency is the major health problem in India. Worldwide, the most common cause for goitre is iodine deficiency. A **goitre** or **goiter** (Latin *gutteria*, *struma*), is a swelling in the thyroid gland, which can lead to a swelling of the neck or larynx (voice box).[10-14]. In countries that use iodized salt, Hashimoto's thyroiditis is the most common cause. Other causes are:overproduction or underproduction of hormones. They are classified in different ways:

"Diffuse goitre" is a goitre that has spread through all of the thyroid (and can be a "simple goitre", or a "multinodular goitre"). **"Toxic goitre"** refers to goitre with hyperthyroidism. These are most commonly due to Graves' disease, but can be caused by inflammation or a multinodular. **"Nontoxic goitre"** (associated with normal or low thyroid levels) refers to all other types (such as that caused by lithium or certain other autoimmune diseases).

Other type of classification is by grading: GRADE 0,GRADE I, GRADE II & GRADE III[16,17]

Materials and Method

The patients were selected from the Endocrinology outpatient clinics of Madras Medical college and Rajiv Gandhi government hospital, Chennai,Tamil Nadu, India. Informed consent was obtained from all the participants. The clinical and pathological stages were obtained from the medical records of the patients.



Control Group: The control group consisted of 50 healthy volunteers (Male-20 & Female-30) with a mean age of 34.22. They showed no signs of any Thyroid disorders and no thyroid enlargement by physical and clinical examination. They were are all non diabetic, non smokers, non-alcoholics and with normal renal function. They were all tested for TFT and UIE level. Control subjects with abnormal TFT were excluded from the study.

Study Group: The study sample comprised of 100 clinically proven Hypothyroid patients of mean age 35.52 (Male-26 & female-74). Histopathological investigations and thyroid scan were taken for all the patients. Grading of goiter was determined according to the criteria recommended by the joint WHO/UNICEF/ ICCIDD[6].

Sample Collection: Blood samples were collected in two plain red-top veni puncture tubes. The tubes were centrifuged at 2000 rpm for 15 minutes for TFT estimation and for other investigations too. Along with blood samples spot urine samples was also collected in sterile plastic containers. Urine samples were analyzed on the same day even though they could be stored at 2-8° C for 5 days or at-20 °C up to 20 days.

- TFT was measured by ELISA method with an open system automated ELISA analyzer (Triturus analyzer).
- UI Excretion was measured manually by Sandell–Kolthoff reaction by Dunn et al or ammonium persulfate method) [18-20].

Findings: A standard curve was constructed on graph paper by plotting iodine concentration of each standard on the abscissa against its optical density at 405 µg/l (OD 405 nm) on the ordinate.[18,19,20] (graph 1) from which urinary iodine value was calculated.

We used SPSS version 16 for data processing. Quantitative data were presented as mean and SD. For comparison of means, the independent t-test was used.

Table 1 depicts the comparison of mean values of free T_4, TSH and Urinary iodine between control subjects and the patients group by Independent t-test. A Significant difference was noted between the two groups. Since all confounding factors were matched.

Table 1: Comparison of mean values between control and Test subjects

Variables	Control n = 50	Test n = 100	P Value	Significance
FT4	1.71	0.85	0.000	Significant
TSH	1.41	48.38	0.000	Significant
UI	150.28	233.74	0.000	Significant

Table 2 depicts the classification of test subjects into 3 groups based on urinary iodine excretion. Group 1 (UI < 100), Group 2 (UI 101-200), Group 3 (UI >200). The mean values of all the parameters between the 3 groups were compared using independent t test (t-test for equality of means). Out of 100 patients 48% had increased UI excretion level.

Table 2: Classification of Test subjects (n=100) into 3 groups based on UI excretion level

Variables	Group 1 (n=16) UI < 100	Goup 2 (n=36) UI 101-200	Group 3 (n=48) UI > 200
FT4	0.706	0.735	0.987
TSH	52.58	39.42	53.71
UI	76.625	149.94	348.95

Figure 1 shows the five different sub groups of hypothyroid and the Maximal excretion of UI was seen in Thyroiditis 71%,when compared to other sub groups. It is represented by a pie chart.

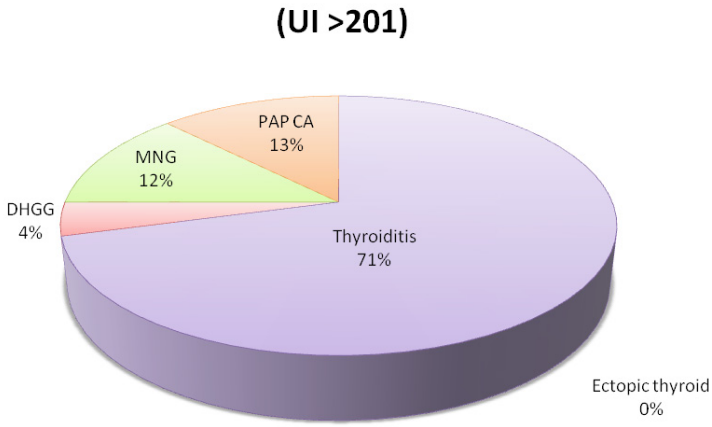


Figure 1: Five different sub groups of hypothyroid and the Maximal excretion of UI

Table 3: Classification of Hypothyroid patients based on various thyroid disorders

Variables	Control n = 50	Thyroiditis n = 70	DHGG n = 8	PAP CA n = 8	Ectopic thyroid n = 4	MNG n = 10
FT4	1.71	0.84	0.88	1.02	0.98	0.73
TSH	1.41	49.22	87.60	23.65	8.95	46.64
UI	150.28	222.65	190.5	385.5	152.5	257.00

Table 3 and Fig 2 shows The Hypothyroid patients were grouped based on the disorders and compared with control groups by bar diagram. The mean Free T4, TSH & UI values of control subjects with that of various thyroid disorders associated with hypothyroidism was compared. Out of 100 clinically proven hypothyroid nearly 70% had Thyroiditis and 10% multi nodular goiter.

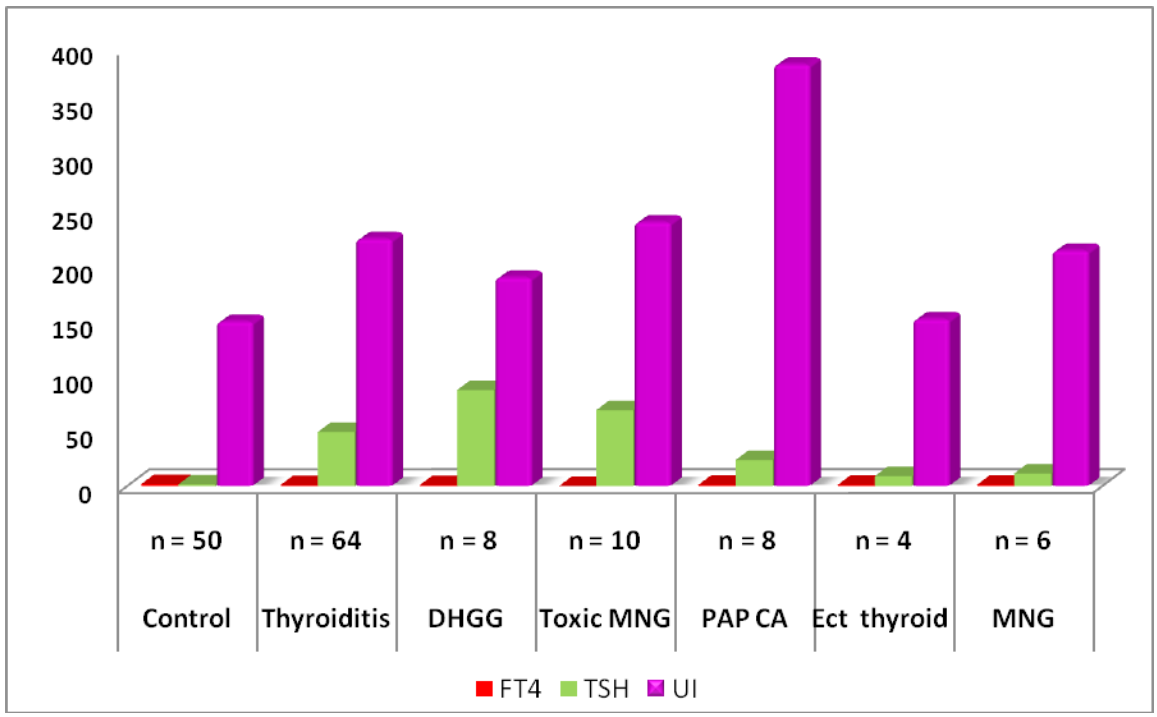

Figure. 2: Hypothyroid patients based on various thyroid disorders

Discussion

The most common problems of the thyroid gland is an Over-active thyroid gland, referred to as ' Hyperthyroidism', and an Under-active thyroid gland, referred to as 'Hypothyroidism'[17]. Seawater is the most important reservoir for terrestrial iodine (mean concentration 58 (µgl–1I).Soil iodine content is also strongly influenced with coastal soils being much enriched and central continental soils being depleted due to heavy rainfall. A type of seaweed, kelp, tends to be high in iodine as well,with from 0.03–0.45 dry weight percent. About 19,000 tons are produced annually from natural sources[18-22].

Naturally occuring Goitrogens like thiocyanate, thiooxazolidone, isothiocyanates are known to exhibit antithyroidal activity and inhibitors of iodine uptake may have contributed to the pathogenesis of Hypothyroidism. Besides eating iodine-rich foods, it is important to slow down or stop eating goitrogens (iodine blockers) like peanuts and soybeans in our diet. Percholate is actively transported by NIS (sodium iodide symporter) and has 30 fold affinity towards perchlorate than iodide. Percholates both inhibit iodide uptake by NIS and also stimulates iodide efflux from thyroid follicular cell[23].

Excess iodine has symptoms similar to those of iodine deficiency. For the synthesis of normal quantities of thyroid hormones, approximately 1 mg of Iodine is required per week or about 50 mg Per year. Excess iodine can be more Cytotoxic in the presence of selenium deficiency. Universal salt iodisation was successful in the country and consumption of iodised salt by the households should also be monitored regularly. So Further studies on Excess consumption of iodine through diet, Iodine toxicity, role of goitrogens and perchlorate metabolism in thyroid function are required for better understanding of Iodine Deficiency Disorders[24, 25].

Conclusion

The present study suggest and recommends the implementation and success of universal salt iodization programme (USI) need continuous monitoring of the quality of salt provided to the population. In order to achieve the goal of Iodine deficiency disorders elimination. Intake of required iodine uptake may prevent the pathogenesis of hypothyroidism. Further increased consumption of iodine also should be avoided to prevent toxicity.

A Study on Awareness and Perception Regarding Eye Donation among Students of a Medical College in Kanchipuram District

Sathish D.[1], Mohankumar P.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Corneal infections establish a huge reason for visual weakness and visual deficiency in the creating scene. The quantity of corneal transplants done is far not exactly the genuine prerequisite in India. This is generally because of the insufficient number of corneas gathered.

It is seen that 12% of the world's visually impaired populace is influenced by corneal visual impairment, a visual debilitation that is amiable to treatment. The disturbing figures rise each year, keeping India in the number one spot. Corneal transplantation remains the pillar of treatment for reestablishing vision in such patients. Writing survey in India uncovers that the mindfulness about eye gift in broad daylight, particularly among the adolescent is exceptionally low. Subsequently formation of mindfulness conveys foremost significance. A semi-organized poll on eye gift was self-regulated for gathering the important data in the wake of acquiring educated assent. The lion's share (86%) of understudies realized that eyes can be given simply after death and (81%) realized that the perfect time of gift was inside six hours of death. Most members (80%) were eager to give eyes. The saw purposes behind not giving eyes should be considered while making mindfulness about eye gift in the community. The therapeutic understudies could be effectively included as volunteers in eye gift crusades and they can go about as advisors for eye contributors. They can likewise contribute by taking part in making mindfulness and spurring individuals to progress toward becoming eye benefactors.

Keywords: *Blindness, corneal transplantation, eye donations, medical understudies.*

Introduction

Corneal ailments are a noteworthy reason for visual weakness and visual deficiency in the creating scene. The significant reasons for corneal visual impairment incorporate trachoma, corneal ulceration following xerophthalmia because of nutrient A lack, ophthalmia neonatorum, and the utilization of destructive customary medications, onchocerciasis, uncleanliness, and visual trauma[1-3]. The visual debilitation contemplate (2010) assessed that 285 million individuals are outwardly weakened, out of which 39 million individuals are blind. Corneal visual deficiency represents 12% of the world's visually impaired and India represents the dominant part, in this way making it a worldwide priority[2,3]. The quantity of patients anticipating corneal transplantation is extensively developing in India. The Andhra Pradesh Eye malady think about (APEDS) revealed the predominance of corneal visual deficiency at 0.13% (95% CI: 0.06-0.24), establishing 9% of all visual impairment. APEDS likewise proposed a huge weight of corneal visual deficiency in the country populace of Andhra Pradesh, of which 95% was avoidable. Despite the fact that systems to counteract corneal visual deficiency are probably going to be more expense effective,visual restoration by corneal transplantation remains a noteworthy treatment choice for reestablishing sight in the individuals who as of now have corneal blindness[4]. Approximately 18.7 million individuals are visually impaired in India and 190,000 are visually impaired from reciprocal corneal disease[5]. Consistently, another 20,000 join the rundown[6].

Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

The late Dr. Muthiah began the absolute first eye bank in India and he effectively played out the primary corneal transplant in 1948. Even after over 50 years, patients hanging tight for corneal transplants establish a significant accumulation, which keeps on developing. The need, subsequently, is to instruct the majority about eye gift with an end goal to build the obtainment of corneas. Therefore, there is a requirement for attention to eye gift with an end goal to expand the acquirement of corneas. According to the Eye Bank Association of India, the cornea acquisition rate in India is 22,000 for every year. It is assessed that a huge extent of giver corneas are unacceptable for corneal transplantation. Based upon our present proportion of accessible safe benefactor eyes, we would require 277,000 contributor eyes to perform 100,000 corneal transplants in a year in India. There is roughly a 20-overlay increment from the contributor eyes accessible at this point. A lack of transplantable corneas is normal and has been the subject of much consideration. To build acquisition of corneas, raising the degree of state funded training on eye gift is a significant initial step. Requesting for real eye gift at the season of death is a vital and acknowledged practice. Though the components influencing obtainment of corneas and the open mentality towards eye gift have as of late gotten consideration in the created world, very little has been distributed from the creating world. With this foundation, an investigation was attempted in a restorative school in kanchipuram locale to survey the mindfulness about eye gift among the medicinal understudies

Objectives

Point: To make a mindfulness towards eye gift among the restorative understudies

Objectives:

(i) To survey the information with respect to eye gift among therapeutic Students.

(ii) To bring mindfulness among the understudies about eye gift and shortage of giver eyes in India.

Materials and Method

Study Type: Cross sectional investigation

Study Area and Population: Students of a Medical College in Kanchipuram locale.

Sample Size: 100

Sampling Method: Convenient examining technique

Study Tool: Semi-organized Questionnaire

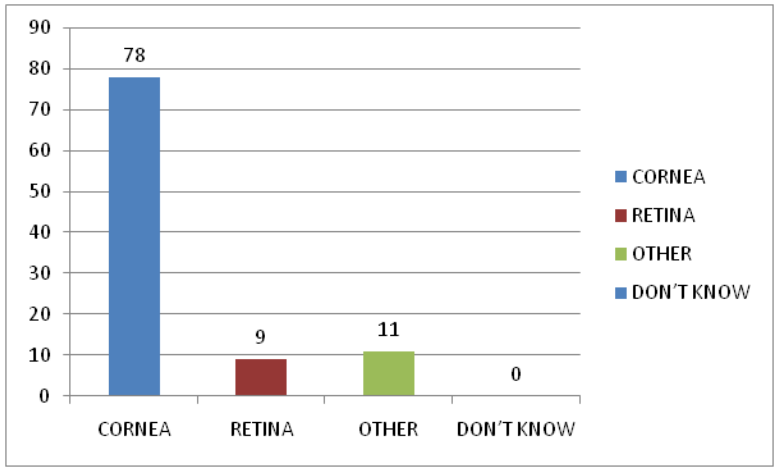
Study Period: April to June 2019

A test size of 100 therapeutic understudies of a medicinal school in Kanchipuram locale was taken by helpful examining strategy. The Students of second and third year were chosen for the study. A semi-organized survey, self-managed for gathering the essential data in the wake of getting educated assent. The survey contains inquiries on statistic subtleties, mindfulness with respect to eye gift, explanations behind giving and not giving eyes, expectation to give eyes, and wellsprings of data. The subsequent information was gathered and entered in Microsoft Excel Software and examined utilizing SPSS v22. Descriptive measurements like recurrence, mean, standard deviation were determined.

Consideration Criteria: Medical understudies who were available upon the arrival of study and who gave assent are incorporated

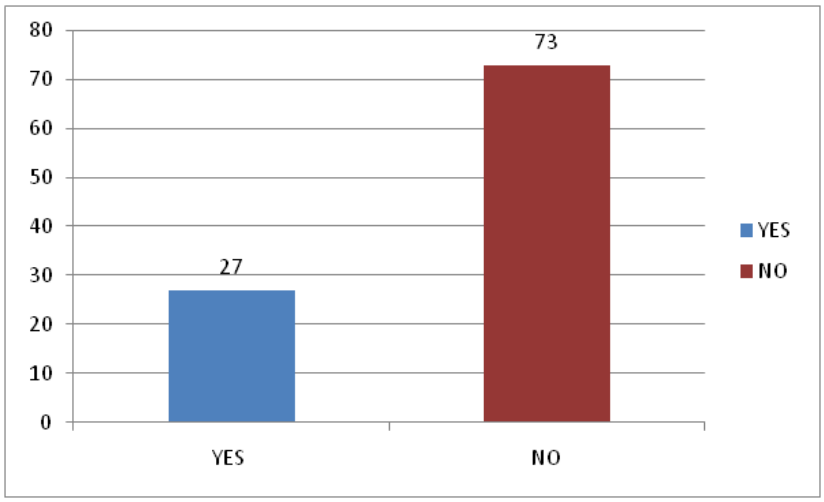
Avoidance Criteria: Medical understudies who were absent upon the arrival of study and understudies who didn't give assent for the investigation are rejected

Measurable Examination: After noting the appropriate response sheets were gathered for assessment.



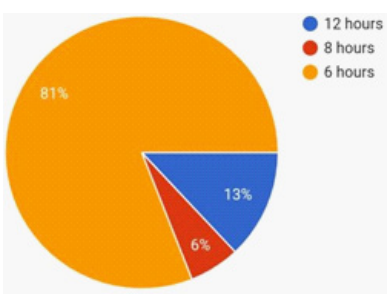
The gathered information was gone into Microsoft Excel Sheets. The information were dissected utilizing SPSS (Statistical bundle for the Social Sciences) Software form 22 (IBM SPSS Statistics,Chennai,Tamil Nadu, India) and the distinct insights, for example, number and rate were determined for the gathered information.

Findings: Out of 100 understudies, 83 (83%) were guys and 17 (17%) were females. Age fluctuated from 19 to 23 years of age with 15 (15%) understudies who were 19 years old, 37 (37%) understudies who were 20 years of age, and 28(28%) understudies who were 21 years old, 15(15%)students were 22 years old, 5(5%) understudies were 23 years of age. Of the 100 understudies, it was seen that 86 students (86%) realized that eyes can be given simply after death; that they ought to preferably be given inside 6 hours of death was known to 81 (81%) of the 100 understudies. The contact place for eye gift in Chennai was known to just 43 (43%) of 100 understudies. The vast majority of the understudies



(73%) knew that people with transmittable sicknesses can't give their eyes just 25% understudies accept eye gift is against their religious conviction. Most members never knew people who has donated (69%) eyes and who has received (77%) benefactor eyes. Most of the members, 80 (80%) of 100 understudies, were either ready to give eyes or had effectively promised to give their eyes

Responses to the Questionnaire on Eye Donation:



The most important part of the eye which is transplanted_____

A Person with communicable diseases can donate his/her eyes?

Ideal time for Donating eyes is within _____ hours after death?

Are you willing to donate your eyes in future?

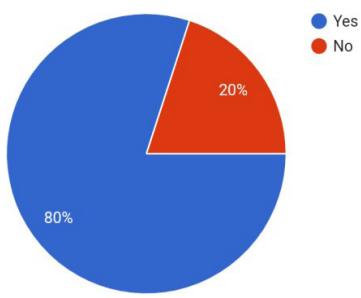


Table 1: Percentage of Response given by total of 100 students (n=100)

Questions	% of Students Aware	% of Students Not Aware.
Eyes can be donated only after death	86%	14%
Ideal time for donating eyes is within 6hours after death	81%	19%
Knows the contact place for eye donation in Chennai.	43 %	57%
The most important part of the eye which is transplanted.....Cornea	78%	22%
Knows a person who has donated eyes?	31%	69%
Knows someone who has received a donated eye	23%	77%
Corneal diseases are the major cause of visual impairment and blindness	85%	15%
Donor's eyes can be preserved in the eye bank	87%	13%
Donated eyes can be used for corneal grafting	96%	4%
Knows there is shortage of eye donors in India	92%	8%
Eye Donation can be performed only after the written consent of the family/relations of the deceased	92%	8%
The identities of both donor and recipient are kept confidential	90%	10%

Discussion

Corneal visual impairment is the real reason for visual impairment. This is because of the expansion in the deficiency of the giver eyes in India. Therefore, there comes need to make mindfulness about eye gift and to teach the general population in regards to the significance of it. This concentrate done in kanchipuram region accompanied intriguing outcomes, examined underneath.

In this investigation, 86% of the understudies knew that eyes could be given simply after death. In an investigation among the south Indian populace, 50.7% of members knew about eye gift. In another examination among medical clinic staff, 97% of them had great to amazing learning about transplantation of different human organs. Information by broad communications could be identified with the abnormal state of mindfulness in our examination participants. A enormous number of understudies, 96 (96%) out of 100 realized that they gave eye is utilized for corneal uniting and 81% realized that the perfect time for

Gift is inside 6 hours of death. An examination on restorative and nonmedical understudies additionally seen that 79.6% of therapeutic understudies realized that eyes can be given after death and 63.3% realized that it ought to be done inside 6 hours. Another investigation in the overall public demonstrated the mindfulness level on eye gift to be 73.8%. In this investigation, just 43(43%) out of 100 understudies thought about the suitable spot for an eye donation. Our study demonstrated that 92 (92%) of 100 members concurred that there is a deficiency of eye givers and 80 (80%) of 100 were either eager or had effectively swore to give their eyes. In an examination among restorative understudies, 87.8% of the respondents were happy to be eye givers. Another investigation in the urban populace saw that 73.8% knew about eye gifts and just 44.9% were eager to vow their eyes. Willingness to give eyes was less (41.5%) even among relatives of after death cases who knew about eye gift. Other purposes behind not giving eyes included complaint by relatives, aversion of distorting the body, postponing of religious customs, and religious confinements.

Comparative reasons were additionally announced in different examinations. Mandatory assent for gift communicated before the passing of the giver ought to in a perfect world structure the reason for eye gift. Nonetheless, on account of inaccessibility of such assent, assent from grown-up relatives of the expired benefactor ought to be gotten for eye gift. In an examination done on the reactions of relatives of posthumous cases, it was uncovered that out of the potential after death benefactors, just 44.3% of relatives of such cases gave assent for gift after serious advising. Mass media as TV, papers, magazines, and notices were significant wellsprings of data on eye gift. Different examinations likewise discovered attention crusades and the media to be the significant wellsprings of data on this issue.

Conclusion

The present examination uncovered that therapeutic understudies were very much aware of eye gift and the vast majority of them were slanted to vow for eye gift. The apparent purposes behind not giving eyes should be considered while making mindfulness about eye gift

in the network. The medicinal understudies could be effectively included as volunteers in eye gift crusades, wherein after appropriate preparing in advising method, they can go about as advocates for eye givers. They can likewise contribute by taking part in making mindfulness and propelling the general population for eye gift during their postings in network prescription.

A Case Study on Pierre Robinson Syndrome

Arjun Umesh[1], Uma Devi[2], Gopala Krishnan[2], Suresh R.[3]

[1]MBBS Student, [2]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai, [3]Consultant Surgeon, PARABRAHMA Hospital, Ocahra, Kerala

Abstract

Pierre Robin arrangement (PRS) is traditionally portrayed as a set of three of micrognathia, glossoptosis, and aviation route impediment. Babies every now and again present during childbirth with a hypoplastic mandible and trouble relaxing. The littler mandible uproots the tongue posteriorly, bringing about hindrance of the aviation route. Normally, a wide U-formed congenital fissure is additionally connected with this wonder. PRS isn't a disorder in itself, yet rather a succession of disarranges, with one anomaly bringing about the following. Notwithstanding, it is identified with a few other craniofacial abnormalities and may show up related to a syndromic conclusion, for example, velocardiofacial and Stickler disorders.

Newborn children with PRS ought to be assessed by a multidisciplinary group to survey the anatomic discoveries, outline the wellspring of aviation route impediment, and address aviation route and nourishing issues. Situating will settle the aviation route block in ~70% of cases. In the right position, most youngsters will likewise have the option to encourage typically. In the event that the baby keeps on demonstrating proof of desaturation, at that point arrangement of a nasopharyngeal cylinder is shown. Early sustaining by means of a nasogastric cylinder may likewise decrease the measure of vitality required and take into account early weight gain. An extent of PRS newborn children don't react to traditionalist measures and will require further mediation. Preceding thinking about any surgery, the clinician should initially discount any wellsprings of hindrance beneath the base of the tongue that would require a tracheostomy. The two most basic techniques for treatment, tongue–lip bond and diversion osteogenesis of the mandible, are talked about.

Keywords: *Pierre Robin arrangement, Micrognathia, Glossoptosis, aviation route block, diversion osteogenesis.*

Introduction

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

PRS is portrayed by a great set of three of Micrognathia, Glossoptosis, and aviation route obstacle. Micrognathia is quickly distinguished during childbirth and is a characterizing highlight of the determination. Hypoplastic mandibles are little in both the vertical and flat measurements[1]. This thusly represents the decline in the anteroposterior projection of the jaw and its resulting great retrognathic appearance. Aside from the Micrognathia, Randall portrayed the striking finding of Retrogenia, or back relocation of the jaw, to describe the starting oddity in this succession[2].

Introduction

In 1923, Pierre Robin, a French stomatologist, reported a turmoil which presently bears his namesake. Pierre Robin grouping (PRS) was initially portrayed as comprising of Micrognathia (which he named

"Mandibular Hypotrophy") and Glossoptosis (an irregular back position of the tongue), which result in aviation route obstacle and encouraging troubles. The little mandible is believed to be because of an innate hereditary issue or a deformational issue where intrauterine development is limited or mandibular situating is modified. As opposed to a[1] syndrome, which is characterized as different peculiarities emerging from a solitary basic pathogenesis, note that PRS is, where numerous oddities result from a consecutive chain of deformities–one involving the following. In PRS, the micrognathia prompts glossoptosis, which thusly results in aviation route deterrent and failure to nourish.

Materials and Method

Case History: We report the instance of a kid name Shruti, Age: 8 years, Sex: F

Antinatal History: No antinatal sickness in mother

Nataland Postnatal History: Normal full term vaginal deleivery. She weighed 2.6kg. No noteworthy antenatal history. No birth asphyxia, Developed breathing trouble not long after birth. Required oxygen support for a few days. She went through 15 days in the neonatal unit and was in every case extremely hard to bolster orally, with huge regurgitating from the begin. She was prevalently nourished through NG tube in spite of the fact that she retched hugely. Guardians were informed that the child has some inherent anomalies including a congenital fissure. There was likewise history of repetitive respiratory disease and rehash ear contaminations. The congenital fissure was revised at 11/2 years old

At the Time of Examination: Weight: 17kg; moderately fabricated, small lower jaw (Micrognathia), Displacement of the tongue towards back of the oral depression (Glossoptosis).Cleft sense of taste which is precisely rectified. Different frameworks are typical

Analysis: Pierre Robin Syndrome

Findings: Following conveyance the infant was conceded in NICU. Since there was desaturation the infant was given 100% oxygen 2-4 liters/minute through nasal prongs. As a result of diligent regurgitating was given IV liquids, at first 10% dextrose pursued by 10% isolyte P. Enteral bolstering began through a nasogastric tube. Communicated breatmilk and recipe feeds were given. When the child began enduring enteral feeds the NG cylinder was expelled and bosom bolstering began. The infant was breast fed in inclined and parallel position to evade desire. A Nasopharyngeal cylinder was acquainted for quite a while with assuage aviation route block. Hearing test and eye examination was typical. Intermittent respiratory diseases in early stages required anti-infection agents and nebulisations. The mother was encouraged to sustain the infant in an upstanding, sitting position to keep the equation from streaming once more into the nose zone. Careful fix of congenital fissure was done at one and a half years old. Since there was no noteworthy aviation route block Tongue Lip Adhesion was not done.

Discussion

Pierre Robin disorder likewise named as Pierre Robin succession, or Robin anomalad, is described by a few degrees of micrognathia seriousness, glossoptosis and palatal contortion. In this distortion, the tongue size is typical yet buccolingual lopsidedness due to micrognathia, expanding the glossoptosis is habitually watched[2]. The word "succession" recommends that one peculiarity prompts resulting oddities, and micrognathia is viewed as the actuating abnormality in patients with PRS. Aviation route obstacle and nourishing challenges emerge and the seriousness of the issues fluctuates. PRS may happen alone or in relationship with different disorders, for example, stickler disorder, velocardiofacial disorder thus geneticist ought to be counseled to know the likelihood in future kids. In about 30% of cases PRS might be a disengaged event, while, in the accompanying 30%, it is identified with different inconsistencies and in the last third of cases it is a piece of a progressively perplexing disorder (most habitually Stickler Syndrome). This assortment of articulations is the aftereffect of a blended hereditary starting point: in 40% of cases PRS is hereditarily confined, else it is a latent or predominant autosomal condition[3]. For our situation no relationship with different inconsistencies were watched. Notwithstanding the reason, neonates and babies with Pierre Robin arrangement may experience fluctuating degrees of aviation route obstacle and bolstering challenges[4]. PRS can be perilous during the neonatal period with the beginning of aviation route obstacle, which can happen whenever directly after birth. Whenever left untreated, delayed aviation route block can prompt intense or interminable hypoxia, cyanosis, apnea scenes, goal, respiratory tract disease, nourishing troubles, lack of healthy sustenance, and inability to flourish. Resulting entanglements of unending hypoxia

are incessant carbon dioxide maintenance, raised pneumonic vascular obstruction, cor pulmonale, right heart disappointment, and cerebral hypoxia. Most of the patients with PRS gets eased by traditionalist measures anyway patients with articulated micrognathia, inability to flourish, delayed utilization of nasopharyngeal aviation route or delayed endotracheal intubation needs careful rectification. As for our situation moderate measures were adequate to deal with the indications of neonate.

Fig. 1-U-Shaped Cleft Palate

Fig.2-Showing Micrognathia

Fig.3-Showing Glossoptosis

Conclusion

Every one of the instances of PRS ought to be altogether examined to determine relationship to have other disorder and to figure the further line of the board. Every single instance of PRS is remarkable and should be evaluated exclusively. It is our duty as doctors to perceive this issue opportune, to give close development and suitable treatment and guiding.

A Case Report on Prostate Ductal Adenocarcinoma Presenting with Hematuria

Chandika Surya Teja[1], Umadevi R.[2], Gopalakrishnan S.[2]

[1]MBBS Student, [2]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Prostatic ductal adenocarcinoma is a rare neoplasm arising from the urethra of the prostate. We present in the prostatic cavity an 85-year-old man with an exophytic lesion that was diagnosed after the prostate's transurethral resection. Histopathologically, the tumor was diagnosed with endometrioid symptoms and a Gleason score of 6 as a ductal adenocarcinoma.

Keywords: *Prostate Ductal Adenocarcinoma, Hematuria, Degarelix and Lupron.*

Introduction

Prostate malignant growth is the most widely recognized kind of disease in guys. The World Health Organization 2016 partitioned epithelial tumors of the prostate into numerous subcategories including acinar and ductal adenocarcinoma. Practically all prostate malignant growths are acinar adenocarcinomas and create from the organs themselves. Unadulterated ductal adenocarcinoma starts from the pipes and it speaks to 0.2–0.4% of every single prostate malignancy. It is generally blended with acinar subtype[1]. The frequency of the ductal adenocarcinoma has been expanding over every decade, and around like the rate of increment of acinar carcinoma[2]. However, it isn't accounted for in prostate specimens[1]. Many examinations report increasingly forceful highlights of acinar prostate malignant growth, including their higher phase of the ailment and metastases and furthermore higher mortality rate[1,3]. This is a case report of an individual who was determined to have blended ductal and acinar prostate adenocarcinoma.

Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Materials and Method

A 85-year-elderly person gave two months of irregular effortless perceptible hematuria. His medicinal history demonstrates considerate prostatic hypertrophy (evaluated prostate volume 50 cc) and Grave's illness status post I-131 removal; he was fit and healthy barring the ailment. His lab discoveries exhibited gentle sickliness and a pretreatment PSA of 5.63 ng/ml, which had remained moderately stable in the 4–6 ng/ml go for in any event the previous 5 years.

Findings: During cystoscopy, a papillary injury in the prostate with related discharge was watched (Fig.1). Transurethral resection of this example indicates prostatic adenocarcinoma with blended acinar and ductal types, Gleason 4 + 5 = 9 (Fig. 2). Advanced rectal examination affirms prostatic hypertrophy with the tumor reaching out from original vesicles to prostatic pinnacle.

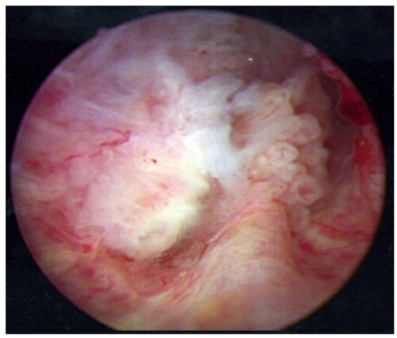

Fig 1: Cytoscopic Image. This is the papillary lesion of prostate ductal adenocarcinoma with hemorrhage seen during cystoscopy

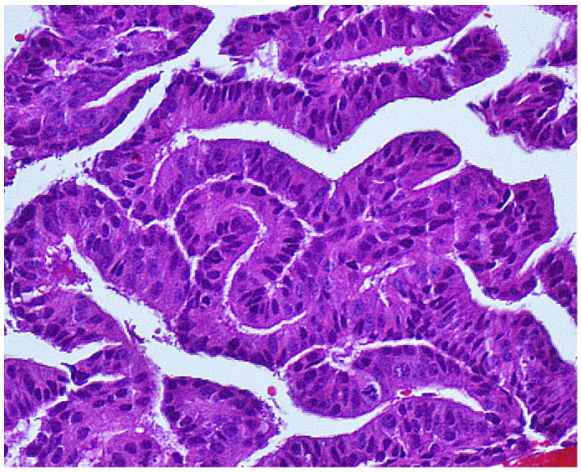

Fig 2: Microscopic Image of Bladder Lesion. This bladder lesion was diagnosed as prostatic ductal adenocarcinoma, Gleason 4 + 5.

A MRI showed a 3.1 cm multifocal infiltrative tumor which stretched out to the bladder with pelvic adenopathy. Every single other output, for example, bone sweep and CT chest, belly, pelvis were negative for far off infection. In this way, he was arranged with cT4N1M0 illness. He is with privately propelled ailment, the patient was not a careful hopeful, and thus he was treated with conclusive radiation treatment, force balanced radiation treatment (IMRT) to 5040 cGy to pelvic lymphatics, prostate, and fundamental vesicles, trailed by the lift to 7920 cGy absolutely to the prostate and original vesicles. He additionally gotten simultaneous and adjuvant androgen hardship treatment with Degarelix and Lupron about for 10 months

The patient has all around reacted to treatment. He stopped to have hematuria, his PSA was imperceptible, and MRI was rehashed. It exhibit goals of pelvic adenopathy and relapse of the prostate tumor. 2 years after his underlying finding, he again gave discontinuous easy plainly visible hematuria, which was treated as hemorrhagic radiation cystitis at first. Nonetheless, rehash cystoscopy and biopsy affirmed intermittent illness at the privilege ureteric hole.

Restaging outputs got 2 years 6months after his underlying conclusion included bone sweep and CT chest, guts, and pelvis, which were negative for far off illness with the special case being that there was an expanded take-up on bone sweep at the distal right tibia and fibula. This area was modestly agonizing as was additionally encouraged to take a MRI, which demonstrated broad bony metastatic illness in the distal lower limit. This was treated with palliative radiation.

The patient was approached to restart on Lupron and started Zometa for hard metastases. His PSA had expanded to 0.23 ng/ml before the season of beginning androgen-hardship treatment. He at first declined chemotherapy and created dynamic sickness throughout the following a half year with across the board rigid scleroticmetastases, dural metastasis along the falx, multitudinous aspiratory knobs, and lymphangitic carcinomatosis. Despite the fact that he endeavored one cycle of Docetaxel 60 mg/m2, he was not ready to endure it and ceased it. He passed away around 3 years 2 months after his underlying determination.

Discussion

Ductal adenocarcinoma of the prostate, with or without a blended acinar part, speaks to fewer than 5% of every single prostate malignant growth. Tumors are described by tall, columnar, pseudostratified epithelium with papillary design. Perceptibly, ductal adenocarcinoma will in general show up exophytic with villous development, and can include the prostatic urethra, original vesicles, or periprostatic delicate tissue, including the bladder. Men with PDA are bound to give privately propelled illness, in spite of the fact that lymph hub metastases appear to be practically identical among ductal and acinar pathology[2].

Studies have demonstrated that men with PDA experience comparative rates of radical medical procedure as their acinar partners. Notwithstanding, PDA will in general have a high momentary disappointment rate after radical prostatectomy[4]. PDA can likewise be treated with conclusive radiotherapy, similarly as with our patient. PDA reaction to hormone treatment is far from being obviously true. A few investigations have discovered a phenomenal long haul reaction to endocrine control dependent on PSA level. In any case, while PDA tumor cells do deliver PSA, this lab worth isn't raised in all patients[3]. In our patient, PSA was conflicting with infection movement and hormone treatment did not control his illness. His PSA pattern during hormonal treatment may propose the nearness of emasculate safe malignancy as a transformative break strategy for the tumor.

PDA will in general metastasize to uncommon areas. For instance, our patients at first created singular distal limit rigid metastases. This was trailed by dural metastases to the falx and lymphangitic carcinomatosis. Instinctive metastases are likewise moderately regular

with PDA. This might be because of the affinity of PDA to disperse by means of hematogenous as opposed to lymphatic routes[5].

Conclusion

This case is a case of how PDA is an increasingly forceful type of prostate malignant growth. PSA may not be an adequate tumor marker for neighborhood repeat of sickness movement. The area of inaccessible metastases in PDA will in general be less unsurprising. More endeavors are required to contribute learning of this tumor science and to evaluate its reaction to treatment.

A Study on Symptoms of Stress and Stress Management Strategies among pre-final and Final Year Medical Students in Kanchipuram District, Tamil Nadu

PriyaReshma T.[1], Mohan Kumar P.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Foundation: In a medicinal or organic context stress is a physical, mental or passionate factor that causes real or mental pressure. This examination is to survey the manifestations of worry among the pre-last and last year medicinal understudies and the procedures they use to deal with the pressure they face.

The primary targets are (i) to research the relationship between conduct changes, physical troubles and enthusiastic status of the classification of understudies chose for the study, during stress times. (ii) To explore the systems they use to deal with the pressure they face. (iii) To realize a mindfulness about the hurtful impacts of worry in our body.

Method: This cross-sectional examination was led from among pre-last and last year therapeutic students from the urban zone of Kanchipuram area, Tamil Nadu, India, utilizing an advantageous inspecting system. The determined all out example size was 100. A pretested self-controlled survey was utilized for the information gathering. The subsequent information was examined.

Result: This study has yielded intriguing outcomes about the pressure side effects and stresses the executives techniques among pre-last and last year medicinal students, which are portrayed underneath. The relationship between social symptoms, emotional manifestations and physical side effects on the body at the season of pressure and the systems used to oversee worry by pre-last and last year understudies.

Keywords: *Behavioural symptoms, Emotional indications, physical side effects of pressure.*

Introduction

Everybody is presented to worry sooner or later in their lives, that awkward circumstance that influences our feeling of prosperity and nature of life[1]. As indicated by the intellectual value-based model of pressure, stress is the dynamic connection between an individual and the earth wherein a boost (whatever it is) exasperates a person's homeostasis, causing him/her to react to the circumstance with all accessible resources[2]. When this happens, we assess the interest in respect to our accessible assets, and the measure of pressure we experience is represented by the accompanying standard: the more assets we have, the less pressure we will involvement.

The pressure may prompt poor basic leadership and cut down the presentation of the person in their field of work. The general attributes of an individual in trouble are: being over-stirred; tense or incapable to unwind; unstable, effectively resentful or bad tempered; effectively surprised or restless, and exhibiting narrow mindedness of any intrusion or delay[3]. Over the top pressure results in an expanded predominance of mental issues like sorrow, tension, substance misuse and suicide ideation[4].

Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Materials and Method

A cross-sectional investigation was led in a urban

area, Kanchipuram region of Tamil Nadu, India. The institutional moral advisory group endorsed the investigation.

The present investigation was attempted so as to evaluate the commonness of worry among understudies of restorative college, especially among the pre-last and last year understudies and the relationship of worry with different behavioural, emotional and physical manifestations and the procedures they pursue.

Subjects of age bunch 19 to 25 years in pre-last and last year of medicinal school in Kanchipuram locale is chosen. An example size of 100 is taken by advantageous inspecting technique. The psychosocial aspects, behavioural changes, passionate status and physical manifestations of them during the season of pressure were surveyed dependent on a pre-tried, self-controlled questionnaire. The poll was isolated into six areas. The primary segment secured as age, the subsequent segment secured the year if think about,the third area conduct indications, the fourth segment secured the enthusiastic side effects,the fifth segment secured the physical side effects and the 6th segment involved the systems the understudies due to deal with the stress. Stress Scale (DASS-21), which has been validated. Then the members of the examination are then assembled and are contrasted and the feelings of anxiety of the members utilizing Depression, nervousness, and stress scale (DASS) information are investigated statistically[5]. Then the methodologies of stress the executives are additionally analyzed.

Findings: In this investigation around 100 pre-tried poll were appropriated and gathered and were utilized for last analysis. They chose test bunch populace had a place with age bunch between 19-25. Overall there were hundred pre-last and last year medicinal understudies[6]. Out of these hundred students, 31% was last year understudy and 69% were pre-last year understudies.

Out of the all out respondents for conduct side effects of stress, 65% experienced irritability, 55% experienced fatigue, 66% experienced anxiety and 73% experienced incapacity to focus.

Out of the all out respondents reacted for passionate indications of stress, 41% regularly and 49% here and there stress a lot over things, 26% frequently and 60% here and there experienced episodes of anger, 33% frequently and half in some cases feel apprehensive that things may turn out badly dependably and 21% regularly and 43% some of the time had meddling contemplations.

Out of the complete respondents reacted for physical side effects of stress, 53% of them encountered cerebral pain sometimes, 47% experienced spinal pain sometime, 48% experienced indigestion, about 2% experienced constipation, 54% have encountered changes in eating pattern (either eating excessively/very less), 32% regularly and 51% once in a while experienced change in dozing pattern (either a sleeping disorder/over rest).

Out of the complete respondents reacted for pressure the board methodologies practically 95% tune in to music at times when they feel stressed,88% select web based life utilization to ease stress,12% picked rest to oversee stress,87% picked investing energy with relatives and companions and around 40 percent selected doing exercise, yoga and perusing books to oversee pressure.

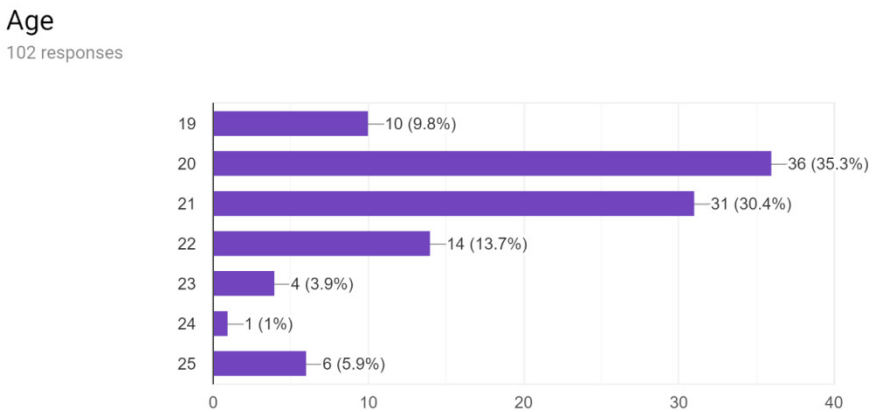

Table 1:

Behavioral symptoms	Often %	Sometimes %	Never %
Irritability	25	65	10
Fatigue	20	55	22
Restlessness	23	56	15
Disability to concentrate	21	76	9

spend time with family	76	25
spemd time with friends	87	13
listening to music	95	12
sleep	90	7
use social media	82	18
do exercise or yoga	47	49
read books	43	57

Discussion

Medicinal training is innately distressing and requesting. A high pervasiveness of worry among restorative understudies to be sure required consideration as it might debilitate the learning capacity that may at last influence the nature of patient consideration they give after graduation.

Restorative understudies are over-burden with a gigantic measure of data, particularly during preclinical experiences[7]. They have restricted time to disguise all the data examined. The over-burden data makes a sentiment of misery and dissatisfactions, since they don't deal with all themes secured and, in this manner, are not fruitful during the examination time frame. The intemperate measure of worry in medicinal preparing inclines understudies to experience issues in taking care of issues and diminished fixation lastly create wretchedness. Moreover, worry among medicinal understudies can break the psychological solidness, debilitated decisions, and non-attendance from class exercise. In actuality, each one of those things bargains scholastic accomplishment of understudies.

This could be clarified that over the top pressure results in unreasonable emission of a pressure hormone cortisol that causes decrement in memory recovery elements of hippocampus and amygdala because of complete blockage of glucocorticoid receptors. This examination has yield a fascinating outcome that has been talked about below.

A Study of Stress among Students of Professional Colleges from a Urban territory in India Vivek B. Waghachavare,* Girish B. Dhumale, Yugantara R. Kadam, and Alka D. Gore,conducted in Maharashtra demonstrated comparable outcomes as this undertaking, though Abu-Ghazaleh et al. in Jordan, stress was seen in 70% of the respondents. Much lower feelings of anxiety were seen in the present examination, a discovering which could be credited to geological and social varieties. Moreover, it is essential to take note of that Supe considered apparent worry in the investigation subjects,6 though Abdulghani et al. connected the Kessler Psychological Distress Scale (K10) stock, which measures non-explicit mental distress and Abu-Ghazaleh et al. connected the 12-thing general wellbeing poll (GHQ-12), which is planned to screen for general mental morbidity. In the present investigation, the scale utilized was the DASS-21, which estimates worry in a manner which is very like the DSM-IV conclusion of GAD. These distinctive screening strategies used to decide pressure may have added to the distinctions in the watched predominance of stress[8,9].

This present venture has likewise yield comparative outcomes as Journal of Cognitive Behavioral Therapy in the three head reactions to stress were 1) tuning in to music, 2) conversing with a companion about the issue, and 3) working out.

Restrictions: Absence of speculation of our outcomes to other therapeutic schools in India is a significant constraint of this investigation. Cross-sectional plan of our examination is one more confinement since scores exhibited need fleetingness. Despite the fact that reaction rates out of complete understudies (95% for example who was available on that day) were genuinely great there could be some determination (nonresponse) inclination. The primary reasons that surfaced were the touchy and individual nature of the examination. Different reasons were nonappearance from school because of affliction or travel upon the arrival of the overview.

Conclusion

From the discoveries, the outcomes plainly demonstrate that adolescent is worried toward abnormal state. The side effects recognized are being eating, sorrow and migraines are more among understudies

It is seen that because of the expansion us of web-based social networking the youthful age become conceited and just interface with the innovation. It lessens the physical development of the body and investing energy with relatives and companions. All these make pressure which builds the instance of despondency and suicide. It is vital and proposals to the youngsters that make target arranged methodically use innovation inside point of confinement and offer your feelings with your friends and family.

Study on Alopecia and its Impact in Everyday Life among Alopecia Patients Visiting Tertiary Health Centre in Thiruvalluvar District of Chennai

Swetha Srinivas[1], Anantha Eashwar V.M.[2], Gopalakrishnan S.[2]

[1]MBBS Student, [2]Assistant Professor, [3]Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: Alopecia is an endless dermatological fiery issue in which individuals lose a few or the majority of the hair on their head. Once in a while on their body too. It is neither dangerous nor difficult there can be disturbance of skin, also physical issues coming about because of loss of eye lashes and eye foreheads. Etiology and ensuing improvement of alopecia isn't completely comprehended. Be that as it may, it is an immune system issue emerges from blend of hereditary and natural influence. Its physical results are for the most part considered and treated .But its mental outcomes are not considered in treatment much of the time.

Method: This is a graphic crosssectional study led among 100 patients experiencing Alopecia in a tertiary wellbeing place for skin and hair n Thiruvalluvar area of hennai Tamil Nadu.

Results: we have attempted to evaluate the effect of Alopecia in consistently life among the patients. Most of the age gathering influenced by alopecia is age bunches over 35. Alopecia areata is commonest sort of alopecia pursued by androgenic alopecia.

Conclusion: With globalization and absence of touch with nature, and huge heaps of stress, both physical, passionate nature, over-burdening of free radicals in our body, it causes areal toll on our worries .there is a critical need to advance further research in the zone of brain science and mental mediations for the administration of this disorder. Flushing out poisons from our body, utilization of sulfate and paraben free items, great sustenance, less unpleasant personality, moderate exercise when rehearsed consistently and stringently alopecia can be controlled. For the most part it tends to be imagined that instance of alopecia on the off chance that gathering is higher than the control gathering, subsequently appropriate mindfulness and awareness about mental and expert back grounds is fundamental for desireable administration of the sickness.

Keywords: *Alopecia,Dermatologists, Alopecia Areata*

Introduction

There numerous a man has more hair than mind, was expressed by William Shakespeare in the parody of Errors. Be that as it may, in this day and age, individuals are so grieved by male pattern baldness they may step more hair than mind; Alopecia is characterized as loss of have from zones where hair ordinarily develops. It very well may be fractional/complete loss of hair. There are various kinds of alopecia the primary sorts are Alopecia Areata(AA) Alopecia Totalis (AT) Alopecia Universalis (AU) Alopecia Barbae, Androgenic alopecia (AGA), Scarring alopecia: telogen exhaust (diminishing of hair) less normal courses of male pattern baldness without[1]. Scarring incorporates hauling out hair (footing alopecia) chemotherapy, ailing health, Fe, microbial infusion, Radiation treatment, endocrine issue. Treatment of this

Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

includes tolerating the condition hair transplantation, wig, minoxidil, finastride, dutastreide, pulsed electro attractive treatment, for FPHL, about 2% of individuals create alopecia some point in time. It very well may be because of trichotillomania known as hair pulling. Is a psychological issue wherein there is Long term hauling out ones hair, places basic incorporates around eyes and head. The deggree of hair pulling results in trouble all the more regularly watch habitual issue treat by subjective social treatment .Alopecia can be mental. Can have genuine psychosocial results coursing exceptional enthusiastic enduring individual, social business related issues. The distressing life occasions can lead toevents of activating alopecia[1]. Contrasted and all inclusive community, expanded commonness rates of hallucinogenic issue are related with alopecia. Being a higher SSR for advancement of real burdensome issue nervousness issue, social fear and neurotic issue. Be that as it may, essentially an uncovered man is socially satisfactory, a bare lady isn't. The mindfulness among alopecia can prompt change in their ways of life adjustments. Sound and the self control to battle back against it.hence the intend to examine are the results looked by Alopecia influenced patients influencing physical and psychological well-being and their disposition towards alopecia in todays world[1].

Materials and Method

The investigation includes alopecia influenced individuals visiting tertiary wellbeing place for skin and hair in Thiruvalluvar area Chennai Tamil Nadu. An example size of 100 individuals is gotten by assignment of patients by the head of tertiary wellbeing focus from her emergency clinic for alopecia and testing strategy pursued was helpful examining technique. Age gathering includes individuals from 1year to 80 years. The causes, various pieces of the body influenced by alopecia, its restorative camouflage, recommended treatments, challenges they face in regular day to day existence languishing over the patients partaking in this exploration are surveyed utilizing a page poll simply subsequent to getting assent from them by marking in the assent structure .Data was gathered and MS Excel and broke down utilizing SPSS form 22.

Findings: Our results included 100 individuals influenced by alopecia which includes 62%male and 38%female .the age gatherings required for male and female are spoken to as a table outline. Higher pervasiveness (41%) was found in those over 35 years old. (Table 1).

Table 1: Socio demographic details of the study participants

Age group	Percentage/Frequency the same
<less than 18 years	27%
18-35 years	32%
>greater than 35	41%
Sex	Percentage/frequency the same
Female	38%
Male	62%

The table 2 represents the type of alopecia people are most commonly affected with Alopecia Areata [70%] is the most common type of alopecia affected cases followed by Androgenic Alopecia [45%], Telogen effluvium [40%], alopecia totalis [20%], trichotillomania[10%], alopecia barbarae[5%].

Table 2: Types of alopecia-among the study participants

Types of alopecia	Percentage	Frequency
Alopecia areata	45	45
Telogen effluvium	15	15
Alopecia barbarae	2	2
Alopecia totalis	5	5
Alopecia universalis	2	2
Androgenic alopecia	20	20
Cicatrical alopecia	2	2
Trichotillomania	9	9

Figure 1 shows the cosmetic concealment options used by the study participants for alopecia. Around 43% of them use wig, 28% use hair extensions, 14% use resatinfibers.

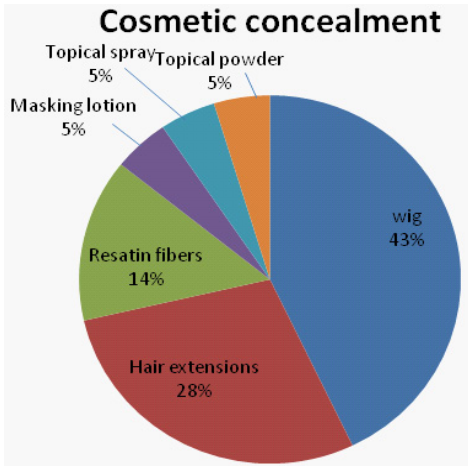

Figure 1: Details regarding Cosmetic concealment among study participants

Stress is being the major killer triggering alopecia .findings from the above pie chart shows stress people take in their studies, job, personal and family problems being the reasons for hair loss around 9% of people marriage especially for men being rejected inspite of their god profession and monthly income 10% move into depression and are under pscychatric guidance .23 % people have felt to attempt suicide because of the mockery they face in the society due to alopecia (Figure 2).

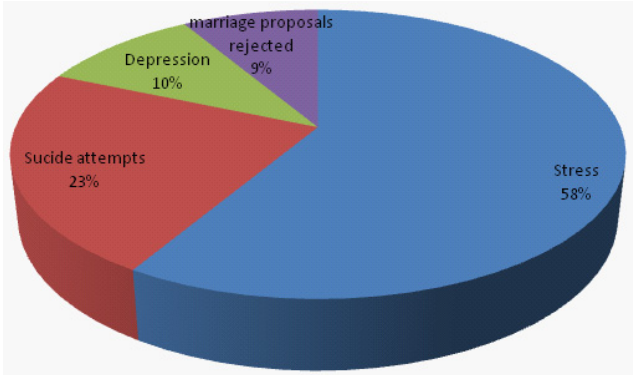

Figure 2: Psychosocial problems faced by the study participants due to alopecia.

Most of the study participants had a alopecia pattern of scalp being affected followed by eyebrows and eyelashes. (Figure 3).

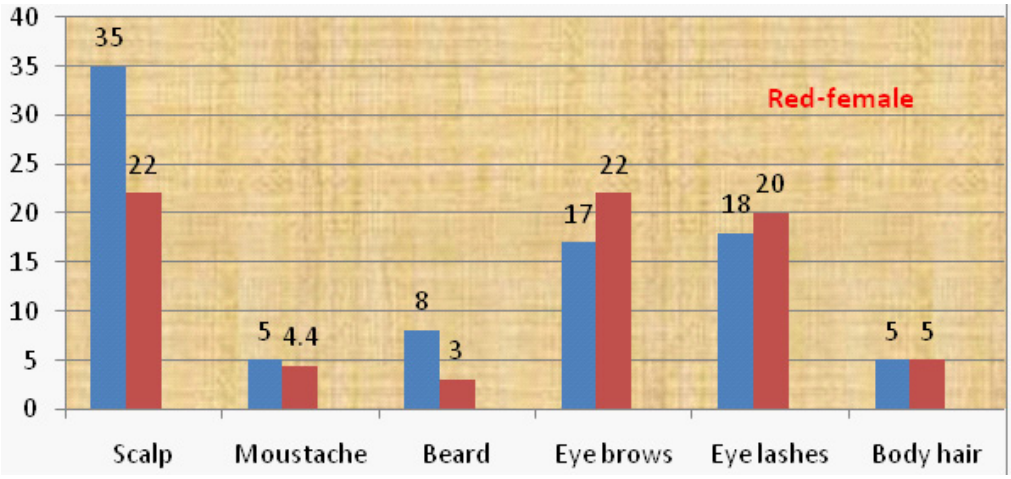

Figure 3: Alopecia affected parts of the body among study participants

Discussion

The examination depends on the effect of alopecia in regular day to day existence. for example, nervousness, stress, despondency, character profile, neurobiological bits of knowledge, nature of life. This study center upon the reasons and cause for alopecia in today world. This study manages the outcomes gotten by investigating the point of view of alopecia among the 100 individuals of various age bunches in today world how they adapt up, manage it,discoveries of kinds of hairloss pattern, different regions of body influenced by alopecia by clear chronicles from the information acquired after discussion with the alopecia affected people is acquired dependent on these discoveries about the effect of alopecia in regular day to day existence individuals of different social back grounds are break down.

Research thinks about by Gupta MK have revealed following the issue to antagonistic youth encounters and formative points of view have been elusive[2]. Alopecia influenced understudies express that mental trouble because of alopecia was not endless supply of patient or phase of baldness study[1] done by Priktt J recommends that ladies who have recuperated from chemotherapy face worry for failure to style their hair[3]. Study by Petkhova L with respect to the evaluating of alopecia have indicated varying outcomes in the clinical example of male and female example hair male pattern baldness propose that they 2 separate entities[4].

Stress is a wide build and specialists have differing meanings of what comprises pressure. Analysts likewise fluctuate in what are flitting or long haul suffered pressure. This makes hard to translate discoveries from research papers regarding the matter and most examinations take on insight of intrapsychic and different individual directions that might be influencing everything in the individual patient[5]. Uneasiness and melancholy have been accounted for generally crosswise over different examinations in patients with alopecia areata. The scopes of patients influenced by the clutters are 30-80% crosswise over examinations. Sentiments of instability and inferiority alongside inactivity in light of feelings has been accounted for in this patient population Personality profiles in alopecia Areata: alopecia areata patients have a trademark character profile with low oddity looking for, low reward reliance and low self-amazing quality, youngsters with alopecia areata are progressively pulled back, discouraged and forceful demonstrating sorrow in almost 40-half cases[6]. There are very few examinations on character qualities of these patients and neither has the frequency of character issue in this gathering thinks about. There is one research that reports raised sorrow, social self preoccupation sub scale on appraisal on the Minnesota multiphasic character stock (MMP) in this group[7]. Neurobiological bits of knowledge into alopecia areata: the impact of mental factor in alopecia areata however entrenched has discussed. Late examinations have attempted to clarify a neurobiology fothesame[8]. Intense enthusiastic pressure might be hasten alopecia by enactment of over communicated type 2b corticotropin discharging hormonal receptors around the hair prompting neighbourhood information[9].

Personal satisfaction in alopecia areata: personal satisfaction is an expansive idea and is gone for whether confusion restrains a patient's capacity to satisfy an ordinary job and furthermore surveys weight and results of medicines advertised. It is characterized as the emotional impression of the effect and social working and prosperity of patients[10]. This is significant pointer in scatters like alopecia areata in light of the fact that the turmoil has solid effect on social connections, consistent schedule actives and psychosocial status. Life occasions and alopecia areata: life occasions assume a significant job in causation of alopecia areata. Life occasions alone are not adequate independent from anyone else to achieve etiological significance[11]. Female patients with alopecia areata: female patient with alopecia areata have progressively enthusiastic hints and adding to the stress might be a trivialization of the issues by unpracticed physician Communication and consistence alopecia areata: relational abilities are an unquestionable requirement when managing a patient of alopecia as great correspondence is imperative in the recuperation procedure. Correspondence needs to incorporate tuning in to the patient, understanding the patient, advising about different tests and symptomatic methodology just as helpful onsiderations and prognosis,it includes onvincing the patient while giving expectation and joinly cheering over restorative advancement. Understanding instruction and advising alongside psycoeducation of relatives in helping patients adapt is another region which is significant[12]. Data of utilization psychotropic medications just as antidepressants this populationas well as on relative examinations on preliminaries on this respect was unavailable clinical experience recommends that choice will be on case to casebias[13].

Job of mental mediations in alopecia areata: there is a requirement for dermatologists to work in contact with emotional wellness experts when it comes the effective administration of alopecia areata a disorders[14].

Conclusion

With globalization and absence of touch with nature, and monstrous heaps of stress, both physical, passionate nature, over-burdening of free radicals in our body, it causes areal toll on our worries .there is an earnest need to advance further research in the zone of brain research and mental intercessions for the administration of this issue.

Flushing out poisons from our body, utilization of sulfate and paraben free items, great nourishment, less unpleasant personality, moderate exercise when polished routinely and stringently alopecia can be controlled. By and large it very well may be imagined that instance of alopecia in the event that gathering is higher than the control gathering, thus legitimate mindfulness and cognizance about mental and expert back grounds is fundamental for desireable administration of the ailment.

Are Pets Stress Busters or Cause of Allergy

Tejas M.[1], Anantha Eashwar V.M.[2], Gopalakrishnan S.[3]

[1]MBBS Student, [2]Assistant Professor, [3]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Background: In brain science, stress is a sentiment of strain and pressure. Stress is a kind of mental torment. Sensitivity to pets are for the most part because of their hide which is truly unimportant .coming up next is the exploration done on the advantages of pets on undergrads and their conceivable unfriendly consequences for them.

Method: Philosophy Cross Sectional examination done by convenience testing strategy. Information was gathered with the assistance of a poll. The subjects utilized for this investigation were College understudies from Kanchipuram area.

Result: Out of the 150 respondents it was discovered that 66% had pressure and just 20% had hypersensitivity because of different causes. Among the pet proprietors there is a noteworthy decrease in worry after the entry of the pet.

Conclusion: There are numerous advantages of pets. One such advantage is the decrease of pressure. The prevalence of sensitivity because of pets is truly immaterial .Thus the advantage of having a pet exceeds its hazard. The significant levels of pets give help and are regular pressure buster.

Keywords: *Man's buddy, Hypersensitivity response, allergens, Cortisol.*

Introduction

An ongoing statics uncovered that a normal of 600000 pets is being embraced every year. China has the most astounding populace of canine proprietors of 27.4 million proprietors. India positions fifth with 10.2 million proprietors behind Philippines. An ongoing overview uncovered that Chennai participation issues licenses for around 160 pooches every month[1]. One of the greatest false impressions with respect to pet hypersensitivities is that they are brought about by creature hide. Specialists state this isn't valid and that even two pets from a similar breed may cause altogether different degrees of hypersensitivity. The pets hide isn't the most serious issue with regards to allergens rather it is the feline or canine dander which causes the genuine problems[2].

Stress is a sentiment of strain and weight. Stress is a sort of mental torment. Studies have additionally demonstrated that association with treatment creatures can diminish worry in people. Playing with or petting a creature can diminish levels of the stress. The human body reacts to occasions that incite worry by actuating the sensory system and explicit hormones These hormones accelerate pulse, breathing rate, circulatory strain, and digestion. The physical changes set you up to respond rapidly to deal with the weight existing apart from everything else. This regular response is known as the pressure reaction. This reaction improves your capacity to perform well under strain. Stress influences everyone in an alternate manner. What makes one individual become over-focused might not have a similar impact on another person. The primary driver if stress are as per the following Exams,Problems at school or work, New duties, Moving to another spot, Traumatic occasion–, for example, the passing of a friend or family member,

Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

New or endless disease or incapacity, Peer weight, being harassed and Unrealistic desires put on you without anyone else, companion, family or culture[3].

The most hazardous thing about pressure is the manner by which effectively it can crawl up on you. You become accustomed to it. It begins to feel recognizable, even ordinary. You don't see how much it's influencing you, even as it causes significant damage. That is the reason it's imperative to know about the regular cautioning signs and side effects of pressure overload[4].

At the point when stress comes your direction, your body goes into battle or-flight mode, discharging hormones like cortisol to wrench out more vitality boosting glucose and epinephrine to get your heart and blood siphoning. When we live in a steady condition of battle or-departure from progressing worry at work and the frantic pace of current life, these physical changes negatively affect our bodies, including raising our danger of coronary illness and different hazardous conditions. Contact with pets appears to balance this pressure reaction by bringing down pressure hormones and pulse. They likewise lower nervousness and dread levels (mental reactions to stretch) and raise sentiments of smoothness. Studies have discovered that mutts can help simplicity stress and forlornness for seniors, just as assistance quiet pre-test worry for school students[5]. Animals can fill in as a wellspring of solace and backing. Treatment pooches are particularly great at this. They are here and there brought into clinics or nursing homes to help lessen patients' pressure and anxiety[6].

Materials and Method

Coming up next was a cross sectional investigation done by convenience inspecting technique. The investigation is done on understudies from Sree Balaji Medical School in Chrompet. The information was gathered with the assistance of a poll .An assent structure was issued alongside the poll expressing that the subtleties of the review were disclosed to the subject and the cooperation is simply deliberate. The survey was set up so that it helps to recognize whether the subject experiances stress and if being a pet proprietor lessens this pressure. Additionally the reasons for hypersensitivity amoung the subjects were gotten to.

Test measure: 150.

Study area: Sree Balaji medicinal school and clinic

Study populace: Students from Sree Balaji medicinal school and Hospital who have a place with first, second and third year.

Study technique: Cross sectional engaging investigation

Study period: April 2019-June 2019

Consideration criteria: All those will be available upon the arrival of study

Avoidance criteria: All the individuals will's identity missing upon the arrival of study

Findings: The graph shows that 60% of the students were girls and the remaining 40% were boys.

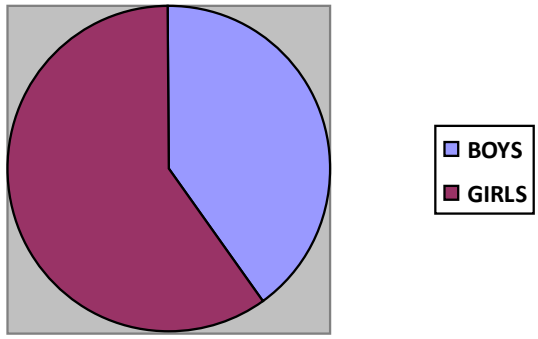

Figure 1: Percentage of Boys and girls

The bar graph indicates that 16 individuals had dust allergy, 8 individuals had allergy to food, 4 individuals had allergy to certain drugs and only 3 individuals had allergy towards a pet animal .Out of the three individuals who had an allergy towards an animal only one person had a pet at home.

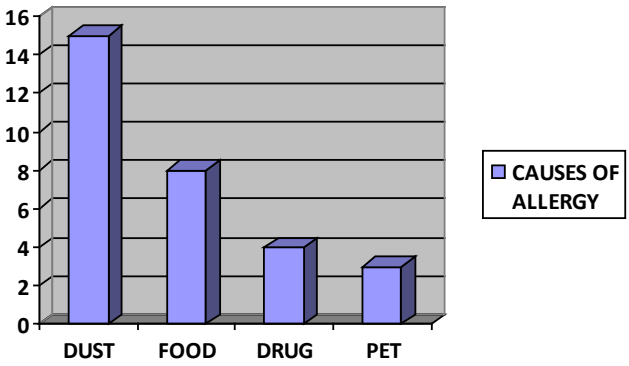

Figure 2: Causes of Allergy

Table 1: Factors Related To Pets

S. No	Variable	Frequency	Percentage
1	Do you experience stress?		
	Yes	99	66%
	No	51	34%
2	Do you have a pet at home?		
	Yes	90	60%
	No	60	40%
3	Is there a reduction of stress after the arrival of the pet?		
	Yes	72	80%
	No	18	20%
4	Do you have allergy?		
	Yes	30	20%
	NO	120	80%

The above table demonstrates the elements identified with pets. The principle elements contemplated here is the central advantage of pets on pressure and the unfavorable impact is an outcome of hypersensitive sign on the respondents.

The investigation uncovered that 66% of the people had pressure. 60% of the subjects had a pet and there was 80% decrease of pressure amoung the pet proprietors. 20% of the people had hypersensitivity.

Discussion

In the present period marvel of pressure isn't limited to grown-ups yet additionally influences understudies. In this examination an endeavor has been made to distinguish whether pets are pressure busters or reason for hypersensitivity.

From this investigation it is discovered that 66% of the understudies had stress. Similiar considers amoung restorative understudies in Chennai has demonstrated that around 78% of the subjects were worried because of different causes like tests and companion weight. 60% of the subjects were found to have pets. The subjects were solicited whether there was a decrease from worry after the entry of the pet. 72% addressed that there is a resulting decline in worry because of their pets. Comparative examinations in Israel revieled that brief time of petting a creature brought about decreased state-uneasiness amoung non clinical people in a distressing condition[7].

Another examination in the US found that 74% of pet proprietors announced psychological wellness enhancements from pet possession, and 75% of pet proprietors detailed a companions or relative's emotional well-being has improved from pet ownership[8, 9]. This investigation additionally uncovered that 20% of the subjects had hypersensitivity out of which just 7% had sensitivity to pets. An article in the ABC news uncovered that 15% of the populace is adversely affected by pets and 30% if the general population with asthma are sensitive to pets.

In this way from this investigation it was discovered that in urban zones where huge numbers of them were worried because of friend and parental weight the nearness of pets impressively decreased pressure. There is sufficient proof to help a case that we are 95% sure that a great many people accept they have decreased worry from time gone through with their pets.

Conclusion

In this chaotic existence where it would seem that everybody is out to get us. A pooch is the one thing on earth that cherishes you more than you yourself. People lie to one another, they double-cross, why they are even prepared to murder one another, yet our pet creatures realize just to adore us. They stay steadfast till the final gasp of our lives. It is just an irrelevant level of pets which cause sensitivities, the significant level of pets give help and are common pressure busters. On the off chance that you purchase a toy for a tyke he will be cheerful for some time; however in the event that you blessing a pet to your kid he will be glad forever. Pets are unquestionably our best mates for they will neither judge nor reprimand simply totals love. You have to deal with your pet and keep it in clean conditions. The pet must be consistently inoculated and all medical problems took care of improvised.

Atrophoderma of Pasini and Pierini in an Adolescent Male: A Case Report

Anam Hiranmayi[1], Gopalakrishnan S.[2], Anam Tanuja Reddy[2], Abhinaya C.[1]

[1]UG Students, [2]Professors, Department of Community Medicine,
Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Atrophoderma of Pasini and Pierini (APP) is an uncommon and unmistakable type of dermal decay of dubious etiology. It displays as one or a few, pointedly discouraged patches, with no encompassing erythema, sclerosis and indurations. Normally happens in youthful grown-ups, for the most part in the storage compartment. For this situation consider we present a multiyear old kid giving grievances of a dull shading asymptomatic skin sore over the lower back

Keywords: *Pasini, Pierini, erythema.*

Introduction

In 1923, Pasini portrayed an atrophic injury on the storage compartment which he revealed as dynamic idiopathic Atrophoderma. In 1958, Canizares et al renamed this condition as 'Idiopathic atrophoderma of Pasini and Pierini'[1]. It is typically a kind issue which exhibits as asymptomatic, hyper pigmented, somewhat discouraged patches with sharp "bluff drop" fringes[2] or impression in snow appearance[3] with symmetrical and respective dissemination. These plaques are commonly round or ovoid fit as a fiddle with their long hub parallel to the lines of cleavage[1].

Findings: A multi year old BOY exhibited to a private skin center with a dim hued asymptomatic skin injury over the back of the storage compartment for as long as a half year, with No history of other comparative skin injuries in the body related with or without agony. Dermatological examination uncovered 7cm x 4cm single, unbalanced, very much outlined, pigmented, atrophic, discouraged plaque with trademark bluff drop fringes. No delicacy was available.

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Foundational examination was ordinary. Routine lab examinations, for example, CBC, pee investigation, liver capacity tests, renal capacity tests and serum electrolytes were accomplished for incase of any differential determination and basic infection and observed to be ordinary.

A skin biopsy of 0.2cm was taken from the injury for histological examination, demonstrated dispersed epidermis and dermis indicating somewhat thickened collagen packs and gentle lymphocytic invade. Atrophoderma of pasini and pierini was made dependent on clinical and histopathalogical discoveries.

Figure 1: gross lesion on the lower back

Discussion

There are different choices with respect to whether Atrophoderma of pasini and pierini speaks to isolate element or is a principally shallow and atrophic variation of morphea. They are symmetrically circulated

truncal sores generally yet single sores and zoster form conveyances[4] are likewise observed. The sores are non-indurate; blue-dark to darker, hyper pigmented and forcefully differentiated discouraged patches, with bluff drop fringe or impression in snow appearance[3].

Etiology: It is an uncommon condition with obscure etiology that speaks to 0.1% of youth morphea. This issue is more every now and again experiencing in ladies than in men in the proportion 6:1[2]. It as a rule begins treacherously in the second or the third decade of life and has likewise been accounted for in youngsters more youthful than 13 years old. The sores happen more often than not on the storage compartment, particularly on the back and the lumbosacral region[5]. Two kin with phenylketonuria demonstrated morphea in one and atrophoderma of pasini and pierini in another, inspire of this familial inclination, a hereditary factor has not been dependably incriminated[6]. Job of borrelia burgdorferi has likewise been suggested[7].

Pathology: Histopathological appearances are variable: show typical to mellow lymphocytic invasion along decreased dermal thickness and ordinary or sclerotic and hyalinized edematous collagen. Flexible stains may likewise demonstrate a range of changes[2] (atrophoderma indicates a greater number of changes in versatile tissue than morphea) extending from typical to insufficient fracture of bunched flexible fiber network[5, 2]. Immunofluorescence studies may demonstrate igM and C3 in the dermal blood vessels[8]. A couple of most recent examinations have said that histopathological studies have no demonstrative worth.

Clinical highlights: The injuries are single or various and for the most part round or ovoid, all around surrounded delicate plaques with a discouraged focal point of 1 to 8 mm top to bottom and an old style bluff drop appearance going in size from a couple of centimeters to patches covering enormous territories of the storage compartment, the shading fluctuates from somewhat blue dark colored to violet[3]. They are normally asymptomatic and need irritation. at the point when various injuries combine, they give huge, sporadic, dark colored fixes generally numerous sores can have Swiss cheddar appearance[3]. The skin encompassing the patches is typical in appearance and there is no erythema or lilac ring as in morphea[1].

Differential determination: The most plausible differential finding is Morphea and Atrophoderma of moulin[5]. Morphea is described with a lilac ring and cobblestone[9]. Appearance of the sore with erythema and induration[10]. Thus discounted here. Where atrophoderma of moulin are has no histological changes and is altogether different from atrophoderma of pasini and pierini. In this manner Atrophoderma of pasini and pierini was made dependent on clinical and histopathalogical findings[5, 1].

Treatment: No treatment as been demonstrated successful. in any case, PUVA(psoralen and bright A), hydroxychloroquine and Q-exchanged Alexandrite laser has been tried[8] it was just powerful in decreasing the hyperpigmentation by half after 3 medicines in just barely one case[9]. In perspective on the likelihood of a basic Borrelia disease, penicillin and antibiotic medication has additionally been utilized for treatment[7] when the finding is built up; follow up of the patient for improvement of new regions is to be done where ultrasonography is utilized. Careful treatment has commonly not been useful in improving the presence of decayed skin[9].

Conclusion

Atrophoderma of pasini and Pierini is a sort dermal atrophy with obscure etiology, regardless of whether it's a different infection substance or essential variation of morphea is still discussed and to be additionally contemplated. Patients assent was acquired. There are no irreconcilable circumstances.

Case Report Respiratory Failure Presenting H1N1 Influenza with Legionnaires Disease

Haleemathu Sahdiyya[1], Krishna kumar J.[2], Gopalakrishnan S.[2]

[1]MBBS Student, [2]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

This is a case report of patient who displayed in 2018 with coinciding H1N1 infection and Legionella diseases in a 69-year-old male. For this situation every one of the signs and side effects, including regurgitating, dynamic respiratory sickness prompting respiratory disappointment, headstrong hypoxemia, leukopenia, lymphopenia, thrombocytopenia, and raised degrees of creatine kinase and hepatic aminotransferases, were steady with basic disease because of 2018 H1N1 infection contamination. Different irresistible issue may mirror H1N1 viral contamination particularly Legionnaires' ailment. I do feel that my doubt of Legionella contamination dependent on clinical history and X-beam variations from the norm was major for a fruitful goals.

Keywords: *Respiratory Failure, H1n1 Influenza, Legionnaires Disease, Legionella.*

Introduction

Flu is an intense self-constrained febrile disease brought about by contamination with flu type An or B infection. While respiratory side effects are most normal, myositis, rhabdomyositis, myoglobinuria, myocarditis, pericarditis, and focal sensory system contribution have all been portrayed with flu infection disease. Media emotionalism on the H1N1 episode may have affected decisional forms and clinical finding.

Materials and Method

This case report proposes that patients with H1N1 ought to be screened for Legionella, which isn't right now regular practice. This is especially significant since the signs and manifestations of the two diseases are comparable.

Catchphrases:

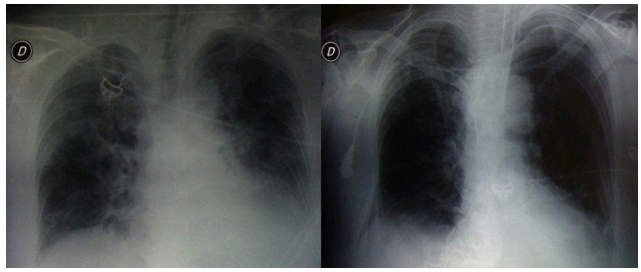
- Respiratory disappointment
- Viral contamination
- Legionella
- Swine influenza

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Findings: Flu is an intense self-restricted febrile sickness brought about by contamination with flu type A or B infection. While respiratory side effects are most normal, myositis, rhabdomyositis, myoglobinuria, myocarditis, pericarditis, and focal sensory system association have all been depicted with flu infection disease. Media sentimentality regarding the swine influenza flare-up may have affected decisional forms and clinical determination. This is a report two instances of patients who present during 2009 in whom H1N1 and Legionella contamination existed together. Optional bacterial pneumonia is perceived as a standout amongst the most widely recognized reasons for death in flu cases. Coinfection has been found in 30% of all flu cases in people with occasional flu. The pathogens regularly included are Streptococcus pneumoniae, Staphylococcus aureus, and Hemophilus flu. From July 2009 through February 2010 there was a pandemic. In the year 2010 there had been 2850 cases detailed and 1833 passings from H1N1 swine flu in kerala.

Case: This case is a 69-year-elderly person with a past restorative history of coronary vein ailment, interminable renal deficiency, hypertension and type 1 diabetes. Two weeks sooner, he had been presented to

a youngster with an upper respiratory contamination. He lived in a rustic territory. He had no history of bug nibbles, however was presented to cultivate creatures and lake water.



He had been well until nine days sooner, when profitable hack, myalgias, fever (39.4°C), disquietude, sore throat and nasal blockage displayed. On physical examination in the Emergency Room (ER), the patient had a temperature of 39.2°C, a pulse of 50 beats for every moment and a respiratory rate of 35 breaths for each moment. A buccal swab was negative for flu An and B antigens, and no parasites were seen on a fringe blood smear. Acetaminophen, ketorolac, levofloxacin and typical saline were regulated.

Following 24 hours he gave tireless fever (39.0°C), profitable hack and respiratory disappointment and was admitted to the emergency unit). Imperative signs were as per the following: circulatory strain 135/70 mm Hg; pulse 50 beats for every moment; respiratory rate 34 breaths for each moment; oxygen immersion 88%, on half propelled oxygen. On physical examination bronchi were recognized in the lower lung fields.

Rehashed trial of nasopharyngeal emissions for flu infections, parainfluenza infection, respiratory syncytial infection, and adenovirus were negative. Testing for antibodies to toxoplasma was suggestive of past contamination. Societies of examples of blood, pee, and sputum were sterile. Polymerase chain response assurance of buccal swab for H1N1 flu A infection was sure. Urinary tests for Legionella antigens were certain.

On affirmation principle research center examinations were as per the following: white platelet check (WBC) was 9.8 K/mL (87% neutrophils, 4% lymphocytes); C-responsive protein 205 mg/L; serum sodium 132 mEq/L; serum phosphorus 2.3 mg/dL; serum glutamate pyruvate transaminase (SGPT) 175 IU/L; serum oxaloacetate transaminase (SGOT) 184 IU/L; serum ferritin 4100 ng/mL; creatinine phosphokinase (CPK) 241 IU/L. Winthrop scale score was > 15.

Chest radiograph demonstrated low lung volumes, with inconsistent air-space malady predictable with multifocal pneumonia (Figure 1). Intravenous azithromycin (500 mg twice day by day), levofloxacin (500 mg twice every day) and oral oseltamivir (150 mg twice day by day) were controlled. Inside 18 hours after entry, tachypnea and hypoxemia (PaO2: 58 mm Hg, while breathing half oxygen) expanded further requiring intubation and mechanical ventilation. Hypotension and renal disappointment created; methylprednisolone and vasopressors were controlled.

Right board: antero-back chest x-beam of patient 1. Left board: antero-back chest x-beam of patient 2.

On the third day turn around transcriptase polymerase chain response (RT-PCR) on a bronchoalveolar lavage example was as yet positive for H1N1 flu disease. Legionella antigens were likewise affirmed positive. On the fifth day he was extubated and non-obtrusive ventilation was begun. He was released from the ICU on day 21.

Discussion

The pandemic was painstakingly trailed by the media however with a dash of sentimentality that caused an across the board a feeling of dread in the populace. Human services frameworks and doctors were abruptly in the spotlight. For this situation every one of the signs and manifestations (counting respiratory disappointment, recalcitrant hypoxemia, leukopenia, lymphopenia, thrombocytopenia, and raised degrees of creatine kinase and hepatic aminotransferases) were steady with basic sickness because of contamination with the 2018 H1N1 infection.

Different irresistible issue may impersonate H1N1 viral contamination particularly Legionnaires' illness. Starting endeavors to analyze H1N1 disease utilizing immunochromatography depended on test units created for regular flu An and B infections, a large number of which demonstrated fundamentally less delicate to H1N1. Subsequently, tests with monoclonal antibodies that respond with H1N1 yet not regular flu A (H1N1 and H3N2) or B infections were created.

Perceiving viral hemagglutinin and nucleoprotein, explicitly permits the location of H1N1 infection in nasal wash liquid or nasopharyngeal liquid from patients with flu like sicknesses. Early and fast conclusion of H1N1-related respiratory deficiency needs quick screening

during a pandemic however clinicians can't depend just on the buccal swab test and need to preclude false positive and negative cases by RT-PCR on oral/nasal liquids or bronchoalveolar lavage examples.

In the event that one the visit by a tyke with an upper respiratory contamination five days before the beginning of disease in the patient speaks to likewise a conceivable presentation to the 2018 H1N1 infection; . The quick doubt of Legionella disease dependent on clinical history, X-beam anomaly was principal for effective goals.

Practically all patients influenced by pandemic H1N1 diseases admitted to an ICU due to lung association get empiric anti-infection treatment. Be that as it may, fundamental clinical information have neglected to show a steady job of bacterial co-disease proposing that extreme aspiratory harm happens because of viral pneumonia[1, 2]. An ongoing post-mortem examination study uncovered proof of simultaneous bacterial contamination in 29% of cases[3]. In 45% of these the pathogen was S. pneumoniae. These discoveries affirm the aftereffect of past investigations of dissection examples demonstrating that most passings credited to flu A infection happened simultaneously with bacterial pneumonia. Then again, they feature the significance of treating flu patients with both empiric antibacterial treatment and antiviral meds. It is significant that zoonotic contaminations must be precluded. The absence of known contact with creatures in an immunocompetent host seems to preclude zoonotic diseases, for example, Coxiella burnetii. One of the patients had worked close water lakes, which could have been polluted by creature pee, yet he didn't have aspiratory drain so leptospirosis appears to be impossible. Without introduction to feathered creatures, Chlamydia psittaci is impossible. Network procured pneumonia (Streptococcus pneumoniae, Hemophilus influenzae, S. pyogenes, or Staphylococcus aureus) can cause serious pneumonic infection, particularly in patients with precursor flu. These pathogens ought to have reacted to the wide range antimicrobial treatment; in this way, they are probably not going to have been the sole reason for ailment. Atypical bacterial pathogens, for example, Legionella pneumophilacause multifocal pneumonia yet as a rule don't cause upper respiratory tract indications

Anaplasmosis could result in a lower respiratory tract malady yet fulminant sickness is uncommon and clinical improvement ought to have happened with levofloxacin treatment. Radiographic variations from the norm additionally should have been precluded. Numerous fundamentally sick patients have radiographic discoveries of viral pneumonitis, with two-sided interstitial and alveolar invades. Multifocal and inconsistent variation from the norm as found in this patient has been accounted for in instances of 2018 H1N1 flu A infection contamination however don't totally preclude obtrusive bacterial disease[4]. Ground glass mistiness and cavitary lobar murkiness should concentrate consideration on Legionnaire's sickness[2].

Another potential contributory factor that should have been discounted was viral disease of the respiratory tract. Disease with adenovirus or flu infection must be considered. Adenovirus type 14 is the undoubtedly reason for serious viral pneumonia in grown-ups. Radiographic discoveries may incorporate lobar invades, despite the fact that these are increasingly normal for bacterial pneumonia. The way that bacterial contaminations ought to have reacted to levofloxacin contends against the way that an optional bacterial pneumonia superimposed with flu A or B causing extreme aspiratory illness. The absence of late travel in H5N1 (winged creature influenza) endemic territories or presentation to wiped out or dead poultry contend against H5N1 flu (fledgling influenza)

Conclusion

This case report proposes that the patient with H1N1 ought to be screened for Legionella, which isn't at present regular practice. Specialists ought to never be stunned by possibility and media drama in basic leadership. With brief distinguishing proof of the bacterial etiology of pneumonia, proper treatment can be begun with both antibacterial treatment and antiviral meds. The length of emergency clinic remains and the mortality of both pandemic and occasional flu can be decreased.

Depression in Primary Healthcare

Janani M.[1], Krishnakumar J.[2], Gopala Krishnan S.[2]

[1]Student, [2] Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Despondency causes huge affliction and is regularly found in essential consideration. Since essential consideration suppliers once in a while neglect to distinguish patients as discouraged, methodical screening programs in essential consideration might be useful in improving results in discouraged patients. Discouragement screening is predicated on the idea that recognizable proof will enable powerful medications to be conveyed and that the advantages of treatment will exceed the damages.

Keywords: *Antidepressants, essential consideration, specific serotonin reuptake inhibitors, Adverse responses, psychotherapy, social changes.*

Introduction

Real sorrow is a temperament issue that presents with either a tenacious sentiment of trouble or loss of delight, or both. Despondency causes huge affliction and is regularly found in essential consideration. Since essential consideration suppliers once in a while neglect to distinguish patients as discouraged, methodical screening programs in essential consideration might be useful in improving results in discouraged patients. Discouragement screening is predicated on the idea that recognizable proof will enable powerful medications to be conveyed and that the advantages of treatment will exceed the damages.

Materials and Method

One thousand patients chose haphazardly and by accommodation from 4 essential consideration centers were surveyed by PRIME-MD and finished a poll estimating the accompanying approval factors: useful status and prosperity, handicap days, substantial manifestations, misery seriousness, self-destructive musings, medicinal services use, and the doctor persistent relationship.

Corresponding Author:
Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Side effects: Various manifestation spaces–passionate, physical, and conduct–structure the heavenly body of gloom. Not all patients experience all indications. The impact of sadness on certain spaces can be either an expansion or a reduction. For instance, craving (and regularly body weight) might be raised or decreased, and either a sleeping disorder (of a few distinct examples) or hypersomnia can occur[1]. The extent of side effects additionally can fluctuate from patient to understanding and after some time inside a given case. Enduring and handicap generally connect with the seriousness of manifestations.

Determination: It is regularly hard to recognize sorrow as an essential state of mind issue in a patient with a general ailment since it might be seen as auxiliary to the medicinal disease itself[2].

Accurate finding can likewise be a test as a result of the cover of side effects, for example, weight reduction and weariness, which happen in despondency just as in numerous medicinal ailments, for example, diabetes, malignant growth, and thyroid illness. The regular mental, conduct, and physical side effects related with sorrow incorporate, however are not restricted to, uneasiness, low confidence, diminished fixation, absence of intrigue or delight, decreased profitability, social withdrawal, cerebral pains, gastrointestinal issues, and heart palpitations.

Findings:

Pharmacotherapy: Pharmacotherapy for sadness should comprise of intense treatment up until the best clinical reaction or abatement is accomplished (typically 6-12 weeks) and continuation treatment for a further a half year to avoid backslides. Some of the time, upkeep treatment will proceed for quite a long time or years if there should be an occurrence of intermittent or persevering issue[3]. Rates of backslide are about twice as high when energizer drug is stopped before the finish of the continuation stage so adherence is significant.

In picking a stimulant, the essential consideration doctor ought to consider the symptom profile of the prescription, cost, the patient's age, the nearness of comorbid ailments, inclination, previous history or reaction/non-reaction to the upper, current meds and potential medication sedate collaborations, and the danger of lethality in overdose.

Medications: Particular serotonin reuptake inhibitors or SSRIs are the most broadly utilized class of antidepressants. They work by expanding the degree of serotonin in the cerebrum[4]. Unlike MAOIs and TCAs, SSRIs don't essentially influence norepinephrine levels in the mind. SSRIs likewise have less and milder symptoms.

First-line antidepressants incorporate particular serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors, mirtazapine, bupropion, agomelatine and vortioxetine. Different antidepressants, for example, tricyclic antidepressants (TCAs) and monoamine oxidase inhibitors (MAOIs) are viewed as second-line and third-line, individually, because of their fairness and wellbeing profile.

Symptoms:

- Weight addition or misfortune
- Headache
- Insomnia
- Agitation
- Restlessness
- Sexual brokenness[5].

SNRIs may expand circulatory strain, particularly at high portions. Hypertension brought about by SNRIs might be overseen by lessening the portion of the SNRI.

TCAs are related with various cardiovascular (heart and veins) impacts, for example, orthostatic hypotension and anomalous pulses and rhythms. Orthostatic hypotension may prompt dazedness, falls, and breaks. Orthostatic hypotension might be overseen by diminishing or suspending the TCA portion, expanding salt admission, or treatment with steroids.

Psychotherapy:

Psychological Therapy: Cognitive treatment is the possibility that our musings can influence our feelings. Subjective treatment encourages patients to figure out how to distinguish regular examples of negative reasoning, called psychological bends and to transform those negative idea designs into progressively positive ones, subsequently improving the patient's state of mind[6].

Social Therapy: Behavioral treatment is a kind of psychotherapy that spotlights on changing undesired practices. It utilizes the standards of traditional and operant molding.

Intellectual Behavioral Therapy: Because psychological treatment and social treatment function admirably together to support melancholy and uneasiness issue, the two are regularly consolidated in a methodology called subjective conduct treatment (CBT)[7].

Persuasive Behavior Therapy: Dialectical conduct treatment is a sort of CBT. Its primary objective is to show the patient aptitudes to adapt to pressure, direct feelings, and improve associations with others. This sort of psychotherapy additionally consolidates care rehearses from Buddhist customs.

Psychodynamic Therapy: Psychodynamic treatment depends on the suspicion that downturn can happen on account of uncertain–generally oblivious–clashes, regularly starting from youth. The objectives of this sort of treatment are for the patient to turn out to be progressively mindful of their full scope of feelings[8].

Relational Therapy: Interpersonal treatment is a sort of treatment that spotlights on over a wide span of time social jobs and relational connections. During treatment, the advisor by and large picks a couple of issue regions in the patient's present life to concentrate on.

Discussion

Wretchedness is the second most regular interminable condition (after hypertension) treated when all is said in done restorative practice. Significant sadness is basic in the essential consideration setting. In the last article of this arrangement, we delineate the way to deal with the administration of gloom in essential consideration. Psychotherapy has been demonstrated to be as successful as antidepressants for gentle to direct significant gloom. Antidepressants ought to be begun at a sub remedial portion to evaluate averageness, at that point bit by bit expanded until an insignificantly powerful portion is accomplished. Aside from pharmacotherapy and psychotherapy, the executives of melancholy ought to incorporate overseeing stressors, connecting with social and network support, managing disgrace and segregation, and overseeing accompanying comorbidities.

Conclusion

The best types of psychotherapy are those with organized and brief methodologies, for example, subjective social treatment, relational treatment, and certain critical thinking treatments. Notwithstanding the psychotherapy started, "mental administration" must be coordinated in the meantime. Drugs, for example, antidepressants ought to be recommended with psychotherapy. Patients, who live with sadness, and their family and companions, have huge difficulties to survive. Essential consideration doctors can give humane consideration, significant instruction, mental checking, social help, consolation, and support for these patients and their friends and family.

Emergence of ADHD among Young People: A Review Article

Gurveer Singh Chawla[1], Krishnakumar J.[2], Gopalakrishnan S.[2]

[1]Student, [2]Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Consideration deficiency hyperactivity issue (ADHD) is an unending conduct issue described by industrious hyperactivity, impulsivity, and carelessness that debilitates instructive accomplishment as well as social working. Its conclusion is made by finding out whether the youngster's particular practices meet the demonstrative and factual manual of mental issue IV-updated criteria. Its etiology is as yet vague yet late examinations propose that hereditary qualities assume a noteworthy job in presenting helplessness. Comorbidity with mental issue, for example, tension issue, gloom, oppositional resistant issue and lead issue; and with explicit learning inability isn't extraordinary. In spite of the fact that drug functions admirably much of the time of ADHD, ideal treatment requires coordinated therapeutic and conduct treatment. Mental instructive intercessions in school can help increment the effective working of influenced youngsters and improve their scholastic execution. Practically 50% of influenced kids keep on demonstrating huge indications of the confusion into pre-adulthood and youthful adulthood[1].

Keywords: *ADHD, etiology, mental issue.*

Introduction

For more than 100 years it has been recorded that a few kids can have over the top and hindering hyperactivity, impulsivity, and mindlessness. In 1902, the English pediatrician George Still displayed a progression of three addresses to the Royal Society of Medicine portraying 43 youngsters from his clinical practice that were regularly impervious to train, who indicated minimal inhibitory volition, had difficult issues with continued consideration and couldn't gain from the outcomes of their activities. He recommended that these critical social issues were because of a hidden neurological shortfall and not brought about by nature. in any case, it was not till 1968 that the demonstrative and measurable manual of mental issue (DSM) of the American Psychiatric Association initially named this clinical issue as hyperkinetic motivation issue (DSM-II). As more up to date clinical research rose, the name changed to a lack of ability to concentrate consistently issue (DSM-III) in 1980, and inevitably to consideration shortage hyperactivity issue (ADHD) (DSM IV) in 1994[1].

Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Bharath Institute of Higher Education and Research, Chennai-73

Materials and Method

Family doctors should start an assessment for ADHD when a youngster presents with indications that incorporate scholastic underachievement and disappointment, troublesome homeroom conduct, absentmindedness, poor confidence, or issues with setting up or keeping up social relationships. The conclusion of ADHD depends on clinical discoveries and is made by learning whether the tyke's particular practices meet the DSM IV-R criteria. These criteria characterize three subtypes of ADHD:

1. ADHD fundamentally of the scatterbrained kind (ADHD/I)
2. ADHD fundamentally of the hyperactive-indiscreet sort (ADHD/HI)
3. ADHD, joined sort (ADHD/C).

A youngster meets the demonstrative criteria for ADHD by documentation of:

1. Nearness of at any rate six of the nine practices portrayed in the distracted area (ADHD/I), or, in any event six of the nine practices depicted in the hyperactive/indiscreet space (ADHD/HI), or six of the nine practices depicted in the two areas (ADHD/C), and these practices ought to happen ''frequently'' and to a degree that is maladaptive and conflicting with the kid's formative level.
2. Nearness of these practices in at least two settings (for instance, at home and at school) for at any rate recent months;
3. Nearness of certain manifestations of ADHD before 7 years old (history from guardians);
4. Clear proof of clinically critical impedance in scholastic or social working, or in both;
5. These manifestations not happening solely over the span of an unavoidable formative issue, schizophrenia, or another insane issue, and worse represented by another psychological issue (for instance, a disposition issue or a nervousness issue)[1].

What causes ADHD?: There is nobody single brought together hypothesis that clarifies the etiology of ADHD. Later utilitarian MRI cerebrum studies show that the turmoil might be brought about by atypical working in the frontal projections, basal ganglia, corpus callosum, and cerebellar vermis. Pharmacological investigations have additionally involved days guidelines of frontal sub cortical cerebellar catecholaminergic circuits (dopamine and norepinephrine synapse frameworks) in the pathophysiology of the turmoil (Table 1 and Table 2). Family studies have given solid proof that hereditary qualities assume a noteworthy job in presenting powerlessness to ADHD. Studies have shown that low-birth weight and psychosocial difficulty (for instance, extreme parental strife, low-social class, encourage arrangement) are inclining danger factors for ADHD. Also, babies destined to moms who devour liquor or smoke during pregnancy are in danger for ADHD[1].

Table 1: Environmental risks that have been most commonly studied in relation to ADHD[2].

Pre- and perinatal factors	Environmental toxins	Dietary factors	Psychosocial adversity
Maternal smoking, alcohol and substance misuse *Risk but not proven causal risk factor*	Organophosphate *pesticides* *Risk but not proven causal risk factor*	Nutritional deficiencies eg zinc, magnesium, polyunsaturated fatty acids *Correlate not yet proven risk factor*	Family adversity & low income *Correlate not yet proven risk factor*
Maternal stress *Risk but not proven causal risk factor*	Polychlorinated biphenyls *Risk but not proven causal risk factor*	Nutritional surpluses eg sugar, artificial food colourings *Correlate not yet proven risk factor*	Conflict/parent–child hostility *Correlate not yet proven risk factor*
Low birth weight and prematurity *Risk but not proven causal risk factor*	Lead *Risk but not proven causal risk factor*	Low/high IgG foods *Correlate not yet proven risk factor*	Severe early deprivation *Risk, likely causal risk factor*

Findings: The three medicines that have been approved as being fundamentally powerful for ADHD seem to be: (1) prescription administration, (2) social treatment, and (3) a mix of the two methodologies

1. Medication the executives of ADHD: To accomplish enhancement of the center ADHD side effects, prescription administration is better than social treatment. MPH and atomoxetine are the two medications which are as a rule as of now recommended and their adequacy in diminishing the manifestations of ADHD is very much reported. Meds are not prescribed for use in youngsters who are beneath 6 years old.
2. Behavioral treatment: Parents are instructed by therapists or social specialists to accomplish reliable and positive connections with their influenced kid. They are instructed how to fortify positive practices by recognition or by utilizing every day possibility

outlines (star or 'glad face' graphs), how to quench negative practices by dynamic disregarding, and how to successfully rebuff for unbearable practices.

Parent preparing is the sole treatment for youngsters with ADHD who are beneath 6 years old.

Table 2: Candidate genes with the most consistent meta-analytic evidence for association with ADHD[2].

Gene name	Codes for	Variant	Risk allele	Pooled odds ratio
Dopaminergic genes				
DRD4	Dopamine D4 receptor	VNTR in exon 3	7-repeat	1.33 (Smith, 2010)
		Polymorphism in promoter region	5-repeat	1.68 (Li et al., 2006)
			T allele	1.21 (Gizer et al., 2009)
DRD5	Dopamine D5 receptor	Dinucleotide repeat in 5′ flank	148-bp allele	1.23 (Gizer et al., 2009)
DAT1	Carrier protein involved in dopamine reuptake	VNTR in intron 8	3 repeat	1.25 (Gizer et al., 2009)
		Polymorphism in 3′UTR	G allele	1.20 (Gizer et al., 2009)
		VNTR in 3′UTR	10 repeat	1.17 (Yang et al., 2007)
Serotonergic genes				
5HTT	Carrier protein involved in serotonin reuptake	5HTTLPR polymorphism in promoter region	Long allele	1.31 (Faraone et al., 2005)
HTR1B	Serotonin 1B receptor	Polymorphism in exon 1	G allele	1.11 (Gizer et al., 2009)
Other				
SNAP-25	Protein involved in neurotransmitter release, synaptic plasticity and axonal growth	Polymorphism in 3′UTR	Not known	1.19 (Faraone et al., 2005)

VNTR, variable number tandem repeat; UTR, untranslated region.

3. Combined treatment: Optimal treatment of ADHD requires incorporated medicinal and social (joined) treatment. Although consolidated treatment does not yield essentially more prominent advantages than prescription administration for center ADHD side effects, it lessens the all out day by day required drug portion and the related non-ADHD side effects viz. indications of tension and despondency, and oppositional/forceful practices; and accomplishes positive working results for friend collaborations, parent–tyke relations, and perusing accomplishment. Ongoing exploration proposes that joined treatment may help forestall the advancement of future mental issue[1].

Age group mainly affected: In age bunch over 19 years we see that there are all the more Predominantly unmindful sort pursued by transcendently hyperactive-imprudent than joined. Comparative pattern is found in age bunch 13-18, where overwhelmingly scatterbrained sort is most extreme, while joined and prevalently hyperactive-incautious have proportionate number of cases.

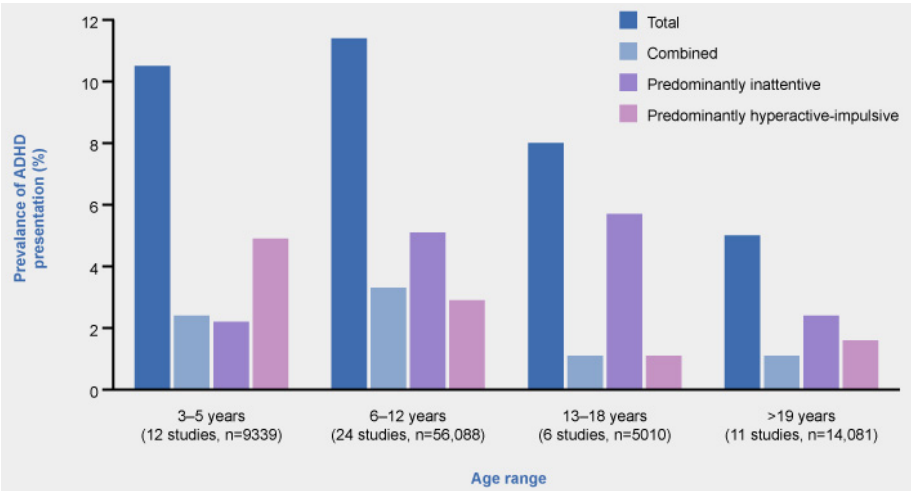

Fig. 1: Prevalence of ADHD in different age groups[3]

Discussion

Immaturity may realize a decrease in the over activity that is regularly so striking in more youthful kids, yet distractedness, indiscretion, and internal eagerness stay real challenges. A twisted feeling of self and an interruption of the ordinary improvement of self has been accounted for by youths with ADHD. Moreover, unnecessarily forceful and standoffish conduct may create, including further issues (fig 4). An investigation by Edwards et al inspected youngsters with ADHD and oppositional insubordinate issue (ODD), which is characterized by the nearness of notably resistant, rebellious, provocative conduct and by the nonattendance of increasingly serious dissocial or forceful acts that abuse the law or the privileges of others. These adolescents appraised themselves as having more parent-high scholar struggle than did network controls. Expanded parent-adolescent clash was additionally revealed when guardians of young people with ADHD did the rating exercise. Also, a study of 11–multi year olds demonstrated that those with hyper kinesis were twice as likely as the general populace to have ‘’a serious absence of friendship’’. Young individuals with ADHD are at expanded danger of scholastic disappointment; dropping out of school or school, high school pregnancy, and criminal conduct Driving represents an extra hazard. People with ADHD are effectively occupied from focusing on driving when going gradually, however while driving quick may likewise be risky. It has been demonstrated that, contrasted and age coordinated controls, drivers with ADHD are at expanded danger of criminal traffic offenses, particularly speeding, and are viewed as to blame in more car crashes, including lethal ones. The danger of such occasions was expanded further by the nearness of attending ODD. In any case, it has been proposed that treatment may positively affect driving aptitudes[4].

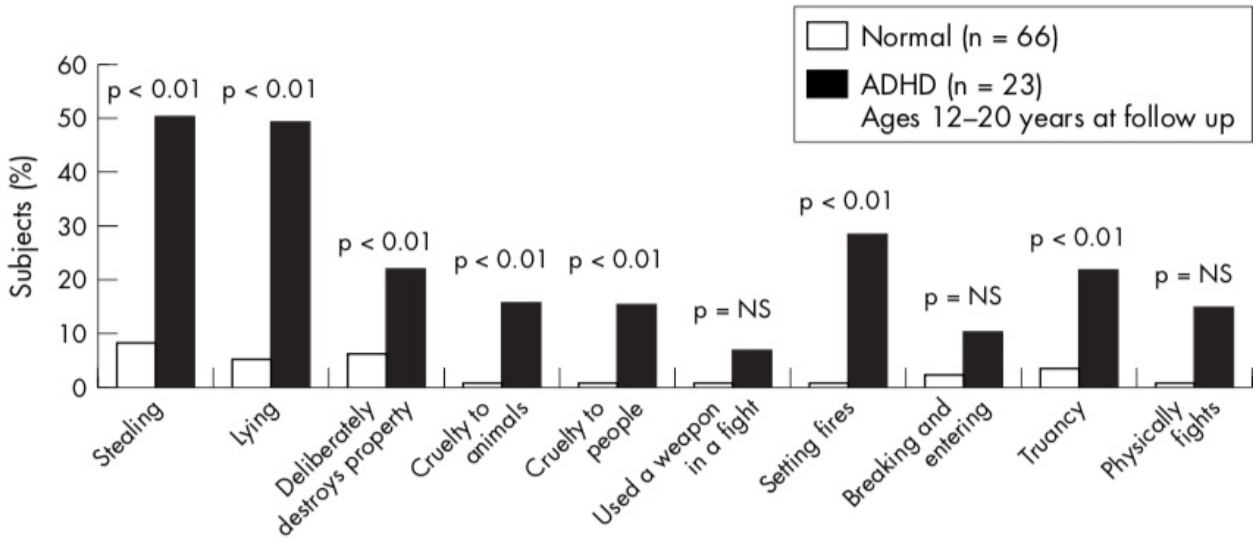

Fig 2: Antisocial behaviour in adolescents with ADHD. Data primarily represents outcomes in those with conduct disorder[4].

Conclusion

In synopsis, there is solid proof of an acquired commitment to ADHD, in spite of the fact that non-acquired elements that reasonable incorporate natural dangers and chance occasions (counting again hereditary changes) are likewise significant. There is no single reason for ADHD and the hazard factors that have been recognized so far have all the earmarks of being non-explicit. That is, dangers, for example, chromosomal micro deletions (e.g., VCFS), enormous, uncommon CNVs, extraordinary low birth weight and rashness seem to influence a scope of various neurodevelopment and mental phenotypes. Hereditary dangers likely likewise incorporate different regular quality variations of little impact measure that presently can’t seem to

be recognized, with the conceivable special case of a couple dopaminergic qualities. With the expenses of DNA sequencing dropping, there is probably going to be an expanding center around distinguishing uncommon hereditary variations, including basic variations, for example, CNVs and other uncommon changes with bigger hazard impacts. In spite of the fast advances in hereditary qualities, there is as yet a requirement for further investigation into ecological dangers. Albeit numerous variables are related with ADHD, various structures are expected to test which are causal.

The most grounded proof identifies with the connections between ADHD/ADHD-like practices and generally uncommon extraordinary afflictions, explicitly outrageous rashness, exceptionally low birth weight, fetal liquor disorder and an example of practices related with institutional hardship in the early years. Less is thought about hazard factors that alter ADHD results. One exemption is the relationship among COMT and reserved conduct in ADHD that is all around duplicated now and features that social issues in those with ADHD may have various birthplaces to social issues when all is said in done. In total, the accessible proof goes some path towards featuring bunches who are at higher hazard; explicitly the individuals who have a family ancestry of ADHD and additionally neurodevelopment or learning issues, and the individuals who have been presented to the natural difficulties depicted before. Nonetheless, none of these dangers, including the hereditary ones, give tests or biomarkers of ADHD. It is trusted that, later on, improved ID of ADHD hazard variables and pathways will expand our comprehension of the so far obscure pathogenesis of ADHD and make ready for improving analysis and treatment[5].

Anthropological Concepts in the Development of Masticatory System

Sweta Pattanaik[1], Snigdha Pattanaik[2]

[1]MSc Student, Department of Geology, Indian School of Mine, Dhanbad, [2]Associate Professor, Department of Orthodontics and Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Teeth play a fantastic role in the line of mammalian evolution. Apart from being covered in one of nature's hardest substances so that it can take anything a million years of geology can throw at it, a tooth's 3D shape is a phenomenally subtle food processing surface. Much like Charles Darwin found out about the beaks of finches, different types of teeth have an evolutionary history as well. Darwin found that the birds' beaks were specially shaped depending on the type of food they ate. Short, sturdy beaks belonged to finches that needed to crack nuts to get nutrition, while long and pointy beaks were used to poke into the cracks of trees to find juicy insects to eat.

Some of the most noticeable changes in the evolution of the genus have been in the dentition and the jaws which support them. In general, living people have smaller teeth and less robust jaws than people living 25,000 years ago. Neanderthals, from perhaps 120,000 and becoming extinct in Europe after 30,000 years ago, had unusually large incisor and canine teeth, together with several other unique dental features. The oldest British hominin fossil teeth, at about 500,000 years ago, from the Boxgrove site in Sussex, were more significant still. In order to understand such differences, it is essential to see the teeth in the context of their use during life.

Keywords: *Anthropology, Evolution, Dentition, Masticatory System.*

Introduction

In a typical non primates: dog, sheep or hedgehog, the facial skeleton projects in front of cranial region of skull. During primate evolution facial skeleton bent gradually more downwards until in man it lies below overhanging frontal region of cranium. Erect posture in humans. The arms and hands have become freed. The manipulation of food and other objects and defense, offense, and so forth, utilize primarily the hands, rather than the shortened jaws[1].

The large size of the human brain also relates to a rotation of the orbits toward the midline. This results in a binocular arrangement of the orbits, a feature that complements finger-controlled manipulation of food, tools, weapons, and so forth. The absence of a long, protrusive muzzle does not block the close-up vision of hand-held objects[2].

Complete orbital rotation into a forward-pointing direction,however, has also caused a marked reduction in the interorbital part of the face. This is significant, because the area involved is the root of the nasal region, and the result of man's close-set eyes is a narrow nose. Reduction in nasal protrusion is accompanied by a more or less equivalent reduction of the jaw. The downward rotation of the olfactory bulbs and the whole anterior cranial floor by the enlarged frontal lobes of the cerebrum has caused a corresponding downward rotation of the nasomaxillary complex. Facial rotation has led to the development of the humanmaxillary

sinus beneath the orbital floor and above the shortened maxillary arch. Because of its adaptation to facial rotation, the humanmaxilla is uniquely rectangular, rather than triangular like that of most other mammals. It is a distinctively shaped upper jaw.An orbital floor has also been added to the humanmaxilla because the middle and lower parts of the face have been rotated to a position beneath the eyes[3].

Evolution of Jaws and Joints: The first vertebrates did not have jaws. These are collectively referred to as the "Agnatha" (a=without, gnath=jaws), or jawless fish. There is a general trend to reduce the number of pharyngeal arches over evolutionary time.

Placoderms, an extinct group of early fishes, had 7 arches. The first arch was lost. Their new 'first' arch became the mandibular arch that formed jaws. The upper half of the mandibular arch became the palatoquadrate cartilage, the lower half became the mandibular or Meckel's cartilage. At about the same time in the fossil record there appears several major groups of fishes, in these groups, the jaws were formed by components of arch #1 and #2. Arch #2 is called the hyoid arch (upper half = hyomandibular cartilage, lower half = hyoid cartilage)[4].

Amphibians: Some arches are lost in adult amphibians while others are modified. In amphibians, the hyomandibular cartilage became the stapes in the middle ear. The hyoid apparatus supports the tongue and larynx. With the loss of gills, associated dermal bones that connected the head to pectoral girdle was lost creating an independent neck region[5].

Reptiles and the evolution of the secondary palate and middle ear ossicles: Reptiles invented the secondary palate that allows us to eat and breathe at the same time. The reptile line that led to mammals substantially increased bite force by ultimately redesigning the articulation of the jaw joint. This in turn led to the development of the malleus (hammer) and incus (anvil) ossicles in the middle ear[6].

The secondary palate: Fish have good noses. They smell by passing water through a loop located on their snout. The loop does not connect to the mouth cavity. The lobe finned fishes (Sarcopterygii) breathed atmospheric oxygen. One of the consequences of air breathing is that the olfactory loop became redirected. Instead of exiting back to the outside environment, the loop turned and entered the anterior margin of the mouth cavity, forming the internal nares. Thus, these fish could breathe by bringing the tip of their snout to the surface. This saved energy and allowed air breathing to be less conspicuous to predators[7].

Amphibians inherited this anatomy. Because the internal nares are at the anterior margin of the mouth, amphibians have to hold their breath while they eat. Amphibians can use cutaneous gas exchange until the prey is swallowed. Reptiles, with their hardened, dry skin do not have that luxury. Any reptile that did a better job of eating while breathing would be favored by natural selection.

Over evolutionary time, the fossil record shows a second shelf of bone forming across the roof of the mouth. Over evolutionary time, first the premaxilla bone, then later, the maxilla bone, then finally the palatine bone all extended a shelf from each side of the jaw and met in the middle. This shelf formed a separate passage for air from the external nares. Over time, the internal nares entered the mouth further and further toward the throat. This shelf is the secondary palate. We know it in humans as the hard palate[8,9].

Evolution of TMJ: In reptiles generally, including the now extinct early synapsid reptiles that gave rise to mammals, the jaw joint is formed by the articular (lower) and quadrate (upper) bones. The joint was a simple hinge at the posterior of the jaw. The jaw closed putting even pressure along its margin therefore, the force exerted on the joint was in proportion to the bite pressure. In mid to late synapsid reptiles, the dentary bone (lower jaw) increased in size as muscle and bite force increased, but force on the joint decreased[10]. This was because muscle insertion points shifted to allow greater jaw mobility. The looser the joint became, the more control synapsids had over specialized processing of food along regions of the jaw margin. The articular and quadrate bones at the jaw joint became smaller and more loosely associated with the dentary. The coronoid process of the dentary bone formed to accommodate these changing forces. Ultimately, the jaw joint shifted from aarticular-quadrate joint to a dentary-squamosal joint. The condyloid process formed to create a new articulating surface[11].

Freed from jaw mechanics, selection pressure favoring perception of sound took the evolutionary opportunity of the articular and quadrate bones adrift at the margin of the jaw joint and incorporated them into the middle ear. The articular became the malleus

(hammer) and the quadrate became the incus (anvil). Humans, and all mammals, have these bones to this day.

Evolution of Socket or Attachment of Teeth[12]: Four method of attachment of teeth in animal world:

1. Fibrous
2. Hinged
3. Ankylosis
4. Gomphosis

Fibrous attachment: Seen in sharks and rays. The teeth are fixed by the means of fibrous bands to the submucosa of the fibrous membrane which covers the jaws.

Hinged Attachment: The hinged teeth occur in the centre and front of the mouth and those around the periphery of jaws being attached by anchylosis. Three main fishes have to be discussed as they have different types of hinge attachments.

1. Angler
2. Hake
3. Pike

1. **Angler:** This fish has 2 rows of teeth an outer anchylosed and inner hinged row. A hinged tooth is supplied posteriorly by fibrous elastic ligament, while its anterior free edge rests upon a buttress of bone. The teeth bent towards the throat, the hinge compresses and teeth return to their original positions upon the force being removed.
2. **The hake:** Hake teeth is composed of vasodentine, which requires a rich blood supply and the vessels pass from the tooth in a backward direction and enter the bone attachment about the rotating axis in the posterior hinge which has 2 parts.
   - A. **Calcified elastic part** of hinge which prolong downwardsto the bone of attachment of the lingual surface of dentine (outer area of dentine-no blood supply)
   - B. **Uncalcified fibrous part** of hinge which lies in front of the calcified, elastic portion. Between two part of hinge is a triangular area containing interlacing fibres - elastic in nature. The labial edge of base of teeth - thickened and rounded-adapted for resisting shock. This edge is at higher level - than the lingual edge and fits upon a buttress of bone. So that tooth cannot be bent outward without injury to lingual hinge.
3. **Pike:** The hinged teeth of pike sit anteriorly on a small pedestal of bone - but posterior hinge does not possess elasticity. In pike teeth (osteodentine) , the central trabeculae do not calcify but remain soft and elastic-responsible for returning the teeth to their erect posture when backward pressure isreleased[13].

Anchylosis Attachment: When a tooth is fixed to the jaw by calcified tissue it is said to be anchylosed. There is no intervention of fibrous or uncalcified tissue.

Eel fish: The teeth of the Eel rest upon little cylinder or cups of bone of attachment and is described as "Acrodontanchylosis".Here dentinal tubules do not fuse with bone of attachment, but little fibrous "annular ligament" surrounds the base of tooth and allows a slight movement.

Mackerel: Teeth are slung up between the plates of the jaws by means of osseous trabeculae which pass between the inner sides of the alveolus and outer sides of teeth, the bases of latter resting upon nothing hard, the attachment is pleurodont.

Gomphosis (attachment in sockets): Seen in man, mammalia, reptiles and in some fish eg: saw fish, pristis. In man, mammals and crocodile, a membrane (alveolar dental membrane) exists between the tooth and the socket of bone in which the tooth is situated. Our field exists today due to excellent remodeling capacity of the PDL and alveolar bone in gomphosis type of attachment

Anthropologists and dentists: Future Presprctive: Following 10000 years, dental anthropologists, will have a field day with our fossilized teeth. In the event that they break down our finish science, they'll have the option to figure out which of us grew up as vegetarian and which didn't. Maybe they will be shocked to see that people from a similar population had such contrasts in diet. It is almost certain, they'll interpret these contrasts in habits as a characteristic expansion of our evolution– our brain permits us social adaptability, including the versatile capacity to eat assorted nourishments. Future anthropologists will likewise be astonished by the degree of our dental issues. A couple of instances of dental disorders exist in the human fossil record, yet today we are regularlyaffected by malocclusions (when teeth don't meet up effectively), third molar impactions, caries, periodontitis and other dental diseases that will leave their imprints in our remaining parts[14].

Research findings may also draw upon the possibility of "developmental anomalies"–that the chasing and assembling diets of our predecessors didn't set us up for the quick convergence of delicate and sugary foods that we eat today. Basically, we are not adjusted to the cutting edge Western eating routine. The nourishments our tracker gatherer precursors ate were hard to bite and did exclude refined sugar. Delicate nourishments don't animate jaw development during youth, prompting malocclusions, and sugary food sources give situations to caries-making microscopic organisms flourish[15,16].

Truth be told, by removing bacterial DNA from calcified plaque in antiquated teeth, one gathering of anthropologists found that caries-causing strains of microbes turned out to be progressively regular with the approach of horticulture. These strains particularly thrived in human mouths during the Industrial Revolution, with the primary large scale manufacturing of prepared sugar. Despite everything we're enduring these impacts today[17].

At long last, what will future anthropologists think about the bunch ways individuals change their teeth? In Western societies, individuals make careful arrangements to misleadingly brighten their teeth. As indicated by one examination, directed in the U.K., subjects found more white teeth progressively appealing, particularly in ladies. The specialists recommend that white teeth may fill in as an age marker in human mate decision, with guys inclining toward white teeth as a sign of youth.

Conclusion

The evolution of the human masticatory system is not only related to diet and food processing techniques but also brain size, bipedalism, and speech (language). Appearance of spoken complex language is believed to be the result of the critical change in the human evolution that occurred 40.000 years ago, named "the great leap forward" which resulted in the formation development of human civilization. It has been claimed that the formation of the anatomic basis for the complex speech was the cause of this leap. Variation in size, shape, number, arrangement, and wear pattern of the teeth of man has long been an area of great interest to physical anthropologists. It is important that orthodontist cultivates an anthropologists eye for tooth variation. Since the orthodontist ponders many of these same variables in his daily battle with malocclusion, many aspects of dental anthropology can prove helpful in understanding orthodontic problems and in formulating their successful treatment.

Oral Submucous Fibrosis: Interdependance on Pernicious Habit

Nagma Permin

Intern, Institute of Dental Sciences, Sikhsha O' Anushandhan (Deemed to be University), Bhubaneswar, Odisha

Abstarct

Arecanut, a main integrant in betel leaves is usually a great contributing factor for change in the biology of oral mucosa. This change leads to degradation of collagen fibre and increase in hyalination of mucosa. Oral submucosais commonly affected. So, its named as oral submucous fibrosis. Furthermore, its a long-term inflammation of abutting epithileum of oral mucosa which can lead to a precancerous condition. Oral submucous fibrosis results in change in structure as well as function of oral cavity. Decrease in interincisal distance associated with trismus which directly affects over all health. However, it not only targets oral cavity but also the associated areas of it. Increasing consumption of Arecanut can be fatal also. Youths are the prey of such condition. This article basically aims in describing cause ,method of invasion and consequences of oral submucos fibrosis. Various signs and symptoms are shown by the patient and grading it into severity is required. Early detection can give a good prognosis but late detection can be fatal. Morbidity and mortality is totally dependent on a person's pernicious habit.

Keywords: *Oral submucous fibrosis, Arecanut, Abutting epithelium, alkaloids, flavonoids, blanching.*

Introduction

Oral submucous fibrosis (osmf) is a long-term enervative and lame condition of Rima oris. Such a state is always analogue with abutting epithelial reaction which abide by change in the collagen consistencies with degradation of membranous tissue commencing to stiffness of buccal mucosa and neighbouring structures followed by trismus[1]. According to Pindborg, it is also accompanied with vesicle formation in mucosa. WHO involved in and coined oral submucosa fibrosis as 'a slow progressive disease in which fibrous bands in oral mucosa, ultimately leading to severe restriction in mouth movement including tongue'[2]. Chronic use of Arecanut causeoral submucous fibrosis, which is a premalignant condition[3]. Such habit is prevalent in South Asia[4]. Pernicious habit like chewing of tobacco with combination of Arecanut lead to peak rise in malignant condition of oral mucosa[3].

Aetiology: Packet gutkha, pan masala, mawa etc. has a warning on wrapper ' injurious to heath' but it is preferred most as it provides a sense of being well, it increases body temperature, a sense of quivering, vigilance, acceptance to hunger, reaches peak of vigour and determination to work[4].

Exact a etiology is unknown. The suggested factors are[5,6]:

1. Chronic irritation from Betel nut and tobacco chewing, Slaked lime, Chillies
2. Nutritional deficiency
3. Defective iron metabolism

Mechanism: Arecanut contains alkaloids and flavonoids as main ingredient. Alkaloids consists of arecoline, on hydrolysis produce arecaidine. Along with it, alkaloids have guvacine and guvacoline. Both arecaidine and guvacine, guvacoline increases the proliferation of fibroblast with rapid collagen synthesis. On the other hand, flavonoids includes tannin and catechin inhibits the Collagenases leading to reduced breakdown of collagen[7]. Alkaloids and flavonoids have a major impact on oral mucosa progressing to oral submucous fibrosis. Pronounced hyalination of abutting epithelium, there is obliteration in blood supply causing muscle fatigue and degeneration with limitation of mouth opening.

Clinical Features: The initial signs and symptoms of oral submucous fibrosis is redness along with gradual limitation of mouth opening which shows blanching of

buccal mucosa. Moreover, due to advanced state of oral submucous fibrosis, vesicle formation starts with rupture of it burning sensation is felt in oral mucosa. Increase in fibroblastic activity, vascular supply reduces causing white patches in the affected area. Deposition of fibrous band causes difficulty in check retraction. It looses its elasticity and patient finds difficulty while blowing whistle or inflating balloon. Stiff buccal mucosa with firm Rimaoris, patient is unable to maintain oral hygiene progressing to future dental problems. Sometimes it affects tongue and uvula. Patient finds difficulty in protruding tongue. Hockey stick appearance of uvula is often observed in oral submucous fibrosis. If it affects gingiva, stippling may be absent.

Classification was given based on clinical feature and severity[9].

According to pindborg JJ (1989):

- **Stage I:** Inflammation of oral cavity includes erythematous mucosa, vesicle, mucosal ulcers, melanotic mucosal pigmentation.
- **Stage II:** vesicles and ulcers heals leading to its fibrosis which is the hallmark of this stage. Blanching of oral mucosa is primarily detected. More the older lesion, more is fibrosis and blanching seen with palpable circular and vertical fibrotic band in buccal mucosa and around the lips. Marble like appearance of the mucosa because of thickening of mucosa. Reduction in mouth opening, stiff and small tongue.
- **Stage III:** It is the advanced stage. There is decrease in speech efficacy and sometimes it affects hearing ability.

Preventive Measures: Patient is advised to quit habit as soon as possible. Counselling of patient is done properly. Further patient is asked to avoid Arecanut. Progression of the lesion can be stopped by public awareness. Selling of gutkha and paan should be banned. Social awareness programs should be conducted.

Management: Various treatment modality has been put forward.

Nutritional Support: Micronutrients and vitamins are the main support system for management of such condition. Sometimes high protein and calories is also required[10].

Immunomodulatory Drugs: Glucocorticoids can be administered locally in the lesion or systemic route can be chosen. The glucocorticoids have ability to prevent or suppress inflammatory reaction by decreasing fibroblastic proliferation and decreasing fibrosis[10].

Physiotherapy: The most common method to overcome fibrosis is forceful opening of mouth with blowing action and heat therapy can also be done.

Local Drug Delivery: Hyalurodinase, Collagenases, antifibrotic drug can be injected locally which breakdown the intercellular cement substances and also decreases collagen formation[11].

Surgical Management: Submucosa resection of the fibrotic bands and replacement with partial thickness skin or mucosal graft can be done.

Conclusion

'An ounce of prevention is worth a pound of cure'[12]. Oral submucosa fibrosis is a fast and widespread premalignant condition of our society. Arecanut with slaked lime is a deadly combination which targets malignancy by altering the healthy tissue. Public awareness and proper diagnosis should be carried out with a strict follow up so that we can manage such situation.

Hemisected Mandibular Molar a Strategic Abutment: A Case Report

Abhijita Mohapatra[1], Pradyumna Kumar Sahoo[2]

[1]Professor, [2]Associate Professor, Department of Prosthodontics, Crown Bridge and Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan, (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Every patient wants to maintained his dentition remain in oral cavity. Most commonly mandibular first molar is affected by dental caries and periodontal disease. These teeth are regarded as key of occlusion in prosthodontics because of wider periodontal surface areas. So, these teeth have to preserve in dentition to prevent shortened dental arches. It is better to extract the diseased part of teeth and remaining part of teeth should restored with proper treatment plan. A multidisciplinary approach was planned to fabricated the prosthesis.

Keywords: *Hemisected Mandibular Molar; dental caries and periodontal disease; prosthetic treatment.*

Introduction

Loss of Posterior tooth often leads to mesial drift of molars, lack of centric stops, loss of masticatory function leads to shorten dental arch. This requires prevention and maintenance measures.[1,2] Inrecent advancement of dentistry, there are multidisciplinary approach to save the decayed and periodontally compromised tooth rather than extraction. Management of periodontally involved molars with extensive decay is challenging cases for the dentist toretainsuch tooth.[3] A multidisciplinary approach like periodontal, prosthodontic and endodontic was made to retain such teeth.[1,4] Resection means excision and removal of any segment of the tooth or a root, with or without its accompanying crown portion. Various resection procedures described are: root amputation, hemi section and bisection.[5] Hemi sectionis a conservative procedure in which as much as healthy original tooth structure should retained[6,7]. Compiled results of several studies have shown that the average failure rate of hemisected tooth supported prosthesis is close to 13.1% which is comparable to the failure rate of implants. According to Buhler et al, hemisection should be considered an option prior to molar extraction, as this procedure can ensure cost savings with good long-term.[8,9] Following the several factors enlisted by Weine for hemisectioning case like. Weine[5,10] listed the following indications for tooth resection.[10]

Periodontal indications:

1. vertical bone loss involving only one root of multi-rooted teeth.
2. furcationinvolvement.
3. proximity of roots of adjacent teeth, which preventing adequate hygiene maintenance in proximal areas.
4. Severe root exposure due to dehiscence.

Endodontic and restorative indications:

1. Perforation of the pulp chamberor pulp canal of one of the roots of an endodontically involved tooth which cannot be instrumented.
2. Vertical fracture of one root
3. Furcation involvement due to sub-gingival caries, traumatic injury etc.

e-mail: abhijitamohapatra@soa.ac.in

Contraindications:

1. Teeth available for idealbridge abutments as alternatives to hemisection.
2. Inoperable canals in root to be retained.
3. fused root.

The success of treatment depends upon the above factors.

Case Report: A female patient age of 52 years reported to department for management of endodontically treated tooth in relation to 36(Figure 1a). On clinical examination tooth was endodontically treated with grade 1 mobility. There was a probing depth of 9 mm on distal root of the tooth. On radiographic examination, severe angular defect was evident in relation to distal root and tooth was root canal treated (Figure 1b). So, the distal root should be hemisected. The treatment plan was explained to the patient and consent obtained.

Periodontal Phase: Under local anaesthesia, a gingival crevicular incision was given and full thickness muco-periosteal flap was reflected to provide for easy visualisation and instrumentation. There was angular bony defect along the distal root which was curetted and debrided (Figure 2a. A tapered fissure diamond bur was used to split the mesial and distal half of the tooth and distal root was extracted. Patient was called for prosthesis after one month (Figure 2b). A conventional fixed partialdenture was planned in which retained mesial half of tooth nos. 36 and 37 were the abutment with sanitary pontic.

Prosthodontic Phase: Diagnostic impression made with alginate. Zelgan Plus DENSPLY. A all metal crown tooth preparation was done in relation to 37 and distal root of 36.Putty wash impression made with putty and light body (AquasilLv Ultra, Smart Wetting Impression Material, Dentsply; Figure 3). Temporization done in indirect technique(FREEGENOL TEMPORARY PACK; GC Corp., Tokyo, Japan, Figure 4). A master cast was obtained and die sectioning was done and wax pattern was fabricated using inlay wax. (GC INLAY WAX MEDIUM). The entire wax pattern assembly was casted with induction casting machine (BEGO FORNAX T CENTRIFUGAL CASTING MACHINE). The temporary restoration was removed and the fixed component were cemented with resin modified glass ionomer cement (FujiCEM; GC America, Alsip, USA) over the prepared teeth(Figure 5, 6). Postoperative instruction was given and reviewed periodically to assess the prognosis of the treatment.

Discussion

According to the literature the effective treatment options for molars with furcation involvement is root resectivetherapy.[11] There are many studies about survival rate and success of root resected teeth. Some of them stated that over 10 years, 30% of molars subjected to root resection failed.[12] Others suggested that survival rate of such teeth is more than 90 Carnevale et al. found that survival rate of both root resected tooth and nonresected tooth in 10 years of observation were 93% and 99%, respectively.[13] Zafiropoulos et al. found that majority of both dental implants and root resected teeth had not any complication within at least 4 years maintenance care. However, complication of root resected mandibular molars was more than dental implants.[14]

Choosing a molar for root resective therapy is influenced by several factors including root morphology, attachment of the remaining root, the divergence of root and location of the furcation.[15] Mesial root is more difficult to prepare because its concavity is toward the distal. Biomechanical, endodontic, and periodontal factors are the main reasons of failure in restorations of root resected teeth. In a study of Langer et [16]failure reasons of the root resected molars were as follows: root fracture (75%), endodontic treatment failure (18.4%), dissolution of the cement (7.9%), and periodontal problems (26.3%).Patients motivation is highly required for careful planning and execution of treatment in hemisection procedure. If all these criteria are met, hemisection surgery is an alternative for tooth extraction and its replacement with either a dental implant or aconventional fixed/removable prosthesis.

Conclusion

A conservative approach has been the main stay of dentistry and medicine for the preservation of natural body structures. Hemisection is considered to be a viable and conservative alternative to tooth extraction and implants. It conserves bone and also serves as a natural abutment and prevents the necessity of preparing and cutting adjacent teeth for use as abutments. However, proper case selection and preoperative evaluation are the cornerstones for a successful procedure.

Adenoid Cystic Carcinoma of Sub-mandibular Gland: A Case Report

Devi Prasad Mandal[1], Neeta Mohanty[2]

[1]PhD Scholar, [2]Professor & Head, Department of Oral & Maxillofacial Pathology & Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Adenoid cystic carcinoma is an uncommon salivary gland tumor with high rate of recurrence and metastasis. The unpredicted clinical course is countered-back by regular clinical follow-up for at least >15 years. The traditional treatment protocol is surgery with postoperative radiotherapy to optimize local metastasis. Research has been carried out to understand the molecular biological process of the tumor that can cure the patients at high risk of recurrence. This article presents a case of sub-mandibular gland malignant neoplasm of a 34 years male patient.

Keywords: *Adenoid cystic carcinoma (ACC), Salivary gland neoplasm.*

Introduction

Adenoid cystic carcinoma (ACC) is a slow growing but aggressive tumor with a remarkable capacity of recurrence. It was first reported by three French scientists (Robin, Lorain, and Laboulbene) in two different articles published in 1853 and 1854.[1]Billroth in 1859 termed this lesion as "cylindroma". Spies in 1930, coined the term adenoid cystic carcinoma, in a discussion of tumors of the basal cell variety.[2] It is characterized by proliferation of ductal or luminal epithelium and myoepithelial cells in cribriform, tubular, solid and cystic patterns.[3] According to recent AFIP (Armed Forces Institute of Pathology; 4th ed.; 2008) grading ACC is the fifth most common malignant epithelial tumor of the salivary gland after mucoepidermoid carcinoma, adenocarcinoma, acinic cell carcinoma and polymorphous low-grade adenocarcinoma.[4] The uniqueness for ACC is because of two reasons, first is its prolonged duration for clinical presentation even after local or distant metastasis; and secondly, its tendency to spread along peri-neural root.[5,6] ACC have been known for its high survival rate for 10 to 15 years,even with pulmonary metastases.[7]

ACC is biologically aggressive and impulsive tumors of the head and neck that has tendency to recurred even after radical excision has been performed.[8] Radical or supra-radical surgery were previously practiced treatment method, but gradually it was observed that only surgery may not improve survival rate nor it may reduce local recurrence rates, as compared with conservative surgical approach followed by postoperative radiotherapy.[9]

Incidence of ACC accounts for approximately 10% of all salivary glands neoplasms. Parotid gland is the most common site of origin followed by submaxillary and the accessory glands in the palate and tongue. ACCs occur mostly in fifth and sixth decades of life but rarely occurs during third decade of life with more female predilection than male.[10]

Case Report: A 34 years male patient reported to our Institute of Dental Sciences, Bhubaneswar with pain and swelling on his right submandibular gland region since one and half year. On examination the patient was moderately built and normal gate. Patient had an average oral hygiene not associated with habit.

Extra oral examination showedbilaterally asymmetric face with a single well-defined growth

present on the superior border of right side of the mandible, size measuring of 2cm x 2cm in its greatest dimension, oval in shape,slightly tender on palpation and firm in consistency. [Figure-1] There was no colour change of the overlying skin. Bimanual palpation reveals the swelling is inside the submandibular salivary gland. The associated submandibular lymph nodes are slightly tender on palpation, mobile and firm in consistency. There were no relevant intraoral findings recorded. [Figure-2] On the basis of clinical findings we suspected the growth to be any benign tumor of the oral cavity, and further investigation were carried out.

Figure 1: Extra oral view

Figure 2: Intra oral view

The routine blood profile had no relevant result and all the parameters were in normal range. The aspiration cytology showed numerous cohesive cell cluster & few dislocated cells bordered by rim of hyaline basement membrane material. Cells were round to oval, with sparse cytoplasm & bland nuclear chromatin. Variable amount of stromal basement material was seen in clumps. These findings were in accordance with monomorphic adenoma of tubular variant.

The submandibular gland was surgically removed with a conservative approach to maintain aesthetics of the patient. Histopathological findings showed the tumor mass arranged in the connective tissue in a Swiss cheese pattern. Numerous cystic spaces were present with some of them filled with eosinophilic coagulum like material. High power magnification showed individual tumor cells which were monotonous in appearance with nuclear hyperchromatism. Few areas of solid pattern of tumor cells were also evident. Areas of basophilic stained glycosaminoglycan within the lumen was also seen. Intervening connective tissue fibrous septa at places were separating tumor masses. Occasional areas of hyalinisation were seen. The tumor cells were seen invading into the lymph vessels. Hence a final diagnosis of adenoid cystic carcinoma of cribriform pattern was given. [Figure-3].

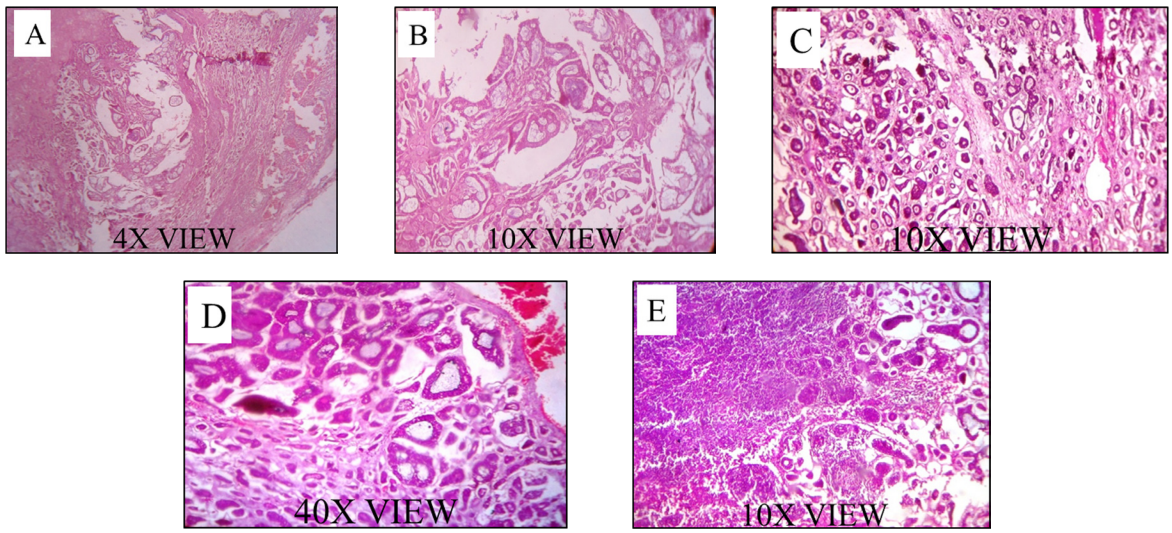

Figure 3: Photomicrograph A–Cribriform pattern in scanner view, B–Cribriform pattern with cystic degeneration, C/D–Classic Cribriform pattern, E–Cribriform pattern infiltrating into Lymph nodes.

Discussion

Ten to fifteen percent of salivary gland neoplasms are malignantthat occurs with a higher frequency in the submandibular gland.[8] Patients are 54 years old on average, when first diagnosed with salivary gland ACC.[5]The minor salivary glands and the sub mandibular gland are common site for ACC where the sublingual and parotid glands are less frequently affected. Nevertheless ACC may be found inthe aero-digestive tract, lachrymal glands and sebaceous glands.[11]Sometimes it may appearas a primary intraosseous tumors of the maxilla and mandible.[12]

ACC originates from the intercalated ducts of the mucous secreting salivary glands. The electron microscopy imaging shows that it arises from the cells that have potency to differentiate into epithelial and myoepithelial cells.[13] ACC affecting major salivary gland were reported clinically at 2- 4cm at its greatest dimensionand intraoral lesion arerarely larger than 3 cm at its greatest dimension.[14,15] The lesion is non-capsulated and infiltrative which invadesinto underlying bone. There is less incidence of cervical metastasis.[16]Maxillary lesion mayinvade to the base of the skull which leads to death.[17]

There are three ACC morphologic patterns, often mixed: tubular, cribriform, and solid, with the last one having a more aggressive clinical course. The cribriform pattern is most commonly found.[16] The similar layer of the myoepithelial cells of salivary ducts form the tubular pattern to the lesion. The solid variantconsists of solid epithelial cell islands with central areas of necrosis. This solid type has a poor prognosis than the cribriform type. Wide surgical excision with margins is choice of treatment. Post-surgical radiotherapy is advised to avoid chance of metastasis.[9] Histopathologically the small tumor cells are basophilic, hyperchromatic with a densely granulated nucleus and occasionally shows mitotic figures.[19] Available treatment possibilities for ACC include surgical therapy, radiotherapy, chemotherapy and combined therapy (surgery and radiotherapy, radiotherapy and chemotherapy). Only surgical excision or radiotherapy isolation may be unsuccessful to eliminate the possibility of recurrence and metastasis in surgical margins, as well as the to the cervical lymph nodes, bones, lungs and brain.[20] Considering the aggressiveness of the tumor the combination therapy has mostly been recomended.[21,22] Long-term follow up of patients with adenoid cystic carcinoma is mandatory to reduce any chance of loco-regional recurrence and metastasis.

Conclusion

Adenoid cystic carcinoma should be considered as an aggressive lesion in maxilla and mandible and especially when it is involving palate. It should be considered in the differential diagnosis of minor salivary gland tumors. The early detection of the lesion is mandatory, in order to ensure a more favourable prognosis and better quality of life.

Dental Implants: Contemporary and Ancient Facts

Gopal Krishna Choudhury[1], Sangram Panda[2]

[1]Professor & Head, [2]Reader, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The antiquity of the advancement of dental implants is an amusing and mesmerizing travel talk through time, Since the establishment of human life, man have been using dental implants in some way or the other form to compensate the missing tooth. The first known to be used dental implants is certified to Mayan inhabitants somewhere around 600 Ads. In those times they outclassed the substitute of mandibular teeth by making use of pieces of shells as implants. Evidence of radiographs that were taken in the 1970's of mandible of Mayan reveals formation of compact bone around the foreign implants placed- these bones astonishingly appears so much like that is visible around implant blade. In early Honduran culture around 800 A.D. an implant made up of stone was first constructed and used.

Keywords: *Dental Implants; Contemporary Facts; Ancient Facts; History.*

Introduction

The basic value implant treatment has focused on since the very beginning of its existence is patient presented. The primary and ultimate aim of a modern dental setup is to preserve the patient to normal contour function, speech, aesthetic, comfort and health, in case of a carious affected tooth or any missing tooth. Due to the lack of advancements in earlier times such as adding abutments traditional dentistry could not achieve this and the design for restoration is always directly related to the present oral health. Implant dentistry is considered unique in a way as it has the ability to achieve this milestone irrespective of atrophy, injury or disease of the stomatognathic system. The uniqueness of implant dentistry is that it can provide a range of supplementary abutments.[1]

The modification of the prevailing edentulous space and ultimate prosthetic design is further modified by augmentation of the bone. As an outcome of several continuous research investigative tools, planning of the treatment, designs of implants, techniques and the materials to be used, the success rate has now been increased for rehabilitation of many complex and complicated situations. Ultimately this has resulted in several treatment options for partially edentulous patients as well as the completely edentulous patients. Each and every creation even simply an art, building, or teeth it needs the ultimate result to viewed and carefully planned for an optimal outcome. To get an ideal design of the prosthesis, the preexisting structural anatomy is thoroughly evaluated to find out if a removable or fixed prosthesis is needed. An axiom of treatment of implant is to meet the basic patients' needs which includes easy, most predictable and most cost-effective treatment which will meet the patient esthetic needs as well as personal desires.[2]

In the beginning days implant dentistry was thought of to be the treatment alternative to treat the edentulous jaw. On the other hand,today, it is clinically and scientifically proven standard of care for replacing edentulous area. The requirement for the long-term success of the implant reinforced treatment concept is the development and re-evaluation of standard treatment protocols based on the patient's request. New criteria for "evidence-based implant dentistry" is evaluated in order to confirm expected accomplishment.[3]

Each and every treatment rule can be looked upon as the result of nonstop learning process where to avoid failures rules are setup. The earlier implant protocol is based on pragmatic data that were introduced 25 years ago with the initial of this continuing learning curve. Earlier in those time no clinically or scientifically based results were accessible, or if any they were not very satisfying. The firstly suggested healing period of three months in the mandible, and six months in maxilla have confirmed to assurance uninterrupted osseointegration clinically. Nevertheless, there is no proof that safe osseointegration may not have been achieved after a decreased healing time.[4]

According to Branemark set al the historical protocol for implant was constructed on the basis of serial preconditions which today is thought to be restrictive. Earlier during those times, the primary implications for placing a dental implant was to restore the edentulous area, mandible that is atrophied with attaching segments for removable over dentures. A single tooth replacement was never under consideration as an option for treatment. The information on critical risk assessment and perfect suggestions were not existing.[5]

Biomechanical and biological constraints capable of quickening hard and soft tissue incorporation were abandoned. Over several years,the site of implant preparation was mainly focused from a surgical point of view in a treatment protocol, with the healing of implants guaranteed. As the process of osseointegration process is restricted to some weeks, the reactions occurring in the cellular level during the functional loading phase was now taken as more significantly important viewing a long-term victory.[6]

Historic background of the dental implants: Way back over 1350 years prior when Branemark started to work with the titanium, the Mayan civilizations have shown to have used the almost first known endosseous implants. In 1931 archeologist while excavating a Mayan burial site in Honduras discovered a mandible originating from Mayan, back dating about 600 A.D. The discovered mandible was believed to be ageing in her early twenties of a women, had shells pieces of tooth shaped placed in her sockets of lower incisor teeth which as missing. Earlier it was believed that the shell implants were placed after the death, but later on in 1970 a Dental academic of Brazil Professor Amadeo Bobbio inspected the mandibular specimen and subjected it to multiple radiographs. He discovered compact bone formation around the two shell implants, from which he concluded that they were placed when she was alive.[7]

Figure 1. Site of Mayan Burial the First ever implant made up of Implant

In 1950 investigation was being held in Cambridge University, England to study the in vivo blood flow. These workers developed a technique of fabricating a titanium compartment which was then implanted into the rabbit's ear. A Swedish orthopedic surgeon, in 1952, PI Branemark was fascinated in learning bone healing and regeneration and embraced a Cambridge designed 'rabbit ear chamber' for use in rabbit femur. After several months of study, he tried to retrieve this exclusive chamber from rabbits and found that he could not remove them. Branemark detected that bone had deposited in so near with titanium that it effectively glued to the metals. Branemark further went on many studies with animal and human subjects which all established this uniqueness of titanium.[8]

Although he had originally considered that first work should center on knee and hip surgery, Branemark finally decided that mouth was more accessible for continued clinical observation and high rate of edentulous space in broad population offered more subjects for widespread study. He termed clinically observed adherence of bone with titanium as 'osseointegration'. In 1965 Branemark, who was by then professor of anatomy at Gothenburg University in Sweden, placed the first titanium dental implant into a human volunteer named Gosta Larsson. This patient had a cleft palate defect and required implants to support a Palatal obturator. Gosta Larsson died in 2005, with the original implants still in place after 40 years of function.[9]

Synchronous autonomous studies in the United States by Stevens and Alexander have led to in the year

1969 United Stated patent filling for dental implants of titanium.Branemark published several studies for over next 14 years on the effective use of implants are of titanium in dental implantology till he joined hands for commercial partnership in the year 1978 with the Swedish defense company before AB for the expansion and advertising of dental implants made by him. With Before (later to become Nobel industries) as the parent company, Nobel pharma AB (later to be renamed Nobel Biocare) was founded in 1981 to focus on dental implantology. To the present day 7 million Branemark systems have been placed and hundreds of other companies produce dental implants. The majority of dental implants now available are shaped like small screws with either tapered or parallel sides. They can be placed at the same time as the tooth is removed by engaging with the bone of the socket wall and sometimes also with the bone beyond the tip of the socket. Current evidences suggest that implants placed straight into an extraction socket have comparable success rates to those placed in the healed bone. The success rates and radiographic results of immediate restorations of dental implants placed in fresh extraction sockets (the temporary crowns placed at the same time) have been shown to be comparable to those obtained with delayed loading (the crowns placed weeks or months later) in carefully selected cases. The Osseointegration concept evolved closely coupled with the design of a cylindrical titanium screw with a specific surface treatment to enhance its bio acceptance.[10]

The first of the parameters on what is thought of a successful implant treatment among the strict guidance of the scientific community was held in the year 1982 at the conference that was held in Toronto in Osseo integration in Clinical Dentistry. Only after this conference the initiation of acceptance started and in North America the use of Dental Implants started. From then many local as well as exotic system of implant system have been emerging. Many of these design are similar to that of "Branemark Titanium Screw". Still many companies have improvised and the research has still been continuing to place an impact in the designs and concept of the upcoming implants.[11]

Branemark external hex was the first amongst the abutment system that is anti-rotational. It was reformed to prevent the abutment rotations those are present on the body of implants, but initially it was designed only for allowing the engagement of a driver in seating the implant. The small stature of the hex, and the dearth of an abutment with correct tolerances, for the rotation of single tooth made it a poor option in stabilization. To add, the abutment with flat to flat connection resulted in the entry of bacterial components as well as various fluids into the implant connection. This thrusting act for the duration of repeated loading eventually leads to stress in the retaining screw. The loosening of the screw was widespread in the design with letting down of the components of the prosthesis and the volume of soft issue. Screw loosening became endemic in this design with failure of the prosthetic components and soft tissue volume. The move from external to internal attachments initiated as a means to diminish the abutments loosening as they were being exposed to clinical and functional forces. Reduction of Crystal bone remodeling, was marked radiographically, was a clinical outcome of this kind of change.

Percolation of liquids occurs in the abutment implant surface during the regular micro-mobility that it results in bacterial penetration. Matrix metalloproteinase (such as elastase, collagenase, gelatinase) is result of chronic inflammation which lead to the breakdown of soft tissues and the osteoclastic activity potentiation. The reduction of micro leakage at the interface of an abutment/implant was the main challenge.[12]

Recent researches in the field of dental implantology is emphasizing on the use of materials made up of ceramics like Zirconia (ZrO2) in the processing of the dental implants. Zirconia is a metal that is close to titanium mentioned in the periodic table, it is the dioxide form of the element Zirconium with somewhat similar properties of biocompatibility. Even though usually the similar shape as titanium implants, ZrO2 which has been used effectively in surgery of orthopedics since several years, has the benefit of being more cosmetically appealing owing to its bright tooth like color. Nevertheless, clinically long-term follow-up data is needed prior single piece Zirconia implants, then can be suggested in day to day practice.[11,12]

Conclusion

To conclude, the history of the growth and progression of the implants related to dental is a glorious and captivating journey through the course of time. NO one can stop man's inventiveness as followed with years of new research and scholarship. There is a wide range of materials have been used as dental implants starting

from ligature wire made up of gold, ivory to chromium, cobalt to iridium and platinum. Changes involving from modifications in the implants physical structure to changes in coating of surface and treatment of surface of the implants. In the recent scenario coating of Laminan is being used. With days passing by in the studies of dental implant, the materials, forms and the coating in the surfaces is expected to be more precise so as to provide the patient with edentulous arches or area the best possible treatment in future.

Contour to Conserve: A Justified Way to Practice Dentistry

Kajal Kiran Sahoo[1], Sudipta Sahu[2], Nikita Sahu[2], Sashikant Sethy[2]

[1]Tutor, Department of Prosthodontics, [2]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha India

Abstract

For the long-term survival rate of dental restoration, the adjacent periodontium must also remain healthy and vice versa. In today world as patients are keen about getting a comfortable, durable and most importantly as esthetic filling, we as dentist are encroaching the gingival crevice are a while giving subgingival margins. In this article we will get a clean idea to give a restorative therapy to the patient while maintaining physiological periodontal health.

Keywords: *Contour; Dentistry; Long-Term Survival; Dental Restoration.*

Introduction

The restorations whether composite class II or V or metal or PFM or all ceramic crown, all should be such that it should prevent caries progression, maintain proper periodontal health and allow the patients to clean the tooth surface properly to avoid plaque accumulation. The relation between the periodontal health and restoration of teeth is intimate and inseparable. In healthy oral condition both epithelial as well as connective tissue attachment contribute to a protection mechanism is a most challenging area where natural tooth penetrates the ectodermal integrity of the body.[1] This junctional area on tooth is called "Dento-gingival Junction" the term as coined by Sicher. The vertical dimension of the dento-gingival junction comprises sulcus depth (SD), junctional epithelium (JE) and connective tissue attachment (CTA). It is physiologically formed at a level dependent on the location of the alveolar bone.[1,2]

Evaluation of Biological width: Firstly, the clinicians should assess the biologic width at the area where the restoration be it simple filling, inlay or onlay or crown. It can be done by two method.

1. By Radiography
2. By using periodontal probes.

Periodontal probe method is also called Bone sounding. Here the topography of the alveolar process is done by penetrating periodontal probe into the anaesthetized soft tissue.[3]

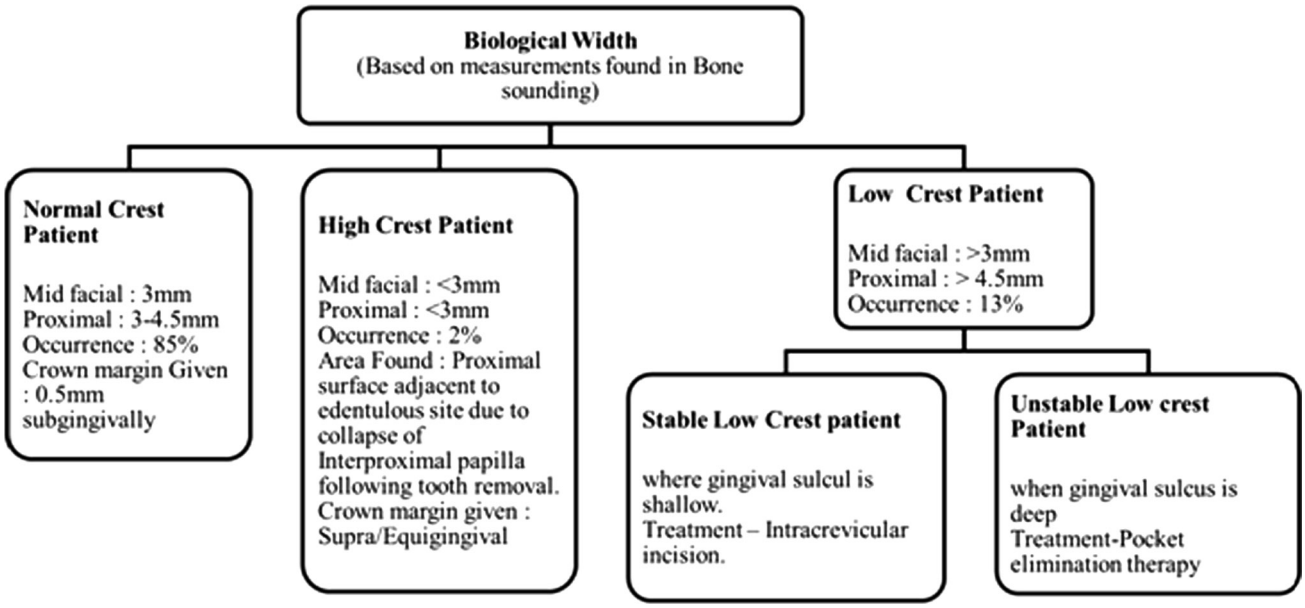

Figure 1. Evaluation of Biological width

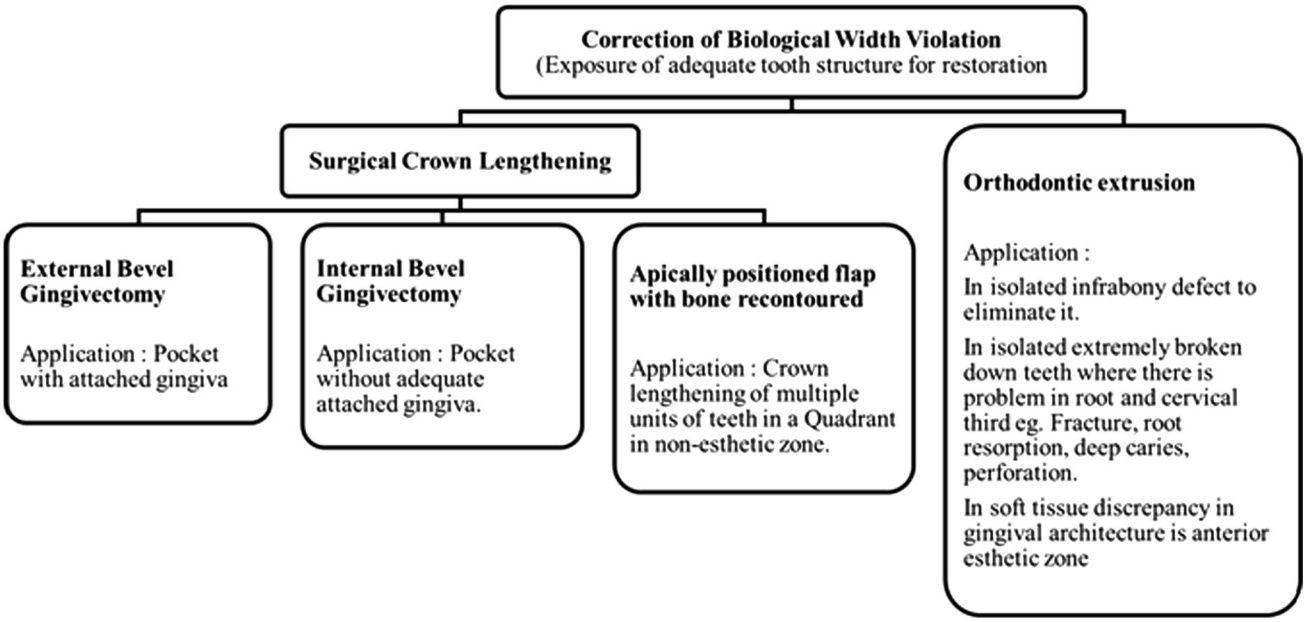

Figure 2. Correction of Biological width

Periodontal restorative interrelationship[4]: 6 Characteristics that are important of restoration from a periodontal point of view:

I. Margin of restoration

II. Contours of restoration/crown

III. Occlusion of restoration/crown

IV. Material of restoration/crown

V. Bridge design of restoration/crown

VI. Procedure involved in restoration/prosthetic dentistry.

I. Margin of Restoration:

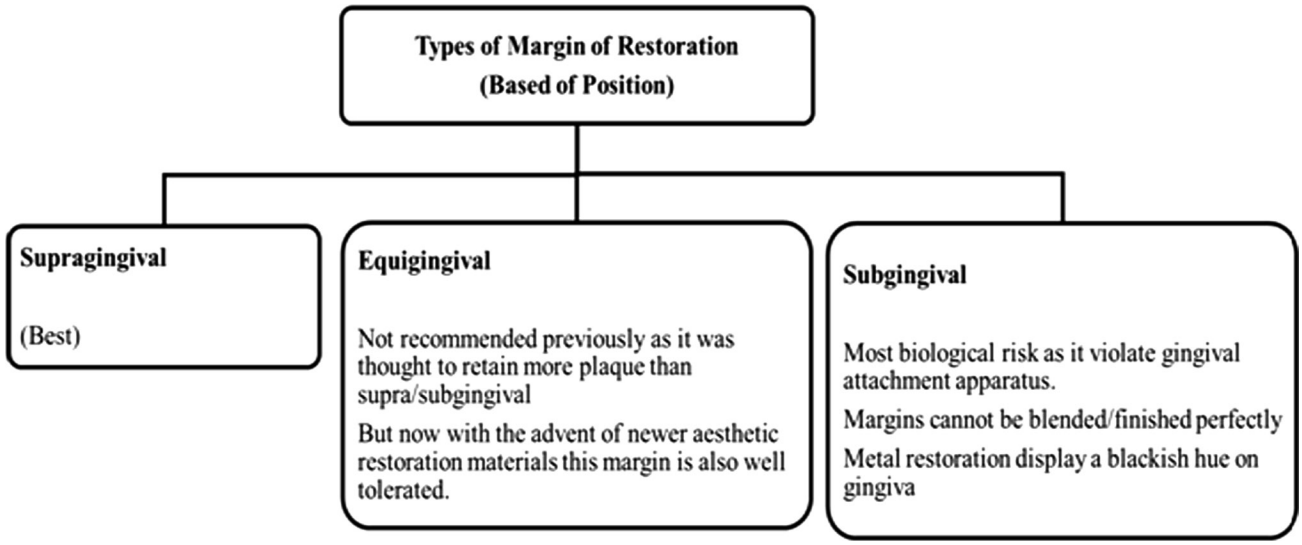

Figure 3. Margin of Restoration

3 Rules for application of subgingival margins:

a. If sulcus probes 1.5mm or less the restoration margin should be 0.5mm below gingival margin specially in esthetic zone

b. If the sulcus probes more than 1.5mm the restoration margin should be placed one half of the gingival sulcus depth. If margin is given below there is change of tissue recession.

c. If the sulcus probes more than 2mm gingivectomy should be performed to lengthen the teeth and create 1.5mm sulcus[5]

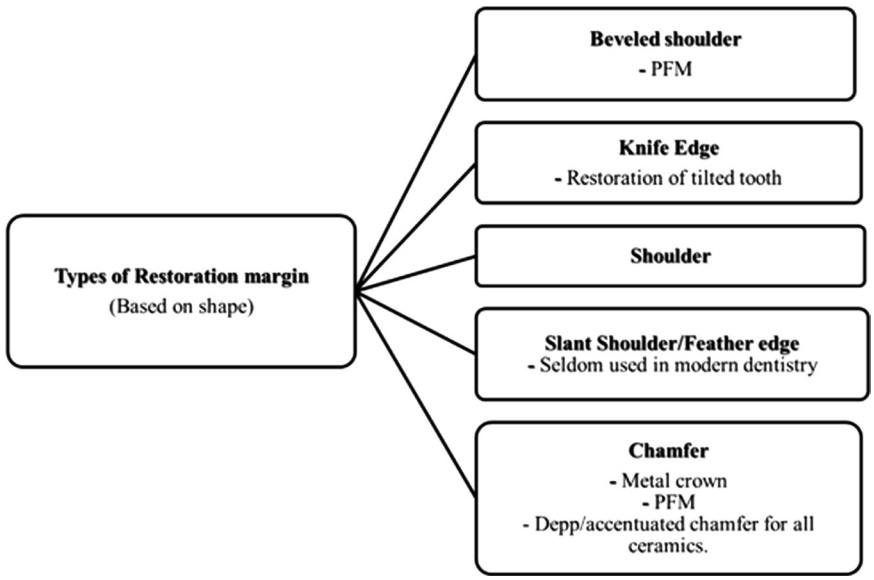

Figure 4. Types of Restoration margin

Beside the position and shape of the restoration margin the factor which plays a critical role in case of inlay, onlay and crowns is the luting material or cement. The dissolution and disintegration of cement causes cluster formation between preparation and restoration leading to plaque accumulation and inflammation.[6]

II. Contour of restoration/crown:

- With the advent of advanced light cured composite materials the proximal contour build-up is done by proper wedging, ultra thin metal matrix band placement and centripetal build-up technique. In this technique the 1st small increment of posterior composite is condensed towards the matrix band → light cured → 2nd small increment for occlusion margin → light cured → 3rd increment for building cusp slopes → light cured. After completion of curing metal matrix is removed and wooden wedge is left in place.
- The buccal and lingual surface of the crown should not be over contoured as it results in creating area where oral hygiene procedure cannot reach to remove plaque. Apparently under contouring is not nearly as damaging to gingiva as over contouring.
- Crown should be given self-cleansing contours. In case of giving crown to bifurcation involved tooth furcation should be "bevelled" from the margin of restoration to occlusal surface. The crown should be "barreled out" to eliminate plaque traps and facilitate plaque control.
- The greatest buccolingual dimension of the crown should not be more than 1mm than the buccolingual dimension of that tooth at cement-enamel junction. Except lower molars and premolars which have larger lingual curvatures.
- The convexity given to the restoration should be gradual and in the cervical third of the tooth. These feathers allow less food entrapment and allow the patient to access to the sulcus and tooth surface for cleansing.
- Contact area of the restoration should be high (directed incissally) and buccal in relation to the central fossa except maxillary 1st and 2nd molar. This created a large lingual embrasure for optimum health of lingual papilla.[7,8]

III. Occlusion: Restoration or prosthetic replacement which does not conform to the occlusal pattern creates excessive forces on the abutment leading to periodontal injury of the opposing tooth, abutment tooth itself and some of the other teeth in the arch also. Reshaping of plunger cusp should be done. Occlusal contour should be developed such that it allows escape of food embrasures.

IV. Materials: Glass ceramics and porcelain veneers offer a clear advantage over other types of restorative materials in maintenance of gingival health.

V. Bridge design: The bridge design with least effect on periodontium is sanitary or hygienic pontic. The ovate bridge is the most hygienic type with best patient acceptance. It is extremely important to remove all excess cement from the sulcus after cementation.

VI. Restorative Dentistry Procedure: Improper placement and use of the retraction cord can result in tissue tearing and inflammation. So, the retraction cord is handled meticulously. Interim restoration should be made such that it does not cause periodontal inflammation and gingival recession. The use of rubber dams, matrix band and polishing discs should be such that it does not injure the tissues. Injudicious tooth separation or orthodontic extraction should be avoided.[9,10]

Conclusion:

The health of the periodontal tissues is dependent on the properly designed restoration and healthy periodontium leads to longevity of the restoration. This accepted truth will help the dentist to deliver a more promising prognosis to the patients.

Intrusion Arches in Orthodontics

Subhrajeet Narayan Sahoo

Assistant Professor, Department of Orthodontics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar. Odisha, India

Abstract

Not all patients with deep overbite should be treated with the same mechanics. Some patients require intrusion of the anterior teeth, while others require primarily extrusion. This article has discussed the principles of incisor and canine intrusion and has demonstrated the use of intrusion springs that are capable of intruding incisors with minimal side effects on the posterior teeth. Six principles must be considered in incisor or canine intrusion: the use of optimal magnitudes of force and the delivery of this force constantly with low-load-deflection springs; the use of a single point contact in the anterior region; the careful selection of the point of force application with respect to the center of resistance of the teeth to be intruded; selective intrusion based on anterior tooth geometry; control over the reactive units by formation of a posterior anchorage unit; and inhibition of eruption of the posterior teeth and avoidance of undesirable eruptive mechanics.

Keywords: *Deepbite, Intrusion. Orthodontics, Segmented arch technique*

Introduction

Most orthodontist come across cases with excessive incisor exposure and increased overbite in their clinical practice. These patients require a comprehensive treatment plan, which establishes how the incisor exposure should be reduced and deep overbite, corrected depending on the cause. Correction of the deep overbite can be accomplished in a number of ways depending on the initial diagnosis and treatment objectives. Deep bite can be corrected by various tooth movements.[1]

Extrusion of the posterior teeth, will result in increased lower facial height, steepening of the occlusal plane, downward and backward rotation of the mandible, resulting in worsening of the class II skeletal relationship. The long term stability of the correction is questionable unless suitable growth occurs. Deep overbite correction by intrusion of anterior teeth offers a number of advantages including, simplifying control of vertical dimension and allowing forward rotation of the mandible. Intrusion of anterior teeth to correct deep overbite may be indicated in patients with unaesthetic excessive maxillary incisor showing at rest position of the lip, and deep mandibular curve associated with long lower facial height. Numerous method have been described for incisor intrusion, and all of the employ the same principle, a tipback bend at the molars, or a V bend in the posterior region of the arch to provide an intrusive force at he incisors.[2]

Utility Arch: Utility arch designed by Robert M. Ricketts in the early 1950's and has been popularized as an integral part of bioprogressive therapy. One of the most versatile auxiliary arch wires that can be used in either mixed or permanent dentition treatment is the utility arch. Utility arch is a continuous wire that extends across both buccal segments, but engages only the 1st permanent molars and four incisors It was developed originally to provide a method for leveling the curve of spee in the mandible but through the incorporation of loops, has been adapted to perform additional functions in addition to incisor intrusion in both arches.[3]

Basic components: Regardless of the presence or absence of loops, all utility arches have a common design, which consist of Molar segments, Posterior vertical segment, Vestibular segment, Anterior vertical segment, Incisal segment.[4]

Molar Segments extends into a tube on the 1st molar. This segment may be cut flush with the end of the tube or may be bend gingival if the utility arch is to be tied back. When utility arches are used in combination with full arch appliances, it is necessary to have auxiliary tubes located in the gingival portion of the 1st molar bands.

Posterior Vertical Segment is formed by making a 90° bend with 142 arch forming pliers. Posterior step typically is 3-4mm in length in the mandible and 4-5mm in maxilla. It is often necessary to place a 3rd order bend at the function of molar segments and posterior vertical segment to avoid impingement of utility arch on adjacent gingiva.[5]

Vestibular segment is formed by placing a right angle bend at the inferior portion of posterior vertical segment. The wire then passes antero-inferiorly along gingival margin.

Anterior vertical segments should be about 4.5mm in length when the utility arch is used in the mandible and about 5-8mm in length, when used in the maxilla. Depth of the maxillary and mandibular vestibules of the individual patients, along with the design of the fixed appliances used during treatment, determine specific length of both vertical segments.

Incisal Segment: Final 90° bend creates the incisal segment that should lie passively in the brackets of anterior teeth.[6]

Wire selection: As advocated by Ricketts, utility arches are fabricated from chrome–cobalt wires. With regard to selection of appropriate size of wire for 0.018" slot appliance, recommended wire for mandibular utility arch is either 0.016" x 0.022" or 0.016" x 0.016" wire. For maxillary arches 0.016" x 0.022" wire is recommended, with 0.022" slot, 0.019" x 0.019" wire can be used in either arch. Generally rectangular wire is preferable to round wire to control torque and prevent unwanted tipping of incisors. [7]

Intrusion Utility Arch: Intrusion utility arch is similar in design to passive utility arch, except that the posterior vertical segments do not lie against auxiliary tube on the 1st molar bracket. Arch is activated to intrude the anterior teeth. Utility arch should produce 60–100 grams of force on the mandibular incisors, force level considered ideal for mandibular incisor intrusion. As with the passive arch, intrusion arch is stepped gingival at the molars, passes through the buccal vestibule, and then is stepped occlusal at the incisors to avoid distortion from occlusal forces. In contrast to the passive utility arch, posterior vertical segment is at least 5mm, anterior to the auxiliary tube of molar.[8]

Intrusion of anterior teeth can be produced in one of the two ways:

1. First the utility arch can be bent passively to fit the existing occlusion. After ligating the utility arch into the anterior brackets, an intrusive force can be produced by placing an occlusal directed gable bend in the posterior portion of the vestibular segment of the arch wire.
2. Bench has advocated an alternative method of activation of utility arch to produce intrusion. This type of activation involves placing a tip–back bend in the molar segment. Tip-back bend causes the molar segments of the arch wire to lie in the vestibular sulcus. Intrusive force is created by placing the incisal segment of the utility arch into the bracket of the incisors; however, placing a tip back bend can occasionally lead to unintentional posterior tipping of 1st molars which in the maxillary arch can be minimized by concurrent use of trans–palatal arch.[9]

Connecticut Intrusion Arch: Connecticut intrusion arch introduced by Ravindra Nanda is fabricated from Nickel–Titanium alloys as it is the material of choice for delivering continuous forces under large activation. These alloys have high memory and low load deflection rate producing small increments of deactivation over time and thus reducing the number of reactivation appointment. [6-8]

Appliance Design: Connecticut intrusion arch incorporates the characteristics of utility arch as well as those of conventional intrusion arch. C.T.A on preformed with appropriate bends necessary for easy insertion and use. Two wire sizes are available 0.016" x 0.22" and 0.017" x 0.025" Maxillary and mandibular versions have anterior dimensions of 34 mm and 28mm respectively. The by pass, located distal to lateral incisors is available in two different length to accommodate for extraction, non-extraction and mixed dentition.[7,9]

Mechanics: C.T.A's basic mechanism of force delivery is a V bend calibrated to deliver approximately 40–60 g of force. Upon insertion the V bend lies just anterior to the molar brackets. Incisor intrusion requires about 50g of force directed apically along the center of resistance. Although the C.T.A is calibrated for this purpose, slight difference in placement may alter the force system during activation. Moment created at the molar will also vary, according to the amount of force at the incisors multiplied by the distance to the molars. These

minor changes can be measured with a spring gauge when the arch is inserted and necessary adjustments can be made to ensure proper force delivery.[10]

Burstone Intrusion Arch: In the 1950's Burstone developed the segmented arch technique, which had different crossection of the wire within the same arch and wires that did not run continuously from one bracket to the adjacent bracket. Burstone concluded that one of the limitations of the continuous arch therapy is its inability to produce genuine intrusion. Basic mechanism of Burstone intrusion arch consist of Posterior anchorage unit, Anterior segment, Intrusive arch spring. To increase the stability of the posterior segment, wires that are .018" x .025" or .021" x 0.25" Stainless steel can be placed following initial alignment and maintained in placed through out treatment. When alignment is completed in the posterior segment, right and left buccal segments are joined together across the arch by means of trans-palatal arch in maxilla and low lingual arch in mandible.[11]

Intrusive Spring: Intrusive arch consist of an 0.018" x 0.022" or 0.018" x .025" wire with a 3mm helix wound 2½ times placed mesial to the auxiliary tube. Curvature in placed in the intrusive arch, so that the incisal portion lies gingival to the central incisors. When the arch is tied to the level of the incisors, an intrusive force is developed. In order that the arch does not increase its length during the activation, a gentle curvature should be placed with the amount of curvature increasing as one approaches the helix. In this way the activated arch wire will appear relatively straight, and as it works out during intrusion arch length will decrease and no anterior flaring is produced.[12]

Anterior Segment: Intrusive spring as not tied directly into the incisor bracket. Anterior alignment arch or anterior segment is placed in the central incisor or four incisors and intrusive arch is either tied labially, incisally or gingivally to the wire.

Tip Back Springs (Intrusion Springs): Originally proposed by Burstone, these springs are made of 0.017" x 0.025" inch. T.M.A wire, upper and lower arches have to be leveled and aligned and rigid stainless steel wire, preferably of 0.017 x 0.025 inch dimension.

Anchor molars should be re–inforced with a T.P.A in the upper and lingual holding arch in the lower arch. The intrusion springs are made from 0.017" x 0.025" TMA wire without a helix or 0.017" x 0.025" stainless steel wire with a helix so that forces can be made optimal for intrusion. Wire is bend gingivally mesial to the molar tube and then a helix is formed. The mesial end of the spring is bend into a hook and is engaged distal to lateral incisor, which according to Burstone is the approximate center of resistance of the four incisors.

Mesial end of the spring lies passively at the height of mesio–buccal fold and spring is activated by pulling the hook down and engaging it on to the arch wire.[7-9]

Three Piece Intrusion Arch: The Three piece Intrusion arch consist of the following parts

Posterior Anchorage Unit: After satisfactory alignment of the pre-molars and molars, passive segmented wire (.017 x .025" stainless steel) are placed in the right and left posterior teeth for stabilization. A precision stainless steel trans-palatal arch (.032 x .032) placed passively between the first maxillary molars consolidates the posterior unit now consisting of right and left posterior units. Canines may be retracted separately and incorporated into the buccal segment.[9]

Anterior Segment: The anterior segment is bent gingivally distal to the laterals and then bent horizontally creating a step of approximately 3mm. The distal part extends posteriorly to the distal end of the canine bracket where it is formed into a hook. The anterior segment should be made of (.018 x .025 or larger) to prevent side effects created by bending of wire during force application.[10]

Intrusion Cantilever: The intrusion cantilever is fabricated from .017 x .025 inch T.M.A. the wire is bent gingivally mesial to the molar tube and a helix is formed. The mesial end of the cantilever is bend into a hook. The cantilever is then activated by making a bend mesial to the helix at the molar tube, such that the anterior end with the hook lies passively in the vestibule. This is then brought down and engaged onto the horizontal portion of the anterior segment. This allows further distal placement of the intrusive forces, that is , lateral to the lateral incisor, so that the resultant forces are made to pass through the center of resistance of anterior teeth. An elastic chain can be attached to the hook to facilitate simultaneous intrusion and retraction or to redirect the forces more parallel to the long axis of incisors.

However to achieve true intrusion of anterior teeth it is always necessary to balance the effective force of intrusion. [11]

Kalra Simultaneous Inrusion Retraction: The K- SIR archwire is a modification of segmented loop mechanics of Nanda and Burstone. It is a continuous .019" x .025" TMA arch wire with closed 7mm x 2mm U loop at the extraction site. To obtain bodily movement and prevent tipping of teeth into the extraction space a 90° V bend is placed in the arch wire at the level of U-loop. This V-bend, when centered between the Ist molar and the canine during space closure, produces two equal and opposite moments to counter the moments caused by activation force of closing loop. An off centered 60° V bend located posterior to the interbracket distance produces an increased posterior clockwise moment on the Ist molar which augments molar anchorage as well as intrusion of anterior teeth. To prevent the buccal segment from rolling mesiolingually due to force produced by loop activation, a 20° anterotation bend is placed in the archwire just distal to each U-loop.[12]

Activation: A trial activation of the arch wire is performed outside the mouth. Trial activation releases the stress built up in bending the wire and thus reduces severity of the V bend. After the trial activation, the neutral position of each loop is determined with the legs extended horizontally. In the neutral positon, the U-loop is about 3.5mm wide and the archwire is inserted into the auxiliary tube of the Ist molar and engaged in the six anterior brackets. It is activated about 3mm so that the mesial and distal legs of the loop are barely apart. IInd premolars are bypassed to increase the interbracket distance between the two ends of the attachment, which increases the efficacy of the off enter V bend.[6-9]

When the loops are first activated, the tipping moments generated by the retracting force will be greater than the opposing moments generated by the V bend in the arch wire. This will initially cause controlled tipping of the teeth into the extraction space. As the loops deactivate and force decreases; the moment to force ratio will increase to first cause bodily and then root movement of teeth. The archwire should therefore be not reactivated at short intervals, but only every 6-8 weeks until all the space have closed.[10-12]

Conclusion

Intrusion of the tooth involves resorption of the bone, particularly around the apex of the tooth. In this movement, the whole of supporting structures are under pressure with virtually no areas of tension. Unlike extruded teeth, intruded teeth in young patients undergo only minor positional changes after treatment. Relapse usually does not occur, partly because the free gingival fiber bundles become slightly relaxed. Stretch is exerted primarily on the principal fibers. A light contentious force, such as that obtained in the light wire technique, has proved favorable for intrusion in young patients.

Latex Allergy in Clinical Practice: An Overview

Nikita Mohanty

Intern, Institute of dental sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The use of latex has been increased in this few years. The medical staff and students appear to be at high risk for latex sensitization. The increased use of latex has led to many mucosal and cutaneous reactions. Allergic to latex is the main allergic occupational for health workers. The prevalence of latex allergy in the general population is only 1%. Latex exposure can be via skin or mucous membrane. Some of the allergens may also be associated with the gloves lubricant powder and can become aerosolized causing respiratory, ocular or nasal symptoms.

Keywords: *Allergic reactions, Latex allergy, gloves.*

Introduction

Latex Allergy is an allergic reaction to certain proteins found In natural rubber latex[1]. Latex protein contains less than 1% of protein. Latex get thoroughly washed during the manufacturing. When they are not washed properly,free latex present on the surface and this free latex are responsible for allergies[2]. When an individual is allergic to Latex, his immune system recognizes latex as a harmful substance and triggers histamine and other chemicals in bloodstream and produce signs and symptoms. Latex can cause type I and type or type IV allergic reactions**.** Contacted with natural rubber latex in dental equipment products must be avoided with patients diagnosed with type I NRL allergy and NRL free products should be used.[1]

Product containing Latex: Latex Gloves, Rubber dam, Rubber file stops, Orthodontic elastics, Rubber mixing cup, Prophylaxis polishing cups, Needle guards, Dappens pot. The most effective way of latex allergy in dental and medical environment is via aerosolized latex protein from powdered latex gloves, which is commonly used as dry lubricant in latex gloves. Persons who have undergone multiple dental surgery have high risk for latex allergy[5]. Persons having direct mucosal contact with NRL devices have a very important route for sensitization to latex in the body. Atopic patients, Dentists and other health care individuals, children with spina bifidia, Rubber industry workers, Florists may develop Latex allergy.[2]

Signs and symptoms of latex allergy: In most of the cases, latex allergy develops after many previous exposures to latex. Symptoms begin within minutes after the exposure to latex containing products. The most severe latex allergy can result in anaphylaxis, a serious allergic reaction including severe breathing difficulties and fall in blood pressure. Allergic skin problems or signs can occur while direct contact with allergic latex proteins in latex gloves products. Direct physical contact with latex product is not needed to have an allergic reaction. Severe asthmatic reactions have been caused by inhaling latex proteins in the air from the powder latex gloves.[3]

Signs and symptoms of Latex Allergy: Coughing, Sneezing, Shortness of breath, Nasal congestion, Runny nose, Nasal or palatal it itching, watery eyes, Dizziness, Hypotension, confusion, Nausea, Vomiting, Hives, Swelling and rashes, Rapid or weak pulse.[4]

Other allergic reactions while using latexare:

1. **Irritant contact Dermatitis:** This is a skin reaction not an allergic reaction. This occurs when a person is exposed to latex powder while wearing latex gloves.
2. **Allergic contact Dermatitis:** This reaction occurs when chemical additives used during manufacturing. Signs of blisters seen in next 24 to 48 hours.

Diagnosis: It requires a thorough history of patient then few tests to Confirm it.[4]

Skin prick testing: The easiest and very low cost. A drop of latex extract is diluted with the saline and is pricked gently in skin by a needle. A wheel and flare reaction will develop in 20 minutes if a person is sensitized. The reaction is graded according to the redness and swelling at that site. The test should have performed by an expert. Also there should be emergency equipment and drugs to treat any emergency allergic reactions. This test can be interfered if a person is taking some specific medicines or having severe dermatitis.[5]

Intradermal skin test: Performed only if skin test is negative. It is more sensitive than skin prick test. It can induce systemic reactions.

Patch test: This test is helpful for differentiating between irritant contact dermatitis and allergic contact dermatitis. This takes for 2 to 3 days. Because this reaction is at peak in 48 to 72 hours. They can be differentiated by onset of action.

Use Test: Test using allergic substances. This test is very difficult to standardize.

In vitro Immunoassay: It is not easily available as skin prick test. This a high cost and Safe test. In this test the patient is not exposed to latex protein.

Treatment: Medicines are available for latex allergy but patient need to have education to avoid latex. If he or she needs a treatment, then they need to use non latex products. But still an individual can come in contact with the latex. An individual need to carry an injectable epinephrine for a severe allergic. If an anaphylactic reaction appears then he needs to attend the emergency room. Doctorsmainly prescribe anti-histamine or corticosteroids for a less severe reaction.[6]

Education: The doctor needs to educate the person about the sensitivity of latex, mechanisms,risk factors and management. Doctor has to say about the alternatives of latex products and should know how to manage the severity of allergic reaction.

Latex and alternative items: Latex items: Surgical gloves, Surgical for examination, Adhesives, Adhesive bandages, Medications vials with use ampules

Non-latex items: Neoprene triblock co polymer, Nitrile gloves, vinyl or nitrile gloves, Non latex adhesives, sterile dressing with tape, Rubber stoppers

Protocol to how to attend latex allergy patient[7]:

1. Take a thorough history for the known latex allergy patient and ask questions like–has the patient ever experienced any adverse effects to balloons, condoms, household gloves or any dentaltreatment. Does the patient have an allergy to foods cross-reacting with NRL like bananas, kiwi, chestnuts, avocados. Has the patient experienced hives, asthma, or hay fever chestnuts as a result of their work, where the latex gloves are used?
2. Verify with the latex allergy tests
3. Label the patient chart or any slip with LATEX ALLERGY.
4. Discard all the latex containing products from the patient's area. Direct or indirect contact can give rise to a severe allergy
5. Strictly the doctor or the physician has to use some latex free products.
6. Educate the patient's family about all the risks and management of latex allergy.

Gloves selection guides:

1. Use non-latex gloves for activities that are not likely to involve contact with infectious material.
2. Appropriate barrier protection is necessary when handling infectious materials. Skin care protocols-Ensure that gloves comply with national and international standard of performance. In market there are gloves for the allergic people like low-protein gloves. Powder-free gloves, Non-latex gloves. But studies show that low-proteins gloves are not appropriate for the latex-free environment.

Conclusion

Natural rubber is manufactured from the sap of and is allergenic to some of the chemicals which are added to during the production. Latex products are found in both the home and workplace such as in form of balloons, carpets, condoms, textiles and medical gloves. Immediate allergic reactions to latex range from pruritusto urticarial, rarely anaphylaxis. Contact dermatitis is usually eczematous and only appears after 24 to 48 hours. Testing of latex is kind of problematic. Interdermal injection can induce anaphylactic shock. Treatment at the beginning is preferred as the environmental levels of allergens rise, as activities in

the surgery continues. A proper education should have given to the patient and to their families. Patient in high-risk group must be diagnosed properly so that proper protocols can be taken. So encourage the patient to use proper skin care to avoid unnecessary irritations.

Sports Dentistry: An Overview

Sudeepta Hota[1], Antarmayee Panigrahi[2], Sambit Samal[1], Lipsa Nayak[1]

[1]Intern, [2]Reader, Department of Pediatrics and Preventive Dentistry, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

'Sports Dentistry' is the branch of dentistry that involves treatment of dental athletic injuries and prevention of oral sports injuries. It also involves the compilation and distribution of information on dental athletic injuries and encourages research in the prevention of such injuries. In children, sports activities were found to be responsible for 13% of overall oral trauma. It is emphasized that there is a great need for "Team Dentist" from high schools to specialized teams. In this review, we discuss the relationship between sports and dentistry, and the importance of educating parents, teachers, and children in prevention of injuries related to the sports. Dental trauma in sports is the main connecting waterway between the dentistry and sports.

Introduction

A game is derivedfrom old combinations of words that literally mean, "to carry away from work". A sports consists of a normal physical activity or skill carried out under a publicly agreed set of rules, and with a recreational purpose, for competition, for self-enjoyment, to attain excellence, for the development of skill, or some combination of these.[1]

The combined effect of traffic accidents, fighting, along with sportactions have givenconcern of shocking dental injury as a problem of community dental wellbeing.[2] "Sports dentistry" can be defined as the prevention and treatment of orofacial muscular injuries and related oral diseases, as well as the collection and distribution of information on dental athletic injuries and the encouragement of research in the prevention of such injuries. The dentist has avested interest and a professional responsibility to contribute their unique skills in serving special needs of the patient who participate in sport safety measures and therefore it becomes necessary for them to have a thorough information of this upcoming branch of dentistry.[2].

How Dentistry is Related to Sports: For all age groups a physically active lifestyle is important. Reasons to participate in sports and physical activity are many, such as relaxation, pleasure, competition, preservation, socialization, and improvement of fitness and health. Sports participation may carry a risk for injuries, which leads to enduring dysfunction.[3]

Teeth and facial damage are very popular sports education injuries. It has been extensively concluded from several reports, that contribution in sports carries the jeopardy of supporting dental damage,the maxillary central incisor are the most commonly damaged tooth and males are troubled more as compared to females.

With amplified occurrence of orofacial injury in sports, there is a better apprehension for the crisis and long-term worry of orofacial injury and practice of defensive measures like helmet, mouth guards in these sports education.[4]

Incidence and Location: Face is the most vulnerable area of the body and is typically the slightest confined. Of all facial soft tissue injuries, sports-related facial injuries account for about 8%. Approximately 11-40% of all sports injuries involve the look[6]. Some sports injuries result from accidents; others are due to, improper

Sudeepta Hota
Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

tackle, poor training practices and or insufficient warm up or lack of conditioning, and stretching.[5,6]

Prevention of Sports Related Traumatic Orofacial Injuries: Physical fitness, stress reduction, skill development, and team building are among the many positive aspects linked with contribution in energetic and planned sports. Despite these benefits, many a risks exist to those who engage in these endeavor. Face is the most exposed part of the body in athletic competition[1]. Besides, as the prognostic threat factors linked with these injuries are more visibly recognized plus clear, the plan in addition to growth of new defensive devices may add to prospect sporty intersubstitutable

Oral Diseases in Sports Community: Tooth wear or tooth substance loss is becoming an increasingly common problem in athletic group of people. It has been recognized that dental problems are arising from the using up of acidic food and drinks among several spotting groups.

Dental erosion is a non-carious pathologic loss of tooth substance by chemical process. Dehydration reduces in turn its buffering capacity to clear acids from mouth and the salivary flow rate.[8]

Risk Factors for Sport Injuries: For any such unknown and unexpected events, it is firstly important to know, understand and appreciate the various predictive considerations. In this way we can be capable enough to prevent any sort of injury and other loss related to it. Theserisk factors can be collaborate classified as extrinsic and inherent factors.[9]

External factors: External factors are usually derived from any sort of outer source while performing activities like running, jogging etc. They are usually independent of the individual.

These usually results in any sort of stress injury, that usually results from any contact sports[8.]

Intrinsic factors: Intrinsic factors are biologic and psychosocial and depend on the individual. They are the characteristics which are inbuilt within an individual sport participant. The various factors, on which the intrinsic risk factors depend are:

Age: The complex realm of intrinsic factors is strength of body, coordination, physical maturity, healing ability and growth and development are all part of it and mainly are the contributing factors. In another study done we get to know that the danger of wound decrease with rising age and the majority occurs in adolescent and young children.[10]

Sex: The role of sexual category as a possible hazard factor may be an indication of an evident tendency for boys plus men to select additional“contact” otherwise assertively energetic games.[10]

Body size: An increased body size of the participant may enhance the chance of injury in sports in various ways. These include an, increased influence due to greater length of limbs, higher center of gravity and strain on joint unpaid to extra weight. Number of studies done predispose that excessive tallness and heaviness individuals are prone to wound.[10]

Broad mind aptitude: Study recognized an associations tuck between inferior scores on aptitude tests and sports injuries, suggestive of that injury proneness might be due to intelligence.[11]

Protective Equipment for the Prevention of Sports Related Craniofacial Injuries:

Organized sports at the amateur level that mandate the use of helmets, facemasks, and mouth guards during practice and in competition include boxing, football and ice hockey.[12]

Helmets: These are the equipment’s well delineated for the protection of the sensitive areas of the head including the skin of scalp, skull, brain, central nervous system and ears of the athlete from contusions, abrasions, fracture, lacerations, concussions, sleep, cerebral hemorrhage, paralysis, brain damage,and death[9].

Facemaks: These are intended to guardnose, eye, zygomatic arches, pyramid of nose, and jaws from armed forces directed towards the face. One of the major disadvantages of facemask is that it presents a protruding object within the ready grip of adiffering player.

Mouthguards: Prevention of sports related dental injuries is enhanced further when a properly fitted athletic mouth guard is included as an essential protective device.

Types of Mouthguards:

Classification of mouth guards: The ASTM(American society of testing and materials) in Designation: F697-80 established the classification system for athletic mouth guards:[1]

Type I: Stock mouth guards

Type II: Mouth-formed mouth guards

Type III: Custom fabricated mouth guards

Custom-made mouth guards are effective for junior players in reducing the injuries. A significant reduction regarding these injuries can be reduced with the use of mouth guards. Asatisfactory custom made mouth guard may be capable of preparing for allyoung person; therefore, they preserve and should be used in contact sport. An ideal situation is, wherever nearby is a possibility of dental damage is the requirement of a team dentist.[8]

Role of Various Specialities In Prevention:

(A) Role of a pediatric dentist: Identification of injury-prone groups: Very young children whose motor development is not complete, therefore susceptibility to trauma is also increased. Special children with those like cerebral palsy are also susceptible to falling and trauma. Children with a curved profile are more prone to injuries.

Counseling of parents: They should be well-versed of their child's risk of dental trauma, and the relatively simple and comparatively inexpensive means of preventing such injury. Children should not be compelled to play a certain sport. If that is done the child will not play with full concentration, and may sustain injuries more often.

Counseling about basic post dental trauma management: The parents should be informed that the child should be immediately taken to a doctor. If broken tooth piece is there, it should be kept to be reattached, and if a tooth comes out completely, the child should be brought to a dentist within half an hour of the injury. The parents should also be counseled regarding the diet and nutrition of their child as it is essential to provide a balanced diet for proper fitness.

Counseling of school teachers: Teachers, specially the sports in-charges should also be counseled about the basic preventive plan and also the post injury management[1].

(B) Role of orthodontist: Malocclusions have long been recognized a contributing to the risk of dental trauma. Patients with Class II Division I malocclusion demonstrate excessive overjet that places the maxillary incisors in a vulnerable position. The procumbent incisors, often without benefit of lip coverage, are more likely to be traumatized in frontal blow to the face. If concern about esthetics and function have not already prompted the patients or parents to pursue orthodontic treatment, the dentist should also explain the benefits of trauma risk reduction.[1]

(C) Role of oral surgeon: Impacted third molars create areas in the mandible which are highly susceptible to crack in a traumatic event. Thus in older adolescents and adult athletes, unerupted or impacted third molar should be removed. A mandibular fracture in the area of third molar may confine the athlete for 3 to 4 months as bony healing occurs. By contrast, the osseous regeneration after removal of impacted third molar does not result in n total interruption of athletic activity.[1]

Indian Perspective of Sports Dentistry: It is advisable for sporting community to have the sports dentistry centers identified for a quick approach when needed. Millions of rupees are spent every year in treating dental trauma injuries caused due to sporting accidents. However, in India only a very few athletes wear mouth guards to prevent these injuries. It was observed that 82% injuries were related to nonuse of protective devices.

For 58% coaches in the study, boxing was more likely to produce orofacial injuries. The coaches observed more injuries in hockey followed by cricket and boxing. In other studies, 63-75% of such injuries occurred when mouth guard was not used. Team of doctors including a pediatric dentist, Orthodontist, Oral Surgeon, Physician, Orthopedic Surgeon, and Laboratory technician skilled in making mouth guards is required to start sports dentistry clinic setup. In India dental procedures should be performed at cheaper costs, with best of quality in different cities at various dental clinics.[6]

Conclusion

The pediatric dental surgeon should hold a sound medical working information about sports-related injuries in adolescent along with children. When a patient with oral/facial athletic injuries enters the dental clinic, it's the utmost important role of a dentist to deal to the related oral diseases associated with the injuries, with varying manifestations, complications and consequences. The dentist should possess a sound clinical working knowledge on various methodologies of prevention procedure and treatment modalities. The available facilities are dependent on the situation of the

nation, sports practiced most commonly and the level of community education in this regard.

Criterion for Selecting a Study Design

Swati Patnaik[1], Shakti Swaroop[2], Sashikant Sethy[3]

[1]Senior Lecturer, Dept. of Public Health Dentistry, S'O'A University, [2]Senior Resident, Dept. of Orthopedics, AIIMS, Bhubaneswar, [3]Tutor, Dept. of Public Health Dentistry, S'O'A University

Abstract

A research question may be answered by more than one research design. The next logical step after designing a research question is to select an appropriate study design. A research question may be answered by more than one research design. All types of research design have a place, and all have advantages and disadvantages. But not all types of design are always possible for a study.

Keywords: *Epidemiology, Study designs, causality.*

Introduction

Epidemiology is the only scientific discipline that directly addresses phenomena of disease occurrence in the human population with the aim of explaining and clarifying them as well as advising public health agencies regarding preventive measures.[1] Epidemiology studies are conducted using human populations to evaluate whether there is a correlation or causal relationship between exposure to a substance and adverse health effects. These studies are quite different from clinical investigations which evaluate the effect of any drug or therapy on a given population while epidemiological studies measure the risk of illness or death in an exposed population compared to that risk in an identical, unexposed population (for example, a population the same age, sex, race and social status as the exposed population).Epidemiological research helps us to understand how many people have a disease or a disorder and how this disorder affects the society and its long-term impact on the economy as well as health statistics. Hence, selecting an appropriate study design an important factor in biomedical and public health research quality, execution and interpretation.[2,3]

Study Designs[4,5,6]: The most critical elements of the design of the epidemiology study include: a control group, enough time span and statistical detection of an effect. More specifically, the control population used as a comparison group shall be as like, for instance, age, sex, race, social condition, geographical area and environmental and lifestyle influences as possible to the test group. The study design determines the statistical ability to detect an effect or the power of the study and in order to gain precision, the study and control populations should be as large as possible.

The designs of research can be primarily categorized in experimental and observational studies. A non-analytical or descriptive research does not seek to measure the relationship but attempts to give us an image of, for example, prevalence, effect or group experience, what is happening within a population. In description studies, case studies, qualitative studies and intersectional surveys are included that measures the frequencies and the extent of the problem and measure the frequency of several factors.

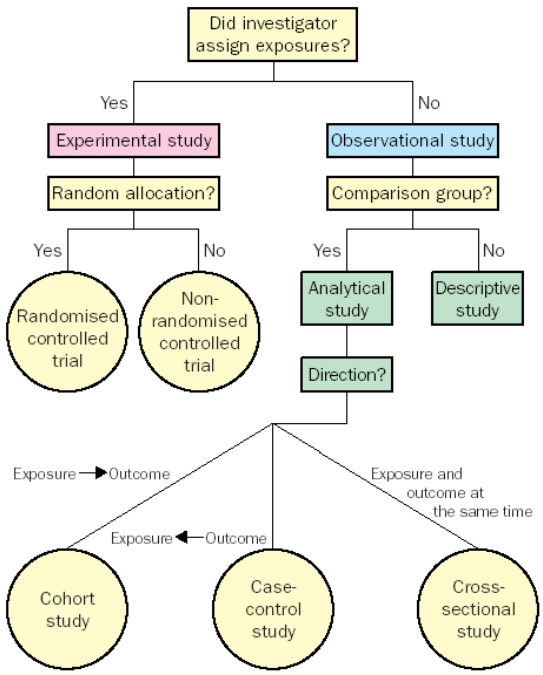

Fig 1: Framework of selecting a study design[7]

Observational studies investigate and record exposures (such as interventions or risk factors) and observe outcomes (such as disease) as they occur. Such studies may be purely descriptive or more analytical.

In analytic observational studies, the researcher simply measures the exposure or treatments of the groups. Analytical observational studies include case control studies, cohort studies and some population (cross-sectional) studies. These studies all include matched groups of subjects and assess of associations between exposures and outcomes.

An analytic study attempts to quantify the relationship between two factors, that is, the effect of an intervention (I) or exposure (E) on an outcome (O). To quantify the effect, we will need to know the rate of outcomes in a comparison (C) group as well as the intervention or exposed group. Whether the researcher actively changes a factor or imposes uses an intervention determines whether the study is observational (passive involvement of researcher), or experimental (active involvement of researcher).

The aim of an experimental study is to provide "scientific proof" of etiological factors which may permit the modification or control of those diseases. In experimental studies, the researcher manipulates the exposure, that is he or she allocates subjects to the intervention or exposure group. Experimental studies involve some actions, intervention or handling such as intentional application or removal of the suspected cause or the modification of one variable within the causative chain within the experimental group, with no changes in the control group, and observation and comparison of the results in both groups of the experiment. Such studies-controlled trials, particularly if randomised and blinded, have the potential to control for most of the biases that can occur in scientific studies but whether this occurs depends on the quality of the study design and implementation.

Spotting the Study Design[8,9,10,11]: A study design is a specific plan or protocol for conducting the study, which allows the investigator to translate the conceptual hypothesis into an operational one.

Study designs can be classified based on their aim or purpose i.e. to simply describe a population (PO questions) implies descriptive or to quantify the relationship between factors (PICO questions) implies analytic. For observational study the main types will then depend on the timing of the measurement of outcome, so our third question is: what is the time frame we are looking at?

In observational studies, scientists observe and gather data on some phenomenon that's already happening patterns of olive oil consumption, who tends to take vitamin D supplements, how much people exercise, and so on. But they don't intervene at all to change anything in people's lives; they merely gather descriptive information on habits, beliefs, or events.

With experimental research, on the other hand, scientists do intervene, or at least use statistical method to mimic intervention: they give some people a drug, they perform an operation on others. In the best-designed experiments, study participants are randomly divided into at least two groups: those who get the intervention (i.e., treatment) and those who don't (i.e., placebo). Random allocation ensures that the groups are statistically comparable with potential "confounding factors" equally distributed among them. The only difference between the groups is the intervention, which allows researchers to tease out what effect that intervention causes. Therefore, conclusions from experiments are generally considered to be more reliable and trustworthy.

Observational studies[7,12,13,14]: There are many different types of observational studies, but here are the four most common that you need to know about: cross-sectional surveys, cohort studies, case-control studies, and case reports.

"Cross-sectional surveys" take a random sample of people and record information about them at one point in time. This study describes a given population in terms of time, place, person and disease. The data collected from these surveys help in formulating a hypothesis

"Cohort studies" are just like surveys but they track the same groups of people over an extended period. Data are obtained from groups who have been exposed, or not exposed, to the new technology or factor of interest (e.g. from databases). No allocation of exposure is made by the researcher. Best for study the effect of predictive risk factors on an outcome. Cohort design is ethically safe; can be standardised in terms of time, direction and eligibility criteria. It is much cheaper than a RCT. But establishing controls can be difficult to identify and the disease can be linked to a confounding factor too. Blinding is not feasible in this study hence, ruling out bias is difficult.

The cases under study need to be uncommon and must be followed up for a long time. This can be a hassle as following large no. of patients for a long time is difficult.

"Case-control studies" are often called "retrospective studies." That's because researchers start with an end point and work backward, figuring out what might have caused that outcome. The study goes from "effect" to "cause". This study design is preferred for investigating very rare disorders or diseases with long lag between exposure and outcome. The study design is very economical and doesn't require a large sample size. A major drawback of this study is that it must depend on the records to determine exposure status, hence, selection of control groups is difficult and confounders and potential bias cannot be ruled out successfully

"Case reports" are basically detailed presentation of a patient's medical history. If a doctor writes up case reports about a cluster of patients with the same condition or disease, this is a "case series." Though these are considered the weakest kind of observational studies, they can still be very helpful for rare diseases and powerful for advocacy. This type of studies is helpful in hypothesis generation and can be informative for very rare disease with few established risk factors. Case reports cannot be used to study cause and effect relationships and can assess disease frequency.

From a single observational study, researchers will only be able to suggest whether there's an association between a risk like fat consumption and an outcome like heart diseaseand not that one caused the other. That's because the research participants were already eating fat or already had heart disease (or not) when the study began. What if people who eat lots of fat happen to be less health conscious? What if they are poorer and therefore more stressed? What if this group of fat-eaters just happened to be chubbier than those who stick to a low-fat diet? These things are called "confounding factors," or the difficult-to-predict variables that are associated with both the cause (e.g., saturated fat) and potential effect (e.g., heart disease) under study.

Experimental studies[15,16,17]: There are two basic types of experimental research. There are two basic types: randomized controlled trials and quasi-experimental designs. The gold standard of medical evidence is "randomized controlled trials" but it is not necessarily the best design for every research question. The reason they are so strong is because they are designed to disincline relationships between cause and effect; randomizations means treatment groups can be equated, and the only difference between them is the intervention (i.e. if the drug has been received or not). They are even stronger if these experiments are blinded. Blinding means either the students or the doctors or the two (double-blinded) do not know whether they are receiving the actual therapy or a placebo.

Lastly, there's a type of study design that lies somewhere between experimental and observational research: that's the "quasi-experiment." The prefix quasi means "resembling." Thus, quasi-experimental research is research that resembles experimental research but is not true experimental research. Although the independent variable is manipulated, participants are not randomly assigned to conditions or orders of conditions Because the independent variable is manipulated before the dependent variable is measured, quasi-experimental research eliminates the problem of directionality. However, as participants are not randomly assigned–probably, other conditions differ–quasi-experimental research doesn't remove the problem of confusion. So quasi-experiments are usually somewhere between correlational studies and real experiments in terms of internal validity. Quasi-experiments are most likely to be conducted in field settings in which random assignment is difficult or impossible. They are often conducted to evaluate the effectiveness of a treatment–perhaps a type of psychotherapy or an educational intervention.

Systematic reviews[18]: A systematic review summarizes the findings of carefully designed research (controlled trials) available and offers a high level of evidence on the efficacy of health care treatments. Judgments on the facts can be taken and medical decisions can be told.

These reviews address that problem of the single study puzzle piece. Rather than relying on just one person's experience or even just one randomized controlled trial, synthesized evidence draws on multiple sources and weighs their contributions to arrive at a more fully supported conclusion according to each study's rigor and relevance. This kind of research is regarded as the highest form of evidence and the best science to inform decision-making.

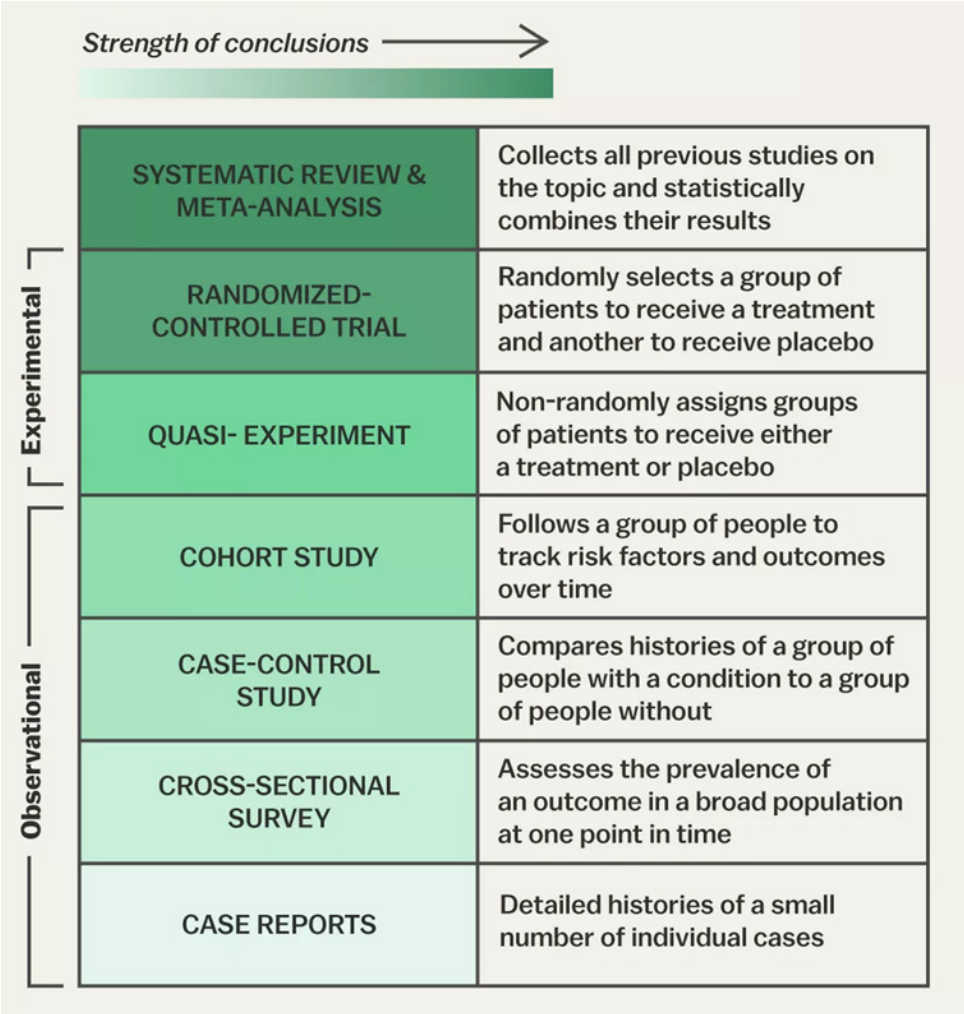

Fig 2: Hierarchy of evidence[19]

Advantage of selecting a good study design[20]:

Benefits of Study Design in Producing a Valid Result: A good study design strongly contributes to increasing different aspects of validity while adhering to the research question and previous literature. The main advantage of the study design in providing a valid result (the greatest validity in answering a given question) is avoiding systematic error. Further advantages may include the ability to rapidly conduct a study in a relevant environment and address issues of the effectiveness, as opposed to efficacy, of an intervention or diagnostic test. A fitting study design strengthens the internal validity while increasing the chances of a good generalisable result.

Resource Use, Size, and Duration: Available resources are never practically enough for conducting an elaborate research. Hence, a study designs helps one determine the needs of the population as well the research and allocate the available resources accordingly. Resources are not only expressed as finances but also as manpower, material/equipment required and the time of the investigators as well as the time allotted for the study. Randomized controlled trials (RCTs) can be very expensive, but large, simple trials have also been conducted for relatively modest costs; trials requiring only a short duration (communicable disease trials) are less expensive than non-communicable disease trials, which may need to be observe subjects for years. The size of a study depends on a variety of factors, including the expected number of outcome events occurring. The duration of a study depends on the anticipated accrual of recruited subjects, the incidence of outcome events, and the natural history of the condition studied.

Availability of Data and Ability to Recruit: This dimension assesses the likelihood that the study design

will be able to achieve the basic inputs (data or patients) required for launch. Data and recruitment are partially dependent on study design and partially dependent on the content area. For example, subjects are generally much easier to recruit into observational studies than intervention trials. FRN researchers may know of already existing secondary databases that might address an identified evidence gap.

Ethical, Legal, and Social Issues: This dimension deals with the external issues that could affect the feasibility or desirability of different study designs. Potential problems with ethical conduct of research are likely to vary depending on the content of the proposed measurement and intervention and the current standard of care and may not be a consistent feature of a study design.

These guidelines should be applied with flexibility to considerations of study designs for FRNs. The advantages and disadvantages of a study design may change depending on the study question or the setting. The resources required for a study design depend on the intervention proposed. The features of a specific FRN may make some study designs better suited under those circumstances. Considerations should include an understanding of the context of the research, including the condition or health policy being investigated, the existing body of evidence, and potential utility and quality of the data gained through different study designs. The urgency with which an answer to the research question is needed may be an additional ethical consideration in prioritization of research needs.

Conclusion

Appropriate selection of the design of the study is only one element of successful research. The selection of the design of the study should include consideration of costs, access to cases, identification of exposure, the epidemiological measures required, and the level of evidence currently published on the specific exposure-outcome relationship to be assessed. The review of appropriate published standards in the design of the study can significantly enhance the execution and interpretation of the results of the study.

A Guide for Selection of a Research Topic

Swati Patnaik[1], Shakti Swaroop[2]

[1]Senior Lecturer, Department of Public Health Dentistry, Institute Of Dental Sciences, Siksha O Anusandhan (Deemed to be University, [2]Senior Resident, Department of orthopedics, AIIMS Bhubaneswar

Abstract

The initial step in the research process is to select a research topic. A researcher needs to be aware that it is perhaps not easy to choose a good topic, as the topic selected must be restricted and steady enough to be interesting, and at the same time sufficiently broad for enough information. This article aims to shed light on the basics guidelines of choosing a good research topic.

Keywords: *Health Research, Medical Literature, Cochrane Reviews.*

Introduction

Research is a systematic investigation and study of materials and sources in order to establish facts and reach a new conclusion. 'Creative work is endeavoured on a systematic basis with a goal of increasing the knowledge base in every sphere including knowledge of man, culture and society, and utilizing this knowledge to develop new applications.' Research validates evidence to asserten the findings of previous work, to solve new or existing problems, to endorse theorems or to develop new theories.

A research project may also be based on past work or on existing literature in the field. Research may be conducted in order to test the viability of instruments, experiments or procedures, the research may reproduce the elements of previous projects or the project. Research should always aim to contribute something new to existing literature. Until diving into research, it is essential to know how to pick and develop a good research protocol.[1,2] The purpose of this article is to shed light on the basics guidelines of choosing a good research topic.

Factors affecting research[2,3,4,5]: Selection of a research subject may be motivated by incentive, need based or profit driven. The opportunity arises from the availability of funding, the prospect of engaging in joint international research and collaborating with the pharmaceutical industry. Work is often motivated by the accessibility of resources that may or may not meet local priority needs or the interest of scientists. Quality and quantitative work is becoming increasingly expensive, and additional funding is required to perform good research.

Health research funding can be given either from public sectors, as well as central/state governments and United Nations inter-governmental bodies, or from private sectors, counting in for-profit pharmaceuticals and non-profits, such as philanthropic foundations and non-governmental organizations. Public sector and the pharmaceutical industry are expected to be among the topprone to disease burdens in developed countries. The path for research and development in industry is underpinned by latest technological advances, which provide new guides for the development of novel drugs. Nevertheless, the market has an impact on the technological drive and thus on the prospects for study. Only a very small part of the industry's massive investment in research is related to the health problems of developing countries. Expenditure for industrial research is driven by market forces.

Health policy makers at national and international level would like to see work dictated by health needs, with a return on investment that can reduce the implications of

disease on their population. The importance of the health problem is measured by its prevalence and severity. A health problem may be widespread but not serious and vice versa. The fact that the health problem is prevelant does not necessarily mean that it should be a indicated for research. The solution for the health problem may already be present, but it is not implemented or made available.

A health problem may also be of great severity, and there may be a need for studies to fix it. Nonetheless, other questions need to be asked before it can be prioritized for analysis. E.g.: Is the question understood enough to consider looking into potential interventions? Is the development of new technologies needed to go forward? How economic are these approaches to be? Can they be produced early and at a ninimal expense? This may not always be the case.

Sources for research ideas come:

1. **Searching the medical literature:** In the first progress towards research development, medical literature should be read, including reviews that outline research gaps, take part in scientific meetings, and be active in teaching. Ideas are often conceived from talks and conversations and therefore discussions should be held with colleagues or advisors in the same or separate disciplines. A research scholar would have to know about the needs of research organizations, develop specific scientific fields, get new ideas, be a good observer and creative. Research should be selected by understanding that "science should not be admired but questioned."[6]
2. **Scientific literature:**

Open access: At the World Summit on the Information Society in Geneva in December 2003, open access to scientific information was prioritised. The Declaration of Printing has been adopted by delegates from 176 nations who pledged themselves to "having universal access to research, to developing and sharing scientific and technical knowledge with equal opportunities for everyone, including open access data publishing initiatives"[6]

Health Inter-Network Access to research Initiative (HINARI)[7]: Hinari's "Access to Science for Health Programs" offers local non-profit institutions in developing countries free or very minimal charge online to major newspapers for biomedical and social sciences. Hinari was started in January 2002, with approximately 1500 journals from 6 major publisher: Blackwell, Wolters Kluwer International Health & Science, the Harcourt Worldwide STM group, Elsevier Science, Springer Verlag and John Wiley. Since then, there has been steady increase in the number of participating publishers and journals and other complete articles. In Hinari, up to 160 publishers ' contents are available, and many other publishers join the program. The publishers are financing WHO for training librarians in using HINARI. Improved functionality has provided a connection to the HINARI journals from PubMed (the database for the United States National Library of Medicine).

Eastern Mediterranean Region Virtual Health Sciences Library[8]: The Eastern Mediterranean WHO Regional Office has initiated to link libraries in the region to a virtual network. The Network's aim is to make the fullest scope of health and biomedical literature available and/or open to potential users throughout the area in an economical manner. The internet, which is now in most Member States in the region, enables the network to operate as a virtual network.At present, most of these journals are not internationally indexed or abstract. Local health and biomedical literature were mapped in order to increase coverage at national, regional and global scales. The Medicus Index is a powerful resource to index, review, track, preserve and share information on local health.

PubMed central[9]: This initiativetaken up by the United States National Library of Medicine (NLM), gives free online access to the full text of articles on Medical research. PMC acts as an electronic complement to the vast print journal archive of the NLM, in compliance with NLM's statutory obligation to preserve and conserve the biomedical literature. The NLM National Centre for Biotechnological Information (NCBI) was established and is managed by the PMC. It offers free access to peer-reviewed primary life science research reports and gives the international scientific community and users in general the freedom to search the literature of life sciences and to findentire reports of research free of charge n not merely the titles and abstracts.

CochraneCollaboration[10]: CochraneCollaboration is an international organization that focuses on helping people to make sound healthcare decisions and health policy through the preparation and retention of systemic reviews of high quality. It's a "non-profit organization that relies heavily on volunteer work."One cannot pay

for Cochrane membership; they have to earn it through participating in our work. Contribution to the work of The Cochrane Collaboration may include:

- Systematic review as the part of a team
- Provide editorial support for a Cochrane Review Group acting as a support group in advocate of evidence health care and the work of the Cochrane Collaboration
- Provide training for review authors or editors, or users or other researchers; Cochrane Fields include health care such as child health, complementary medicine, vaccines or primary care. People associated with Fields help to ensure that priorities and outlook in their area of interest are reflected in the work of CRGs.

Index Copernicus[11]: It is an online database of information provided by users including profiles of scientists, scientific institutions, publications, and projects established in Poland in 1999. The database includes several tools for productivity assessment that allow the impact of scientific works and publications, researchers or research institutions to be tracked. The Copernicus Index also offers the traditional abstraction and indication of scientific publications in addition to the productivity aspects. The Copernicus International Index operates the database.

Criteria for a good research topic[12,13,14,15]:

Feasibility: The study population required to answer the research question should be able to be recruited within the scheduled research framework. Equipment supplies and other research requirements should be available for the research establishment of investigators. Researchers need the expertise they need. Research costs must be cost-effective, and resources should be available. There should not be too many or too ambitious research goals. The development of the study program should always be focused on a single primary objective. This can be complemented by secondary targets that can also generate rational findings.

Significance to the discipline: A problem selected by the researcher should be of importance to the profession or discipline. When a discipline develops or perfects the professional knowledge body, a research problem is important. Some of the criteria to evaluate the importance of a profession are as follows: The research findings benefit the consumers/interested parties. This will enhance current practices. Encourages theory or testing. Facilitates solutions to current needs in practice. Generate information for the profession to have practical implications.

Originality: Every investigation should be new and unique. It is therefore up to the scientist to use innovative knowledge to select a research issue in order to increase the growth of existing knowledge within a profession.

Peer support: Many research ideas have failed because the researcher did not receive any peer support. A climate of shared interest among the professional members promote research activities smoothly.

Availability of subjects: In some cases, potential subjects may not meet the study criteria or may not be willing to participate in the study or may already be a part of other studies. The availability of subjects should therefore be well ensured in advance.

Researcher's competence: A research problem can only be workable if it is in accordance with the competence of the researcher. A researcher should be able to deal with a specific research issue. A new research scholar should not attempt taking up topics which require substantial experience as well as knowledge. A person needs to get acquainted to the idea of the research first and then dive into the vast field of research.

Current: A good research problem must be based on the current challenges and needs of the profession. The result generated will therefore be of more use. In addition, more professionals will be interested in the research carried out on the current issues of their profession.

Interesting: The research problem must be the motivation of the researcher, and it should be fascinating for the researcher. Research will therefore be conducted with full enthusiasm, and not just for its achievement. The investigators should be personally interested and must be able to allure colleagues towards the subject or else the project may not be worth doing.

Clear & unambiguous: The research issue selected should be clear in its ability to reflect or provide guidance on the various aspects of the methodology. The research problem chosen to be investigated should be subject to a scientific inquiry. Research should be verifiable by means of scientific calculations.

Relevant: The research problem chosen to be investigated should be relevant to the profession, time, need and competence of the researcher.

Systematic: The research problem should be systematic- in the sense the researcher should have arrived at the problem statement following relevant selection parameters or criteria. To do so, write the research theme as a declaration of the purpose of the study. The statement will usually be one or two sentences that states precisely what is to be answered or proven, in relation to the research theme.

Ethics: Some ethical issues must be addressed at the early stage of selecting the research topic while other need to be addressed during planning the research and some ethical problems may indicate that the research should not be considered from the beginning.

Conclusion

A thorough understanding of what research is and following the steps of selecting a good research topic methodically is essential to lay down a strong foundation for research. A researcher needs to remember that if the selection of a research topic is not good then it will lead to failure of the entire protocol, no matter how strong the study design is.

Retreatment of Root Canal Failure, Possible? A Review

Debkant Jena[1], Siba Prasad Jena[2], Sumit Dash[1]

[1]Professor, [2]Senior Lecturer, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha India

Abstract

The main aim of endodontic treatment was to eliminate the bacterial load from the canal by mechanical, chemical preparations and three dimensional obturation of the canal. There are various factors which are responsible for endodontic failure, different root canal system, presences of addition canal or lateral canal, over obturation. The aim of this review article was to how to manage these retreatment cases and prevent root canal failure cases.

Keywords: *Retreatment, Bacterial infection, Root canal treatment.*

Introduction

Retreatment procedure is performed on that tooth that received an earlier attempt of root canal treatment but fails due to bacterial, iatrogenic factor that resulted in a condition requiring additional new endodontic treatment to achieve a successful outcome.[1] The Rass et al., hypothesized that the main cause of treatment failure depends on insufficient cleaning and inadequate obturation.[2] Lack of biological-technical-scientific base is one of the commonest cause of Endodontic failure. Many general practitioners venture in the area and the rate of failure within this group is quite high about 98.0% according to Leonardo. For successful endodontic retreatment there should be proper cleaning of root canals, so clinicians should pay special attention to the technique used for removal of theobturation material, the most used being cements, pastes and guttapercha points.[1,3] In retreatment we have to reach the actual working length and completely remove the obturation material, thereafter cleaning the root canal and proceed with the final obturation. Several techniques are used for the removal of gutta-percha including rotary instruments, manuals, solvents and their associations.[3] The aim of the present review article was to evaluate, through a literature review, the endodontic retreatments with rotary and mechanical files, which is the best efficacy.[4]

Factors Responsible for Endodontic Failure: Endodontic procedures are high chances of success as compare to the other disciplines if done with proper protocol. For successful endodontic procedure you know the mechanisms of root canal failure, these have been classified in three phases.[5]

Pre-operative factors responsible for endodontic treatment failure

1. Poor diagnosis
2. Tooth fracture cases
3. Medically compromised patients
4. Pt was not willing to sign consent from

Factors that involves in during the endodontic procedure

1. Missed lateral canal
2. Formation of ledge at the middle third of the root
3. Peri-apical infection
4. Periapical extrusion of chemical irrigations causes swelling and sever pain.
5. Over obturation or incomplete obturation
6. Apical extrusion derris's

7. Breakage of endodontic file

Diagnosis of Endodontic Failure:

Clinical Examination: For clinical examination, we look for periapical area of redness or pain by pressing the apical end of the tooth, other signs that indicate retreatment procedure are swelling, Spontaneous pain, pain on biting.[6]

Radiographic Findings: In failure cases we seen widening of lamina dura, radiolucent area associated with respected root. Intraoral periapical radiographs play an important role to detect any endodontic failure. [7]

Rationale for Retreatment: Proper knowledge of root canal anatomy of every tooth plays a significant role in endodontic success or failure. There are chances of 2 to 4 accessory canal present in the tooth that communicate with the surrounding periodontal fibers, and an important source of infection if left untreated. One of the most important factors responsible for root canal failure improper coronal sealafter completion of root canal treatment other important factor is leakage of sealer and bacterial contamination. In most of the case retreatment correct the pain and other symptoms if it re-occurs frequently extraction will last choice of every dentist.[8.9]

Endodontic Mishaps and their Prevention:

1. **Access cavity perforations:** During the access opening perforation in the furcation area was irreversible complication

Diagnosis: Continuous bleeding, leakage of saliva and other chemical.

Treatment: After completion of root canal obturation perforation repair was done with any of the following material like GIC, gutta- percha, calcium hydroxide paste, MTA gives best results as compare to other perforation repair materials.[10]

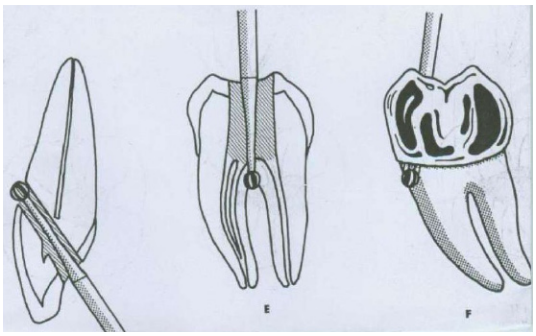

Figure 1. Perforation

2. **Missed Canal:** In most of the case of maxillary first molar MB2 canal was not find, and missed by undergraduate students because not easily accessible or readily apparent from the chamber.It can be found in different x-ray position or by the endodontic probe. The treatment of missed was endodontic retreatment.[11]

Figure 2. Missed Canal with Post

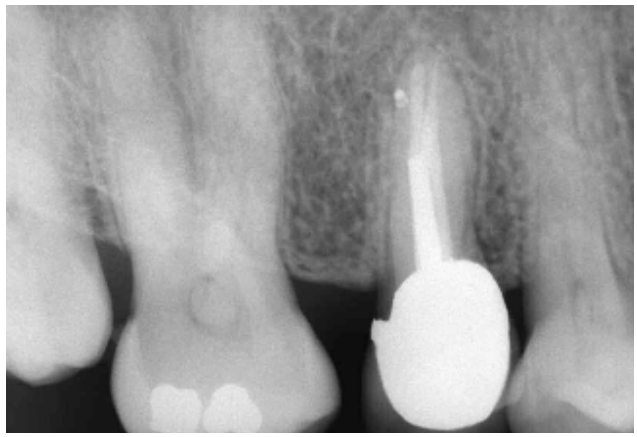

Figure 3. Retreatment

3. **Separated Instruments:** Long term use of same files may cause losing in the flutes of file in the canal we apply the extra forces it may lead to breakage in the canal. It can be seen in radiograph, small size blunt tip. Treatment protocol will be different in each case if the file will break on access opening area, we try to remove with the ultrasonic tips and enlarge the size of the canal. If file break in the middle third we have by pass with the smaller file after by passing the file we will obturation done. If file brake outside the canal, endodontic surgery will be done.[12-15]

Figure 4: Separated Instrument

Conclusion

This article has identified a variety of techniques to successfully retreat endodontically failing teeth. It should be recognized certain endodontically failing teeth are notamenable to successful retreatment. In these instances,the various interdisciplinary treatment options can bethought fully considered to ensure each patient is best served. However, as the potential for health associated with endodontically treated teeth becomes fully appreciated,the naturally retained root will be recognized as the ultimate dental implant.

Special Child Management in Dentistry: An Overview

S. Kaustuv Kanta

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Dental treatment of the special children is mostly given at least priority by parents or dentists which is a real pity for society. The term disabled child is often added to their innocent identity only because they are impaired daily activities in some fashion. Thereby these handicapped children can be divided into medically compromised & developmentally disabled children. These children seek our help, so they can establish them self in front of the society well. They are even unaware what is importance of basic oral health care. Despite opening new windows for them may dentists are unwilling to treat them as patients. This may be due to many reasons like lack of knowledge about their symptoms, unfamiliarity with the measures to treat these kinds of children, who took an initiative in the year of 1981 for special children.

Keywords: *Dental treatment; special children; compromised & developmentally disabled children.*

Introduction

World Health Organization (1980) defined a handicapped person as one who ever an appreciable period is prevented by Physical or mental condition from full participation in the normal activities of their age groups including those of a social, recreational, educational & vocational nature. Primarily, these patients should be evaluated by the dentist, what are their dental needs & his/her ability & willingness to accept any sort of procedure. Management techniques must be TLC (Tender, Lavin, Care). empathy; the ability to understand & sense the fears of another w/o differencing one's from others. With the handicapped patient it may be a four way or 5-way professional relationship i.e., head of the residential special school. Brief clinically first requirement in their comprehensive treatment. The according person role is to take decision about the treatment plan required. The dentist's attitude should always be positive, but most it is Negative because lack of equipment. [1,2]

- Lack of patient to treat such type of patients.
- Substandard fees.
- Fear of law and order.

Management of Developmentally disabled child: Mental retardation Is known as the low intellectual development than that of normal people & least fit to the environment. It is calculated be well known formula.[3]

Mental age/Chronical Age x 100:

- The IQ guide gives as gradation of children from very superior to mentally retarded having IX above 140& 69 respectively.
- Mental retardation never be ignored than any fatal disease.
- The special children may present with anomalies of fungal structure delayed eruption,anodontia, enamel hypoplasia, malocclusion, multiple carious feet.

T/t:

- Comfort the mentally retorted child to the clinic atmosphere, very low & simple with the patient.
- ISD&TLC measures helps in mild cases & anesthesia in moderate cases.
- Only day appointments are preformed & it should be kept as short as possible.

- Permanent restriction should be done in multiple appointments.

Down's Syndrome (Trisomy 21): Late pregnancies, uterine & placental disturbances & chromosomal aberration can cause this disease.[4]

Features:

- Round skull resulting in a flattened just interior to posterior fontanelle.
- Oblique palpebral fissures with permanent epithelial fold.
- Scanty eyelashes.
- Dysplastic ears with abnormal pinna.
- Neck- short & broad with excess skin posteriorly
- Short little finger, IQ level within 25 to 50

Oral Manifestations:

- Small dropping month, fissured tongue, Macroglossia.
- Dry & fissured lips, Class-II tendency, short maxilla.
- Bifid uvula, cleft lip & palate.
- Nitrous Oxide analgesia or TSD in mildly apprehensive patients can be used chlorhexidine can be prescribes.
- Pulp treatment in milk tooth is restricted in patient with involved in understanding or using spoken or written language.
- Minimal brain injury damage to CNS can be a cause.[5]

Cerebral Palsy: It is a non-progressive lesion which occurs is any stage of child birth. Number of neuromuscular defects can occur in the child paralysis improper co-ordination & balance, unregulated gait, involuntary muscle control.[6]

Cause: Decrease in oxygen supply during child birth to the brain.

- Complicated pregnancy, Heavy metal & drugs poisoning nearly birth than normal IUL.
- Spastic cerebral palsy is the condition in which child has motor tone increased & restricted limb moments, Short maxilla & mandible, mouth breathing etc.

Athetosis:

- Study says it occurs in 15% children.
- Bull neck is a characteristic feature. Tongue protruding, peri-oral muscles hypotonic with mouth breathe.
- Aburt closing of jaw or bruxism in high rate.

Ataxia:

- Less common variant.
- Slow movement is characteristic features.
- Eyes are chance of risk.

Epilepsy: Any abnormality in the electrical activities of brain can cause chronic, recurrent changes in cerebral functioning known as epilepsy. The single episode of incidence is called seizure.

Causes:

- Idiopathic or symptomatic
- Brain malformation or injury during pregnancy.
- Genetic factor is also responsible.

Classification:

Scrums are broadly classified as:-

i. Partial seines: simple partial slimness

   Complex partial

ii. Primary generalized seicums:

   Grandmal epilepsy

   Petitmal epilepsy

   myoclonic seizures

iii. Status epileptics:

   Most commonly children suffer from primary generalized seizures.

   Characteristic: Characteristic of absence seizures.

- Patient stops continuing work suddenly & loss postural control.
- Urgent integrals of consciousness. Which lasts only for sometimes.

6-14 years are mostly affected eyelids roll upward &distortion of face occurs when seizures comeuninformingly.

- After 10 to 30 seconds the toxic phase is followed by a clinic phase of several minutes. Where in severe muscle contraction occurs with increased rate of sweating.

When the seizures symptoms cease child goes to deep sleep.

Precautions: Phenothiazenes promote seizures so should drugs are restricted.

- Dental chair light should be turn off while treating such patients.
- diazepam is the drugs of choice for sedation if necessary.
- Vegabartin, lamotrigine, gabapentin & topiramate are drugs available for treatment.
- Dilantin sodium used in treatment of seizure before caused gingival hyperplasia.
- Dentist should make the chair position supine if it occurs during appointment Tongue blade should be Placed to avoid injury of tongue & scalpel like sharp objects are kept away from the patient.
- Proper airway should be maintained. O_2 supply should be maintained. Take the patient to nearby hospital if situation gone out of control.[7]

Deafness & Blindness:

Causes: Viruses like rubella & influenza, ototoxic drugs, elemental syphilis.

Injury to features during pregnancy, toxemia in late pregnancy in appropriate Oxygen supply to features.

Treatment: Sign languages can help to communicate with the patients.

Tell show do techniques applied to create better communication with children.

Management of Medically Compromised Patients:

Heart disease: 2 types of diseases can be there i.e. 1) Congenital 2) Acquired.

Cyanotic & cyanotic congenital heart disease are two types of congenital variant depending upon .

Cyanosis: A trial, septal & ventricular defects in which shunting of blood from left to right in heart.

- Cyanosis just vice versa i.e. right to left shunting of blood within heart.

Causes: Viral infections, metabolisms errors, Genetic feature.

Acquired Heart disease: Eg- Rheumatic fever, infective bacterial endocarditis

Infective bacterial endocarditis:

- Microbial colonization of endocardium.
- Acute phase responsible for species like streptococcus, staphylococcus, Pneumonia.

T/t:

- Consultation with cardiologist is must prior to any surgical procedures.
- Preventive treatments are preferred
- Antibiotic therapy has major role in treatment.
- Detailed clinical history is required.

Diabetic Meaitus:

- Children it is considered to be most common endocrinal disorders.
- 2 forms
  i. Insulin dependent diabetes mellitus.
  ii. Non insulin–dependent diabetes mellitus (NIDDM)

T/t:

- Early morning appointments are preferred for these patient & patient is asked to do prior screening tests.
- In type I. insulin can be administered.
- If the patient shows following symptoms like excessive sweating, Irritation, Nausea, Tremors, Sudden decrease in body temperature then stop all the procedure.
- Insulin overdose can lead to insulin shock. [8]

Management:

- Oral carbohydrates orange juice & candy are given .
- Dextrose IV (50ml in 5% concentration).
- Glucagon in (1 MG) followed by in epinephrine 10.5 mg of 1: 1000 concentration).
- If the patient does not respond after 5 minutes emergency procedures should be initiated.

Astha:

- Persons airway narrower, inflamed & produce extra mucous causing difficulty in breathing.
- Dyspnea, cough & wheeling are common clinical feature.

Causes:

- Allergy to dust or any other substances can lead to this condition, even atmospheric condition has a significant role.

T/t:

- Brief clinical history.
- Patient is allowed to sit in upright posture.
- Drugs like aspirin, NSAIDs are contra indicated.
- Procedures can be done under general anesthesia if necessary.
- Nitrous–oxide sedation is mostly preferred.
- 0.3 ml of epinephrine can be administrated in sudden attack of Asthma.

Autism: Mental& emotional balance is disturbed in such kind of patients, causing difficulties in social activities of life.

Discussion

India has 12 million children living with disabilities, and only 1% of them have access to school. About 80% of children with disabilities do not survive past age 40. Many conditions such as mental retardation, developmental disabilities, cerebral palsy, craniofacial abnormalities, and seizure disorders can impact a child's oral health. Children with SHCN generally have increased prevalence of poor oral hygiene, compromised gingival and periodontal health, and increased prevalence of dental caries than the general population. Dental diseases and its treatment present several problems in this group of patients. These children may not understand or assume responsibility for preventive oral health practices. Many caregivers do not practice appropriate oral hygiene or choose a proper diet. Their parents also have the burden of medical treatment. They usually do not seek dental treatment. Moreover, the importance of dental care for these children has often been overlooked by the health planners.

Conclusion

In recent years, the dental profession has shown increased concern in providing complete oral health care to the mentally- or physically-challenged children. The specialty of pediatric dentistry provides both primary and comprehensive, preventive and therapeutic oral health care to children with SHCN. These special children are entitled to the opportunity to achieve appropriate rehabilitation, to enable them to realize their maximal level of functioning, and to assist them in not only "normalizing" their lives but also lengthening their life span.

Rampant Caries in Adolescents: A Review

Ghanashyam Singh

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Rampant caries is a common destructive and intense progressing nature of carious infection. The supervision of these problems assists one of the most challenging activities under several dental offices because of the weight and huge chance of recurrence. Some initial investigation concerning this infirmity and testimony of the hazard agents permits specific key of the condition including avoiding constant, careless and offensive operative method. Besides these common protective plans, the application like some dental unit should think upon securing the victim knowledgeable regarding the unique chance factors moreover adapt his performance and view towards systemic moreover oral health. Here continues some performance of the status concerning an adolescent outpatient among rampant caries, which explains the particular complexity of the pathogeny also the aggregation of determinants associated under the etiology of the condition.

Keywords: *Rampant Caries, Tuberculosis, Economic State.*

Introduction

None particular patterns of examination, "rampant caries" holds a state that nearly every practitioner becomes faced throughout the modern ages.[1] Toward adults the session normally assigns a dynamic and quickly proceeding kind of caries epidemic including various teeth moreover including teeth and surfaces such denote habitually on a reasonable prospect of caries. There are various movements following the encounter and succession regarding rampant caries in youngsters and adolescent. In most states some variations in psycho-social development yield dietary remodelling's and seldom degeneration of sanitation.[2] Most of certain young adults cannot yield a precise strategy and specific health policy-related toward dental approach is negative supportive for those victims following the period of eighteen. Within the recent age, some of certain patients force to be pretended via systemic sicknesses that people denote not conscious about our attempt to protect because they hit scared to be discarded because of that. The rising amount regarding such events and some importance of significant injuries demand that any dental practitioner should understand how to evaluatea comprehensive investigation and recognize the prospect parts of the form under succession to establish the defensive and healing approaches ready to regulate the illness. The analysis of these patients should rely on completely including precise selection and relationship of each accessible report given by patient records, hazard estimation, clinical review, x-rays, and adjunctive examinations.[3]

Review of Literature: Our victim owned particular chance factors that could remain correlated including caries. These alterations during familiar world existed like to generation (adolescence) and the immigrant situation, both states producing toward tremendous anxiety, improper nutrition, inadequate cleanliness, absence of interest during personal well-being, and reduced path toward dental and therapeutic applications. Each predominance regarding rampant caries in evolved nations is 1.12% while in emerging nations including disadvantaged communities within devolved nations, special currency may approach 70% of preschool adolescents.[3] Indeed, externally leading toward attention to the socio-economical situation

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: ghanashyam7827@gmail.com

which strength do a questionable effect,[3-5] immigrants are supposed to remain a long chance collection. Meanwhile adolescents and young adults, occasional exchanges of psycho-social agents can regularly happen compared among qualifications of intake or oral fitness routine exercises. Certain variations may appear during an imperfect nutrition, usually relying upon toward food that means accessible, simple and quick to arrange. Special dietary alteration may enhance further exceptional to remineralization agents to equalize these demineralisations difficulties. Periodic loss of extremely sweetened carbonated refreshment significantly boosted this venture of helping dental caries.[6] In that state the loss of carbohydrate liquids including sugar also caffeine mixture continued added chance factor for rampant caries because of addictive potential associated with sugar including use as stimulating moreover refreshing food. During the inadequacy of severe systemic condition,rampant caries remains a symptom of severe flaws of nutrition. Some salivary bacterial analyses established the principle that intake remained the main hazard part. While some numbers of salivary mutants streptococci show significant levels of bacterial immigration on teeth, preparing relevant predictors of caries prospect, lactobacilli numbers last un fit during caries foresight, however, they continue notice regarding cavitation, of sugar consumption, plus oral health standing, implying essential during the estimation of victims including rampant caries. Sufferers among tuberculosis may encounter xerostomia and/or salivary gland inflammation, including granuloma or cyst form in the altered glands.[7] Temperature, vital falls of weight also vomiting added on salivary debt and reduction of the oral pH. Certain meaningful changes in the oral conditions could appear under active choice of acidogenic bacteria and diminished capacity of protection, buffering furthermore remineralization mechanisms.[8]

Treatment: The removal of rampant caries remains fulfilled within restorative treatments that comprise the elimination of the infected part of the tooth-supported with the induction of cement to restore the tooth. If too much regarding tooth continues lost into rampant decay, the dentist may prefer to set a crown on the tooth to preserve the tooth.[9] The rehabilitation selection is conditional upon how much of the sound tooth persists including where the tooth exists. Despite the time, the special diagnosis for patients who possess rampant caries is subordinate in their readiness to alter their practices. Nutrition differences, enhancing oral hygiene plus accepting to your dentist's guidance are helpful in producing sure their mouth endures healthful post-treatment.[10]

Conclusion

In adolescents and young adults, the development of psycho-social parts can be united including poor nutrition and unwanted oral health. Still in adolescent cases, report regarding pharmaceutical records and existing status maybe really necessary toward identifying systemic hazard circumstances to rampant caries. Migration influences now un unique in adults but additionally youngsters plus adolescences and well-being management should think these inmates in sessions of estimation including restriction of dental medicine. During this arrives to rampant caries, the purpose concerning the dental unit should concentrate not only on negotiating specific lesions yet including the initial analysis of the situation and description regarding these jeopardies.

Effect of Informational Support on Quality of Life among Pregnant Women with Antiphospholipid Syndrome

Fatma Zaghloul Mahmoud[1], Yousria A. Elsayed[2], Abeer S. Eswi[2], Rania M. Abdel Ghani[3]

[1]Assistant Lecturer, Maternal and Newborn Health Nursing, [2]Professor, Maternal & Newborn Health Nursing, [3]Assistant Professor, Maternal & Newborn Health Nursing, Faculty of Nursing, Cairo University, Egypt

Abstract

Antiphospholipid syndrome is a disorder of the immune system that is characterized by excessive clotting of blood and adverse pregnancy outcome which affects negatively on women's quality of life.

Aim: Evaluate the effect of informational support on quality of life among pregnant women having antiphospholipid syndrome.

Design: Quasi- experimental design (One group only pretest – post test design) was adopted purposive sample of 43 pregnant women with antiphospholipid syndrome.

Setting: The high-risk pregnancy department at obstetrics and gynecology Cairo University Hospitals. Two tools of data collection were used: an interviewing questionnaire, the Arabic version of World Health Organization Quality of Life Questionnaire.

Results: There was improvement and a highly statistically significant difference between the perception of pregnant women as regard to rating their quality of life and health satisfaction before and after informational support; the social relationships domain, presented the highest mean score (13.64±3.32) was assessed as the domain with the best perception of QOL and the environment domain was associated with the lowest score (8.56±2.56) considered the worst perception of QOL there was a better perception of quality of life physical and environmental domains after informational support.

Conclusion: Before the implementation of informational support, the worst QOL domains were environmental then psychological domain, while after informational support there was an obvious improvement related to environmental and physical domains.

Recommendation: Implement informational support as a part of nursing care protocol in high risk pregnancy department.

Keywords: *Antiphospholipid syndrome, quality of life, informational support.*

Introduction

Antiphospholipid Syndrome (APS) is a systemic autoimmune disease which is characterized by recurrent arterial, venous thrombosis and pregnancy morbidity such as recurrent abortions, fetal losses[1]. It is classified into primary and secondary APS[2.] Worldwide statistics have shown that the prevalence of APS in the general population ranges between 1% and 5%. While in Egypt no accurate incidence represented, but according to Rawhya, et al, 2016, the rate of fetal loss in Egypt among pregnant women with APS may exceed 90% in untreated women[3].

The cause of APS is unknown although there is evidence that genetic, environmental influences and a variety of infections have been implicated as potential

inducers of APS[4]. APS affects young women, in the most productive years of their life, and the consequences of tissue damage involve disability, limitation in activities of daily living, cognitive dysfunction, and fatigue. In the case of pregnancy complications, emotional and psychological distress reflected as to impair the mental domain in quality of life (QOL)[5].

Significant of the study: Improving QOL can be in term of knowledge of the disease which involves information about the causes, exacerbating factors, symptoms, and available method of treatments and consequences about the disease; all these have been shown to facilitate adaptation to a chronic disease and improve physical, psychological, and social functioning. Even though previous studies already been conducted in the field of QOL of APS, the knowledge gained in this field in the Egyptian context is still very limited, so this study conducted to evaluate the effect of informational support onQOL among pregnant women having APS.

Hypothesis: Providing informational support to the pregnant women with antiphospholipid syndrome may improve QOL

Materials and Method

A purposive sample of 43 women with APS was recruited for this study. The sample was calculated using power analysis (G power version 3.1.1) with a power of. 95 (β = 1-.95 =. 05) at alpha. 05 (two-sided) was used as the significance level, and large effect size= (.05)

Inclusion criteria: Criteria for inclusion were any pregnant woman who had one or more pregnancy losses associated with APS either primary or secondary; at any reproductive age

Tools for Data Collection

Two tools were used:

A. **An Interviewing Questionnaire:** It included data related to (a) socio-demographic data (b) past and present obstetric history; (c) medical history, (d) menstrual history.

B. **(WHOQOL-BREF):** It is a short version of the world health organization quality of life 100- scale instrument, it contains 26 questions; two general and the other 24 questions in the domains of physical health, psychological health, social relations and environment domain. It is a likert scale of 5 degree. The Arabic version of WHOQOL-BREF translated by Awadalla, & Jude, 2009 has been shown to display good discriminant validity, content validity, and test-retest reliability[6]

Procedures

Interview Phase: Each woman was interviewed to collect data related to socio-demography, obstetric, medical, and menstrual history; also an assessment of pregnant women quality of life using The WHOQOL-BREF questionnaire. The interview lasted for about 25-35 minutes for each pregnant woman.

Second phase: Included providing informational support to pregnant women having APS; the researcher met the woman four times per month (once weekly). Session duration ranged from 15-25 minutes. The first session contained the definition, classification, and the effect of APS on health; the second session contained diagnosis of APS, screenings and risk factors; the third session contained early reporting for danger signs, utilization of medical treatments; information about heparin, the fourth session contained promoting healthy behavior through better adherence to appropriate diet, physical activity recommendations

Third phase: Each pregnant woman was interviewed to assess QOL. The duration of the interview ranged from 15-25 minutes.

Results

I. **Description of the Pregnant Women according to their Sociodemographic Data:** Results indicated that, the pregnant women age ranged from 20 to less than 45 years old, with a mean of 31 years old. The highest percentage (34.9%) was in the age group 30 < 35 years while the lowest percentage (7%) was in the age group 40 < 45 years. moreover, 51% of them lived in rural areas. As for occupation, 83% were housewives. In addition, 88% of them reported that they had not enough family income (**Table 1).** As regards the level of education, less than half of the pregnant women completed their technical/ secondary education, more than one-quarter of them 18.6% can read and write, and 14 % completed their university education (Figure, 1)

II. **WHOQOL-BREF before and after informational support:**

   A. **Description of the overall QOL and the perception of their health before and after informational support:** Results revealed that

20.9% of the pregnant women rated that their overall QOL were good compared to 32.6% after informational support. In relation to how pregnant women were satisfied with their health, 20.9% perceived that their health was good compared to 32.6% after informational support. There was improvement between the perception of pregnant women as regard to rating their QOL and their health satisfaction before and after informational support. Also, there was a highly statistically significant difference between the items of rating QOL and the items of health satisfaction before and after informational support (Table 2).

B. **The relationship between the four domains of QOL mean scores (physical, psychological, social, and environmental)before and after informational support**

The results indicated that the social relationships domain, which presented the highest mean score (13.64) was assessed as the domain with the best perception of QOL and, the environment domain, which was associated with the lowest score (8.56), was considered the worst perception of QOL. After informational support a significant difference (P < 0. 05) was identified in the Physical, and environment domains which leads us to conclude that there is a better QOL perception in these domains (table 3).

Table (1): Distribution of pregnant women according to their socio- demographic characteristics

Socio-demographic data	N = 43	%
Age		
(20-<25)	5	11.6
(25-<30)	13	30.2
(30-<35)	15	34.9
(35-<40)	7	16.3
(40-<45)	3	7.0

Table (3): Mean scores of QOL for the four domains among pregnant women having APS before and after informational support

Domain	Informational support		Wilcoxon test	
	Before	After		
	M±SD	M±SD	Z value	p- value
Physical health	11.77±2.32	12.03±2.18		.022
Psychological	11.64±2.32	12.03±2.25	-1.516	.129
Social relationships	±3.32	13.45±3.26	-.715	.475
Environment	±2.56	10.36±2.12	-5.247	.000

Discussion

The current study results revealed that there was an improvement between the perception of pregnant women having APS as regard to rating their QOL and their health satisfaction before and after informational support. Also, there was a highly statistically difference between the items of rating quality of life and the items of health satisfaction before and after informational support (p-value < 0. 05). This result may be the information provided to women which consequently changed their attitude which become positive toward better pregnancy outcome.

Also in Egypt the health care providers have no time to give the women any information about the disease specially when the mother follow in the governmental hospital due to the flow rate of the women; Also lack of nurse's knowledge regarding the APS. So, providing information for pregnant women with APS about illness and its treatment, caring, being present, communicate all kind of this support provides the patient with the sense of normality in their life, support also affect the mental balance, sense of relief, decrease fears, anxiety, stress, increase in women satisfaction through increasing their knowledge and their ability to cope all this might affect health-related quality of life

This result similar to the study finding's of Georgopoulou et al, (2018) who studied The relationship between social support and health-related quality of life in patients with APS, and concluded that social support in the form of emotional, instrumental and informational support was linked to improving health-related QoL, and perceived informational support through provision of disease-specific education was highly statistically difference with physical, social functioning and vitality domain of QOL (p = .05, p=.02, p=.01 respectively)[7]

In the current study findings, The highest mean scores were for the social relationship 13.64 ± 3.32 and the physical 11.77±2.32 then psychological domain 11.64 ± 2.32 and mean scores were lower for the environment domains 8.56 ± 2.56 which contains questions about (safety life, physical environment, financial state, information, living place, health services, transport). The lowest mean score was for the psychological domain and environmental. This may due to, the economic burden that the women suffering from the expensive treatment and the low level of the information that the women had, also the low score of the psychological domain, This may due to the threats and the pregnancy complications that the women faced due to this disease. the highest score for the social relationship may be due to the social context of the Egyptian culture in which people enjoy strong social relationships and family connection.

The previous findings also supported by Georgopoulou1 et al (2018)[7] who described the health-related quality of life (HRQoL) for people with APS, and concluded that QOL in better in physical domains, but poorer in psychological domains. While Alba et al, (2016) who assessed organ damage and quality of life in antiphospholipid syndrome, clarified the presence of low scores in the physical and mental health domains [5]

The current result revealed that, there was a better QOL perception in the physical and the environmental domains after providing informational support for the women having APS, as there was a statistically significant difference (p < 0.05) before and after informational support regarding those domains. This result is similar to the study of Reis, and Costa (2010) who evaluated the quality of life (QOL) of women with systemic lupus erythematosus (SLE) and the association between QOL domains; and detected a significant difference (P < 0.05) in the physical, psychological, and

environment domains, when confronting QOL domains with education about SLE[8].

Conclusion

Before the implementation of informational support, the worst QOL domains were environmental then psychological domain, while after informational support there was an obvious improvement related to environmental and physical domains. So the research hypotheses were accepted

Recommendations:

1. Implement informational support as a part of nursing care protocol in high risk pregnancy department.
2. Studying the lived experience of women with APS using qualitative approach

Ethical Clearance: A primary approval was granted from the Ethical Research Committee at faculty of nursing, Cairo University to carry out the current research in November 2017. Informed written consent was taken from each pregnant woman who was willing to participate in the research and the researcher emphasized that, their participation in the research is entirely voluntary, and that they have the right to withdraw at any time without giving any reason and without affecting their care. At the same time, pregnant women were informed that, the research posed no risks or hazards on their health. Measures were taken to assure confidentiality as coding of data and participants were ensured that the collected data will be used only for the purpose of the research.

Source of Funding: Self-funding.

Conflict of Interest: The authors declare that there is no conflict of interest.

Nutritional Content and Quality Analysis of Palm Sugar in Pledokan Village, Sumowono

Fahmi Arifan[1], Sri Winarni[2], RTD. Wisnu Broto[1], Ariza Fuadi[3], Hafiz Rama Devara[1], Dina Elviana[1]

[1]Programme Diploma of Chemical Engineering, Vocational School Faculty, [2]Department of Biostatistics and Population Study, Public Health, [3]Faculty of Economics, Diponegoro University, Semarang, Indonesia

Abstract

Palm sugar is a natural sweetener containing nutrients and antioxidants. The aim of this research is to measure nutrient content (reducing sugar, sucrose, water and ash content), number of bacteria, and antioxidant level of palm sugar. The sample in this study was palm sugar randomly taken from ten different production sites. Nutrient content determination used luff schoorl method and antioxidant measurement used DPPH method. Based on the analysis of reducing sugar content, all samples met SNI 01-3743-1995 criteria, with an average of 7.16% (5.14% up to 8.73%). The average of sucrose was 76.6% (62.50% up to 88.58%). There was 40% of the palm sugar samples having sucrose content that meets the criteria. The average of water content was 10.34% (7.79% up to 11.86%). The water content of palm sugar suitable with the criteria was 30%. While the total ash content of palm sugar suitable with the criteria was 50%. The ash content average was 3.1% (1.1% up to 6.3%). The number of lactic acid bacteria found was still within normal limits. The average number of bacteria was 6.4 x 10^4 (CFU/ml), (0 x10^4 (CFU/ml) up to 27 x 10^4 (CFU/ml). The average antioxidant content was 84.60%, with the lowest strength of 89.71% and the highest strength of 74.73%. In conclusion, The nutritional content of the sample has not met the SNI 01-3743-1995 criteria as a whole. The palm sugar produced in Pledokan Village, Sumowono are still safe to eat (based on the number of bacteria). The antioxidant activity of palm sugar in Sumowono Village is strong (50% - 100%).

Keywords: *Nutrients; antioxidants, bacterial count, palm sugar antioxidant.*

Introduction

The increasing of community needs and dependency on sugar consumption every year on a national scale is not appropriate with domestic production capacity so the fulfillment of sugar is more fulfilled through imports. One effort that can be taken to help this condition is the diversification program, especially the source of non-cane sugar. Sugar palm is a product produced from palm trees that can be used as one source of raw materials in terms of quality and attractive appearance.

Palm sugar is one of the natural sweetener derived from *nira*, a sweet liquid of palm tree, as the main ingredient. *Nira* or palm juice is a sweet liquid obtained from the stems or sap bunch plant flowers such as sugar cane, beetroot, sorghum, maple, *siwalan*, dahlia flowers or palm family such as palm, coconut, *nipa* palm, sago and date palm.[1] Sugar trees in Sumowono are still growing wildly and widely used by the community. This is because the palm tree has economic value from the processing of the physical parts of the tree. The processing of palm juice into sugar is still in traditional way. The palm juice used is including commodities that rapidly change into acid because of the fermentation process that began when the palm juice out of palm tree bunches. It is also supported by the condition of the reservoir that is not clean and the presence of microbes that cause the fermentation process more quickly. The degree of palm juice acidity (pH) of the sap when it first comes out of the bunch is about 7 but it can decrease as the fermentation process occurs.[2, 3]

One of the processed product that quite popular in the community from raw materials of palm sugar / palm

juice is made as brown sugar. Palm sugar has several advantages and uniqueness in terms of taste, nutrition, micronutrient level and distinctive flavor that become the main attraction for consumers.[1, 4] There are some things that serve as the quality parameters of brown sugar such as ash level stating the metal solids contained in the sugar which in brown sugar has ash level exceeding the applicable standards it could be bad for the body because of the metal will accumulate in the body consumers. For the parameters determining the quality of others can also be known from their ability to prevent the free radical and maintain the body's immune through the antioxidant activity it has.[5, 6]

The purpose of this study is to provide information on the nutritional content and quality of brown sugar products produced in Sumuwono village so it can be used as reference to know the quality of brown sugar production in Sumuwono village.

Method

The research were made on brown sugar, where the variables observed in brown sugar included sensory (color) and chemical parameters (reducing sugar, sucrose sugar, moisture level, ash level, antioxidant activity, and total bacterial).

Sugar palm samples were taken from 10 different production sites in Sumuwono village and color sensory tests were performed. Other substances used as reactants in the test of reducing and sucrose sugar are luff school solvent, water level test, BAL test, reducing sugar, sucrose, and ash (analytic balance, porcelain cup, furnace, oven and desiccator).

The stages done include sampling and tested the water level, ash level, reducing sugar, sugar level of sucrose, BAL and color organoleptic examination conducted in the laboratory. The determination of reducing sugar content and sucrose analysis was done by luff school method in Nutrition Chemistry laboratory of Diponegoro University. The determination of ash level and water level used gravimetric method involving furnace. The principle of this method is the difference of sample weight before and after through the oven in 105°C for two hours, while on the test of combustion ash level with furnace in 521°C for 4 hours.[3] The antioxidant antivity of palm sugar was analyzed using DPPH (1, 1-defenyl-2-picrihidazil) method by duplicating *spetometrophotometry* to know the sample of absorbance wavelength.[7, 8] The examination of total bacterial on palm sugar using BAL test method (lactic acid bacteria) conducted in integrated laboratory of Diponegoro University.

Results and Discussions

The analysis of reducing sugar level, sucrose sugar level, moisture level, ash level, antioxidant activity, and total bacterial in palm sugar sample can be found in following table:

Tabel 1. The Level of Reducing Sugar, Sucrose Sugar Level, Moisture Level, Ash Level, Antioxidant Activity, and Total Bacterial in palm sugar sample (n = 10)

Sample Name	Reducing Sugar Level (%)	Sucrose Sugar Level (%)	Moisture Level (%)	Ash Level (%)	Antioxidant Activity (%)	Total Bacterial (CFU/ml) × 10^4
A	5.14	88.58	11.78	4, 3	74.73	1.11

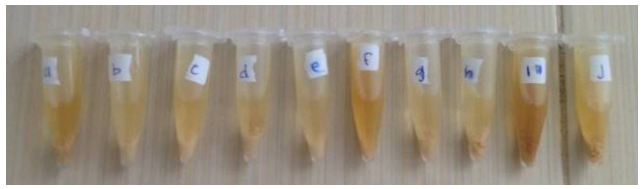
The Average of	7.16	**76.60**	10.34	3.1	84.60	6.40
SNI 01-3743-1995	Max 10	Min 77	Max 10	Max 2		Max 500

Sucrose is a disaccharide group with a single glucose molecule attached to a single fructose molecule. Sucrose is not included in the reducing sugar group because it has no free carbonyl group. The reducing sugar group



includes glucose and fructose monosaccharides. The inversion process that occurs shortly after the palm juice is tapped until become sugar can affect the reducing sugar and sucrose. The presence of acids during the boiling process of sucrose solvent will cause the hydrolysis process to produce reducing sugar where the inversion velocity is affected by temperature, heating time, and pH of the solvent.

A good palm sugar has characteristics in accordance with the National Standardization Agency (BSN) which is safe to consume if in accordance with SNI 01-3743-1995.2 The normal limit of sugar reducing of sugar level should be no more than 10% wet weight and a minimum sucrose level of 77% wet weight of the product. The palm sugar samples from Sumowono village have fulfilled the requirement of reducing sugar but for sucrose sugar parameter, not all samples meet the standard criteria.

The water content in a substance can affect the durability of the product during the storage process. Microorganisms will grow at a fairly high water level because it will make the conditions of water activity suitable as the medium for life. Based on SNI 01-3743-1995 the water level of palm sugar should be no more than 10% by weight of the product. As the samples tested only three samples that meet the criteria, they are D, E, and I. The high sugar levels indicate that the product has water vapor absorption from the environment. It is suitable with the nature of palm sugar, hygroscopic that is easy to absorb water from the environment.

The analysis of ash level on a material is needed to see the mineral content of the product. In food, the mineral content is determined by spying method. According to the government regulations in SNI 01-3743-1995 regarding the requirement of the quality of brown sugar, a good palm sugar has ash level no more than 2% bb, otherwise if the level of ash exceeds the standard then brown sugar is classified as low quality.

From the research results, it can be seen from 10 samples tested, 5 of them have levels above the specified standard, while the other 5 have good quality. Based on the research conducted by Maharani (2014) mentioned that one of the causes of high ash level in palm sugar is high temperature during the production process, the presence of insoluble solids derived from non-sugar materials such as impurities entering during the production process or from additional ingredients such as preservatives used like Na-Metabisulfate.[9]

There are two classifications of antioxidants based on the source, they are synthetic antioxidant and natural antioxidants. The antioxidants found in plants belong to natural antioxidants. The antioxidant testing method involves DPPH as an indicator because DPPH is a stable free-release compound. DPPH absorbance values ranged is between 515 to 520 nm but in this study the absorbance value is 517 nm.[10, 11] During the test process, DPPH will be incubated with the samples that have reacted with methanol so that the color of DPPH solvent will fade into yellow color derived from the *pikril* group. A compound that has potent antioxidant will have the IC50 value ranges from 50% - 100%.[12] Based on the analysis of antioxidant activity that has been done shows that the sample has a strong antioxidant levels.

Picture 1. The color of sample solvent

The lactic acid bacteria can produce physiologically lactic acid.[13, 14] These bacteria can be found in foodstuffs as well as gastrointestinal and urogenital tracts of humans and animals. During its growth, lactic acid bacteria can produce metabolite components including *bacteriocin*. *Bacteriocin* in sufficient quantities can kill or inhibit other bacteria that also competent in the same ecology.[15] The contamination and growth of microorganisms was also analyzed in samples where based on the Thai ministry of industry that total microorganisms should no more than 500 CFU / ml.[6, 16] As all samples are still below the limit so that palm sugar products are safe.

Conclusions

The palm sugar produced in Pledokan Village, Sumowono are still safe to eat (based on the number of bacteria). The antioxidant activity of palm sugar in Sumowono Village is strong category (50% - 100%) and all samples are still below the limit so that palm sugar products are safe.

Conflict of Interest: The author said that there was no conflict of interest in this study.

Determinants of Unmet Need for Family Planning in Tegal and Klaten Regency

Sri Winarni[1], Najib[2], Yudhy Dharmawan[1], Desi Nuri[2]

[1]Department of Biostatistics and Population Study, Public Health, Diponegoro University, [2]Research and Development of National Family planning Coordinating Board of Central Java Province, Semarang, Indonesia

Abstract

Tegal Regency has the highest unmet need for family planning at 14.54%, Klaten Regency's unmet need is still high at 14.40%. The aim of this research is to analyse the factors causing the unmet need in Tegal and Klaten Regencies. The research population includes all the women of reproductive age in couples, with total number of 483,144 and the samples set, selected by simple random sampling of 268 respondents. The result show that is a significant correlation between the number of live children unmet need (p = 0.001), correlation between attitude and unmet need (p = 0.007), correlation between attitude and knowledge (p = 0.001), correlation between age groups and unmet need (p = 0.035), correlation between opinion on contraceptives as a sin and unmet need (p = 0.002), correlation between the respondent's beliefs that contraceptives are against their religion and the unmet need (p = 0.028), and correlation between social media exposure and unmet need (p = 0.001). The family planning field counselors experience a harder work load as the work areas are getting wider. The paper concludes that perception and knowledge about the definition of unmet need by the family planning field counselors is very limited. The roles of religious and community leaders in providing counseling on contraceptives and unmet need are limited. Based on this study it is suggested that communication, information and education should be developed using interactive dialog method, coordination by and roles of the family planning field counselors should be improved, and family income and wealth should be increased through a family welfare income increasing program.

Keywords: *Family planning field counselors, community leaders, women of reproductive age, contraceptives, unmet need.*

Introduction

The family planning program in Central Java has not shown the maximum results. This can be seen from the result of the Demography and Health survey of Indonesia in 2007, which showed the number of Total Fertility Rate of Central Java, as 2.3, and it became 2.5 in 2012. The result of family census in 2015 showed the percentage of women of reproductive age who were married and using contraceptives was about 74%, who were not using any contraceptives was 26%. These figures indicate that the dropout and unmet need is still high.[1]

Unmet need refers to women who do not want to become pregnant or want to or space out their pregnancies but are not using contraceptives to prevent their pregnancy. The term unmet need does not include unmarried women, women using contraceptives, women failing to use contraceptives, pregnant women considered infecund, or fecund women willing to have the next child in less than 2 years.[2]

Based on the data of the field control report until December 2015, the unmet need in the province in December 2015 was 10.48%. This indicates that optimal efforts are needed to lower the unmet need. The range of the unmet need in the regency/city was from 14,54% in Tegal Regency (the highest) to 6.75% in Demak Regency (the lowest)

Tegal Regency, which has the highest unmet need represents the north coastal areas, and Klaten Regency which has high unmet need with 14.40% represents the mid-south areas and mountainous areas.

Method

The type of research is Explanatory Research. This study utilizes quantitative and qualitative research approaches. The quantitative approach is employed to explain the factors related to the occurrence of unmet need in a society where the research population is women couples of reproductive ages aged 10-49 years. The research population is all women of couples of reproductive age (aged 10-49 years) in Tegal Regency and Klaten Regency with the total 483,144. The sample selection is done by determining the clusters/villages which has high unmet need rate. The samples in those clusters are chosen randomly, with the number of samples based on the Issac and Michael formulas. The number of the samples chosen is 268.

Results and Discussion

Based on the study the average age of women of reproductive age in Klaten and Tegal Regency was 36.4627 in April 2016 with a deviation standard of 7.40954, and a median 37. The percentage of respondent's knowledge between the respondents with the good knowledge and attitude about family planning and those with less knowledge and attitude about family planning was almost the same.

A study done by Waqas Hameed, et all in Pakistan indicates that the higher the age, the higher the chance of unmet need.[3] This happens because unmet need in older age happens more for limiting the number of children. Based on the study done by Susiana Sariyati, Sundari Mulyaningsih, and Sri Sugiharti in Yogyakarta, the respondents assume that at that age they are not in the reproductive age anymore, think that they are already old so there is a little possibility for them to be pregnant, and ages >35 years are the period of the end of reproductive are not true. Instead women at those ages still have possibility to be pregnant.[4] A mother with a lower education or higher education may experience unmet need due to the health problems that they have when using any contraceptives. It differs from the result of study conducted by Ali, in Sudan which shows that the education of a husband and a wife relates to the occurence of unmet need. [5,6] The research by Susiana Sariyati, et all, it shows that the higher of one's education, the higher the occurrence of the unmet need. This happens because they have known how to prevent pregnancies in natural way so they do not want to use modern contraceptives.[4] This study is also in line with the research conducted by Sherin Raj T., V.K. Tiwari and J.V. Singh, which states that education status has no relationship to the unmet need of family planning in Rajahstan. For women with education of 10 years or more, 32 % more experience the unmet need for limiting, whereas 19% of illiterate women have the possibility to experience the unmet need.[7]

Table 1. The characteristics of women of reproductive age (n=268)

Category	f	%

More children cause the chance of higher unmet need than less children.[4] The number of children has a role in the occurrence of unmet need.[2] Based on the 2007 Demographic and Health Survey report of Indonesia, women's intention to stop births increases after they have two children or more.[8] If it relates with the demand of contraceptives for spacing the births, the demand of contraceptives appears when a woman has already had a child. Based on research done in Uganda, women who have 3 or 4 live children have twice the possibility of experiencing unmet need than women who have between zero or two children, and the couples of reproductive age who have 5 children or more are three times more likely to experience the risks of unmet need.[9,10] According to

Ahmadi and Iranmahboob (2005), the less knowledge of the respondents, which is found out from the answers they give suggests that there are still respondents who do not know about the family planning program or its goals or about contraceptives and their purposes.[11] The factors, which have roles in forming the behaviour can be divided into two, the internal and external factors. This study also aligns with the one conducted by Kurnia Wulandari Fitri (in 2015), it shows that there is no relationship between knowledge and the case of unmet need because the case of unmet need is affected by another factor namely side effects. Even though the knowledge is good, someone could stop or not use contraceptives when they experience side effects that affect their health.[12] Respondents identified various side effects including physical weakness, change in body weight, menstruation problems, infertility, malformation in the new born babies and death. The increasing complaints about the side effects causes negative attitudes by reproductive age couple toward using any contraceptives.[13] The reason is it does not follow the sunnah of the apostles which says that children are God's sustenance, so inserting any things into the body is considered haram, it changes the God's destiny, and therefore contraceptives are haram.[7] Woman who have not discussed contraceptives with their husbands in the last year have a higher percentage of unmet need than those who have discuss them with their husband, even if only once or twice.[14]

In carrying out the family planning program, the program management of family planning in Klaten Regency is required. The management of the family planning program aims to giving effective services, which suit the need of society, so the unmet need should not happen. The problems existing in the management of family planning program in Klaten and Tegal Regency are the same. They are the limited contraceptive management fund and family planning promotion, and no promotion segments from the Board of Woman Empowerment and Family Planning. The problems faced by the Board of Woman Empowerment and Family Planning in Klaten Regency in collecting unmet need data that are not valid is because of the limited budget and less coordination between family planning field counselors and cadre and midwives. There is no monitoring from the leaders or The National Family Planning Coordinating Board in family planning data collection which includes the data from village district to sub district until Regency. The work performance of the family planning field counselors affects the occurrence of unmet need.[15,16]

The study results also show that there are problems related to the role of midwives in Klaten and Tegal. The midwives do not fully comprehend the unmet need and target set by the National Family Planning Coordinating Board, which expects them to function as educators to provide understanding to the cadres concerning the unmet need of contraceptives. The facilities provided are only family planning forms and aids for decision-making. Considering those matters, there is a need to provide budget, reward, and punishment for the implementation of the program to reduce the unmet need. The evaluation on contraceptive mounting by midwives in Klaten is intended for IUD contraceptives and Implant contraceptives. The supervision of IUD contraceptives is held every one week, two weeks, 1 month, six months, and a year after mounting, whereas the supervision of implant contraceptives is done 3 days after mounting. This is different from what happen in Tegal Regency where midwives do not do any evaluation since the women there do not have medical records for their family planning program. The midwives in Tegal Regency should have the medical records data so that they can be used for evaluating the program and supervising the society concerning the use of contraceptives.

The midwives in Klaten have another problem that relates to the complaints and complications that happened to one implant contraceptive and IUD acceptor which causes the acceptor become traumatic in using implant and IUD contraceptives. It is worried that the complaints will spread to other societies and create a bad perception about those contraceptives.[12,17]

The role of health workers is very important to provide understanding for society so that they can strive to use contraceptives to reduce the number of cases of unmet need. The roles of husband and spouse will maximize the contraceptive use.[18] Based on the related research on the roles of family planning field counselors in Tegal Regency, they directly throw themselves into society to reduce birth rates and provide counseling by motivating society to use contraceptives. On the other side, the roles of family planning field counselors in Klaten Regency has more organised work-plans. They give routine counselling which is aimed at the acceptors who have 2 children and evaluate the program based on the data results. The other existing problems are there are no additional fees related to their roles, there are no rewards if the program runs successfully and there are no sanctions from the government if their job cannot be performed well.

The religious leaders should be trained by the Board of Women Empowerment and Family Planning in Tegal in relation to their roles as the information giver and the motivator for the couple of reproductive age to participate in the family planning, cause the religious leaders are usually people who are trusted and close to the society and their behaviour is embraced by the community.

Conclusion

Based on the research on unmet need in Klaten and Tegal, it can be concluded that there are some problems related to the role of the Chief of the Board of women Empowerment and Family Planning, midwives, family planning field counsellors, cadres, community leaders and Religious leaders cased of unmet need. The vacuum of contraceptives will cause the increase of the case of unmet need. The access providing the contraceptives have been evenly in various health services. The family planning field counsellors feel the heavy workload since their work areas are getting wider. Monitoring and evaluating on the work of family planning field counsellors are not optimal, they do not give any sanctions if the set work performance targets are not met.

Duta Safety Riding: The Actors of Traffic Accidents Prevention in Samarinda, East Kalimantan, Indonesia

Dina Lusiana Setyowati[1], Risva[2], Andi Anwar[3]

[1]Departement of Occupational Health and Safety, [2]Departement of Epidemiology, [3]Departement of Environmental, Mulawarman University

Abstract

Traffic Accident is the main cause of death for adolescents. The adolescents' thought that they've matured enough to ride motorcycles on roadway, although the knowledge about safety riding they had was low, and it made they usually on dangerous situation which riding which leads to fatal accident, which could cause disabilities or death. Therefore, safety ambassador group as peer group in act on safety as prevention step to decrease the number of accidents on roadway. Training was given to increase knowledge and attitude about safety riding as the priority on preventing traffic accidents. Since safety riding ambassador could be a role model for other teenagers to act on safety riding. The aims of this research was giving training about safety riding to safety riding ambassadors in order to increase the knowledge and behavior on safety riding. This research was a pre-experimental using one group pre-posttest design. There were 25 high school students as the samples using purposive sampling. The results have shown that the average score about knowledge was 18.12 before training, while after training it was 18.32. The average of safety riding behavior before training was 140.6, while after that, it was 141.6. The statistic test had shown that there is no difference on safety riding behavior before and after training (p=0.06), however there was the difference on knowledge before and after training (p=0.05). This research can be concluded that training could increase the safety riding ambassadors' knowledge about safety riding.

Keywords: *Adolescent, Peer, Safety Riding, Traffic Accident.*

Introduction

Each year, traffic accident related death takes 1.25 million people, most of which are teenagers aged 15–29 years old, and 90% of the misfortune occurs in developing countries.[1] Fifty percent of death on the road are walker, bicycle riders, and motorcycle riders.[2] Indonesia, as one of the developing countries, has 120 deaths each day due to traffic accident. The newest data from the Directorate General of Land Transportation showed that the average growth of traffic accidents in Indonesia was 16.59 %.[3]

The mortality among teenagers both in America and Developing countries caused by traffic accident[4, 5] grounded on the fact that most teenagers consider themselves matured enough to ride motorcycles[6] The risk of accidents for young riders (18-24 years old) is as twice as higher than that of adult riders.[7 8]

Department of Transportation of Samarinda reported that traffic accidents took place in East Kalimantan was 1.767 in 2010 and decreased into 1.347 events in 2011. From 2.115 victims-related traffic accident, 463 lost their live, 517 had severe injuries, and 1.135 had minor injuries.[3] Traffic Police Station of Samarinda reported the number of deaths cause traffic accident increased in 2013, 83 people died, while in 2012, within 249 events of the traffic accidents, 67 people died.[9]

Setyowati[10] observed that 50.8% respondents have unsafe behavior, 49.2% respondents have poor knowledge about safety riding, and 57.8% have negative perception about danger on a roadway, the reasons of students riding motorcycle themselves are that no one can take them to school (39.4%) and the schools are too far from their homes (11.7%).

The intervention explored in this paper covers giving education about safety riding to Safety Riding Ambassadors as peer group education, it is expected that participants' knowledge, skills, and awareness about safety riding increase; so that, the number of traffic accidents would decrease.

Given this situation, this paper analyzes the impact of giving training to increase knowledge, attitude, and skill rates of students chosen as Safety Riding Ambassadors among students of Senior High School who act as the peer group educators in Samarinda.

According to Soehodho,[11] the factors, human errors are the most taken place in Indonesia causing death or injuries involving students who has lack of knowledge about safety riding. In dealing with this situation, providing education and training to the students in the right way is expected to decrease the cases of traffic accidents.

The aim of this study was to analyze the impact of training about safety riding on their knowledge, attitude, and skills as the Safety Riding Ambassadors. This research was conducted while giving the training about Safety Riding and analyzes the impact of training to the knowledge, attitude, and skills of 25 Senior High School Students chosen as Safety Riding Ambassadors in Samarinda.

Method

This quantitative study using pre-experimental design on one group was conducted using pre-posttest approach; before and after the experiment. Purposive sampling technique was used to choose 25 Senior High School Students from 315 students who have participated in Safety Riding Research in 2017. The chosen ones were quantified based on the scores in answering questionnaire about safety riding, and they were asked to sign a written permission and an informed consent to participate in the study.

The materials given were including traffic regulation, safety riding, and riding test. The respondents were asked to complete the three sections questionnaires before and after the training. Section A was about The characteristic of Respondent; B: The Attitude about Safety Riding; and C: The Knowledge about Safety Riding. The questionnaire was designed using strict questions of Likert scale; for the attitude about Safety Riding, the answers were 1= Never, 2= Sometimes, 3=Often or 4= Always; meanwhile, the knowledge was measured using Gutman Scale, Correct – Incorrect.

The analyses was conducted using SPSS v 24.0 with Wilcoxon test for 2 related samples, for all results the statistical significance were reported using p value, and the significance level was set at $\alpha = 0.05$.

Results and Discussions

Socio-demographic characteristics

Table. 1 Respondents Frequency Distribution Based on Respondent Characteristics

No	Characteristics	(n)	(%)
1.	**Sex**		
	Men	6	24.0
	Women	19	76.0
2.	**Ownership of SIM C**		
	Yes	4	16.0
	No	21	84.0
3.	**Have Experience Traffic Accident**		
	Yes	15	60.0
	No	10	40.0
4.	**Age (Year)**		
	16	6	24.0
	17	19	76.0
	Total	25	100

Table 1 shows that 76.0% of the respondents are 17 years old female, 84.0% has no driving license (C level), and 60.0% has experiences of traffic accidents.

The results showed that 17 years old female with no driving license and had dealt with traffic accidents dominated the characteristics of the respondents. The law number 22, 2009 About Traffic and Vehicles permitted 17 years old citizens to have driver license. Driving license is the evidence of registration and identification given by the Police of Republic of Indonesia to its citizens who meets all the administrative requirements, such as physically and psychologically healthy, understand the traffic signs, and skill full in riding vehicles.[12] Therefore, as 84.0% of respondents had no driving license, the respondents had no sufficient knowledge and skills in riding vehicles.

This fact suggested that the risk to have a number of traffic accidents could increase for the students did not have sufficient skills on safety riding; while, 60.0% of the respondents had experienced to be the victims of traffic accidents. Unskilled riders have risk of death 0.263 times than skilled riders,[13] and in Indonesia, traffic accident related death is also influenced by the number of population and vehicles, eligibility to have driving

licenses, and distance of a journey.[14]

Traffic police task force of Samarinda and Transportation Department of Samarinda delivered the training about safety riding observed in this study. The training materials were subjects related to traffic and vehicles regulation, traffic signs, vehicles equipment, traffic instructions, safety riding simulations, and riding practice test. The training was conducted in two days at SMA Negeri 3 Samarinda (State High School 3 of Samarinda), and the safety riding simulations and riding practice test were conducted at police station in Samarinda.

All of the materials, simulations, and riding practices test were given to safety riding ambassadors who would act as the peer group educators. This training was given to the safety riding ambassadors since they are still teenagers, and teenagers in the same ages can communicate more openly and easily rather than parents and teachers.[15] Most adults who have regular contact with adolescents understand the value and importance that these young people attribute to their friends and peers. Many people would concede that such groups serve as the primary means by which teenagers share and validate each other's struggles to develop new identities and to assume new, more mature roles. Many would also concede that peers usually provide emotional support and intimate counsel when adults are unavailable or appear indifferent. On the other hand, many adults regard peer groups as the instigators of all the problems we commonly associate with adolescence: defiance of adult norms, the use and abuse of alcohol and drugs, delinquency, sexual experimentation, experimentation with guns, and even suicide.[16] So utilizing peer friends to deliver positive information related to teenagers' safety can be considered as a health promotion strategy.

Table. 2 The Distribution of Knowledge Rate and Attitude Rate of the Respondents Before and After The Training

No	Characteristic	Before		After	
		(n)	(%)	(n)	(%)
1.	**Knowledge**				
	Poor	13	52.0	16	64.0
	Good	12	48.0	9	36.0
2.	**Attitude**				
	Poor	12	48.0	11	44.0
	Good	13	52.0	14	56.0
	Total	25	100	25	100

Table 2 shows the percentage of safety riding knowledge and attitude among Duta Safety Ridings before and after training. Most of them (48.0%) have poor basic attitude regarding safety riding and turn into 44.0% after getting the training. Meanwhile, 48.0% respondents have poor knowledge about safety riding, but turn into 36.0% after getting the training.

Table. 3 The Results of Wilcoxon Test

Variable	n	Median (Min-Max)	Mean	p
Knowledge				
Before	25	17 (13-27)	18.12	0.05
After	25	18 (13-27)	18.32	
Attitude				
Before	25	142 (106-190)	140.6	0.06
After	25	144 (112-171)	141.6	

Table 3 shows the average score (mean) of respondents' knowledge about safety riding, increasing from 18.21 in pre-test to 18.32 in post-test. The average (mean) of respondents' attitude about safety riding increases, from 140.6 in pre-test to 141.6 in post-test. The statistic result using Wilcoxon Test for the variables of knowledge about safety riding has p= 0.05, meaning that there was a significance difference to the level of knowledge before and after training. Meanwhile, the statistic result using Wilcoxon Test for the variables of attitude about safety riding has p=0.06, meaning that there was no significance difference to the level of attitude before and after the training.

In conducting the program, peer educators (Safety Riding Ambassadors) delivered the information related to safety riding to their peer friends, since in peer education continuous interactions between peer educators and their peer friends is possible to happen. Peer education is important, and considered as an effective way to alter people behavior; consequently, peer educators had to have a better level of knowledge, attitude, and skills to be good examples and role models for their peer friends. Meanwhile, the result related to knowledge variables of safety riding was p = 0.05, meaning that the training program influenced the respondents' knowledge level. This result of this research was in line with the one of Erawan[17] that the average score improvement on students' knowledge and attitude related to traffic accident prevention is p= 0.000. In this research, the average score of knowledge before and after training was 18.12 and 18.32 respectively, which meant that there was an improvement of knowledge about safety

riding; although, it was not significant (0.2) since the level of the respondents' knowledge about safety riding was already good (48%).

Furthermore, the score of the respondents' attitude about safety riding before training was poor (48%) and it decreased to 44% after the training, meaning that there was an improvement as the average score of the respondents' attitude before and after the training was 140.6 and 141.6 respectively. The improvement could also be identified from respondents' positive attitude to the statements proposed. For example, the sample statement states: not using helmets even if it is only for short-distance journey. In the pretest, 72% stated that it was wrong attitude, and in the posttest, the numbers of respondents provided similar positively answer improved to 80%. At the statement, "checking the vehicle before using it decreases the risk of traffic accident", 80% of the respondents answered it correctly in pre-test, and it changed to 84% in post-test.

Similarly, almost all of the statements proposed, such as there is no-smoking regulation, listening to the music while riding is not dangerous, obey to traffic light when there is a police and disobey it when it is not crowded, and the riding skill is not important were responded positively. However, since the statistic test was $p = 0.06$, the differences were not significant, so it could be interpreted that there was no difference of respondents' attitude about safety riding before and after the training or the training did not influence the respondents' attitude. This result was not in line with the one of Erawan,[17]who stated that peer education influences knowledge and attitude about traffic accident prevention in Senior High School students.

Dangerous condition, which is also a serious threat for riders, is the distraction while riding.[18] However, this research's finding showed that most of the respondents stated that no smoking prohibition and listening to the music while riding were not dangerous; in fact, smoking and listening to the music through cell phone were unsafe behavior. Smoking can increase the risk, bigger than using cell phones along the way, so that it is needed to promote to the public the information about those risks among people.[19] Using cell phone can decrease the rider's concentration, and teenagers usually use their cell phones while riding.[20 21] Moreover, teenagers usually get serious injuries while using cell phones when riding.[22] The using of cell phones while riding reflects the relationship level between cognitive and behavior.[23] The safety-riding ambassadors as peer educators were expected to deliver the information to their peer friends to decrease unsafe behavior such as smoking and listening to the music while riding.

Conclusions

The training would increase the knowledge about safety riding to the Safety Riding Ambassadors.

Electrolyte Supplementation on Workers Under Heat Stress: A Preliminary Study on Workers' Hydration and Performance

Daru Lestantyo[1], Suroto[2]

[1]Occupational Health Department, Faculty of Public Health, Diponegoro University, Indonesia,
[2]Master of Health Promotion, Postgraduate Program, Faculty of Public Health, Diponegoro University, Indonesia

Abstract

Background: Heat exposure could harmed employees on many aspects. Prolonged activity under extreme heat often results in fatigue, poor concentration and dehydration. Lack of water consumption would make impact either in electrolyte balance or urinary tract system. This study examined electrolyte water supplementation and its impactin urine osmolality and employee's performance under extreme heat condition.

Method: Indoor temperature, workers' performance and indoor air humidity were measured. Seventy people were participated and divided evently into group A (isotonic) and group B (hypotonic). In a single blind experimental study, 3000 ml of isotonic and hypotonic solution were administered into group A and B, respectively, within 8 hours. Urine sample were taken at 10 am and 15 pm and reaction time test was done to measure performance at the end of working time.

Result: Low consuming water (400–1100 ml) in the first 4 hours was found in both group. Most of participants were stated as moderately hypohydrated state (average of urine specific gravity 1.026) in the beginning of working hours. There was no differences of urine specific gravity between two groups (U= 608.00, p=0.954). Workers' performance was found elongated (moderately fatigue) and there was no differences in both groups (U=706.05 and p= 0. 657).

Conclusions: Electrolyte supplementation in this study is not appropriately enough to maintain electrolyte balance among workers under heat stress environment. Heat stress and lack of water replacement will caused moderate fatigue

Keywords: *Heat stress; electrolyte supplementation; hydration status; work performance.*

Introduction

According to the Indonesian Minister of Labour Regulation No. 5/2018 on Occupational safety and Health Standards, it has been assigned that Indoor Temperature Threshold Limit Value (TLV) was at arnge between. TLV is determined with a view to giving limits in occupational safety and health through physical and chemical hazards[1].vv Heat exposures can triggered fatigue and work performances. Research conducted in Central Java on steel billet factory workers find a correlation of ambient temperature and body core temperature rise [2].

Although the liquid adequacy rate has been set in the RDA (Required Daily Allowance/Nutrition Adequacy Score) for Indonesian people, but specifically not obtained figures for the adequacy of minerals (Na, K, Cl) in drinking water either for people working under high temperature. Adequacy of water and electrolytes were also needed by employees who worked with exposure of high temperature [3]. Regulations determine the safe working limits in order to avoid illness and accidents. The objectives of the study were to measure hydration status of employees and examine the role of urine specific gravity test in fluid replacement decision

of workers under heat stress condition. The present investigation was designed to assess the effect of high temperature for employees health, and hydration status.

Heat stress is common for workers in a laundry processing with dry cleaning method. Work processes and tools / machines used have great potential of heat injuries / illnesses. These extreme conditions were sourced from workplace lay out with less functioning of air conditioned. This will increase the temperature of the room. Approximately 10 persons work under hot temperature in 10-12 work hours everyday. Workplace measurements at baseline condition was conducted in February 2018. From baseline survey, we have workplace temperature in production area was 30°C-33°C (WBGT).

Further issue for this study was to observed fatigue level which tecnically correlated with hydration status. People who are involved in hot conditions job, without access to shade or sufficient fluid replacement, are at especially elevated risk in heat related injuries. Heat related injuries can cause discomfort, fatigue, exhaustion, heat cramps, and heat stroke in employees[4,5]. During four hours of work, we observed that employees drank as much as 2-3 cups (400-600 ml) of water and taken outside during lunchtime. Based on observation, employees must cope with, high temperature, humid and less fresh air ventilation. They also have less frequent of water and electrolyte replacement. The employer had never done urine specific gravity test before.

Method

This is an experimental studies with Randomized Controlled Trial (RCT) in a double-blind design. In this study subjects were treated with electrolyte solution for eight hours work. The research observed differences in urine osmolality and specific gravity between treatment group and the comparison through fluid-electrolyte supplementation for 8 hours of work. Affordable population is laundry workers in Semarang District, Indonesia as many as 90 people. Eligible participants were examined before the data was collected. The enumerators reached the workplaces 1/2 hour before work began, after which baseline assessment was carried out. Samples selected by purposive sampling using the inclusion criteria, as follows:

a. Age 20-40 years

b. Working in a place with heat exposure WBGT> 30^{o} C

c. Willing to become respondents (informed consent)

d. NaCl consumption of 2400-2500 mg / day

e. No history of urinary tract disease (infections, *calculi*)

f. No history of hypertension or cardiovasculair disease

Workplace temperature was measured by using a digital Questtemp Heat Area Monitor. NaCl intake measured using a questionnaire of 3 x 24 hour recall and analyzed with open source software for nutritional analysis. The nutritional status was measured by using the Body Mass Index (BMI) refers to the classification from Indonesia Ministry of Health. Urine Specific Gravity was measured by using Urinometer. Electrolyte supplementation given were:

1. Isotonic electrolyte solution, containing 0.9 g of sodium chloride and potassium chloride 0.6 g per 1 L

2. Hipotonic electrolyte solution as a placebo containing 0.52 g of sodium chloride and potassium chloride 0.30 g per 1 L

The solution was preserved and validated by Department of Pharmacy Faculty of Medicine, Diponegoro University. Statistical analysis conducted in non-parametric test (Mann-Whitney) for urine specific gravity and osmolality of the treatment group and control. Workplace temperature was measured in a 3-point measurement of Questtemp. It measured twice daily : at 10:00 and 15:00.

Hydration status based on USG samples in this study are cathegorized in:

1. ≤ 1.015 – optimal level of hydration (euhydrated).

2. 1.016–1.020 – marginally adequate hydration.

3. 1.021–1.025 – hypohydrated.

4. 1.026–1.030 – severely hypohydrated, at increased risk of heat illness and impaired performance. Should not work in hot conditions.

5. > 1.030 – a clinically dehydrated state, based on the criterion used by the Australian Pathology Association (APA)[6]. Flicker fusion test was conducted to identify general fatigue. The test done 15 minutes before lunch break. Subjects were not allowed to drink, eat or going out before the test.

Results and Discussions

Ambient Temperature: The ambient parameters required for calculating the TLV indicator were measured twice a day at the middle, and end of the working hours in the working place of both group (1000 am and 1500 pm).

Table 1. Ambient Indoor Temperature

No	Location	WBGT		Rate Humidity (%)	
		1000	1500	1000	1500
1	1	30,3	31,1	74,4	74, 8
2	2	30,5	33,3	73,8	74,3
3	3	30,1	32,2	74,5	74,6

According to Indonesia Ministry of Labour Regulation No. 5/2018, the observed workplace indoor temperature has exceeded the Threshold Limit Value (TLV) in the amount of 26,7°C. The result was still lower when compared with mining workers with the working environment temperature was higher from 30,7°C to 35,2°C. Studies in Australia on mining workers showed results 29,5°C dry temperature (dry bulb). Both studies demonstrate the need to control the temperature in the workplace so as not to exceed the Threshold Limit Value (TLV). Heat induced injuries are related by a combination of ambient temperature, employees' health status, dehydration, drugs and/or alkohol abuse[7] Many studies reported that working activities in an extreme hot environment (>40°C) could improve peripheral nerve mechanisms and could result in the sweating response[8,1,9]

Participants' age: Respondents who participated in this study were between the ages of 20-40 years. Selection of this age range based on the hypothesis that people under 40 still have good adaptability for extremely high temperature [1].

Table 2. Participant's Age

No	Age group (yrs)	Freq	%
1.	20-25	18	25,7
2.	26-30	2	31,4
3.	31-35	20	28,5
4.	36-40	10	14,2
Total		**70**	**100**

Age plays a role in an individual's health status, especially under continuous hazardous heat exposure. Although not specific, studies have shown a correlation of age with episodes of heat exhaustion in miners. Workers with over 40 years of age were relatively more vulnerable to be attacked by heat exhaustion [10] Physiologically, the age factor relates to the ability of the kidneys to excrete the rest of biochemical metabolites to maintain the acid-base balance of the blood. Increasing age of a person or a disturbance in the kidney will reduce glomerular and tubular function in the formation of urine. A number of studies have examined age-related differences in thermoregulatory function under extreme hot conditions[11,12]. Unhealthy lifestyle such as lack of physical activity, consumption of drugs in the long term as well as the lack of drinking habits can also be a trigger factor [8]

Body Mass Index (BMI): Body Mass Index measurements conducted to determine the anthropometric nutritional status. It could identify possible malnutrition from food intake and/or workplace exposure.

Table 3. Body Mass Index

No	BMI	Freq	Percentage
1	Normal	65	92,84%
2	Overweight	5	7,16 %
Total		**70**	**100 %**

BMI measurements were applied to estimate the individual adaptability to high temperature. Body weight monitoring is beneficial to determine the participant's weight loss due to dehydration. Studies in 51 workers in California in mid-summer earned weight loss of 2.3 kg per day [13]. Excess weight loss, followed by the build up of fatty tissue caused body to produce more heat. Dehydration predisposes the participants to healt exhaustion, heat stroke and heat cramps. This is disadvantageous for employees who worked in a high/ extreme temperature. Adaptability of extreme heat will be low so workers will quickly feel tired compared to individuals with normal BMI [9,3]

Work period:

Table 4. Work Period

No	Work Period (yrs)	Freq	Percentage
1	1-3	30	42,85 %
2	4-6	30	42,85 %
3	7-9	10	14,2 %
Total		**70**	**100 %**

Respondent has been working for - 6 years of average.

3.5. Urine specific gravity (USG) and osmolality

Table 5. Frequency Distribution of Urine Density and Osmolality (Average per group for each sample)

USG I		Osmol I		USG II		Osmol II	
A	B	A	B	A	B	A	B
1,021	1,026	1050	1050	1,0264	1,0264	1050	1050

USG = Urine Specific Gravity, Osmol = Osmolality

Mean of urine sampling in two group were 1.0258 (SD 0.0057). Osmolality mean 893.50 (SD 212.48). Mann-Whitney test for urine specific gravity of the two groups of workers showed U 608.00, and the p value 0.954 which means that Ho is accepted (ρ> 0.05) ie no urine specific gravity differences between two groups. Median value of urine osmolality test results showed UD = 611.00, and the p value was 0.984 which mean that Ho is accepted (ρ> 0.05). There was no difference in mean urinary osmolality of two groups.

Research showed differences in the ability of sweating sensitivity based on tenure. Workers with tenure of more than five years tend to have lower sweating rate compared to the group with a newer ones. This condition is caused by adaptation functions that have been run better. Although there have been adaptations, but does not mean the system is not impaired renal excretion [1].

Urinary density and osmolality was depend on fluid and amount of solute produced by the kidney tubules. Urine osmolality was defined as number of moles of solute per kg of solvent (water)[6]. Examination of urine specific gravity is a method to assess renal function or hydration status, especially in conditions of high ambient temperature [1]. For practical purposes, urine specific gravity were able to assess hydration status either euhydrated (UD = 1.015) as well as voluntary hypohydrated (UD> 1.025) based on the classification of Australian Pathology Association (APA) [9]. Fluid loss due to physical workload or environmental temperature as much as 1.5% of body weight can have an effect on the physical performance of individuals [3].

From laboratory examination result of urine specific gravity,70 respondents earned an average of 1.0258, while the osmolality was 893.5 mOsm / Kg. USG value was related with the "voluntary hypohydrated" cathegory according to APA classification. This condition can be caused by lack of water replacement during work hours. Many studies examined influence of hydration level on body fluids and exercise performance in the heat environment. They addressed the issues of hypohydration and the effects on performance/fatigue[7,1]. From the preliminary data obtained 16 workers (47%) had urinary SG 1,030 which should be monitored physical condition andalso need a rapid fluid and electrolyter replacement. Compared to the USG indicators, urine osmolality levels more believed to evaluate renal concentrating ability because relatively few factors that influence [1]. Results of the examination with the conversion of urine specific gravity showed the average value of osmolality remained at physiological range (normal value 50-1400 mOsm / Kg) This physiological range indicates that the body is capable of adapting to the formation of urine in a state of high temperature[14]. Majority of the respondents (80%) drank less water during work hours and experienced excessive sweating.

It was no difference in mean results of these two groups, could be sourced from the amount of fluid which had drunk and did not meet body metabolic needs and fluid balance. The addition of electrolytes (Na, K) in the fluid being offset by a sufficient volume will not be able to fix the value of urine SG and osmolality, due to a smaller volume than the concentration of solute to produce concentrated urine. Provision of electrolytic more expected shortly on improving the body's electrolyte balance. Giving proper electrolyte is expected to prevent heat cramps or heat exhaustion [15]. Urine density improvement can be achieved when consumption reaches 1.4 to 1.8 liters of fluid per hour in extreme conditions such as underground miners and the military personnel in desert[13]. Consuming water without any electrolytes may be problematic for physical activity under hot environment exceeding several hours that produce high sweat rates[16, 17]

Work Performance (Fatigue Level)

Table 6 Level of Fatigue

Fatigue Level	n	%
Mild	10	14,28
Moderate	50	71,43
Severe	10	14,28
Total	**70**	**100**

Concerning employee's fatigue, table 6 showed that most of participants were in moderate fatigue state. The participants reported that they felt more tired in the hotter weather and experienced sweating and headaches that slowed their job. Participants from both groups

reported that it required a longer time to finish their tasks in extreme high ambient temperature. On average, respondents worked 10 hours a day in their routine job. Most of participants reported that they took breaks to rest every 20 minutes or less. This finding was in the same line with prior research which stated that the highest percent of chronic fatigue was shown in moderate level[18]. There was no differences in both groups (U=706.05 and p= 0. 657) in level of fatigue.

Conclusions

The result showed that urine specific gravity (USG) was high and cathegorized in moderately/voluntary hypohydrated. This condition was caused due to the volume of electrolyte replacement drink had has not reached the required needs. Osmolality value was stated in "normal" cathegory. There was proved that anyn acclimatization and adapttation to high temperatures amongst participants. Due to USG result, it also proved that kidney still be able to compensate urine concentration. Even though,"voluntary dehydration" is the primary issue for this study[1,19]. The company can educate workers to increase consumption of drinking water with electrolytes until it reaches 1.5-2 liters for 4 hours. Urine Specific Gravity could also be examined to check the osmolality every 3 months periodically. Drinking water was expected to be placed closer to the workspace.

Employees should do little exercise on the workplace. It benefits is reducing stress and fatigue at work. They should done every 2 hours. The research showed that heat management based on ambient monitoring but without addressing the hydration status cannot protect workers from the effects of heat stress injuries [7,20]
