EXECUTIVE EDITOR

Vidya Surwade

Associate Professor, Dr Baba Saheb Ambedkar, Medical College & Hospital, Rohinee, Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. **Dr. Abdul Rashid Khan** B. Md Jagar Din, (*Associate Professor*)
Department of Public Health Medicine, Penang Medical College, Penang, Malaysia
2. **Dr. V Kumar** (*Consulting Physician*)
Mount View Hospital, Las Vegas, USA
3. **Basheer A. Al-Sum**,
Botany and Microbiology Deptt, College of Science, King Saud University,
Riyadh, Saudi Arabia
4. **Dr. Ch Vijay Kumar** (*Associate Professor*)
Public Health and Community Medicine, University of Buraimi, Oman
5. **Dr. VMC Ramaswamy** (*Senior Lecturer*)
Department of Pathology, International Medical University, Bukit Jalil, Kuala Lumpur
6. **Kartavya J. Vyas** (*Clinical Researcher*)
Department of Deployment Health Research,
Naval Health Research Center, San Diego, CA (USA)
7. **Prof. PK Pokharel** (*Community Medicine*)
BP Koirala Institute of Health Sciences, Nepal

NATIONAL SCIENTIFIC COMMITTEE

1. **Dr. Anju D Ade** (Professor)
Community Medicine Department, SVIMS, Sri Padamavati Medical College, Tirupati,
Andhra Pradesh.
2. **Dr. E. Venkata Rao** (*Associate Professor*) Community Medicine,
Institute of Medical Sciences & SUM Hospital, Bhubaneswar, Orissa.
3. **Dr. Amit K. Singh** (*Associate Professor*) Community Medicine,
VCSG Govt. Medical College, Srinagar – Garhwal, Uttarakhand
4. **Dr. R G Viveki** (*Associate Professor*) Community Medicine,
Belgaum Institute of Medical Sciences, Belgaum, Karnataka
5. **Dr. Santosh Kumar Mulage** (*Assistant Professor*)
Anatomy, Raichur Institute of Medical Sciences Raichur(RIMS), Karnataka
6. **Dr. Gouri Ku. Padhy** (*Associate Professor*) Community and Family
Medicine, All India Institute of Medical Sciences, Raipur
7. **Dr. Ritu Goyal** (*Associate Professor*)
Anaesthesia, Sarswathi Institute of Medical Sciences, Panchsheel Nagar
8. **Dr. Anand Kalaskar** (*Associate Professor*)
Microbiology, Prathima Institute of Medical Sciences, AP
9. **Dr. Md. Amirul Hassan** (*Associate Professor*)
Community Medicine, Government Medical College, Ambedkar Nagar, UP
10. **Dr. N. Girish** (*Associate Professor*) Microbiology, VIMS&RC, Bangalore
11. **Dr. BR Hungund** (*Associate Professor*) Pathology, JNMC, Belgaum.
12. **Dr Sartaj Ahmad**, PhD Medical Sociology, *Associate Professor*,
Swami Vivekananda Subharti University Meerut UP India
13. **Dr Sumeeta Soni** (*Associate Professor*)
Microbiology Department, B.J. Medical College, Ahmedabad, Gujarat, India

NATIONAL EDITORIAL ADVISORY BOARD

1. **Prof. Sushanta Kumar Mishra** (Community Medicine)
GSL Medical College – Rajahmundry, Karnataka
2. **Prof. D.K. Srivastava** (*Medical Biochemistry*)
Jamia Hamdard Medical College, New Delhi
3. **Prof. M Sriharibabu** (*General Medicine*) GSL Medical College, Rajahmundry,
Andhra Pradesh
4. **Prof. Pankaj Datta** (*Principal & Prosthodontist*)
Indraprastha Dental College, Ghaziabad

NATIONAL EDITORIAL ADVISORY BOARD

5. **Prof. Samarendra Mahapatro** (*Pediatrician*)
Hi-Tech Medical College, Bhubaneswar, Orissa
6. **Dr. Abhiruchi Galhotra** (*Additional Professor*) Community and Family
Medicine, All India Institute of Medical Sciences, Raipur
7. **Prof. Deepti Pruthvi** (*Pathologist*) SS Institute of Medical Sciences &
Research Center, Davangere, Karnataka
8. **Prof. G S Meena** (*Director Professor*)
Maulana Azad Medical College, New Delhi
9. **Prof. Pradeep Khanna** (*Community Medicine*)
Post Graduate Institute of Medical Sciences, Rohtak, Haryana
10. **Dr. Sunil Mehra** (*Paediatrician & Executive Director*)
MAMTA Health Institute of Mother & Child, New Delhi
11. **Dr Shailendra Handu**, *Associate Professor*, Phrma, DM (Pharma, PGI
Chandigarh)
12. **Dr. A.C. Dhariwal**: *Directorate* of National Vector Borne Disease
Control Programme, Dte. DGHS, Ministry of Health Services, Govt. of
India, Delhi

Print-ISSN: 0976-0245-**Electronic-ISSN:** 0976-5506, **Frequency:** Quarterly
(Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare. The journal is now part of DST, CSIR, and UGC consortia.

Contents

Volume 11, Number 07

July 2020

1. Nutritional Status of School Going Children in Government Primary Schools of Varanasi 1
Nitish Kumar Arya, Inu Mehta
2. Dance – As A Source of Relieving Stress among Women..... 7
A.S. Ambily
3. Pulse Oximetry in Comparison to Arterial Blood Oxygen Saturation in Patients with Respiratory Distress in Neonatal Intensive Care Unit (NICU) 16
Aieshwarya Pradhan, R A Langade
4. Pre Operative Magnetic Resonance Cholangiopancreatography in Laparoscopic Cholecystectomy with Special Reference to Hepatobiliary Anatomic Variations and Undetected Choledocholithiasis 22
Ajay Chauhan , Nilesh Mehta, Mitkumar V. Patel, P. P. Sharma, F. S. Mehta
5. The Size of the Sella Turcica in Skeletal Class I, Class II, and Class III using FACAD Software- South Indian Population Study 29
Akriti Tiwari, Srengalakshmi
6. Influence of Patients’ Perception on Doctors Physical Appearance - Kap Study 34
Akriti Tiwari, Arvind Sivakumar
7. Parental Perception of Inclusive Education..... 40
Amitha M. Hegde, Jithin George, Joseph M. John
8. Modifiable Risk Factors of Hypertension: A Hospital based Case – Control Study at Bagalkot, Karnataka. 46
Anand M. Devanagani, Shriharsha C, Deelip S. Natekar
9. The Effect of Fluoride in the Prevention of Dental Caries and Prevalence of Dental Fluorosis among High and Low Fluoridated Areas of Tamilnadu-A Cross Sectional Survey 54
Anisha , M. Vishali, D. Prabu, Sunayana Manipal, Rajmohan, Bharatwaj, Prashanthi
10. Occupational Health Problems among the Farmers of Rural Field Practice Area of Department of Community Medicine, KIMS, Hubballi: A Cross-Sectional Study 60
Anjana R Joshi, Dattatraya D Bant
11. The Two Underlying Factors of India’s Health System Issues. A Comparative Analysis..... 66
Ansuman Swain, Kumar Sumit
12. Immediate Effect of Playing Smart Phone Action Videogames on Audiovisual Reaction Time 73
Anuradha Rajiv Joshi, Richa Tiwari

II

13. Evaluation of Serum Uric Acid Levels in Psoriasis Vulgaris 78
Apurav Kaushik, Aneet Mahendra, Sanjeev Gupta, Suvarna Prasad, Rohit Singla
14. Community De-fluoridation - Experience in Kaiwara Village, Chikkaballapur District, Karnataka, India ... 85
Arjunan Isaac, S Pruthvish, Radhika, N S Murthy
15. Effect of 810nm Diode Laser on Post-operative Pain Adjunct to Periodontal Flap Surgery 91
Arvind Nagaraj, Mamatha Shetty, Srikala Bhandary
16. A Cross Sectional Study on Middle Finger Tip Pinch, Ring Finger Tip Pinch, Little Finger Tip Pinch Strengths : The Correlations with Anthropometric Variables in North Indian Population 97
Ashish Jacob, Vishal Verma, Reena Singla
17. Management Practices among Diabetes Population in Rural Area of North India 104
Ashok K, T. Bano, S.K. Garg, G. Singh
18. Role of Pre Operative Peritoneal Lavage in Patients of Perforation Peritonitis..... 111
Ashutosh Bawa, Ram Gopal Sharma, Kapil Sindhu, Piyush K. Sinha, Ashish K Chaudhary, Minal Panwar
19. Nutritional Assessment Using 24 Hour Dietary Recall Method, Anthropometry and Clinical Assessment among Young Adults Studying in a Private Medical College, Thrissur, Kerala..... 117
Albin John, Navya C J, Vidhu M Joshy
20. Slow Learners and Low Achievers Can be in the Limelight with the Toppers- A Ray of Hope for Zero Rejection-a Qualitative Analysis 122
P Anitha, G.Denish Dhivyan
21. Perception of the Visually Impaired Students Towards Inclusive Education in Mainstream Higher Educational Institutions (with Special Reference to Multimodal Material Preparation Center, Bharathiar University - Coimbatore)..... 127
Sowdeswari. D, Chandramathi. R, F. X. Lovelina Little Flower
22. The Impact of Inclusive Education on Children with Mild Intellectual Disability in Promoting Social Skills and Peer Positive Attitudes in Trichy District..... 132
G.Sasikala, P. Swarnakumari
23. COVID-19 as a Conscious Organism: A Novel Understanding of the SARS-CoV-2 as a Natural Evolution of the SARS Virus 137
Asima Tripathy, Rajat Kumar Pradhan
24. Knowledge, Awareness and Attitudes About Hepatitis B Infection and Its Vaccine among Health Care Workers at a Tertiary Care Centre in Eastern India..... 143
Ayaskanta Singh, Bijayalaxmi Balirasingh, Pratishya Bhatt, Jimmy Narayan
25. Systematic Review on Quality of Life among Migraine Sufferers 149
B.Jayabharathi, K.Silambuselvi
26. Protective Role of Royal Jelly and Honey against Cisplatin Induced Sperm Function Parameters in Male Rats..... 153
Bhalchandra Baburao Waykar, Yahya Ali Alqadhi
27. Organ Donation: Awareness, Attitudes and Beliefs among Undergraduate Medical Students 159
Bharani P.Jada, Meghana Kankanla, Ravi Kumar Jonnalagadda

28.	Internet use and Physical Health Problems in School Going Students	165
	<i>Bhuvan Kumar Singh, Mohan Patil</i>	
29.	Clinical Profile of Dengue Fever and Associated Expanded Dengue Syndrome in a Tertiary Care Hospital.....	170
	<i>Bimal K Agrawal, Robin Gahlawat, Manu Mathew, Gaurav Aggarwal, Usha Agrawal</i>	
30.	Attitude of Medical Students Towards Dissection on Human Cadaver: A Study on the Students of a Medical College of Eastern India	176
	<i>Biswa Bhusan Mohanty, Gyanaranjan Nayak, B. Shanta Kumari, Sujita Pradhan, Sitansu Kumar Panda</i>	
31.	Physical Therapy Approach in Conjunction with Dry Needling on Health Related Quality of Life in Patients with Temporomandibular Disorder: A Randomized Control Trial	182
	<i>Biswajit Kanungo, Ramesh Chandra Patra, Patitapaban Mohanty, Parul Bawa</i>	
32.	Current Radiographic Practices and Radiation Dose Evaluation	188
	<i>Chanchal Kaushik, Inderjeet Singh Sandhu, AK Srivastava, Mansi Chitkara</i>	
33.	Family Interaction Pattern in Wive's of Alcohol Dependents.....	195
	<i>Chinnu Sebastian, Suja M.K</i>	
34.	A retrospective study to assess the trends of Sexually Transmitted Infections among the patients attending Skin and STD OPD KIMS, Hubli	200
	<i>Dattatraya D Bant, Shiv Kumar</i>	
35.	Assessment of Safety Practices of Pesticide Use among the Farmers in Adargunchi and Noolvi, Karnataka - A Cross Sectional Study	207
	<i>Dattatraya D Bant, Laxmikant Lokare, Tewe U Kapfo</i>	
36.	Study of Proportion of HIV in Patients of Malignancy in Tertiary Care Cancer Hospital of Malwa Region of Punjab:A Hospital based Study	214
	<i>Deepak Arora, Parvinder Sandhu, Pooja Arora, Karuna Singhe, Amrinder Singh</i>	
37.	Effect of Two Connector Designs on the Fracture Resistance of All-Ceramic Core Materials for Fixed Dental Prostheses: An In-Vitro Study	218
	<i>Deepanshu Sharma, Sumit Aggarwal, Chandan K Kusum, Arshi Mishra,</i>	
38.	Clinical Significance Versus Statistical Significance with Regards Gingival Scores in Herbal and Chlorhexidine Mouthwash Clinical Trials- A Systematic Review	224
	<i>Deepika Dagar, Pradnya Kakodkar, Sahana Hegde Shetiya</i>	
39.	Impact of Two Grip Strengthening Exercise Protocols on Grip Strength of Non-Dominant Hand.....	231
	<i>Devika Sharma, Saurabh Sharma, Raj Kumar Meena, Sanjai Kumar, Sartaj Ahmad</i>	
40.	Mental Distress among Students of a Private University of Delhi, NCR.....	237
	<i>Dhruva Nandi, Karunanidhi Kaur, Tanvi Yadav, Udit Narayan Chhetri, Neha Taneja, Aanchal Anant Awasthi, Rajiv Janardhanan</i>	
41.	Evaluating the Pain Responses among Infants Receiving Rotavirus Vaccine Versus Oral Polio Vaccine Before the Administration of Pentavalent Vaccine with Inactivated Polio Vaccine: A Randomized Study	241
	<i>Divya Sri Mudundi, Apoorva AC, Juny Sebastian, Mandyam Dhathi Ravi</i>	

IV

42. Menstrual Characteristics among the Nepali Adolescent Girls 247
Duka Devi Chhetri, Maibam Samson Singh
43. Clinical Cure and Microbiological Eradication in Respiratory Tract Infections..... 254
Eema Chaudhary, Shivam Mohan Pandey, Ajay Kumar, Rishi Yadav, Vivek Gautam, Shubham Tiwari
44. Validity and Reliability of Electronic Head Posture Instrument for Measurement of Cranio-Horizontal Angle, Craniovertebral Angle and Sagittal Shoulder Angle 260
Edrish Saifee Contractor, Sweety Shah, Stuti Shah, Parita Dave
45. Significance of Plain Xray Findings in Neck Pain with Relation to Cervical Radiculopathy and Myelopathy 266
Elangovan D, Prem Gowtham E, Kanchana B, Karthikeyan D, Mohan S
46. Salivary Omega6/ Omega 3 Fatty Acid Ratio And Dental Caries-Less is More 272
Geethu Jose, Srikala Bhandary, Amitha M Hegde, Suchetha Kumari, Shilpa Shetty, Roopa
47. Clinical Profile of 46 Non AMD CNVM and Management with Anti-Vegf 277
Girish A. Gadre, Prashant Bulchandani, Vijay H. Karambelkar
48. To Study Various Complications Present amongst Metabolic Syndrome Patients and Control Subjects 283
Gunjan Kumar Mandal, Suvarna Prasad, B.K.Agrawal, Sunita Manhas, Karanpreet Bhutani
49. Hypoglycaemic Effect of Alcoholic Extracts of the Leaves of Abroma Augusta & Gymnema Sylvestre Plants in Type II Diabetes Mellitus Patients 288
H. Venkatesan, S. A. Karthi
50. Explore the Parental Determinants associated with Malnutrition among Children Under Five Years Residing in Rural Areas..... 295
Hanamesh H Karkappanavar, Deelip S Natekar, Utalbasha Dhandargi
51. Web-Based Application Development of Early Detection of High-Risk Maternal Referral System in the Islands Region (SIDILAN) in South Bangka Regency 301
Harindra, Liana Devi Oktavia
52. Knowledge and Awareness Regarding Bruxism and its Management in Dakshina Kannada Population.... 308
Isha Singh, Manoj Shetty, Chethan Hegde, Bharath Raj Shetty
53. Empowerment of Family Planning (FP) Cadres and Influencing Factors with SEM Analysis 311
J.J. Kristiarini, H.M. Syamsulhadi, Kusnandar, E.S.Sulaeman
54. A Study on Prevalence of Metabolic Syndrome in Young Medicos of South Karnataka..... 318
Jai Prakash, Venkatesh P, Rajesh S.S, Krishna Iyengar
55. A Study to Find Out the Effect of Dynamic Soft Tissue Mobilization (DSTM) with Retro - Walking on Hamstring Flexibility and Dynamic Balance in Young Collegiate Students – An Interventional Study. 324
Jaydev Pandya, Krupa D. Tank
56. Relationship between Perceived Stress and Coping among Caregivers of Patient with Schizophrenia 330
G.J. Sara Sapharina, G. Neelakshi
57. Role of Diagnostic Laparoscopy in Chronic Pelvic Pain 337
Imreen Jamal, Devika Mor, Sukla Debberma

58.	Determination of Occlusal Splint Thickness for TMJ Derangement based on MRI- A Review	343
	<i>Jennifer Suhasini S, Kathiravan Selvarasu</i>	
59.	Clinical Profile of Amblyopia in Young Adults.....	348
	<i>Girish A. Gadre, Surabhi Khandelwal</i>	
60.	Estimation of Salivary Heat Shock Protein 70 (HSP70) in Children With Early Childhood Caries	354
	<i>Jithin George, Manju R, Amitha M Hegde, Priyal Sheth, Lekshmi R Suresh</i>	
61.	Pre-Processing and Image Segmentation Techniques	361
	<i>Jyothisri.V</i>	
62.	Cryotherapy in Knee Osteoarthritis.....	367
	<i>Jyoti, Shabnam Joshi, Meenakshi Bagri</i>	
63.	Assessment of the Prevalence of Kidney Stone Disease: A Structural Equation Model	373
	<i>K. Lokesh, K. Alagirisamy, P. Manigandan, D. Pachiyappan</i>	
64.	Comparison of Application of Bio-Statistics in National and International Medical Journals	380
	<i>K.S.Sridhara</i>	
65.	The Role of Ayurveda in Public Health	386
	<i>Kamath M</i>	
66.	A Review on Medication Adherence in Asthma	390
	<i>Kavitha P, Umamaheswari D</i>	
67.	Nutritional Assessment of Japanese Encephalitis and Acute Encephalitis Syndrome confirmed patients of Gorakhpur Uttar Pradesh.....	395
	<i>Khushnoor Ansari</i>	
68.	Clinical Pharmacist Role in Estimation And Evaluation of Treatment Outcomes in Patients Suffering with Respiratory Tract Infections in A Tertiary Care Teaching Hospital	401
	<i>Konduru Manasa, D. Lakshmi Priya, Gummadi Rishitha Sharon, Sri Tanvi, Kudipudi Harinadha Baba, Kanamala Arun Chand Roby</i>	
69.	Effect of PNF in Improving Lower Extremity Function in Adolescent with Spastic Diplegic Cerebral Palsy-A Case Report.....	406
	<i>Kovela Rakesh Krishna, Ajay Thakur, Pamidigantam Raghava Priya, Sunjyoth HS, Subhash Srivastav, Sridevi Prabhu</i>	
70.	Class Imbalance Applied to Medical Neuroimaging for Classification of Alzheimer's Disease.....	409
	<i>KR Kruthika, Rajeswari: Results and Discussion</i>	
71.	The Dearth of Dengue Awareness in Rural Population – Time to Act!!!	415
	<i>Kumar. Vikas, Mayur S. Sherkhane, Shruti. Kardalkar</i>	
72.	Current Scenario of Health Insurance in India: A Study Comprising Various Challenges and Measures For It	424
	<i>Kunuma Das</i>	

VI

73. Impact of Automobile Emission on Pulmonary Function Parameters of Non-Smoking Road Side Vendors and Shopkeepers 431
Lata Mullur, Livingston Sharon, C Mahesh
74. State of Ethical Issues in Published Literatures: A Non-Systematic Review..... 436
Lokesh Kumar S.S, Sowmiya KR
75. Analysis of Physical Parameters in Pre-Obese Women- An Observational Study 441
Manali B Badave, G Varadharajulu
76. A Study to Evaluate the Effect of Proprioceptive Neuromuscular Facilitation Stretching on Balance and Gait in Spastic Diplegic Cerebral Palsy: An Interventional Study 448
Mansi Dabhi, Shweta Rakholiya
77. Metabolic Syndrome: Prevalence of Its Components in Post Menopausal Females 455
Karanpreet Bhutani, Punam Rani, Arvind Kumar, Suvarna Prasad, Sunita Manhas
78. Sociodemographic Characteristics of Pregnancy Induced Hypertension: An Observational Study in the Kolhapur Population 460
Jyosthana Koppula, Vasudha Sawant
79. Utilization of Antenatal Care Package among Women of Urban Slums..... 466
Shruti. Kardalkar, Mayur S. Sherkhane
80. Awareness about Diabetes: A Comparison between Population of Urban Areas and Urban Slums. 473
Mayank Garg, Prerna Mohan Saxena, Raju K Parasher
81. Climatic Variation Water Quality Assessment of Selected Temple Ponds in Kanchipuram..... 479
Meenakshi Perumal, Sriram Gopalsamy
82. Living with Urostomy: Patient's Perspective 486
Meenal Sharma, Sukhpal Kaur, Amlash Seth, Prabhjot Singh
83. A Comparative Study of Abdominal Versus Non – Descent Vaginal Hysterectomy in a Tertiary Care Centre..... 492
Mihir Kumar Sarkar, Arindam Halder
84. A Review on Machine Learning Techniques in the Diagnosis of Psychiatric Disorders..... 497
Mohit Gangwar, Sapna Singh, Rohit Srivastava, Rohit, Chandrabhan Singh, Neha Goyal, Himanshu Kumar Shukla
85. Hospitalized Morbidity & Utilization of Beds in a Rural Health Training Centre 502
Mohite RV, Kshirsagar VY
86. Variation in Blood Pressure and Pulse in Inter-arms and Its Management..... 508
Naresh Vashist, Raveen Chauhan
87. Role of Fine Needle Aspiration Cytology in Classifying Breast Lesions with Special Reference to Borderline Cases..... 515
Naveen Kumar, Purva Sharma, Mamta Gupta, Sangeeta Sharma, Rani Bansal, Veena K. Sharma
88. Invitro Study to Assess the Impact of Chelating Agents on Microhardness of Primary Radicular Dentin .. 522
Needhika Chhibber, Arun Kumar, Deepmala

89. A Study to Compare the Effect of Respiratory Muscle Stretch Gymnastic (RMSG) and Diaphragmatic Breathing on Pulmonary Function Test among Geriatric Population– An Interventional Study..... 525
Nikhil Aggarwal, Nidhi Ved
90. The Effect of X Box 360 Kinect-Virtual Reality Intervention on Balance and Gait Training In Stroke Patient”: An Interventional Study..... 532
Nikita Girishbhai Shobhana, Shweta Rakholiya
91. A Study to Correlate the Vertical Jump Test and Wingate Cycle Test as a Method to Assess Anaerobic Power in Football Players..... 538
Parul A. Rakholiya, Arti Gadesha
92. A study to Assess the Effectiveness of Jacobson’s Progressive Relaxation Technique on Anxiety among Elderly People of Aged 60-70 Years in Selected Old Age Homes at New Delhi 545
Pauline Sharmila, R Sree Raja Kumar, Sonia Mehta
93. Determinants of Depressive Disorder among Elderly Stroke Patients in the Northeast of Thailand..... 552
Peyanut Jantavaree, Pannee Banchonhattakit, Rujira Duangsong, Rajda Chaichit
94. Influence of Family, Peer Factors and Comprehensive Sexuality Education on Teenage Pregnancy in the Northeast of Thailand: A Case Control Study 557
Phandita Sukhumal, Thiti Sungworawongpana, Wongsa Laohasiriwong
95. Endometrial Estrogen and Progesterone Receptor Expression and Blood Vessel Density in Abnormal Uterine Bleeding..... 564
Pradyot Singh, Mamta Gupta, Rani Bansal, Davender Swarup, Mitali Singhal
96. Physical, Psychosocial Determinants and Quality of Life of Elderly in the Northeast of Thailand 571
*Prapat Thammawongsa, Wongsa Laohasiriwong**
97. Assessing the Awareness of Usage of Mouth Washes among the General Population and Patients Undergoing Orthodontic Treatment-A Questionnaire Study 576
Prasanna Arvind T.R, S. Aravind Kumar
98. Morphological Variations in the Branching Pattern of Left Coronary Artery in Adult Human Hearts using Silicon Cast Method..... 583
Najma Mobin, H. Basavanagowdappa
99. Post-Menopausal Sex Hormones in Relation to Type 2 Diabetes Mellitus 590
Priya Alva, Shilpa Shetty, Aditi Bhandary, Laxmi Manjeera, Neetha Nandan, Suchetha Kumari
100. Effectiveness of Foam Texture Versus Sand Texture on Balance with Diabetic Polyneuropathy Patients: A Comparative Study..... 596
Priyanka Parmar, Shweta Rakholiya
101. Knowledge, Compliance and Determinants of Use of Standard Precautions for Infection Control among Health Care Workers – A Teaching Hospital Based Study..... 601
Priyanka Sharma, Pooja Goyal, Raina Chawla, Rashmi Ahuja, Manisha Meena, Annu Sharma, Shobhit Srivastava
102. Parental Awareness of Musculoskeletal Health Consequences Due to Overweight Bag in Primary School Students 609
Rachhanaa Satish Pawaskar, Snehdeep S Patil

VIII

103. Retention of Various Pit and Fissure Sealants in Deciduous Teeth. A Systematic Review..... 615
Rachna Mulani, Aditi Mathur
104. A Cross Sectional Study to Evaluate Tree Plantation and Gardening as an Intergenerational Bonding Activity amongst Geriatric Population 621
Rahul Netragaonkar, Amrut Arun Swami, Shruti Amrut Swami
105. Spectrum of Congenital Heart Diseases in a Tertiary Care Centre, Mysuru, Karnataka 628
Rajani H S, Narayanappa D, Sunilkumar S
106. A Retrospective Study on Risk Habits Associated with the Prevalence and Severity of Oral Submucous Fibrosis in the Indigenous Population of Andaman and Nicobar Islands 633
Ramya R, Rajkumar.K, Arul Mozhi, Harini Priya, Ravi, K.Ravi, Swarnalakshmi.R
107. Status of Oxidative Stress in Patients of Chronic Obstructive Pulmonary Disease 640
Authors: Rashmi Bathri, Ruchira Chaudhary, Ragini Gothalwal
108. Anatomical study of Variations of Median Nerve and Musculocutaneous Nerve in the Arm..... 644
Rashmi C Goshi
109. Demographic Trends and Outcome of Acute Poisoning in a Rural Tertiary Care Hospital of Nalgonda District, Telangana..... 652
Ratna Balaraju, Chandrasekhar Vallepalli, Srujana Reddy Sattari, Komali Reddy Yenna, Kavya Sri Vijayagiri, Navya Chowdary Sunkavalli, M.M.V. Prasad Sharma
110. Cognitive Behaviour Therapy for 'Internet Gaming Disorder A Systematic Review 657
Rekha B. Raveendran, S. Vinod Kumar: Abstract
111. Effects of Stretch Pole Exercises on Pulmonary Functions among Smartphone Users 662
Rekha K, Rubi Kankariya, Roshini Nivetha M
112. A Study on Employee Health and Safety of Weaving Cooperative Society with Reference to Kannur District 667
Reshmi Jk Babu, Ambily AS
113. A comparative study of Venous and Capillary blood glucose in a Tertiary Care Hospital..... 673
Richa Sirohi, Ravi Pratap Singh, Kalpana Chauhan
114. Prevalence of Domestic Violence among Married Women of Urban Slum 678
Richa Deo, Padmaja R Walvekar, MD Mallapur
115. Exploring Impact of Smart Phones Usage on Interpersonal Relationship of Students in Meerut, (UP)..... 683
Rijul Ranjan, Saurabh Sharma, Sartaj Ahmad
116. To Evaluation the Levels of Serum Uric Acid and Triglyceride in Metabolic Syndrome 690
Ritu Devi, Sunita Manhas, Suvarna Prasad, Karanpreet Bhutani, Jaya Jeena
117. Complementary and Alternative Medicinal Use amongst Antenatal in a Rural Tertiary Care Hospital of Haryana 694
Ruby Bhatia, Prem Khosla, Sunita Mor, Neha Vashishat, Gaurav Aggarwal

118. A Review of the Role of Thoracic Imaging in Clinical Practice in a Tertiary Care Centre in Eastern India 700
Runa Das , Debabani Biswas , Aniruddha Ghosh , Amitava Paul , Debabrata Moitra
119. Sero-Prevalence of Transfusion Transmissible Infections in Blood Donors at Blood Bank of a Tertiary Care Hospital - an indicator of Blood Safety in the Region: A Study from North Haryana (India)..... 706
Sachin Garg , Nishant Saini , Rajesh Garg , Shefally Garg , Hemlata Munde
120. Effect of Pnf Stretching on Proprioception and Physical Function in Individual with Knee Osteoarthritis: An Experimental Study 712
Sagar Nathani , Krupa D. Tank
121. Efficacy of Emotional Enhancement Intervention Along with Cognitive Behaviour Techniques for Children with Autism Spectrum Disorder 718
Sagayaraj K , C.N. Ram Gopal , Anjali S N , S Karthikeyan
122. Experiencing Foster Care-Happiness and Wellbeing of Institutionalised Children..... 725
Saleena.M , Suja M.K
123. Physical Activity Level among School Going Children in Surat City, Gujarat: A Cross Sectional Survey. 730
Salvi Shah , Shraddha Diwan
124. Adherence to Medication among the Patients with Type 2 Diabetes Mellitus in a Rural Area: A Community based Study..... 737
Santosh Achappa , Sri Lakshmi G
125. Risk of Dementia among the Elderly in a Rural Community: A Cross Sectional Study 745
Santosh Achappa , Srinidhi P M Bhat
126. Prevalence & Pattern of Tobacco Use among Adolescents in Vijayapura City, Karnataka – A Cross Sectional Study 751
Santosh D.Patil , Praveen Ganganahalli , Mohd Shannawaz , Prakash Chauhan , M.B.Biradar
127. Study of Mobile Phone Usage in Undergraduate Medical and Dental Students During Covid-19 Lockdown 758
Sasirekha M , Mahima Sophia M , Vaijayanthimala P , Leonoline Ebenezer J
128. Meteorological Conditions Associated with AES/JE Outbreak 2019 in Bihar 765
SC Bhan , Anand Shankar , Ragini Mishra , GS Shilpashree
129. Enhancing Health Education about Carcinogenic Liver Fluke among Migrant Labourers 772
Schawanya Kaewpitoon Rattanapitton , Nathkapach Kaewpitoon Rattanapitton , Nattawut Keeratibharat , Pundit Asavaritikrai , Alisa Boonsuya , Phornphitcha Pechdee
130. A Descriptive Cross Sectional Study on Assessment of Haemoglobin Level and Factors Associated with Anemia During Pregnancy among Pregnant women attending OBG Unit of SNMC HSK Hospital and Research Centre Bagalkot, Karnataka 778
Seema Magadum , Kamala K N , Deelip S Natekar

Nutritional Status of School Going Children in Government Primary Schools of Varanasi

Nitish Kumar Arya¹, Inu Mehta²

¹Assistant Professor (Guest faculty), Department of Economics, Mahatma Gandhi Central University, Motihari, Bihar, India, ²Professor and Principal, Mahila Mahavidyalaya, Banaras Hindu University, Varanasi, U.P., India

Abstract

Background: Nutrition is one of the most essential things of life. It plays a crucial role in body growth, development and maintenance of health. The objective of this study is the study of the impact of the mid-day meal scheme on the nutritional status of school children (6-12 years) in Varanasi District.

Methodology: This study was conducted for 320 students of class 1-8 at five government primary schools in two educational blocks in Varanasi district. Simple random sampling was used for selection of children. The variables of the study were the height and weight of selected students.

Results: The results of the study indicated that the nutritional status of MDM children. The study undertaken on a representative and adequate sample of Varanasi revealed that as per Waterlow classification, around 45 per cent of children were found to be normal as per their weight for age and 72.8 per cent of children were found to be normal as per their height for age. The prevalence of wasting and stunting in these children was high (55 % wasted and 27 % of stunted), with boys and girl suffering almost equally. The observations of the present study suggest that the distribution of height of boys were found shorter than boys of WHO standards by -1.8 cm to -6.4 across all ages. The maximum difference was found in age group of 13 years. The weight of boys increased with in age from 6 to 14 years. The weight in the age group 6 to 14 years ranged from 19.5 kg to 50.4 kg in boys.

Conclusion: The overall findings of the study revealed that the mean weight of boys and girls was found shorter than boys and girls of WHO standards. There was no significant difference in the prevalence of stunting and wasting for both boys and girls

Keywords: Nutritional Status, Anthropometry, Mid-Day Meal Scheme, Malnutrition.

Introduction

School age is the active growing phase of childhood. The Mid-Day Meal (MDM) scheme is the largest school lunch scheme in our country. It has been found that mid-day meal scheme has provided to the nutritional needs

of school going children in both rural and urban areas¹. Primary school age is a crucial period of physical growth as well as of mental skill development of the child. In India, the health and nutritional status of school going children is unsatisfactory in the current scenario². For the mental and physical growth of the child, childhood is the most crucial age. Nutritional food is required for the proper growth of the child. The problem of malnutrition is caused by a child does not get adequate food with proper nutrition. This scheme attracted many children from rural and urban areas mostly the girl child who was deprived of Education³.

According to the WHO malnutrition through continues to be a major health problems in South East Asian regions⁴. The main nutritional problems facing the school children include growth retardation, stunting, underweight, anaemia, and vitamin A deficiency. There are no other efforts for children in the age group of 5-14 years, apart from the mid-day meal scheme which is being run by the government of India in government schools⁵. Nutrition plays a vital role in the promotion of health and prevention of disease, and nutritious food is the main source of the proper growth of the body. Good nutrition is a basic component of health. National Programme for Nutritional Support to Primary Education (NP-NSPE) is considered as a goal to achieve the objective of providing free and compulsory primary education of the children age of 6-14 years. This scheme also giving a boost to the universalization of primary education through increased enrolment, improved school attendance, and retention and promoting the nutritional status of primary school children⁶. The present study was carried out to find out the nutritional status of children receiving Mid-Day Meal in schools of Varanasi.

Aims and Objectives

1. To study the nutritional status of children receiving mid-day meal in schools of Varanasi.
2. To compare nutritional status of school going age children of Varanasi with the WHO standard.

Materials and Method

To assess the impact of mid-day meal program on nutrition, the data was collected from five government primary schools from two different educational blocks

in Varanasi. Out of ten educational blocks of Varanasi one from each rural and urban blocks were selected as for sampling. Nagar Nigam block and Kashi Vidyapeeth block was selected from urban and rural area of Varanasi respectively. 160 students are girls and 160 students are boys selected through the simple random sampling. In every school, two students were selected form each classes from primary and upper primary schools (Class 1-8) from selected blocks of Varanasi. The development of an international growth standard for monitoring of school-aged children is driven by 2 contemporary events, the global rise in childhood obesity and the release of a new international development standard for preschool children by WHO⁷. Physical examination of all children was carried out and their height in cm and weight in kg were recorded. Each child's height and weight were measured in the metric system, using standardized techniques⁸. To assess the height of the children a stadiometer (measuring rod) was used which was capable of measuring to an accuracy of 0.1 cm. To record the weight of the children portable balance was used with an accuracy of 100 g. Children were instructed to stand on the balance with light clothing and without footwear and with feet apart and looking straight. The mean height and weight of the children according to age and sex were compared with the mean height and weight for age as per the World Health Organisation standards⁹.

The Nutritional status of the studied children was assessed using Waterlow (1973) criteria¹⁰. Table 1 shows, the Waterlow criteria assume that the expected height and weight measurements of the child follow the fiftieth centile of the growth curves. This assumption is necessary because prior height or weight measurements may not be available¹¹.

Table 1: Waterlow classification of Malnutrition

	Normal	Mild	Moderate	Severe
Height for Age (%)	95	90-95	85-90	85
Weight for Age (%)	90	80-90	70-80	70

Decreased height for age suggests chronic malnutrition (stunting); Decreased weight for age suggests acute malnutrition (wasting). Adapted from Waterlow (1973).

Acute malnutrition (i.e., wasting) measured in terms of weight deficit by Waterlow criteria can be determined by the following equation:

$$\text{Weight deficit (\%)} = (\text{Actual weight (kg)} / \text{Expected weight (kg) for actual height}) \times 100$$

Chronic malnutrition (i.e., stunting) measured in terms of height or length deficit by the Waterlow criteria can be determined by the following equation:

$$\text{Height deficit (\%)} = (\text{Actual height (cm)} / \text{Expected height (cm) at 50th centile for chronological age}) \times 100$$

Data Analysis and Results

The data were checked for completeness, coded and entered into MS Excel and analyzed using SPSS version 21.0. The data were analyzed using descriptive statistics consisting of measures of percentage, frequencies, and central tendency. Table 2 shows the distribution of students according to the age and sex. Maximum number of boys is 33 (20.6 %) and girls is 36 (22.5%) were in the age group of 12.

Table 2: distribution of students according to age and gender

Age (in years)	Boys		Girls		Total	
	No.	%	No.	%	No.	%
6	17	10.62	11	6.87	28	8.75
7	15	9.37	20	12.50	35	10.93

Table 3 indicated that the distribution of height of boys was shorter than boys of WHO standards in age 7, 9, 12, 13 and 14 by -1.8 cm to -6.4 cm. The height and weight of boys increased within the age from 6 to 14 years. The maximum difference was found in the age group of 13 years. In case of weight, age group of 6, 7, 11, 12, 13 and 14 were found lower weight to compare the WHO standard in boys. The maximum difference was found in the age group of 13 years.

Table 3: Comparison of mean height for MDM boy's with WHO standards on the basis of age.

Boys (n= 160)							
Age (in years)	No. of Students	Height (WHO)	Mean Height (in cm)	Difference value (\pm)	Weight (WHO)	Mean Weight (in kg)	Difference value (\pm)
6	17	116.0	118.2	2.2	20.5	19.5	-5.0
7	15	121.7	119.9	-1.8	22.9	21.7	-1.2

Table 4 indicated that the distribution of height of girls indicated that girls were found shorter than girls of WHO standards¹² by 3.1 cm to 8.1 across the age group of 6, 9, 10, 11, 12, 13 and 14. The maximum difference was found in the age group of 6 years. Table 4 also indicated that the weight of girls increased within the age from 6 to 14 years except in 11 years. The weight in the age group 6 to 14 years ranged from 17.9 kg to 52.1 kg in girls. In girls, the weight was found lower than the WHO standard across age group in 6, 7, 11, 12, 13 and 14 years.

Table 4: Comparison of mean height for MDM girl's with WHO standards on the basis of age.

Girls (n=160)							
Age (in years)	No. of Students	Height (WHO)	Mean Height (in cm)	Difference value (\pm)	Weight (WHO)	Mean Weight (in kg)	Difference value (\pm)
6	11	115.1	107.0	-8.1	20.2	17.9	-2.3
7	20	120.8	126.1	5.3	22.4	21.6	-0.8

Table 5 shows 45 per cent of children were found to be normal as per their weight for age. From table 5 also to be found that 55 per cent were malnourished and

6.2 per cent were in a severe degree of wasting. About more than half (55%) of them are suffered from wasting whereas, 26.9 per cent and 21.9 per cent were in a mild and moderate degree of malnutrition respectively.

Table 5: Nutritional status (Wasted) of children as per gender

Gender	No.	Normal	Wasted		
			Mild	Moderate	Severe
Boys	160	74 (46.3)	41 (25.6)	36 (22.5)	9 (5.6)
Girls	160	70 (43.7)	45 (28.2)	34 (21.2)	11 (6.9)
Total	320	144 (45.0)	86 (26.9)	70 (21.9)	20 (6.2)

Figures in parenthesis indicate percentages

Table 6 shows 72.8 per cent of children were found to be normal as per their height for age. From table 6 also to be found that 20.3 per cent children were in a mild degree of stunting and 5 per cent were in a moderate degree of stunting while a very less (1.9%) children were in a severe degree of stunting.

Table 6: Nutritional status (Stunted) of children as per gender

Gender	No.	Normal	Wasted		
			Mild	Moderate	Severe
Boys	160	119 (74.4)	31 (19.4)	9 (5.6)	1 (0.6)
Girls	160	114 (71.3)	34 (21.2)	7 (4.4)	5 (3.1)
Total	320	233 (72.8)	65 (20.3)	16 (5.0)	6 (1.9)

Figures in parenthesis indicate percentages

Discussion

The study undertaken on a representative and adequate sample of Varanasi revealed that as per Waterlow classification, around 45 per cent of children were found to be normal as per their weight for age and 72.8 per cent of children were found to be normal as per their height for age. The prevalence of wasting and stunting in these children was high (55 % wasted and 27 % of stunted), with boys and girl suffering almost equally. The observations of the present study suggest

that the distribution of height of boys were found shorter than boys of WHO standards by -1.8 cm to -6.4 across all ages. The maximum difference was found in age group of 13 years. The weight of boys increased with in age from 6 to 14 years. The weight in the age group 6 to 14 years ranged from 19.5 kg to 50.4 kg in boys. In case of weight, age group of 6, 7, 11, 12, 13 and 14 were found lower weight to compare the WHO standard in boys. The maximum difference was found in the age group of 13 years. Distribution of height of girls

indicated that the girls were found shorter than girls of WHO standards by -8.1 cm to 5.3 cm across all ages. The maximum difference was found in age group of 7 years. The weight of girls increased within the age from 6 to 14 years except in 11 years. The weight in the age group 6 to 14 years ranged from 17.9 kg to 52.1 kg in girls. In girls, the weight was found lower than the WHO standard across age group in 6, 7, 11, 12, 13 and 14 years.

Alim et al. reported that the girls of MDM schools were shorter than the ICMR well to do Indian girls at all ages except at age of 6 and 12 years (higher by 1.7cm and 1.6 cm, respectively) the maximum difference was found in age group of 9 years. Results on the height of boys indicated that the MDM boys were found shorter than boys of ICMR standard by 0.1 cm to 8.7 cm across all ages. The maximum difference was found in age group of 12 years. Gangadharan¹³ et al found prevalence of malnutrition up to 34.20 per cent in Kerala school children. Goyal¹⁴ et al also reported malnutrition among Ahmednagar school children to be only 20 per cent, with 6.8 per cent having severe malnutrition.

Conclusion

In the present study, it was observed that there was a high degree of relationship between height, weight and age. It can be concluded that boys were taller and heavier than girls. Statistically, the mean weight of boys and girls was found shorter than boys and girls of WHO standards. There was no significant difference in the prevalence of stunting and wasting for both boys and girls.

Dance – As A Source of Relieving Stress among Women

A.S. Ambily

¹Assistant Professor (Sr.Gr.) Department of Commerce and Management, Amrita School of Arts and Sciences, Kochi, Amrita Vishwa Vidyapeetham

Abstract

Stress is a natural feeling that people have when they are overloaded with burdens and struggling a lot to cope up with demands. The demands may be related to financial constraints, work related issues, relationships, and other situations, which may be challenging or threat, full for a person's existence. Stress is also called as a motivator. It will act as a fight-to-fight mechanism, which will helps how to fight against danger for survival. However, when there are too many stressors at one time may affect the person's mental and physical health and is very dangerous to the person. The present study focuses to analyze the impact of dance on stress among women with respect to Kerala.

Key Words: *Stress, Dance, Mental Health, Physical Health*

Introduction

Stress is the body's natural defense system against risks. It activates the body with hormones and prepare the systems to evade danger¹. This process is called fight-to-fight mechanism. Thus, the body produces large quantities of chemical cortisol, adrenaline and noradrenaline². These trigger will increase heart rate, muscle problems, sweating, and alertness. The more stressors we have the more stressful the person will be. Short-term stress can be helpful but long-term stress will lead to various health issues and problems³. Excess stress leads to increased blood pressure and pulse rate, breathing will be faster, digestive system slows down very quickly, body muscles will become tense, reduces sound sleep. All these symptoms are dangerous to health and will definitely affect normal body functions. Stress can make an individual productive and constructive when it is identified and well managed.⁴Adaptation towards a new situation from the old will reduce the stress to some extent.

Human beings react towards stress differently. What is stress in one person may not be the stress in another person. Therefore, anything can cause stress. Men and women have many of the sources of stress in common⁵. Possibly a little more stress is found in women since they play many roles in life. Women's role includes family obligations, taking care of children

and elderly people, work responsibilities and as well as other roles. Often they will spend more time meeting the needs of others rather than nurturing their own needs. Since they are working at high stress levels, are not able to recognize their needs even. This study aims to understand how women's of Kerala are managing their stress and whether dance and yoga has any impact on managing the stress.

Results of the studies continue to support a growing literature suggesting that exercise, physical activity and physical-activity interventions have beneficial effects across several physical and mental-health outcomes. Generally, participants engaging in regular physical activity display more desirable health outcomes across a variety of physical conditions. Physical-activity interventions show better health outcomes, including better general and health-related quality of life, better functional capacity and better mood state⁶.

Stress is a part of day-to-day living. In our daily lives, we are often exposed to situations that produce stress. The interpretation and reaction to events that make stress are different for different people⁷

Improving the individual's evaluations and coping skills, and the provided practices to integrate the learned separations with real life situations could lead to a decrease in the perceived stress and an increase in the psychological well-being.⁸

Objectives:

1. To analyze the common major life events that trigger stress.
2. To analyze the physical symptoms of stress.
3. To analyze the emotional reactions of stress.
4. To analyze the behavior's linked to stress.

5. To study whether Dance have any impact for reducing stress.

Materials and Methods

The study is purely descriptive in nature. Both primary and secondary data is used for the study. Primary data were collected from a sample of 49 women engaged in dance and yoga from Ernakulum district.

Table No. 1: Symptoms of Stress

Physical Symptoms of Stress	Sweating	Pain in the back	Cramps	Fainting	Headache	Heart Disease	High blood Pressure	Lower Immunity	Muscular aches	Nervous twitches	Pins and needles	Sleeping difficulties	Stomach upset	Menstrual problems
N	49	49	49	49	49	49	49	49	49	49	49	49	49	49
Mean	.4898	.3265	.2449	.0816	.9184	0.0000	.5102	.1633	.2245	.3265	.0816	.6735	.2857	.3265
Common Major Life Stress	Job issues	Lack of time	Sadness	Family Problems	Illness	Moving Home	Relationships							
Mean	.5510	.2857	.2653	.4898	.3673	0.0000	.3673							
Median	1.0000	0.0000	0.0000	0.0000	0.0000	0.0000	0.0000							
Mode	1.0000	0.0000	0.0000	0.0000	0.0000	0.0000	0.0000							

Source: Primary Data

The table explains the major common life events that trigger stress in women. Majority of stress are due to the Job issues relating to work environment. It comes to nearly 55.1 percent. 49 percent of stress issues are due to family problems. Because of relationships with respect to marriage issues and divorce comes to nearly 36 percent of stress. So number of factors are leading towards stress

for women.

The table explains that the major physical symptoms for stress among women is headache, which comes to nearly 91.8 percent. Nearly 67 percent of women are struggling with sleeping difficulties because of stress.

Other factors like high blood pressure, sweating, pain in the back and mensural problems are other physical symptoms which leads towards stress.

Table No: 2:Reactions because of Stress

Emotional Reactions because of Stress	Anger	Anxiety	Burnout	Concentration issue	Depression	Fatigue	Insecurity	Forgetfulness	Irritability	Nail Biting	Restlessness	Sadness
N	49	49	49	49	49	49	49	49	49	49	49	49
Mean	.7551	.5102	.0408	.4898	.6122	.3469	.2041	.2653	.5918	.2041	.4898	.4898
Behaviors Linked to Stress	Food Carving	Sudden Anger	Drug & Alcohol	Higher Tobacco	Social Withdrawal	Frequency Crying	Relationship Problems					
N	49	49	49	49	49	49	49					
Mean	.4898	.8163	.0816	0.0000	.4286	.3469	.4694					

Source: Primary Data

The table clearly states that nearly 75.5 percent of women emotionally react their stress through anger. Because of high stress, women are leading towards depression, which comes near to 61.2 percent. The study also shows that high level of irritability, anxiety, concentration issue and restlessness are also affecting women very badly because of stress.

The table explains that sudden anger because of stress is one of the major behavioral impact because of stress among women. It constitute nearly 81.6 percent. Other factors like food carving, relationship issues are also another behavioral symptoms of more stress.

Majority of the sample chosen belonged to the age group of 30-40, which covers nearly 44.9 percent. 40.8 percent were from the age group of 20-30. Only 14.3 percent were from 40 -50 age group. The study explains that majority of the respondents chosen for the study were non-working women which is around 61.2 percent. There were 20.4 percent teachers and only 9 percent doctors in the study.

Chi-Square Tests was applied to achieve the following hypothesis.

Ho 1: There is an association between Dance and Physical Health Benefits

Table No. 3: Chi-Square Tests - Pearson Chi-Square

Physical Health Benefits	Value	df	Asymp. Sig. (2-sided)*
Is a full body workout	.628	2	.730

The table shows that the Chi square value, $P > .05$ shows an association at the respective degree of freedom. The test result shows an association exist between Dance and Physical health benefits. The correlation is undertake between the variables. It was hypothesized that a relationship exists between Dance and Physical health benefits. The results above states that , there exists a positive relationship between Dance and Physical health benefits with respect to various variables like

Improve condition of lungs, Increase muscular strength, Stronger bones, Reduce stress hormones, Dance makes you smarter, Gives flat stomach, Is a full body workout.

Chi-Square Tests was applied to achieve the following hypothesis.

Ho 2: There is an association between Dance and Mental Health Benefits

Table No. 5: Chi-Square Tests - Pearson Chi-Square

The table shows that the Chi square value, $P > .05$ shows an association at the respective degree of freedom. Thus, there exist an association between Dance and Mental health benefits. Dance deals to better health benefits of women. The correlation is undertaken between the variables. It was hypothesized that a relationship exists between Dance and Mental health benefits. The results above states that , there exists a positive relationship between Dance and Mental health

benefits with respect to various variables like Sense of satisfaction, Reduces depression, Is a good cardio workout, Great stress reliever, Make you feel better, Good activity for any age, Creates social bonding.

Findings and Discussion

Majority of the sample chosen belonged to the age group of 30-40, which covers nearly 44.9 percent.

40.8 percent were from the age group of 20-30. Only 14.3 percent were from 40 -50 age group.

- Majority of the respondents were non-working women, which is around 61.2 percent. There were 20.4 percent teachers and only 9 percent doctors in the study.

- Majority of stress are due to the Job issues relating to work environment. It comes to nearly 55.1 percent. 49 percent of stress issues are due to family problems.

- The major physical symptoms for stress among women is headache, which comes to nearly 91.8 percent. Nearly 67 percent of women are struggling with sleeping difficulties because of stress. Other factors like high blood pressure, sweating, pain in the back and mensural problems are other physical symptoms, which leads towards stress.

- Nearly 75.5 percent of women emotionally react their stress through anger. Because of high stress, women are leading towards depression, which comes near to 61.2 percent.

- Sudden anger because of stress is one of the major behavioral impact because of stress among women. It constitute nearly 81.6 percent. Other factors like food carving, relationship issues are also other behavioral symptoms of more stress.

- There exists a positive relationship between Dance and Mental health benefits with respect to various variables like Sense of satisfaction, Reduces depression, Is a good cardio workout, Great stress reliever, Make you feel better, Good activity for any age, Creates social bonding.

- There exists a positive relationship between Dance and Physical health benefits with respect to various variables like Improve condition of lungs, Increase muscular strength, stronger bones, Reduce stress hormones, Dance makes you smarter, Gives flat stomach, is a full body workout.

- The Chi square proved that there is an association between Dance, Physical, and Mental Health Benefits with respect to women.

Discussion and Conclusion

Thus as a conclusion to the study it can be revealed that stress is a common issue in every human being, but the increased level of stress leads to various unexpected health problems. However, dance as a good physical exercise will helps to reduce stress to a good level among women. It benefits both mental and physical condition among women. Dance will act as a source of athletes. It helps to reduce anxiety. It provides emotional benefits, improves memory, makes smarter, it is good for brain, muscles and bones. It makes the body healthier. It will definitely reduce stress. Thus it is suggested to all women's irrespective of working or non-working to get involved in dance as part of their life which can be practiced at any age to make prepare them mentally and physically stronger.

Pulse Oximetry in Comparison to Arterial Blood Oxygen Saturation in Patients with Respiratory Distress in Neonatal Intensive Care Unit (NICU)

Aieshwarya Pradhan¹, R A Langade²

¹Resident, Department of Pediatrics, KIMSUDU, Karad, ²Associate Professor, Department of Pediatrics, KIMSUDU, Karad

Abstract

Background: It is essential to monitor the saturation of oxygen in newborns receiving supplemental oxygen to reduce the incidence of exposure to hyperoxemia and their potential hazardous effects of radical oxygen species. The oxygen saturation is measured by pulse oximeter which is a non-invasive tool. Arterial blood gas is used to determine the pH, PaCO₂, PaO₂ and the bicarbonate level.

Aims and Objectives: This study aimed at searching the reliability of non-invasive pulse oximeter in knowing oxygen saturation (SpO₂) in comparison with arterial blood PaO₂ in neonates with respiratory distress.

The primary objective was to correlate the values between partial pressure of oxygen (PaO₂) and pulse oxygen saturation by pulse oximeter (SpO₂). The secondary objectives were 1) To find out the efficacy of pulse oximeter in diagnosing hypoxia in comparison with PaO₂.

2) To find out efficacy of pulse oximeter in diagnosing hyperoxemia in comparison with PaO₂.

Material and Method: Observational study was conducted on thirty neonates suffering from different causes of respiratory distress in NICU of Krishna Hospital, Karad during December 2017 to September 2019.

The PaO₂ measurements were obtained from the blood analyzer; simultaneous pulse oxygen saturation were recorded.

Results: A significant correlation was observed between values of pulse oxygen saturation by pulse oximeter (SpO₂) and partial pressure of oxygen (PaO₂) by arterial blood sampling (r value -0.73, p<0.01)

On ROC curve analysis, sensitivity and specificity of pulse oximetry in prediction of hypoxemia was 87.5% and 85.7% at cut-off of 90% and 91% each. The sensitivity and specificity of pulse oximetry in prediction of hyperoxemia was 100% and 71.4% at cut-off of 94% while it was 88.9% and 76.2% at cut-off of 95% respectively.

Conclusion: Pulse oximetry showed a good correlation with arterial blood PaO₂. Oxygen saturation measured by pulse oximetry is a good diagnostic and prognostic tool for detecting hypoxemia and hyperoxemia.

Keywords: Pulse oximetry, Arterial blood gas, Oxygen Saturation, Partial Pressure of Oxygen, Hypoxemia, Hyperoxemia.

Introduction

The most prevalent cause for a neonate to get admitted in NICU is Respiratory Distress. 30% of late preterm neonates and 14% of term neonates admitted in

NICU develop respiratory morbidity which is due to a significant cause. This morbidity is more in neonates born before gestational age of 34 weeks. In resting neonates if the Respiratory Rate is more than 60 per minute and if there are inspiratory costal retractions or expiratory grunting is present then it is considered as Respiratory distress. The neonate should be diagnosed after seeing in the first few minutes and lifesaving measure should be considered immediately and further plan of management should be drawn.¹

In neonates the common etiologies of Respiratory distress are: Respiratory distress syndrome(RDS), Transient Tachypnea of Newborn (TTN), Meconium Aspiration Syndrome(MAS), Persistent Pulmonary Hypertension of the newborn (PPHN), Congenital pneumonia or Acquired pneumonia, Congenital anomalies of upper airway, hematological Causes(severe anemia, polycythemia), Congenital Heart Disease(CHD), Metabolic disorders- Inborn Errors of Metabolism(IEM), Neurological causes like Seizures.¹

It is essential to monitor the saturation of oxygen in newborns receiving supplemental oxygen in order to reduce the incidence of exposure to hyperoxemia and the Risk of potential hazardous effects of radical oxygen species.²

The adequacy of oxygenation and ventilation are assessed by the Arterial blood gas analysis which is the gold standard.³ Indirectly the oxygen saturation of a patient's blood is measured by pulse oximeter which is a non-invasive tool.⁴ It is necessary to determine whether the non-invasive pulse oximetry which is easy to use and can be used continuously to monitor saturation of the patient with no side effects is preferred for monitoring oxygen in comparison to invasive method of arterial blood gas analysis which might lead to anemia because of repeated sampling and which also requires heparin in order to prevent coagulation of blood.⁵

This study aims to correlate between PaO₂ and SpO₂ values during routine practice and whether pulse oximeter can replace arterial blood gas.

Methodology

This study was carried out in NICU of Krishna Institute of Medical Science, Karad from December

2017 to September 2019. Thirty neonates who were suffering from different causes of respiratory distress in Neonatal Intensive Care Unit (NICU) were enrolled.

Inclusion Criteria:

1. Both Genders
2. Gestational age: Preterm and Term
3. Neonates having DOWNE score of more than or equal to 4

Exclusion Criteria:

1. Major congenital anomalies and acute clinical changes or changes in SpO₂ of more than 1% during arterial sampling, jaundiced as all these factors affect Saturation of Peripheral Oxygen (SpO₂) reading.

2. Congenial Heart Disease and Shock

Analysis of blood gases using arterial samples.

The saturation of Peripheral Oxygen (SPO₂) monitor, reading was observed and recorded

Saturation of Peripheral Oxygen (SPO₂) readings have to remain stable for 60 seconds before and 60 seconds after the blood gas sampling with an accepted maximal variation of Saturation of Peripheral Oxygen (SPO₂) of no more than 1%

Statistical Analysis

Mean \pm SD was applied for quantitative data. Categorical and nominal data was expressed in percentage. Quantitative variables were correlated using Pearson's correlation coefficient. To find the association between pulse oximetry and arterial oxygen saturation linear regression analysis were applied. ROC curve analysis was used to find the efficacy of pulse oximetry and optimal cut-offs for hypoxemia and hyperoxemia. The significance threshold of p-value was set at <0.05. All analysis was carried out by using SPSS software version 21.

Results

Out of the total 30 neonates with respiratory distress, 76.7% were males and 23.3% were females

Mean gestation age of the study cases was 36.3

weeks with half of them delivered after 37 weeks or more.

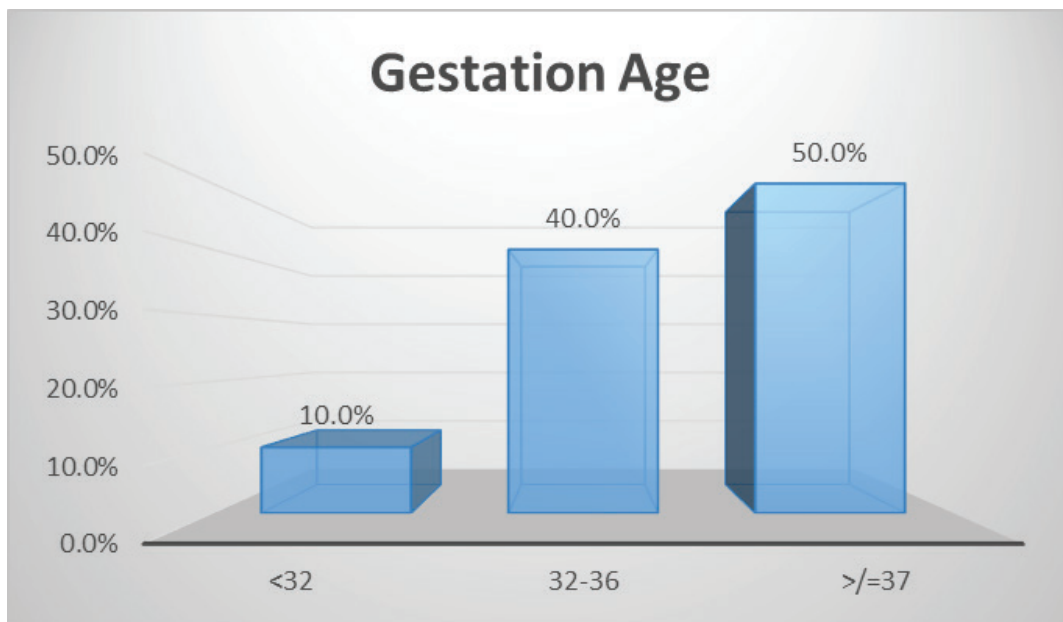

Figure 1: Distribution of study cases as per Gestational Age

Mean birth weight of the neonates was 2.1 Kg with 56.7% cases had low/ very low/ extremely low birth weight.

Most common etiology for respiratory distress among neonates was Meconium Aspiration Syndrome (33.3%), followed by Hyaline Membrane Disease (23.3%), congenital pneumonia (16.7%) and TTN (13.3%).

A significant correlation was observed between values of SpO2 and PaO2 by arterial blood sampling (r- value – 0.73, p<0.01).

Pearson co-relation		
Table 1 : Distribution of study cases as per Correlation between SpO2 & Arterial blood gas analysis		
ABG PARAMETERS	r-value	p- value
SpO2 and PaO2	0.73	<0.01

On Regression analysis, a significant association was observed between pulse oxygen saturation by pulse oximeter (SPO₂) and partial pressure of oxygen (PaO₂)

Regression Equation : PaO₂ = 4.89 (SpO₂) -336.616

On ROC curve analysis, sensitivity and specificity of pulse oximetry in prediction of hypoxemia was 87.5% and 85.7% at cut-off of 90% and 91% each.

Hypoxemia (<cut-off)	Sensitivity	Specificity
90%	87.5%	85.7%
91%	87.5%	85.7%
92%	81.3%	85.7%

Table 2: Screening efficacy of pulse oximetry for detection of Hypoxemia

Figure 2: Screening efficacy of pulse oximetry for detection of Hypoxemia

On ROC curve analysis, sensitivity and specificity of pulse oximetry in prediction of hyperoxemia was 100% and 71.4% at cut-off of 94% while it was 88.9% and 76.2% at cut-off of 95% respectively.

Hyperoxemia (>cut-off)	Sensitivity	Specificity
94%	100.0%	71.4%
95%	88.9%	76.2%
96%	77.8%	90.5%

Table 3: Screening efficacy of pulse oximetry for detection of Hyperoxemia

Figure 3. Screening efficacy of pulse oximetry for detection of Hyperoxemia

Discussion

Respiratory distress in neonatal period is an emergency. Hypoxemia, hypercarbia and acidosis will result from prolonged distress. These changes will cause constriction of pulmonary vasculature and multi system organ dysfunction will occur if fetal circulation remains persistent and there is shunting of blood from right to left side.⁶

It is essential to monitor the saturation of oxygen in newborns receiving supplemental oxygen in order to reduce the incidence of exposure to hyperoxemia and the risk of potential hazardous effects of radical oxygen species.⁷

The fifth vital sign for assessing every newborn is the Pulse oximeter oxygen saturation (SpO₂).⁸ Normally the saturation of oxygen is 93% in healthy newborns in room air and differs according to post-natal age.⁹

The adequacy of oxygenation and ventilation are assessed by the Arterial blood gas analysis which is the gold standard.

Indirectly the oxygen saturation of a patient's blood is measured by pulse oximeter which is a non-invasive tool. Though various studies showed the validity of pulse oximetry as a replacement for ABG, more data is needed for its accuracy. The aim of the present study was to assess pulse oxygen saturation and PaO₂ values and to determine whether PaO₂ levels are related to pulse oxygen saturation values and can it replace the former. Study included 30 neonates suffering from respiratory distress due to various etiologies in neonatal intensive care unit (NICU).

Out of the total 30 neonates with respiratory distress, 76.7% were males and 23.3% were females. Mean gestation age of the study cases was 36.3 weeks with half of them delivered after 37 weeks or more. Mean birth weight of the neonates was 2.1 Kg with 56.7% cases had low/ very low/ extremely low birth weight. Doss WS et al.¹⁰ in their study observed 41 out of 50 neonates being boys (91.9%). The mean gestational age among babies was 35 ± 3.6 weeks and the mean birth weight was 2.3± 0.8 kg. Niknafs P et al.¹¹ in their study 30 preterm infants were observed, male were 16 (53.3%) and female were 14 (46.7%). 31 weeks was the mean gestational age, with while 1340 grams was the mean

birth weight, range being 900 grams to 1500 gram.

Most common etiology for respiratory distress among neonates was Meconium Aspiration Syndrome (33.3%) followed by Hyaline Membrane Disease (23.3%), Congenital Pneumonia (16.7%) and TTN (13.3%).

Doss WS et al.¹⁰ in their study observed most common etiologies as HMD (53.7%), TTN (28.7%) and pneumonia (3.75%). Ritonga SM et al.¹² observed the common etiologies for respiratory distress as Pneumonia (24.2%). In present study HMD was the second etiology to cause respiratory distress while MAS was the primary etiology to cause respiratory distress.

In present study, a significant correlation was observed between values of pulse oxygen saturation by pulse oximeter (SpO₂) and partial pressure of oxygen (PaO₂) by arterial blood sampling (r- value – 0.73, p<0.01). On regression analysis, a significant association was observed between pulse oxygen saturation by pulse oximeter (SpO₂) and partial pressure of oxygen (PaO₂) (p<0.01). PaO₂ = 4.89 (SpO₂) -336.616 was the linear regression equation to predict PaO₂ based on SpO₂ values

Yanda S et al.¹³ observed significant positive correlations between pulse oximeter (SpO₂) and PaO₂ (r-0.403; p<0.05). PaO₂ = 1.912 (SpO₂) - 79.828 was the linear regression equation to predict PaO₂ based on SpO₂ values

Doss WS et al.¹⁰ in their study concluded that PO₂ and SpO₂ were statistically significant. PO₂ increase resulted in SpO₂ increase (r-0.436; p<0.01).

On ROC curve analysis, sensitivity and specificity of pulse oximetry in prediction of hypoxemia was 87.5% and 85.7% at cut-off of 90% and 91% each. On ROC curve analysis, sensitivity and specificity of pulse oximetry in prediction of hyperoxemia was 100% and 71.4% at cut-off of 94% while it was 88.9% and 76.2% at cut-off of 95% respectively. In the study by Niknafs P et al.¹¹ they concluded that pulse oximeter in the detection of hypoxemia had 75% sensitivity and 99.5% specificity while pulse oximeter in the evaluation of hyperoxemia, had sensitivity of 83% and had 92.4% specificity.

Conclusion

Pulse oximetry showed a good correlation with arterial blood PaO₂ i.e. it shows good validity in detecting hypoxemia and hyperoxemia in neonates.

The study thus concludes that oxygen saturation measured by pulse oximetry is a good diagnostic and prognostic tool for detecting hypoxemia and hyperoxemia and can be used safely for continuous monitoring for hypoxemic patients.

Pre Operative Magnetic Resonance Cholangiopancreatography in Laparoscopic Cholecystectomy with Special Reference to Hepatobiliary Anatomic Variations and Undetected Choledocholithiasis

Ajay Chauhan¹, Nilesh Mehta², Mitkumar V. Patel³, P. P. Sharma⁴, F. S. Mehta⁵

¹Associate Professor, ²Associate Professor, ³3rd year PG resident, ⁴Professor, ⁵Professor, Department of General Surgery, Geetanjali Medical College and Hospital, Udaipur, Rajasthan

Abstract

Background: Cholelithiasis is the most common disease state involving the gallbladder and biliary tree. Approximately 5-15 % patients with gallstones are associated with choledocholithiasis. Hepatobiliary anatomic variations are common and routinely encountered during laparoscopic cholecystectomy. Among all investigations, Magnetic Resonance Cholangiopancreatography (MRCP) showed high accuracy in detecting the choledocholithiasis and hepatobiliary anatomical variations. Role of routine MRCP in patients going for laparoscopic cholecystectomy is controversial.

Method: This study was carried out on 68 patients admitted in Geetanjali Medical College and Hospital, Udaipur, Rajasthan in Department of General Surgery from August 2017 to August 2019 with the confirm diagnosis of cholelithiasis and posted for laparoscopic cholecystectomy. All patients underwent MRCP and collected data was analysed.

Results: Among 68 patients, dilated CBD was diagnosed in 4 and 13 patients by USG and MRCP respectively. CBD stone was not detected by USG in any patient but MRCP detected CBD stone in 6 patients. All 6 patients with CBD stones had age of > 50 years. Normal course with right lateral insertion of cystic duct was the most common variant and was found in 57 patients in MRCP and 62 patients intraoperatively.

Conclusion: MRCP is non-invasive, non-ionizing imaging modality having higher specificity and sensitivity for asymptomatic choledocholithiasis as well as biliary tree anomalies prior to LC. But it is a costly investigation. So its routine use in preoperative evaluation for all patients undergoing for laparoscopic cholecystectomy is advisable in patients having age of > 50 years.

Keywords: Choledocholithiasis, Hepatobiliary anatomic variations, Magnetic resonance cholangiopancreatography, Laparoscopic cholecystectomy.

Introduction

The most common disease state involving the

gallbladder and biliary tree is cholelithiasis. Because the gallbladder concentrates bile, the concentration of solutes in the gallbladder differs from that in the rest of biliary tree. This increase in solute concentration combined with stasis in the gallbladder between meals predispose to stone formation in the gallbladder.¹ First open cholecystectomy was done by Carl Langenbuch in 1882 and it was primary treatment of gallbladder disease through the early 1990s.² After more than 100 years, First laparoscopic cholecystectomy (LC) was done by Erich

Mühe of Böblingen, Germany.³ In 1992, the National Institutes of Health (NIH) Consensus Development Conference stated that laparoscopic cholecystectomy provides a safe and effective treatment for most patients with symptomatic gallstones.⁴

Approximately 5-15 % patients with gallstones are associated with choledocholithiasis.⁵ Choledocholithiasis may be asymptomatic or symptomatic with potential complications including post-operative biliary leakage, recurrent biliary colic, cholangitis, and pancreatitis adding further to the burden of management in gallstone disease.⁶ For that reason it is necessary to explore an easy and accurate approach to diagnose the choledocholithiasis preoperatively.

Gallstone disease patients undergo ultrasonography (USG) examination of abdomen and hepatobiliary biochemical serum analyses as part of routine preoperative screening for choledocholithiasis.⁷ Endoscopic retrograde cholangiopancreatography (ERCP) has maximum accuracy in the diagnosis of choledocholithiasis. It is invasive and expensive method and less popular for all patients of gallstones going for laparoscopic cholecystectomy. As well as it is associated with a significant risk of complications like post ERCP pancreatitis, sepsis, bowel perforation, bleeding with 1-7% test related morbidity and a 0.2-1 % mortality rate. Endoscopic ultrasound (EUS) has similar diagnostic accuracy for choledocholithiasis like ERCP but requires special equipment and expertise.⁸

Hepatobiliary anatomic variations are common and routinely encountered during laparoscopic cholecystectomy. Failure to identify some of these clinically important variants may lead to complication during surgery. There is cystic duct variations based on length, course and site of insertion with CHD. Some important variations are low insertion of cystic duct, anterior or posterior spiral course with medial insertion, short cystic duct (length < 5 mm), etc.⁹

MRCP was introduced by Wallner et al in 1991. MRCP is based on the use of heavily T2 weighted fast spin echo sequences. Many literatures showed that sensitivity and specificity of MRCP for diagnosing choledocholithiasis reaches up to 95% and 90% respectively.¹⁰ MRCP is the best noninvasive imaging modality for visualization of hepatobiliary anatomy and

choledocholithiasis. Role of routine MRCP in patients going for laparoscopic cholecystectomy is controversial. So this current study was conducted to check the reliability of preoperative MRCP for hepatobiliary anatomic variations and undetected choledocholithiasis which was not visualized by USG as well as to compare the MRCP findings with intraoperative findings and to evaluate that whether pre-operative MRCP helps in laparoscopic cholecystectomy in anyway.

Materials and method

This was a single-centre prospective observational study conducted in the Department of General Surgery at Geetanjali Medical College and Hospital, Udaipur, Rajasthan from August 2017 to August 2019. A total 68 patients with the confirmed diagnosis of cholelithiasis and posted for laparoscopic cholecystectomy were included. The protocol was approved by institutional ethical committee. Written informed consent was obtained from all participants. The following tests were performed in all the patients: CBC, RBS, BT/CT, B. urea, S. creatinine, S. electrolyte, urine examination, LFT, PT/INR, S. amylase, S. lipase, chest X-ray, abdominal ultrasound, MRCP and ERCP as and when required. Patient diagnosed with CBD stone after investigation were subjected to ERCP stone extraction and then laparoscopic cholecystectomy.

Exclusion Criteria:

- Patients with metallic implant insertion, cardiac pacemakers, metallic foreign body in situ, patients having history of claustrophobia and patients who requires sedation or ventilation.
- Patients with complicated gallstone disease such as acute calculus cholecystitis, empyema of gall bladder, pancreatitis, obstructive jaundice, carcinoma of gallbladder

Results

In our study, the age group of patients ranged from 18-70 years. Out of 68 patients, 16 patients were male and 52 patients were female. Highest incidence of cholelithiasis was found in the age group 18 to 50 years (54.4%). Youngest male was 22 years old and oldest was 70 years old. Youngest female was 19 years old and oldest was 70 years old. Mean age in our study was

48.51±13.31 years. Incidence of cholelithiasis in male and female patients was common in the age group 18 to 50 years and 51 to 70 years respectively. (Table 1)

Wall thickness was found normal in both USG and MRCP in all patients preoperatively. During surgery, wall thickness was found normal in 47 patients (69.1%)

while it was thickened and fibrotic in 19 (27.9%) and 2 (2.9%) patients respectively.

In present study, Dilated CBD was diagnosed in 4 patients (5.9%) by USG and in 13 patients (19.1%) by MRCP. Intraoperatively CBD caliber was found normal in all patients. (Table 2)

Table 1: Distribution of the patients according to Age & Sex

			Age groups		Total
			18 to 50 years	51 to 70 years	
Sex	Male	n	5	11	16
		%	31.25%	68.75%	100.0%
	Female	n	32	20	52
		%	61.5%	38.5%	100.0%

Normal course with right lateral insertion of cystic duct was the most common variant and was found in 57 (83.8%) patients in MRCP and 62 (91.2%) patients intraoperatively. Most common variant of cystic duct insertion was low insertion of cystic duct. It was detected by MRCP in 8 (11.8%) patients and intraoperatively in 3 (4.4%) patients. (Table 5)

Discussion

Gallstone diseases are one of the commonest surgical problems worldwide. Cholelithiasis is more common in females than in males. In our study, 52 patients were female (76%) and 16 patients were male (24%) (N=68). In this study, the participation of patients with different sex ratio was similar to the previous studies indicating female are more affected by cholelithiasis compared to males. In study by Al-Aubaidi T et al¹¹, 86 patients were female and 14 patients were male (N=100). Virzi V et al¹² found that 75 patients in their study were female out of 104 and rest 29 were male (N=104).

Current study included patients of age 18 to 70 years. The mean age of patients in our study was 48.51 ± 13.31 years. Age of youngest male and female patient in our study was 22 years and 19 years respectively. Age of oldest male and female patients was 70 years. Rao GB et al¹⁰ found that mean age of patients in their study was 54 years. Al-Aubaidi T et al¹¹ also noticed mean age of 46.8 ± 8.1 and 45.9 ± 9.5 in their both group. We found that highest incidences of cholelithiasis were present in age group 18 to 50 years which was 37 patients (54.4%) followed by in age group 51 to 70 years which was 31 patients (45.6%). Al-Aubaidi T et al¹¹ also found that highest number of patient were present in both study groups from age group of 45-55 years and second highest patients were found in age group of 55-65 years and 25-35 years in group 1 and group 2 respectively. We divided patients into two age groups, first 18 to 50 years and second 51 to 70 years. In current study we found that male patients were more common after the age of 50 years as maximum number of male patients were present in age group 51-70 years (11 patients, 68.75%) while female patients were more common in age group 18 to 50 years (32 patients, 61.5%). In study by Rao GB et al¹³, male patients were common in age group 41-70 years (19 patients) while female patients were common in age group 21-40 years (27 patients).

It is also important to know the wall thickness pre operatively because thickened or fibrotic gallbladder wall cause difficulty in surgery. In our study we analysed gallbladder wall preoperatively by USG and MRCP. In all patients wall thickness was found normal by USG and MRCP. During surgery we found normal wall thickness in 47 patients (69.1%) while thickened

gallbladder wall was present in 19 patients who were diagnosed as normal wall thickness preoperatively. Fibrotic gall bladder was found in 2 cases (2.9%). So the pre-operative investigations were not giving exact information about wall thickness in all cases. This concludes that MRCP as a tool to assess difficult laparoscopic cholecystectomy in view of wall thickness of gall bladder is not much helpful. In current study, difference found in wall thickness in USG, MRCP and intraoperative was significant (P value 0.000).

In current study, dilated CBD was detected in 4 cases (5.9%) without stone by USG. MRCP detected choledocholithiasis in 6 patients (8.8%). All these patients with choledocholithiasis were asymptomatic. MRCP showed dilated CBD in 13 patients (19.1%) but out of 13 only 6 patients had CBD stone. All CBD stones were removed by ECRP preoperatively. Rest cases with dilated CBD without stone on MRCP had normal LFT and no jaundice and they were diagnosed as type 1 choledochal cyst by Gastroenterologist, so they were directly posted for laparoscopic cholecystectomy (Table 3). These patients were followed up in postoperative period and none of them reported as retained bile duct stones or biliary leak, etc. This suggests that even if the LFT is normal, there are chances of CBD stones and MRCP is helpful in diagnosis of these cases. Result of our study was statistically significant (P value = 0.012).

Singh S et al¹⁴ observed different sizes of CBD stones in MRCP. They found 7 cases of CBD stone with stone size ≤ 6 mm and 13 cases with stone size > 6 mm. The smallest stone detected by MRCP was 4 mm in diameter. In current study we observed that out of 6 cases of CBD stone detected by MRCP, 4 cases had CBD stone size of < 6 mm and 2 cases had > 6 mm. The smallest stone size was 4 mm. In study by Al-Aubaidi T et al¹¹ they found 2 cases of CBD stone detected by MRCP. Both these patients had age of > 45 years. In our study all 6 cases of CBD stone had age of > 50 years. Youngest patient with CBD stone was 51 years old and oldest patient with CBD stone was 70 years old. We conclude that there are higher chances of CBD stone in and after 5th decade of life. All patients having age of > 50 years must be investigated with MRCP before laparoscopic cholecystectomy because of higher chances of CBD stones in these patients. (Table 4)

In our study, findings of MRCP for cystic duct variations was evaluated during surgery and we found normal course with right lateral insertion in 62 cases (91.2%), short cystic duct in 1 case (1.5%), low insertion cystic duct in 3 cases (4.4%) and posterior spiral course with medial insertion in 1 case (1.5%). On statistical analysis this was found to be non-significant (P value = 0.482). (Table 5)

Table 6: Common cystic duct insertion variations in different studies

		Cystic duct insertion			
		Normal course with right lateral insertion	Short cystic duct	Low insertion	Anterior or posterior spiral course with medial insertion
Our study	n	57	0	8	2
	%	83.8%	0.0%	11.8%	3.0%
Sarawagi R et al15	n	102	2	18	32
	%	51.5%	1.0%	9.0%	16.1%
Ausch C et al16	n	258	0	6	15
	%	90.5%	0.0%	2.1%	5.0%

Conclusion

Our study concludes that MRCP is non-invasive, non-ionizing imaging modality having higher specificity and sensitivity for asymptomatic choledocholithiasis as well as biliary tree anomalies prior to LC. But it is a costly investigation. So its routine use in preoperative evaluation for all patients undergoing laparoscopic cholecystectomy is advisable in patients having age of > 50 years. Except detection of CBD stones, MRCP has no role for preoperative estimation of operative ease in relation to gall bladder status like wall thickness of GB, chronic cholecystitis, etc. in surgery.

The Size of the Sella Turcica in Skeletal Class I, Class II, and Class III using FACAD Software- South Indian Population Study

Akriti Tiwari¹, Srirengalakshmi²

¹Post graduate, ²Senior Lecturer, Department of Orthodontics and Dentofacial Orthopaedics, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Saveetha University

Abstract

Background: The sella turcica is a saddle-shaped bony structure in which anterior wall is formed by tuberculum sellae and posterior wall is formed by dorsum sellae. Lateral cephalometric landmark, sella, is of paramount importance in the field of orthodontics and dentofacial orthopaedics for diagnosis, treatment planning and assessment of skeletal maturation. * Significant literature is available indicating that large variations occur in the shape and size of sella turcica among the three different types of skeletal malocclusion classes.* Studies have been conducted in different regions to evaluate the shape and size of sella turcica in different skeletal malocclusions therefore, the aim of this study is to describe the shape and measure the size of the sella turcica in south Indian subjects with different skeletal types.

Materials and Methodology: Lateral cephalometric radiographs of 60 subjects (30 males and 30 females); 20 Class I, 20 Class II, and 20 Class III. The sella turcica on each lateral cephalometric was analysed using FACAD ortho software tracing to measure the linear dimensions of length, depth, and anteroposterior dimension. One-way analysis of variance was performed to study the relationship between skeletal type and sella size.

Result: Skeletal class III subjects presented with a statistically significant difference in the depth of sella turcica on comparison with skeletal class II ($p > 0.01$). There was statistically insignificant difference found in the anteroposterior dimension and length of sella turcica in skeletal class I, class II and class III.

Conclusion: When the size of sella turcica was compared with skeletal type, a statistically significant difference was found in depth skeletal Class II and Class III subjects.

Keywords: *Sella turcica, lateral cephalometric, skeletal malocclusion, FACAD software.*

Introduction

Sella turcica is also known as pituitary fossa. It is situated in the middle cranial fossa and houses the pituitary gland. ⁽¹⁾ It is a saddle-shaped concavity located on the intracranial surface of the sphenoid bone. ⁽²⁾ Pituitary gland is formed before the cartilaginous skeleton of the hypophyseal fossa. There is significant literature which suggests that pituitary gland serves as a functional matrix for the skeletal unit of sella turcica. ⁽³⁾ The development of pituitary gland in succession leads to enlargement in the dimensions of sella turcica. ⁽⁴⁾

Any systemic disease such as cushing's syndrome, hyperthyroidism, etc or pituitary tumor or an abnormally large pituitary gland can lead to change in the size of sella turcica.⁽⁵⁾⁻⁽⁶⁾ The change in hormonal level can also lead to change in the dimensions of sella turcica.⁽⁷⁾⁻⁽⁸⁾

Sella turcica is an important structure in radiographic analysis of craniofacial complex. In orthodontics, sella turcica is an important structure because, sella, a hard-tissue derived landmark, is located in the centre of hypophyseal fossa.⁽⁹⁾ This point is located in the centre of the sella turcica, with the turcica housing the pituitary gland in the cranial base.⁽¹⁰⁾ There is an increase in the interest to study the human craniofacial dysmorphology, but there are few cephalometric standards available in growth and development.⁽¹¹⁾

In order to determine if the sella region presents with any unusual appearance, the study of normal size of the sella turcica has to be done. Several studies have been conducted to analyze the shape and size of sella turcica in skeletal class I, class II and class III. One such study which was conducted by Eman A. Alkofide et al in the year 2007 wherein the size and shape of sella turcica was compared in skeletal class I, class II and class III subjects, concluded that there was statistically significant difference in the diameter between class II and class III ($p < 0.01$).⁽¹²⁾ Another study conducted by Sathyanarayana HP et al in 2012, concluded that statistically significant difference was found in the diameter and length of sella turcica.⁽¹³⁾ Luong HM et al conducted a study in 2016 and concluded that there was no statistically significant difference in the linear dimensions of sella turcica in different skeletal patterns.⁽¹⁴⁾

Cephalometrics have been used as an indispensable tool in orthodontics for diagnosis, treatment planning, and evaluation of dental and skeletal growth, posttreatment evaluation, and research work.⁽¹⁵⁾ Cephalometric tracings can be done either manually or digitally. Manual method has been used for a long time to achieve linear and angular measurements. The drawbacks of this method are time consumption is a lot and also, a

high degree of operator error.⁽¹⁶⁾ With increasing use of computer radiography, digital tracing is now dominating the market. It is more user-friendly, storage is easier, etc. Studies have indicated that Computer-aided cephalometric analysis does not introduce measurement error as long as the landmarks are identified manually.⁽¹⁷⁾

Size of sella turcica varies from individual to individual, and the establishment of normal standards will aid in the process of eliminating any abnormality in such an important region

Therefore, the purpose of this study was to analyse to measure the linear dimensions of sella turcica to determine if differences exist due to different skeletal patterns in south indian population using FACAD software.

Materials and Methodology

This The radiographs were distributed according to skeletal Class and gender; 20 Class I, 20 Class II, and 20 Class III cases were collected and they were equally distributed between males and females in each class. Classification of skeletal type into Class I, Class II, or Class III was based on the ANB angle (difference between SNA and SNB).⁽⁷⁾ The ANB angle indicates the skeletal jaw discrepancy, regardless of which jaw is at fault. Skeletal base Class was categorized as follows: angles ± 2 degrees is Class I skeletal base; angles more than 4 degrees is Class II, and angles less than 0 degrees is Class III. In addition, to overcome the limitations of the ANB angle and to further describe jaw severity/ discrepancy Wits appraisal analysis was used.

The tracing of sella turcica

The sella turcica on each cephalometric radiograph was traced on FACAD software. This tracing was marked in square millimetres to calculate the sella area and measurements were made to the nearest 0.1 mm. The configuration of the sella turcica consisted of the tuberculum sella, the sella turcica floor, the dorsum sellae, and both anterior and posterior clinoid processes, was traced.

Figure 1. Tracing of sella turcica on FACAD software

The Size of the sella turcica

The linear dimensions of sella turcica were measured using the methods of Silverman (1957) and Kisling (1966) ⁽⁸⁾ All the reference lines used in the current study were located in the midsagittal plane.⁽⁹⁾ The length of sella turcica was measured the distance

from the tuberculum sellae to the tip of the dorsum sellae. The depth of the sella turcica was measured as a perpendicular from the line above to the deepest point on the floor of sella turcica and a line was also drawn from the tuberculum sellae to the furthest point on the posterior inner wall of the fossa, and this was considered as the antero-posterior diameter of sella turcica

Figure 2. Morphology and reference lines used to measure sella turcica

Result

Data were analysed using the Statistical Package for Social Sciences version 16.0 for Windows. To study the relationship between skeletal type and sella turcica size, one-way ANOVA was used (p<0.01).

		n	Mean	Standard Deviation
Length	Class I	20	10.6	2.0
	Class II	20	10.5	1.8
	Class III	20	11.3	2.7
	Total	60	10.7	2.3
Depth	Class I	20	8.8	1.1
	Class II	20	8.9	1.2
	Class III	20	9.2	1.2
	Total	60	9.1	1.3
Diameter	Class I	20	13.8	1.7
	Class II	20	13.3	1.5
	Class III	20	14.5	2
	Total	60	14	1.9

Table 1. One-way analysis of variance testing the effects of skeletal Class on sella linear dimensions (in millimetres).

To determine if different skeletal patterns affect the linear dimensions of sella turcica, a one-way ANOVA test was performed. A statistically significant difference was found in the depth of sella turcica between skeletal class II and class III ($p < 0.01$).

Discussion

This retrospective study describes the linear dimensions of sella turcica in south Indian subjects.

The length, depth and diameter of sella turcica in the present study were compared with other investigations. In the current study, it was noted that there was a statistically significant difference in the depth of sella turcica between class II and class III. Study conducted by Ahsan et al in Pakistani population reported that there was no significant difference in the linear dimensions of sella turcica in different skeletal patterns.⁽¹⁷⁾ Som Sudheer et al in the year 2016 conducted a similar study in south Indian population wherein it was reported that there was a statistically significant difference in the length of sella turcica whereas the depth and anteroposterior diameter showed statistically insignificant difference.⁽¹⁸⁾

A similar study conducted by Luong et al evaluated the size of sella turcica in all three dimensions between skeletal class I, class II and class III using CBCT. It was reported that the Skeletal Class III subjects presented with a significantly larger width, axial area, and volume when compared to Class I ($P < 0.001$). There was no significant difference in linear dimension, area, and volume of sella turcica between Class I and Class II.⁽¹⁹⁾ On comparing this study with Alkofide conducted in Saudi subjects reported that the linear dimensions of sella turcica in the Indian population sample were on average 1.7 to 2.9 mm smaller than those of the Saudi subjects.⁽²⁰⁾ The linear dimensions (length, depth, and diameter) can be used to predict the size of the pituitary gland.

It might be of clinical importance when an abnormally large sella is found on the lateral cephalogram.

Conclusion

1. When sella size was compared to skeletal type, no significant difference was found among them.

2. The results of the present study of sella shape and size may be used as reference guide for future studies about sella turcica morphology.

Influence of Patients' Perception on Doctors Physical Appearance - Kap Study

Akriti Tiwari¹, Arvind Sivakumar²

¹Post graduate, ²Senior Lecturer, Department of Orthodontics and Dentofacial Orthopaedics, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Saveetha University

Abstract

Introduction: Despite technological advances and changes that the medical fraternity has experienced in the last few decades, the physical appearance of orthodontists influence the patients. Literature report says that the type of clothing and accessories have the potential to influence the patient-doctor relationship.

Aim: This study was primarily aimed at investigating patient opinion on the physical appearance, behaviour and overall professionalism of the physician or the doctor treating them.

Materials and Methodology: This questionnaire based study was aimed at subjects visiting as outpatients in a private dental set up, who were 18 years or older. Subjects who were not able to read and write were not included in this study. The participants were randomly involved in the study and were provided with a questionnaire formulated with a set of 18 multiple choice based questions. They were asked to choose the more appropriate answer from the options provided.

Result: Most of the preferences made by the volunteers showed that physical appearance did not affect the perception of patients. There was no significant gender variation found.

Conclusion: Within the limitations of this study, it can be concluded that the physical appearance of a physician or doctor did not affect the patients' perception towards his or her treatment. And there was no gender variation found in terms of patient perception.

Key Words: *patient perception, doctor appearance, Doctor's attire, Patient-doctor relationship.*

Introduction

Despite technological advances and changes that the medical fraternity has experienced in the last few decades, the physical appearance of orthodontists has shown tendencies to influence the patients' perception. Literature says that the type of clothing and accessories

have the potential to influence the patient-doctor relationship.

Many studies have been conducted using various methodological approaches in different countries to appreciate the influence of patient-doctor relationship based on the physical appearance of the physicians or orthodontists. Communication is found to be a vital and complex component of the physician-patient relationship.⁽¹⁾ Physicians communicate with patients through verbal and nonverbal messages.⁽¹⁾ In general, it has been reported that patients preferred doctors, male or female, with a conservative style, for instance, wearing white coats. Studies demonstrated that a significant portion of the population associated white coat to the image of physicians with professional attitude, better

prepared and hygienic. ⁽²⁻⁵⁾ As the trends are changing with time, patients prefer to assess the orthodontists based on their clinical skills and knowledge rather than the physical appearance.

Literature evidence provides many studies on the patient perception around the world but very few among the Asian population. And no studies were found to be done in Chennai city. So, this research focused on the importance of patients' perceptions of their dental care provider based on their physical appearance, attire (dress), behavior, and overall level of professionalism.⁽²⁾

Hence, the aim of this study was to investigate patient opinion on the physical appearance, behaviour and overall professionalism of the physician or the doctor treating them.

Materials and Methodology

This questionnaire based study was conducted on 100 male and female patients visiting a private dental college in Chennai. The participants were randomly involved in the study, who were outpatients visiting a private dental set up, to assess their perception towards the physicians physical appearance .

A questionnaire was given with a set 18 questions to the patients wherein they were asked to choose from the options they found more appropriate. Questions asked were like - " Do you prefer your orthodontist to be slim; plump; well-built; doesn't matter. " The items evaluated in both genders were clothing style; piercings; tattoos; dyed hair; extravagant hair color, such as green or red; T-shirt; surgical scrubs; formal wear. ⁽⁶⁾ The items exclusively evaluated for male physicians were beard; moustache; long hair; tie; jeans, and absence of a tie. Items that were evaluated only for female physicians were hairstyle, dressing style.

The identity of the participants was not disclosed and the confidentiality of their identity was assured to them. Prior to the start of the study, Ethical approval was obtained from the Scientific Review Board of SIMATS. ⁽⁷⁾ A written informed was obtained from every participant and their personal identity were masked during data processing and analysis. Sufficient amount of 15minutes was provided for filling up the questionnaire. Following this, data was statistically

analyzed. Descriptive statistics using percentage and mean was used to analyse the results.

Inclusion criteria :

Orthodontic Patients above the age of 18 years.

Exclusion criteria :

Patients who were unable to read and write.

Results

Data collection was carried over a period of two weeks. The collected questionnaires were analyzed for completeness of the answers. 18 questionnaires were discarded due to an excessive number of unanswered questions or due to the errors in the questionnaire. The final analysis was based on 82 questionnaires from patients who were above the age of 18 years.

Most of the preferences made by the volunteers, for both, male and female, showed that the physical appearance did not bother the patients. ⁽⁸⁾ Among the patients, the more frequently chosen option in response to the question of the height of the orthodontist was that it made no significance to them. Statistics showed that 61% of the patients did not bother if their orthodontist was slim, well built or plump.[Table 1] Only 40% of the total respondents were specific on the height as well as complexion of the orthodontist. 61% of the respondents said it did not matter if the orthodontist was tall or short and 60% said that the complexion of doesn't matter. ⁽⁹⁾ Neither the height nor complexion of the orthodontist did not make a difference to the patient's attitude towards the orthodontist.[Figure 1 and 2] More than 65% of the participants did not bother about the hairstyle of the orthodontist treating them. The hairstyle of the male or female orthodontist also did not affect the patient-orthodontist relationship. [Figure 3]

As the trends are changing with time, it did not matter to the patient if the orthodontist treating them had dyed hair; tattoos; body piercings; wore spectacles or not. ⁽¹⁰⁾ It was also seen that it did not matter to them if the orthodontist treating them was young aged, middle-aged or old aged. Even the alignment of the teeth of the orthodontist did not make a difference to them.

Would you prefer your orthodontist (if male) to have coloured hair

40 responses

Figure 6: Pie chart representing the patients' perception on the dyed hair of orthodontists

Discussion

Only questionnaire which were duly filled with all details and those which was returned back were considered valid. The response rate was found to be 82% (N=82) ⁽¹¹⁾ The rationale behind this study was to assess the patients' perception towards the physical appearance of the orthodontist treating him or her.

Literature review says that there are several studies conducted in different parts of the world, but none in the Chennai city, to address to aspects related to value judgments on the manner of dress and the physical appearance of the orthodontists. ⁽¹²⁾ The results obtained demonstrated that the patients preferred orthodontists irrespective of their styles of dressing or physical appearance, per se. The groups did not report any level of discomfort with orthodontists presenting with excessively liberal appearance elements. ⁽¹³⁾

Among the individual styles selected by patients, the option – “did not matter” was frequently selected, both for male and female orthodontists. This finding indicates that such a style of dress should not affect the patient-doctor relationship. ⁽¹⁴⁾

This investigation presented a series of limitations, among which is the collection of data from a single dental centre. Accordingly, the opinions expressed do not necessarily reflect other regional realities of the country. Additionally, it is based on the response obtained by literates. ⁽¹⁵⁾ It is possible that the volunteers would have different opinions in actual situations. ⁽¹⁶⁾

Conclusion

The height of the orthodontist did not influence the patients' perception. Neither the height nor complexion of the orthodontist did not make a difference to the patient's attitude towards the orthodontist. ⁽¹⁷⁾ As the trends are changing with time, it did not matter to the patient if the orthodontist treating them had dyed hair; tattoos; body piercings; wore spectacles or not. It was also seen that it did not matter to them if the orthodontist treating them was young aged, middle-aged or old aged. Even the alignment of the teeth of the orthodontist did not make a difference to them.

Ethical Clearance: Ethical approval was obtained from the Scientific Review Board of SIMATS

Parental Perception of Inclusive Education

Amitha M. Hegde¹, Jithin George², Joseph M. John²

¹Senior Professor and Head of the Department, AB Shetty Memorial Institute of Dental Sciences, Deralakatte, Mangalore, ²Post graduate student, AB Shetty Memorial Institute of Dental Sciences, Deralakatte, Mangalore

Abstract

The attitude of parents of students studying in a government school in Mangalore towards inclusive education set up was analysed using a self-administered questionnaire. Classes 1-7 were chosen. The present study showed that there was an increased concern among the parents of children in the younger age group towards inclusive education and this attitude gradually shifted to the positive side when the parents of older children were consulted regarding the same. Therefore, it is justifiable to conclude by saying that parents have the greatest role in making the inclusive education programmes a success.

Keywords: parental perception, inclusive education, special children, questionnaire.

Introduction

The term inclusive education refers to the complete involvement of differently abled children in schools along with normal children for the purpose of an integrated education programme aimed at the benefit of both the sections of the students. In the past differently abled children were given education as a different section, recent changes in this concept with policies such as Salamanca statement and United Nations Convention on the Rights of Persons with Disability has paved the way for inclusive education in schools. The parents had an important role to play in realization of this model of education and the most important factor being the social participation of differently abled children.¹ This practice is better said than done in actuality as the disabled children may face rejection, victimization and bullying from peers.² There are contrasting studies to this statement where the inclusive education have resulted in frequent social interaction and improvement of social skills which involves communication skills.^{2,3}

The normal children can also benefit by improvement in social and academic skills.⁴ The most important role in the actualization of the inclusive education is played by the parents. The parents of differently abled children are in support of the inclusive education when the majority opinion is considered. But this is not the case when the parents of normal children are considered. They are neutral or less than positive in their attitude regarding inclusive education, they worry that the possible negative behaviour of disabled children can affect their own children.⁵ The parental attitudes can have a major impact on the outcome of an inclusive education system.⁶ Thus the present study aimed understanding the parental attitudes towards inclusive education in a school in Mangalore.

Aim

To assess the attitude of parents towards inclusive education set up.

Materials and Method

A self-administered questionnaire was distributed among the parents of students studying in a government school in Mangalore which had adopted an inclusive education system. The sample comprised of 241 parents of children, belonging to Class I - Class VII, wherein each class had enrolled a minimum of one child with SHCN. The questionnaire was framed in the local

Corresponding Author:

Dr Joseph M. John

Post graduate Student, AB Shetty Memorial Institute of Dental Sciences, Deralakatte, Mangalore.

Phone no: 8050489575S

vernacular language (Kannada). The questionnaire sheets were collected and statistically analysed.

Results

A total of 241 parents of healthy children participated in the study. 146 of the 241 parents agreed to the inclusive education having a positive impact on their child's behaviour. 95 parents did not agree to the same. (figure 1)

The second question assessed the promotion of equality among the children in an integrated school. Out of 241 parents, 182 parents gave a positive response. (figure 2)

117 of 241 parents were completely satisfied in sending their child to an integrated school. (figure 3)

The fourth question assessed whether moral values were fostered in children in the integrated schools. Most of the parents (132 of 241) responded positively. (Figure 4)

The fifth question assessed whether the child participates in the classroom activities without any hesitation. (figure 5)

The sixth question assessed whether the child acknowledged the presence of a child with SCHN in their classroom. (figure 6)

Discussion

Out of the 252 children from class I to class VI, the parents of the healthy children were handed of questionnaires. Each class had 1 to 3 children with SHCN. The parents were well aware of the children with SHCN in class of which the majority of parents whose children belonging to the younger age group (Class I, II, III, IV) were not convinced with the positive impact of inclusive education on their children as compared to the parents of the older age group(Class V, VI, VII). This is in accordance with the study done by Stoiber, Gettinger & Goetz in 1998 who stated that the parents of children without disabilities hold neutral, though less positive attitudes⁵. Other concerns stated by the parents of the healthy children were that the demands of children with SHCN become so great, that they interfere or compromise their own child's growth and education.⁷

A large group of parents of both the younger age group as well as the older age group children agreed to the inclusive education promoting equality between the normal children and the children with SHCN. This was in agreement with the study done by Bennett T in 1997⁸ where he found that a majority of parents showed favourable attitude towards inclusion in terms of promoting positive role models, friendships, facilitating acquisition of pre-academic, social, language and motor skills.

Parents of children in the older age group(class V, VI, VI) were comparatively more satisfied with their children being send to the integrated as compared to the parents of younger age group (class I to VI) as they were worried if their children would emulate the inappropriate behaviour of children with SHCN, which is a similar finding in a study done by Amrutha N were the parents suggested separate classes for academics.⁹

Children of younger age group(class I,II,III) participated in classroom activities without any hesitation whereas the elder age group (class IV,V,VI, VII) did not hesitate to do so as most the younger age group children were not aware of the presence of a child with SHCN within their classroom.

The moral values fostered in children through integrated education had a mixed response. Most of them especially the parents of the older age group agreed to moral values that their children would attain in these integrated classes. A similar observation was made by duhaney LMG where parents of healthy children revealed that they preferred their children in classes which included children with disabilities as there was an increase in personal development and improved self-worth by helping others. Specific gains in terms of social cognition which included awareness of other children's needs, prosocial and personal characteristics and greater acceptance of human diversity.¹⁰

Conclusion

Parental attitudes play a pivotal role in the success of inclusive education programmes. The present study showed that there was an increased concern among the parents of children in the younger age group towards inclusive education and this attitude gradually shifted to the positive side when the parents of older children were

consulted regarding the same. Therefore, it is justifiable to conclude by saying that parents have the greatest role in making the inclusive education programmes a success.

Modifiable Risk Factors of Hypertension: A Hospital based Case – Control Study at Bagalkot, Karnataka

Anand M. Devanaganvi¹, Shriharsha C¹, Deelip S. Natekar³

¹III year B.Sc. Nursing Student, ²Associate Professor and HOD, Department of Psychiatric Nursing, ³Principal, BVVS Sajjalashree Institute of Nursing Sciences, Navanagar, Bagalkot, Karnataka, India

Abstract

Background of the Study: Hypertension is the silent killer disease which increases the cardiovascular disease burden and mortality across the globe.

Objectives of the study: To estimate and compare the distribution of modifiable risk factors among hypertensive (cases) and non-hypertensive (controls) patients.

Materials and Method: A case–control study was conducted at Medical OPD of Hanagal Shri Kumareswar Hospital and Research Centre, Bagalkot, Karnataka using an interviewer-administered structured questionnaire based on the WHO STEPS instrument for chronic disease risk factor surveillance. Crude Odds Ratios were computed for estimating the relative of risk modifiable risk factors on Hypertension.

Results: A sample of 250 (125 cases and 125 controls) subjects was included in the study. Mean age of the sample was 52.82 years. Findings shows that, smoking (Odds ratio=7.289, P<0.001), use of smokeless tobacco (Odds ratio=1.4, P<0.05), alcohol consumption (Odds ratio=1.15, P<0.05), inadequate fruits (Odds ratio=1.19, P<0.05) and vegetables in diet (Odds ratio=5.2, P<0.05), diabetes (Odds ratio=5.21, P<0.001), obesity (Odds ratio=4.12, P<0.001) and family history of hypertension (Odds ratio=1.8, P<0.05) were significantly different in proportion among cases and controls and were found to be significant risk factors of Hypertension.

Conclusion: Hypertension is strongly associated many modifiable risk factors. An extensive public awareness programmes targeting risk factors is essential in controlling hypertension, especially concentrating on physical exercise and control of diabetes, obesity, and on quitting smoking and alcohol and healthy diet.

Key words: Hospital, Case-Control Study, Modifiable Risk Factors, Hypertension.

Introduction

Hypertension is a disease entity of its own. It remains silent being asymptomatic during its clinical course. Because of its asymptomatic appearance, it

does immense harm to the body in the form of target organ damage, hence the WHO has named it the “silent killer.” Hypertension is a major cause of cardiovascular morbidity and mortality worldwide.¹ Excess dietary salt, low dietary potassium, overweight and obesity, physical inactivity, excess alcohol, smoking, socioeconomic status, psychosocial stressors, and diabetes are considered as modifiable risk factors for hypertension.²

Globally, hypertension is estimated to cause 7.5 million deaths a year which is roughly 12.8% of the total. Hypertension is directly responsible for 57% of all stroke deaths and 24% of all coronary heart disease in India.³ A recent meta-analysis has shown prevalence

Corresponding Author:

Mr. Shriharsha C.

Associate Professor and HOD

Dept. of Psychiatric Nursing, BVVS Sajjalashree

Institute of Nursing Sciences, Navanagar, Bagalkot –

Cell: 9845777592

of hypertension as 40.8% and 17.9% in urban and rural population of India respectively.⁴

Hypertension is a tip of iceberg disease and often diagnosed for seeking treatment for other health problems. Sometimes it is diagnosed when it results in severe complications and admission to hospital of a patient. Lack of awareness regarding hypertension among public often leads to fatal consequences due to hypertension and related morbidities. Lack of awareness also results in poor health seeking behavior and reluctance in adoption of healthy life style.⁵

Hence considering the fact that, hypertension is the silent killer disease carry many modifiable risk factors which would pose the individual at many other morbidities, the researcher has planned to undertake a hospital based case-control study to assess the modifiable risk factors for hypertension among hypertensive and non-hypertensive patients attending the medical OPD of Hanagal Shree Kumareshwar Hospital and Research Centre, Bagalkot, so that an estimate of modifiable risk factors among hypertensive patients compared to non-hypertensive patients could be made. Which could be addressed in future interventional studies.

Material and Method

Study Design and Participants

Present study was a cross sectional case-control study conducted between Aug 2017 to Sep 2017. The sample for the present study was patients who came to the medical outpatient department of Hangal Shri Kumareshwar Hospital and Research Centre, Bagalkot during the study period. From them, only those who qualified the inclusion criteria as either a case or control were included in the analysis.

Criteria for Sample selection:

Inclusion Criteria:

Cases (Hypertensive patients):

- Patients who were already diagnosed with hypertension by a physician.
- Patients who are already on blood pressure-lowering medication(s).

- Both old and newly diagnosed patients were included.

- All willing patients aged between 35 and 65 years were included in the study.

Controls (Non hypertensive patients):

- Patients attending the same outpatient service with no history of hypertension and with the blood pressure recorded on the day of study are normal.

- All willing patients aged between 35 and 65 years were included in the study.

Exclusion Criteria:

Cases (Hypertensive patients):

- Patients who are known cases of secondary hypertension and antenatal females were excluded from the study.

Controls (Non hypertensive patients):

Patients whose blood pressure is not normal on the day of study were also excluded from the study.

Sample size

Sample size is 125 cases (Hypertensive patients) and 125 controls (Non-hypertensive patients).

Instruments

A modified WHO STEPS instrument (Questionnaire) for chronic disease risk factor surveillance was used to collect data. The questionnaire consisted of 7 items related to socio-demographic characteristics of sample, 19 items related to behavioral characteristics of sample and 6 items related to the physical characteristics of sample.

Data Collection Procedures

Prior permissions were taken from Hospital authority before the beginning of data collection procedure. The study participants were indentified during the study period at medical outpatient department of Hangal Shri Kumareshwar Hospital and Research Centre, Bagalkot. Every subject who fulfilled the inclusion criteria as either case or control was approached for data collection. Consent was obtained by the researcher

before participants underwent the structured interview which lasted approximately for 15 to 20 minutes. Purpose of the study was explained to the participants and they were interviewed in Kannada or in the language understandable to them. All the information collected was based on patient's self report, but the information related to physical characteristics such height, weight and blood pressure were assessed by the researcher at the time of interview.

Data Analysis

Numerical data obtained from the sample was organized and summarized with the help of descriptive statistics like frequency, percentage, mean, standard deviation. A simple proportion was done for all the relevant variables studied among cases and controls and the overall sample with confidence interval (CI) fixed

at 95%. The proportions of relevant risk factors were compared between cases and controls. Significance was ascertained by using Crude Odds Ratios (ORs). Statistical analysis was done using SPSS Ver. 25.

Results

A: Sample characteristics

Mean age of cases was 56.78 ± 8.65 and mean age of controls was 48.87 ± 11.01 . Most of both cases (63.2%) and controls (51.2%) were males. Majority of both cases (91.2%) and controls (98.4%) were Hindu. Nearly same percentage of cases (34.4%) and controls (39.2%) had no formal education. All most all cases and controls were married. Nearly same number of cases (29.6%) and controls (35.2%) were housewives. Mean family monthly income of cases was 11896 ± 5537 and that of controls was 11568 ± 2837.92 .

cOR: Crude Odds Ratios, CI: Confidence Interval

Table III displays the findings of relative risk estimation of effect of modifiable risk factors on hypertension. Findings reveal that, current smokers (OR: 7.289, CI: 2.09-25.32), daily smokers (OR: 8.386, CI: 1.9 -37.5), daily smokers in past (OR: 3.721, CI: 1.7-8.3), who are using smokeless tobacco (OR: 1.4, CI: 0.8-2.4) and who have habit of alcohol consumption (OR: 1.15, CI: 0.63-2.09) were at higher risk for hypertension.

Similarly, inadequate fruits in diet (OR: 1.19, CI: 0.7-2), inadequate vegetables (OR: 5.2, CI: 0.6-44.9) in diet were also the significant risk factors of hypertension. Whereas people doing work with physical activity (OR: 0.29, CI: 0.16-0.53), who have the habit of walking or jogging (OR: 0.83, CI: 0.48-1.42) were at less risk for hyper tension. Diabetes (OR: 5.21, CI: 2.39-11.4) and obesity (OR: 4.12, CI: 1.33-12.8) were the also the majors risk factors of hypertension.

In the present study, people doing work with physical activity (OR: 0.29, CI: 0.16-0.53), who have the habit of walking or jogging (OR: 0.83, CI: 0.48-1.42) were at less risk for hyper tension. Diabetes (OR: 5.21, CI: 2.39-11.4) and obesity (OR: 4.12, CI: 1.33-12.8) were also the majors risk factors of hypertension.

E. Family History of Hypertension

Percentage wise distributions of cases and controls according to family history of hypertension shows that, in case group majority (57.6%) of them had no family history of hypertension and 42.4% of them had family history of hypertension. Whereas in control group, 71.2% do not have family history of hypertension and remaining 28.8% have family history of hypertension.

Table IV: Results of relative risk estimation of family history of hypertension on hypertension.

N=125+125=250

Variables	cOR	P value	95% CI of ORs	
			Lower	Upper
1. Family history of hypertension				
a. Present	1.8	<0.05	1.08	3.08
c. Absent	Reference			

cOR: Crude Odds Ratios, CI: Confidence Interval

Table IV shows the findings of effect of family history of hypertension on hypertension. Presence of family history of hypertension (OR: 1.8, CI: 1.08-3.08) greatly increased the risk of hypertension.

Discussion

The present case control study was conducted with the aim of estimating the effect of modifiable risk factors on hypertension. Study included a sample of 250 subjects (125 cases and 125 controls) selected using the purposive sampling technique. Odds ratios were computed for estimation of relative risk of modifiable risk factors on hypertension.

Findings of the study showed that, current smokers (OR: 7.289, CI: 2.09-25.32), daily smokers (OR: 8.386, CI: 1.9 -37.5), daily smokers in past (OR: 3.721, CI: 1.7-8.3), who are using smokeless tobacco (OR: 1.4, CI: 0.8-2.4) and who have habit of alcohol consumption (OR: 1.15, CI: 0.63-2.09) were at higher risk for hypertension.

Similar findings were observed by Pilakkadavath Z and Shaffi M⁶ in their study conducted to assess modifiable risk factors of hypertension at Kerala, India. In their study, smoking and alcohol consumption were the significant risk factors of hypertension.

In the present study, inadequate fruits in diet (OR: 1.19, CI: 0.7-2), inadequate vegetables (OR: 5.2, CI:

0.6-44.9) in diet were also the significant risk factors of hypertension. These findings were supported by the study conducted by Wang L et al⁷ on fruit and vegetable intake and the risk of hypertension in middle-aged and older women. Findings showed that, higher intake of all fruits but not all vegetables remained significantly associated with reduced risk of hypertension after adjustment for lifestyle and dietary factors.

In the present study, people doing work with physical activity (OR: 0.29, CI: 0.16-0.53), who have the habit of walking or jogging (OR: 0.83, CI: 0.48-1.42) were at less risk for hyper tension. Diabetes (OR: 5.21, CI: 2.39-11.4) and obesity (OR: 4.12, CI: 1.33-12.8) were the also the majors risk factors of hypertension.

Findings of the present study were supported by the findings of the study conducted by Abed Y and Abu-Haddaf S⁷ to assess the risk factors of hypertension, results showed that, the most common modifiable risk factors of hypertension were physical inactivity (76.7% versus 15.9%), obesity (67.5% versus 29.2%), diabetes mellitus (19.2% versus 7.5%), and ex-smoking (15.5% versus 1%).

Limitations

Although present study has able to explain to some extent the relative risk of modifiable risk factors of hypertension, some limitations need to be taken into account. Sample size was limited to 250 (125 cases and 125 controls), hence the results cannot be generalized to wider population. Limited variables were included in this, as other aspects like blood sugar control in diabetic patients; lipid profile could be also associated with hypertension. Hence further researches may consider these limitations to update the knowledge on modifiable risk factors of hypertension.

Recommendations

Hypertension is strongly driven by a set of modifiable risk factors. An extensive public awareness campaign targeting risk factors is essential in controlling hypertension, especially focusing on physical activity and control of diabetes, obesity, and on quitting smoking and alcohol consumption, healthy diet. Future research should aim at evaluating the efficacy of risk reduction programmes on control of hypertension and their overall

quality of life.

Conclusions

Hypertension is a highly prevalent risk factor for cardiovascular disease and it can also lead to other diseases which seriously harm the human health. Screening the risks and finding a clinical model for estimating the risk of onset, maintenance, or the prognosis of hypertension are of great importance to the prevention or treatment of the disease, especially if the indicator can be derived from simple health profile. In this direction the present study has been successful in finding the key risk factors of hypertension; smoking, alcohol consumption, inadequate fruits and vegetables in diet, physical inactivity, and family history of hypertension, diabetes and obesity validating the findings of various others studies conducted across the globe.

Ethical Clearance: Ethical clearance was obtained from the institutional ethical committee of BVVS Sajjalashree Institute of Nursing Sciences, Bagalkot.

The Effect of Fluoride in the Prevention of Dental Caries and Prevalence of Dental Fluorosis among High and Low Fluoridated Areas of Tamilnadu-A Cross Sectional Survey

Anisha¹, M. Vishali², D. Prabu³, Sunayana Manipal⁴, Rajmohan⁵, Bharatwaj⁶, Prashanth⁷

¹Under graduate, ²Post graduate Student, ³Master of Dental Surgery, Professor and HOD, ⁴Master of Dental Surgery, Reader, ⁵Master of Dental Surgery, Reader, ⁶Master of Dental Surgery, Lecturer, ⁷Post graduate Student, Department of Public Health Dentistry, SRM Dental College and Hospital, Ramapuram, Chennai, Tamilnadu, India

Abstract

Aim: To analyze the effect of fluoride in the prevention of dental caries and prevalence of dental fluorosis in high and low fluoridated areas. **Material and Method:** Dean's fluorosis index (1942)-modified was used to analyze the severity and prevalence of dental fluorosis and the caries prevalence was assessed using DMFS index (1931). The school students of age 12-16 years belonging to Chennai and Vellore areas were included in the study. A total of 400 students were examined in which 200 students belongs to Chennai and other 200 students belongs to Vellore representing low fluoridated area (LFA) and high fluoridated areas (HFA) respectively. **Results:** In the LFA the mean value of DMFS was found to be 0.805, hence it was notably greater than the mean DMFS of HFA which was 0.335. The mean Dean's Fluorosis score of LFA was found to be 0.005 which was significantly lower than mean value of Dean's fluorosis at HFA which was 0.7425. **Conclusion:** Mild increase in concentration of fluoride level in drinking water will decrease the incidence of dental caries in adolescents. Optimal fluoride levels in drinking water looks to be successful in decreasing caries outcome with low risk of dental fluorosis.

Key words: Dental caries, Dental Fluorosis, high and low water fluoride level.

Introduction

Dental caries is one among the most prevalent chronic disease affecting humans of all populations. The multiple disease patterns within and across the countries are associated with several factors like demographic factors, socio-behavioral pattern, environmental factors, and the accessibility and availability of oral health care, particularly, the subjection to various preventing oral health care programs. The principal reason for the increased incidence of dental caries appears to be increase in sugar intake and insufficient availability of

fluorides.⁽¹⁾

Fluorides are the key agent for prevention of dental caries mainly by underlying 3 mechanisms 1) by promoting repair (remineralisation) of early initial white spot lesions caused due to the enamel breakdown induced by the acids produced by the cariogenic bacteria of oral cavity by its activity on fermentable carbohydrate. 2) by making tooth enamel more resistant to caries attack by enhancing the chemical nature of enamel more resistant to acid attack and 3) by decrease in the number of plaque bacteria producing acids.

According to WHO report on oral health given in 2003, it had been shown that the decrease in incidence and prevalence of dental caries is achieved by combined action of individual; oral health professional and communities. Accessibility to oral health care is very limited in many developing countries of the world.

Corresponding Author:

Dr. M.Vishali,

Department of Public Health Dentistry, SRM Dental College and Hospital, Ramapuram, Chennai, Tamilnadu, India, E-mail:vishalimahesh95@gmail.com

Considering this many public health approaches came into play which includes water fluoridation, salt fluoridation, milk fluoridation and use of affordable fluoridated toothpaste twice daily.

Level of 1.0mg F/l by means of water fluoridation is considered to be favorable for prevention of dental caries, excessive intake of fluoride at the time of maturation of tooth enamel may lead to dental fluorosis⁽³⁾. Hence fluorides rightly known as a double edged sword.

On the other hand, High intake of fluoride will result in, mottled enamel, skeletal fluorosis, osteosclerosis, exostoses, calcification of ligaments. With increase in severity, the subsurface enamel along the tooth becomes increasingly porous (hypomineralised), thereby making it more susceptible for caries⁽⁴⁾.

With the use of fluoride dentifrices, the caries decline can be largely attributed but several studies have mentioned about the increase in prevalence of fluorosis due to early utilization of fluoride containing dentifrice.⁽⁵⁾ Above the optimum fluoride level, the incidence of caries is reduced but greater the prevalence of fluorosis. However severe fluorosis also seems to be linked with greater caries incidence. This positive relationship was put forth by many scientists. (Ekanayake, L. and Vann der Hoek, W. (2002).⁽⁶⁾

Hence this study was conducted to study the effect of fluoride in between Dental Caries and fluorosis among High and Low fluoridated areas of Tamil Nadu, India.

Materials and Method

The cross-sectional descriptive analysis was done among 12-16 years aged (indexed age group according to WHO)⁽⁷⁾ school children from high and low fluoride areas in Tamil Nadu, India.

According to Chennai metro water, the permissible limits of fluoride in portable water is $\leq 1\text{mg/L}$ ⁽⁸⁾. The water fluoride level of Vellore is in the range of 2.25-2.75mg/l. Vellore has been reported as endemic area for dental fluorosis. Eight districts identified as fluorosis endemic.⁽⁹⁾

The sample size was calculated using Multistage Simple Random Method, where we have randomly selected 100 children of age group 12-16 years, from

schools in Chennai (Low fluoride area) and 100 children of the same age group from the schools of Vellore (High fluoride area). This study was conducted for a period of two weeks.

The ethical approval for this study was obtained from the Ethical committee of department of Public Health Dentistry, SRM UNIVERSITY and approval was obtained from School Headmasters and consent was given by all the parents of the school children who were examined for this study.

The study performance consisted of demographic data i.e. Name of the patient, age in years, Date of birth, place of birth, residing area from birth till 10 years of life, source of drinking water. The students were allowed to sit in a shady place and they were examined under sunlight, natural light source. Wooden spatulas were used to retract the cheeks.

The dental fluorosis was assessed using Dean's fluorosis study (1942) modified. And the dental caries was assessed using DMFS (1931).

The excluding criteria for this study was 1. Missing anterior tooth, 2. orthodontic treatment. During orthodontic treatment, there is more presence of local factors which might increase the risk of caries and it might alter the results. All the statistical computations were analyzed using Mann Whitney U test, Chi-square test. Data were look over using STATA for windows

Results

This cross sectional descriptive study was done among students from low fluoride area (Chennai) and high fluoride area (Vellore) in South India. There were 200 students of 12-16 years of age from low fluoride area and 200 students of 12-16 years of age in high fluoride area participated in this study.

In the low fluoride area there were 89 females and 111 males and in High fluoride area, there were 120 females and 80 males.

When the population was assessed for duration of stay on the area in LFA, 16 students had stayed for <10 years and 184 students has stayed for >10 years. In the HFA, 9 students had stayed <10 years and 191 students had stayed for >10 years.

According to the source of drinking water in LFA, 63 students had used tap water, 11 students had used shallow well water, 21 students had used bore well water and 105 students had used bottled water (purified water). In HFA, 108 students had used tap water, 25 had used shallow well water, 258 had used bore well water and 39 had used bottled water.

Table 1, indicates the mean (SD) Dean’s Fluorosis score of LFA was found to be 0.005 which was significantly lower than mean(SD) value of Dean’s fluorosis at HFA which was 0.7425. (Mann Whitney Wilcoxon test, p<0.05)

Table 2, indicates crude relative risk ratios of water fluoride concentration on caries and fluorosis prevalence as well as regression models adjusted for age as well

as status of father’s occupation (SES) and there existed a negative and a positive association between fluoride level in drinking water and the risk of caries and fluorosis prevalence, respectively.

In the age- and SES-adjusted model a relative risk ratio of 0.6(0.4-0.8) was calculated. For fluorosis prevalence the risk estimate was 16(8-38) sensitivity analyses for caries (0.7(0.6-0.9)) and fluorosis 15(7-39) yielded to similar estimates as the respective main model.

When the mean caries experience of lifelong residents from high fluoride area was compared to dental fluorosis. According to table 3, the mean DMFS in the HF-area decreases with the increase in dental fluorosis.

TABLE 1 - Mean DMFS and Mean Dean’s Score among lifelong residents in LFA and HFA

	Chennai	Vellore	
	Mean (SD)		Mann-Whitney U sig.value
DMFS	0.805(1.406008)	0.335 (1.34977)	0.00*
DEAN’S SCORE	0.005 (0.04987)	0.7425 (0.6817)	0.00*

* Significant value

TABLE 2-Denotes 95% confidence intervals and relative risks for relation between risk of dental caries as well as fluorosis with water fluoride concentration.

MODEL	CARIES		DEAN’S SCORE	
	Chennai	Vellore	Chennai	Vellore
1	Reference	0.5(0.4-0.7)	Reference	15(8-40)
2		0.6(0.4-0.8)		16(8-38)
3		0.7(0.6-0.9)		15(7-39)

Model #1 - crude relative risk estimates for caries and fluorosis occurrence among lifelong residents

Models #2- adjusted for age and SES

Models #3 - sensitivity models accounting for misclassification of both outcomes adjusted for age and SES

TABLE 3- Mean (SD) of caries experience (DMFS) of lifelong residents from the high-fluoride area related to dental fluorosis (Dean's score)

		DMFS		
		N	Mean	SD
Dean's Score	0	51	1.666667	1.966384
	0.5	49	4.833333	7.652886

	2	19	0.333333	0.816497
	3	5	0	0

($p < 0.05$; Mann-Whitney test) (N=size of sample)

Discussion

In this study, we have proved that mild increase in the level of fluoride in drinking water will lower the prevalence of dental caries in adolescents

In Low fluoride area (Chennai) the mean (SD) value of DMFS significantly higher than the mean (SD) DMFS of High fluoride area (Vellore). The mean (SD) Dean's Fluorosis score of Low fluoride area was found to be significantly lower than mean (SD) value of Dean's fluorosis at High fluoride area.

When the mean caries experience of lifelong residents from high fluoride area was compared to dental fluorosis. The mean DMFS in the HF-area decreases with the increase in dental fluorosis, it is important to note here that the Mean Dean's Score in HFA was mild. A negative relationship is proven. Similar relationship was proven by SA Eklund, BA Burt, AI Ismail and JJ Calderone⁽¹⁰⁾

In areas with very high fluoride levels, DMFS score increases with the increase in the Dean's score. This positive relationship was given by Ekanayake, L. and Vann der Hoek.W. (2002)⁽⁶⁾. Further studies can be done to study more on this topic. A neutral relationship was proposed by Ermis et al (2003)⁽⁰⁹⁾

According to table, the people who are enduring more than 10 years in Vellore, has virtuous tooth condition as the fluorosis content is manifestation high in water.

Wandwossen F, Bjorvatn Ket al, 2004 studied the relation between dental fluorosis and dental caries in areas of high and low fluoride levels of drinking water in Ethiopia⁽¹⁰⁾. The prevalence rate of 91.8% was obtained for dental fluorosis (moderate area) and prevalence of 100% (high fluoride area). The corresponding mean DMFT and caries prevalence in the areas were 1.2 versus 1.8 and 45.3% versus 61.6% respectively. The positive correlation among fluorosis and caries were noted in both of the areas.

Effectiveness of fluorides for the prevention of dental caries, 2004 proved that the use of fluoride tooth pastes and mouth rinses along with water fluoridation significantly decrease the risk of dental caries.⁽¹¹⁾ Cortes D.f., Ellwood et al, 1996 studied Drinking Water Fluoride Levels, Dental Fluorosis, and Caries Experience in Brazil⁽¹²⁾. Here the mean DMFT decreases with increase in fluoride level in drinking water. Caries incidence in 6 permanent teeth was significantly decreases ($P < .01$) in areas of 0.7 ppm of F. Higher TF scores and caries risk were noted in areas of 2-3ppm of F so only the optimum fluoride concentration plays a vital role in preventive

community programs in Brazil.

H. Meyer-Lueckel, H. Paris and A.M Kielbassa, studied caries risk among children aged 6-9 years residing in three areas in Iran⁽¹³⁾. Tooth Surface Index of Dental Fluorosis was observed in the low fluoridated communities compared with the naturally fluoridated town hence higher prevalence of fluorosis is seen in naturally fluoridated town. The intake of naturally fluoridated water which contain 1.3 ppm of fluoride has no or little effect on caries prevention but leads to dental fluorosis Karen M. Yoder^{1,*}, Lameck Mabelya², Valerie A. Robison³, Ann J. Dunipace⁴, Edward J. Brizendine⁵, George K. Stookey studied “ Severe dental fluorosis in a Tanzanian population consuming water with negligible fluoride concentration”⁽¹⁴⁾. Dental fluorosis is more prevalent in different parts of world even in fluoride-deficient water areas in children under 5 years of age cautions use of fluoride supplements and supervision of their use of toothpaste and defluoridation in endemic areas of fluorosis is recommended as two important preventive procedures for fluorosis. Aesthetic effect of fluorosis can be managed by tooth bleaching with or without micro-abrasion, veneering or crowning. The choice of treatment depends on the severity of the fluorosis and this may be analyzed by the use of Thylstrup and Fejerskov index⁽¹⁵⁾

Factors limiting our results- dental setup was not available hence through the utilization of artificial light would enable us to detect caries at the dentinal level; fluorosis was scored without using pressured air.

Conclusion

In this study, we have proved that mild increase in level of fluoride in drinking water will decrease the incidence of dental caries in adolescents. Optimal fluoride level in drinking water is known to be effective in decreasing total caries experience. Caries experience in school children at Chennai was low signifying their effective measures on oral hygiene. The caries experience in Vellore was relatively lower when compared to Chennai because of the presence of fluorosis. We conclude that teeth with fluorosis have got lesser chances of developing caries.

Occupational Health Problems among the Farmers of Rural Field Practice Area of Department of Community Medicine, KIMS, Hubballi: A Cross-Sectional Study

Anjana R Joshi¹, Dattatraya D Bant²

¹Postgraduate, ²Professor and Head, Department of Community Medicine, Karnataka Institute of Medical Sciences, Hubballi

Abstract

Background: India is a land of agriculture. Agriculture plays a vital role in India's economy. Farmers suffer from a multitude of problems; from the socio-economic problems to that related to their health.

Objectives: The study was conducted to assess the occupational health problems and the factors determining the health problems and to assess the health-seeking behavior among the farmers.

Methodology: A community-based cross-sectional study was conducted in the rural field practice area of KIMS, Hubli among 324 farmers. A pre-designed semi-structured questionnaire was used for the study. Suitable descriptive and inferential statistics were used for the analysis.

Results: Out of 324 farmers, the majority were males, Majority of the study participants were small scale farmers working more than 8 hours a day. Only 3.4% of the farmers used Personal protective measures while farming. Most of the farmers experienced occupational health problems- musculoskeletal problems being the commonest followed by respiratory problems. About 11.4% of the farmers experienced symptoms after pesticide exposure. The prevalence of health problems increases as the age advances and increase in years of work

Conclusion: Farmers face many health problems, the occupational health of the farmers should not be neglected as they are the bread makers of the world. There is a need to address the health problems and the measures to reduce these problems.

Keywords: *Farmers, Occupational health, health problems, health seeking*

Introduction

As per the 2011 census, 68.8% of India's population lives in rural areas¹. Two-thirds of the rural population depends on agriculture as their principal means of livelihood with the majority of them being small and marginal scale farmers.² Even a considerably higher

proportion of the female workforce is in agriculture. More than 50% of all female agricultural workers are unpaid family workers.³

Farmers suffer from a multitude of problems; from the socio-economic problems to that related to their health.⁴ Agricultural workers are exposed to a tremendous variety of environmental hazards that are potentially harmful to their health and well-being. Farmers suffer from increased rates of musculoskeletal disorders, respiratory diseases, noise-induced hearing loss, skin disorders, certain cancers, toxicity due to pesticides and fertilizers, injuries related to machinery and animals and heat-related illnesses.³

Mail address: joshianjana22@gmail.com

Occupational health in Agriculture is a very special problem because of the unique nature of the occupation. Farmers work usually dispersed in remote rural areas where the public services may be below the expected level. Farmers perform a variety of tasks and the duration of work is not limited to hours or days. Seasonal variation also occurs. They does not work in sheltered areas but in out of door areas and is exposed to extremes of weather and climatic conditions. Lack of knowledge and also availability of Personal protective equipment and clothes make them vulnerable for many hazards. Workman's compensation, laws, and other social legislations do not apply to the farmers and emergency and first aid services, as well as medical care and hospital services, may not be accessible easily.^{3, 4,5}

The diversified and seasonal nature of agricultural activities, mechanization and the increasing use of pesticides, lack of availability of safe water and basic sanitation facilities at the workplace bring special risks to agricultural workers.

The farmers are at a higher risk of various health problems directly or indirectly as a result of their occupation, working environment, and the socio-economic condition

Despite agriculture being the most important and most hazardous occupation, the health problems and the occupational health and their health-seeking behavior is the least studied and addressed, hence this study was conducted for assessing the health problems and the factors determining them and their mode of health seeking during the illness.

Objectives: To assess the self reported occupational health problems experienced in the previous 6 months and the factors determining the health problems and to assess the health seeking behavior during the health problems

Methodology

A Community based cross sectional study was conducted in the field practice area of department of community medicine among the farmers aged between 18-60 years residing in the Kalghatagi taluk, a field practice area of KIMS, Hubballi during 2018- 2019. Marginal and Small scale farmers aged between 18 to 60

years were included in the study. Farmers with serious illness and pregnant and lactating farmers were excluded. Cluster sampling was used for the selection of villages, and then systematic random sampling was used for selection of study participants. Informed written consent was taken from the study participants. Institutional ethical clearance was obtained for the study.

Sample size: The sample size was calculated by reviewing the previous study among the farmers in Titabor block in Assam, 62 % of the farmers visit government hospital during their illness⁷ the sample size was calculated using the formula

$$n = \frac{1.96^2 pq}{l^2}$$

The sample size of 324 was used for the study.

The predesigned semi structured piloted questionnaire consisting of socio-demographic details, occupational characteristics and the health problems faced by them in the previous 6 months and the preferred mode of treatment during health problems was used for the study. House to house survey was done

Data analysis: The data was entered in MS Excel and analyzed using SPSS v21, Suitable descriptive and inferential statistics were used for the study. Monte Carlo exact and Fisher Exact test was used as tests of significance.

Results

Socio-demographic characteristics: out 324 farmers, 69.8% of them were males and 30.2% were females. Majority (39.8%) of the farmers were in the age group of 50-60years, followed by 30-40 years(25%), 40-50 years and 18-30 years. 54.9% of the farmers were literates, 45.1% were illiterates. Majority of the farmers (53.4%) stayed in nuclear families followed by three generation family and joint family. Most of them belonged to class IV socio-economic status (67%), 16.7% and 16.4% belonged to Class III and Class V according to modified BG Prasad classification.

Usage of personal protective equipment was very poor with only 3.4% of farmers using PPE only during pesticide application.

Musculoskeletal disorders were the most common health problem reported among farmers followed by respiratory problems (Table 1)

The health problems were associated with literacy status, age group and years of work in the farm. (Table 2)

Health seeking behavior: The preference for private and government hospital was almost equal and the many farmers also preferred pharmacies as well (Table 3)

Table 1: Occupational Health problems in the previous 6 months

Health problems	Yes: N (%)	No: N (%)
Injuries due to machinery	48(14.8)	276(85.2)
Injury due to animals	9(2.8)	315(97.2)

Discussion

In the present study 324 marginal and small scale farmers were included in the study in which 69.8% of the farmers were males and 30.2% of the farmers were females.

In the present study the most common health problem faced by the farmers was the musculoskeletal problems (65.1%), followed by respiratory problems (38.9%), about 11.4% of the farmers experienced problems after pesticide exposure.

In a study conducted by Rajesh R K⁴ in the similar set up, the most common morbidity reported was dental problems(62%) which is contrast to the present study

in which only 3.5% of the farmers reported dental problems, Musculoskeletal problems was reported by 21.75% and respiratory problems by 19%. 6.75% of the farmers reported history of animal bite.

In the present study the most common health problem reported was musculoskeletal problems which is in similar to a study by Saket A Patil⁸ where musculoskeletal disorders was the most common morbidity among the farmers (83.8%) and study by A.Sangamithra¹⁰ in Tamil Nadu reported the similar findings.

In a study conducted by Syeda J R⁷ among farmers, the most common cause of morbidity among farmers was respiratory tract infection (54.25%), 23.25% of the

farmers reported musculoskeletal problems.

In the present study 14.8% of the farmers reported history of injuries due to machinery while working in the field. In the study by Vijay Kumar Manwani⁹ 64.15% of the farmers reported injuries due to machineries which is very high when compared to the present study. The animal induced injuries (35.85%) were also high compared to the present study (9%)

In the present study injuries due to machinery, Snake or animal bite, respiratory problems, musculoskeletal problems, problems after pesticide exposure, were high among male farmers, heat or cold related problems and eye and ear related disorders were high among female farmers. This may be because the type, duration of work done by them will be different from female farmers. Carrying heavy loads, Harvesting, working with the machineries predisposes the male farmers to experience the health problems more than the female problems.

In the present study the preferred mode of seeking health care was assessed Government hospital was the first priority for 39.5% of the farmers. 38.9% of the farmers preferred private practitioners/ AYUSH practitioners. 12.3% of the farmers preferred Pharmacies. Self medication was practiced by 5.6% of the farmers. Traditional healers were preferred by 1.5% of the farmers.

In the present study the farmers preferred government and private facility equally in contrast to the study by Syeda S J,⁷ and Rajesh R K⁴ where majority of the farmers preferred government hospital.

In the present study 12.3% of the farmers preferred pharmacies which is high compared to a study by Rajesh R K⁴ where only 1% of the farmers preferred Pharmacies.

Conclusion: The present study concludes that Majority of the farmers faced one or the other type of health problem in the previous 6 months with musculoskeletal disorder being the commonest morbidity. Usage of personal protective equipments is poor.

Preferences of health care facility was almost equal for both private and government facility.

Recommendations: The occupational health of

the farmers should not be neglected. Proper training should be provided about the use of Personal protective measures and the working postures to reduce the burden of the occupational health problems.

Limitations: The possibility of recall bias of illness as the illness episodes in the previous 6 months was included

The Two Underlying Factors of India's Health System Issues. A Comparative Analysis

Ansuman Swain¹, Kumar Sumit²

¹(BDS, MPH), Prasanna School of Public Health, ²Assistant Professor), Prasanna School of Public Health, Manipal Academy of Higher Education

Abstract

Background: Health system in India is multifaceted and is influenced by a conglomeration of several factors. The diversity in the system coupled with disparities in the taxation system, makes it incredibly challenging to manage and consequently, the health system takes a toll. As a result, the infrastructure, as well as quality of healthcare, is in a poor state. Non-affordability of quality healthcare is another issue as many are not covered by insurance, and without it, they are susceptible to catastrophic health expenditures. This paper tries to explain the central role of these dual roadblocks: discrepancies in the taxation system and insufficient health insurance coverage as attributable factors of a number of issues in the Indian health system. Further, this paper analyses the health system of the Netherlands and draws ideas of implementing some ideas of the same in India. Although the two complexities threaten the healthcare system of the country, India can incorporate certain strategies that have yielded good results elsewhere for the betterment of the healthcare sector of the country.

Keywords: *Ayushman Bharat, Dutch healthcare system, Health Insurance, Health system, Income tax, RSBY*

Introduction

With 29 states and a population of over 1.3 billion, the provision of quality healthcare is an arduous task in India^[1]. The country spends 1.4% of the GDP on healthcare while the life expectancy at birth remains a meager 67 yrs which is less than the global average of 72 yrs^{[1][2]}. Healthcare is a complicated, nevertheless booming sector in the country with the advent of private players and stakeholders from the civil society. There exist innumerable impediments like poor healthcare infrastructure, lack of availability of trained medical staff in rural areas, and unaffordability of quality healthcare by the poor^{[3][4]}. What is more, the unaffordability of healthcare seems to be an obvious problem in a country

with 21% population below the poverty line and less than 15% being covered by health insurance^{[5][6]}. Similarly, it is a herculean task to generate a decent budget for the healthcare sector, with less than 2% of the population paying Income tax^[7].

This paper aims to analyze the health system of India and understand the significance of taxation and health insurance in the healthcare sector. It discusses the shortcomings of the current taxation system followed by the lack of adequate health insurance coverage with briefings about the 'Rashtriya Swasthya Bima Yojna (RSBY)' and the 'Ayushman Bharat yojana'. A reflection of the possible solutions follows the analysis of the health system by understanding and taking ideas from the healthcare domains of the Netherlands. Lastly, the paper elucidates the feasibility of several ideas and concepts taken from the European nation in the Indian context.

Analysis of the issues in the Indian Health system

Healthcare is a large and fast-growing sector in the

country. It consists of primary, secondary, and tertiary levels of care provided by both public as well as private providers^[3]. The first contact point between the community and the primary care in rural settings is usually the Sub-centre (SC)^[8]. Likewise, a Primary Health Centre (PHC) is the contact point between the community and the medical officer and a Community Health Centre (CHC) serves as a referral center for PHCs and provides specialized healthcare services to the population^[8]. Furthermore, at the district level health services are rendered by a District hospital or a First referral unit (FRU), which provides emergency care, including obstetric and new-born care^[8]. The following figure explains in detail the hierarchical segregation of healthcare units according to geography and population.

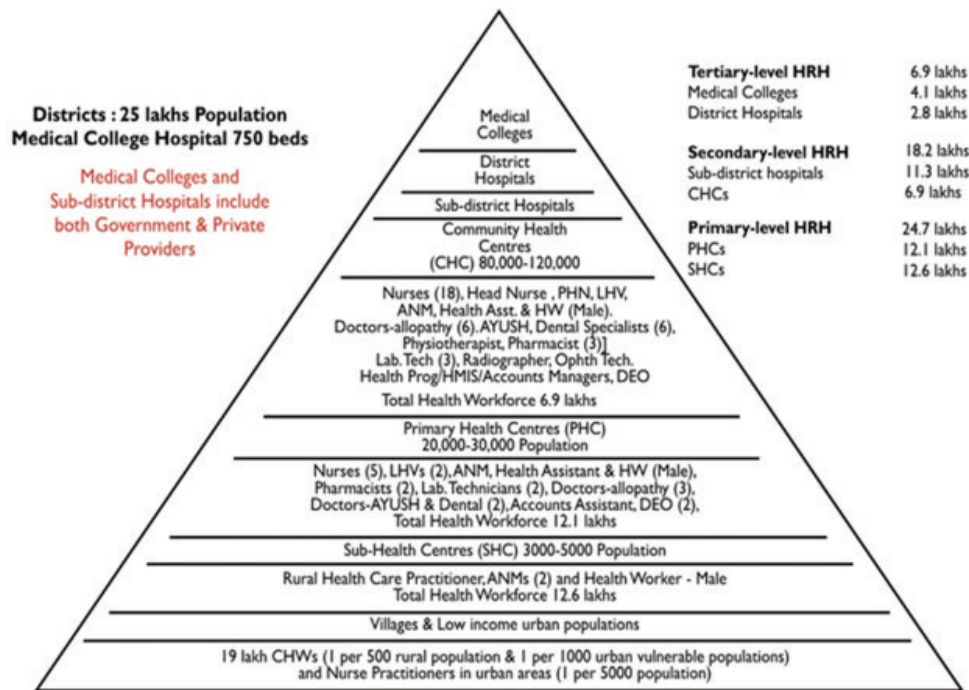

Figure 1. Indian Public Health System. Reprinted with permission from National Rural Health Mission, Ministry of Health and Family welfare, Government of India. Retrieved from <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5144115/> [8]

The above figure explains the several niches of healthcare provision in India from village and panchayat levels to that of a district pertaining to the population catered^[8]. While many Indians pay for health services out-of-pocket (OOP) (80%), less than 20% are covered by health insurance^[9]. Further, less than 2% of the population pays income tax in India. Consequently, the country manages to spend as little as 1.4% of its GDP on healthcare. Thus, it can be seen that inadequate insurance coverage and a small proportion of taxpayers are two of the most significant drivers of the state of healthcare in India.

Issues in Taxation and healthcare spending

India has a structured system of taxation with specified guidelines for the central as well as the state governments. The country utilizes the generated revenue for infrastructure development, salaries of employees, healthcare, etc. According to the Income-tax act of 1961, every individual aged below 60yrs is liable to pay income tax if their annual income is more than 2.5 lakh rupees^{[10][11]}. Students, children and any persons with income from an agricultural source are however exempted from paying income tax.

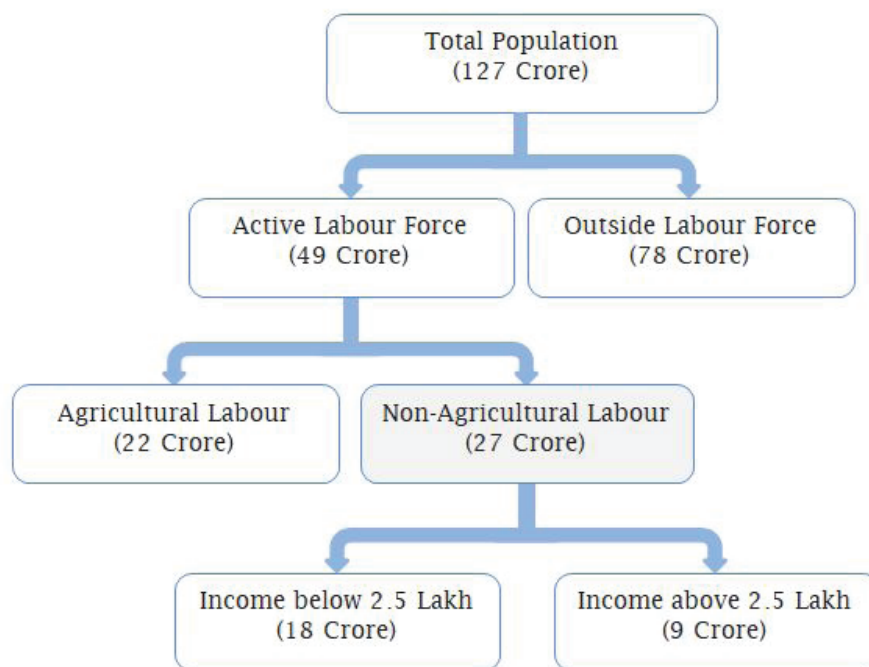

Figure 2. The potential Tax base of India. Source: cbgaindia.org. Retrieved from <http://www.cbgaindia.org/blog/many-indians-pay-income-tax-not-paying/> [12]

The figure explains the number of potential taxpayers in India; the income tax base of the country according to which, around nine crore individuals are liable to pay income tax^[12]. On the contrary, an estimated 2.02 crore individuals filed income tax returns in 2017-2018 but paid no tax^[13]. In particular, it can be deduced that around 1.9 crore individuals (1.5% of the population) pay tax whereas a staggering 7 crore are tax evaders^[13]. With such a large fraction of tax evaders, it is arguably arduous to govern a nation with over 1.3 billion population.

In 2017-2018, only 30 lakh individuals (0.23% of the population) paid a bulk of the tax, which is 77% of the total tax amount paid. Thus, a small portion of taxpayers bears a phenomenal tax burden. There are massive gaps between potential tax amounts and the actual figure of the same in the country, which invariably affects the sectors dependent on it. One such domain which is impacted hugely by this is healthcare. At 1.4% of its GDP being spent on the sector, India's healthcare expenditure is one of the lowest in the world with neighbors Sri Lanka and Bhutan exceeding the percentage by much^[14]. India's modest healthcare spending is one of the major factors

responsible for catastrophic healthcare expenditures.

Gaps in Health Insurance coverage

As mentioned in the previous sections, less than 20% of the population is covered by insurance, and most of them are government employees. Besides, there exist few insurance providers and limited schemes for those employed in the informal sector and the people below the poverty line^[15]. Furthermore, the scenario becomes rationally onerous with increasing healthcare costs, increasing the burden of new diseases, and neglect of primary and preventive care. The government came up with umpteen schemes in the past, for instance; RSBY, Ayushman Bharat, and the Aam Aadmi Bima Yojna (AABY), with a primary focus on the rural population.

RSBY and its shortcomings

The Ministry of Labour and Employment of the government of India launched the RSBY in April 2008 to provide health insurance coverage to BPL families^[16] which is presently under the Ministry of Health & family welfare (MOHFW). The scheme enables every Ration card holder to be eligible to receive a yearly benefit of

up to 30000 rupees by payment of a registration fee of 30 rupees^[16]. Under this scheme, the registered family is entitled to get cashless treatment in any of the impaneled public or private hospitals. Seventy five percent of the annual premium is borne by the central govt and 25% by the respective state governments^[16]. The program has covered 25 states and has received numerous accolades from international organizations like the World Bank and the UN.

However, a pertinent rise in hospitalization and medicine costs has compelled insurance companies to limit their policy benefits. Moreover, it is limited to inpatient treatment and lacks outpatient care coverage, which forms over 65% of the OOP expenditures of the country^[17]. Also, almost 40% of the BPL population is still not covered by the program and many remain unaware of the scheme^[17]. In an attempt to target the highlighted gaps, the govt. launched the Pradhan Mantri Jan Arogya Yojana (PMJAY) in 2018^[18].

Ayushman Bharat Yojana

Launched by the MOHFW, PMJAY or Ayushman Bharat program is committed to reduce the financial burden on the poor and vulnerable groups due to healthcare and ensure the nation's progress towards achieving Universal Health Coverage (UHC) and Sustainable development goal 3 (SDG 3)^[18]. It offers a benefit cover of Rs. 5 lakhs per family, per year to approximately 10.4 crores paltry, impoverished rural families, and categorized urban worker's families^[18]. The scheme provides cashless and paperless healthcare at all public and the impaneled private hospitals. In light of the omissions by the previous programs, the PMJAY ensures coverage for women, children, and the elderly^[18].

However, many private care providers are opting out of the scheme as the costs of healthcare provision are not financially viable for them and due to delay in payments by the government^[19].

The way forward

In the above sections, the health system issues of India have been discussed, and the two significant factors responsible have been briefed about. It is imperative to understand that while no country is free from these

issues, some have elite healthcare systems for instance, The Netherlands.

Highlights of the Dutch healthcare system

Catering to a population of over 16 million, The Netherlands spends 10.9% of its GDP on healthcare^[20]. The Netherlands is one of the few countries to spend more than 4000 Euros per person on healthcare. Five significant healthcare acts dictate the Dutch healthcare system which are: The Health insurance act, the Long term care act, the Social support act, the Public health act and the Youth act^[21]. The country has mandated purchasing health insurance with 99% of the population being covered by health insurance^[20].

Furthermore, the new Health insurance act in 2006 entitles all residents to a comprehensive health insurance package pioneered by the government. It finances the Social health insurance partly with coverage of consultations of General practitioners (GP), specialist and hospital care, medications, mental health care, Dental care up to 18yrs, and maternity care^[22]. In addition to the mandatory statutory insurance, around 84% of the population is also covered by specific voluntary insurance schemes such as Dental insurance, and preventive care^[22]. Thus health insurance plays a central part in the Dutch health system. The Dutch healthcare sector is thus largely financed by the government, and most of the revenue generated for the same is through taxation.

Over 39% of the revenue generated is via taxation. The Ministry of Finance is responsible for the governance of tax laws in the country, and the "Belastingdienst" is the department taking care of it^[23]. The Dutch have a progressive box taxation system with individuals of all income categories are liable to pay taxes^[23]. Further, foreign income, income from a pension, income from business are also liable for taxation. Also, the government has specified penalties for a breach in the code as well. The tax office can issue a penalty up to 4920 Euros in case of a delay in filing a tax return or not filing at all^[24]. Also, any hidden or undeclared income when discovered by the Belastingdienst is liable to a fine up to 300%^[23]. Moreover, the government generates a decent revenue from taxation, and the allocates the same to the aid of healthcare in the country via a defined system of health insurance. The Netherlands has engineered a structured

taxation system which certainly can be the goal to achieve for a country like India.

Potential for the Indian context

While some implementation strategies discussed in the previous sections can be practically installed, it is necessary to keep in mind that the setting in India is contrasting to that of in Europe. Although the regions differ in demography, culture, and economy, some strategies from the Netherlands can be implemented in India with a bit of tailoring as per the context. For instance, the country can increase healthcare spending by prioritizing the sector. One way to increase revenue for healthcare is by strengthening the system of taxation. Considering the insignificant proportion of taxpayers in the country, significant reforms need to be instituted in the taxation system. Like the Dutch system, guidelines can be put in place to organize the rules of income tax in India. For instance, reviewing the current eligibility criteria for income tax, which means including those earning an income from agriculture and other informal sectors as well in the taxpaying category, may be considered. Another strategy could be installing a system of penalties for tax evasion.

Another reason for the elite level of healthcare in the Netherlands is the coverage of health insurance. To start with, the Indian government can reinforce public insurance and encourage private insurance companies to come up. Correspondingly, specific rules need to be strategically implemented, for instance, mandating health insurance. Furthermore, the country needs to develop schemes and programs for special populations, such as; children, and older adults.

Conclusion

With a large population and diversities within, health system functioning in India is a labyrinthine affair. In addition, the sector is not economically well provided, and it reflects upon the state of healthcare affordability in the country. This leads to the two cardinal elements discussed in the paper that are primarily culpable for the state of healthcare in India which are: sparse number of taxpayers and insufficient health insurance coverage. As discussed in the previous sections, the country harbors a massive proportion of tax evaders, thus not generating the potential revenue and eventually cramping up the

country's finances. As a result, catastrophic health expenses drive a large number of the population into poverty, which is one of the ramifications of inadequate insurance coverage, and the lack of awareness about its importance. However, strategies from developed nations such as the Netherlands may be installed in a country like India.

The nation has tackled the issues mentioned in the previous paragraphs long ago by a stringent organization of their health systems and installing a penalty system for any breach in the rules. Some ideas taken from these European nations can surely be implemented in the Indian scenario with a required bit of modification. Some initiatives might have been taken in this regard; however, with changing paradigms in the country, it remains to be seen how these ideas unfold and perpetuate.

Immediate Effect of Playing Smart Phone Action Videogames on Audiovisual Reaction Time

Anuradha Rajiv Joshi¹, Richa Tiwari²

¹Professor and Head, Department of Physiology, BV(DTU) MC, Pune, ² IX sem. MBBS student, BV(DTU)MC, Pune

Abstract

Background: Smart phone gaming has become an integral part of the lives of college students. Studies have given controversial results of playing action video games. Some studies concluded that action video game playing improves visual and attentional skills. On the contrary, other studies have proved that such gaming activities are more likely to cause frustrating experience resulting in mental stress. Medical undergraduate students have more academic pressure and longer educational years than other college students. Computer and mobile games provide a way for medical undergraduate students to relax. Hence this study was undertaken to estimate the immediate effect of playing action videogames on audiovisual reaction time in medical students.

Method: Undergraduate students (n=100) in the age group of 18 to 23 years were included in the study. After institutional ethical committee approval students were voluntarily included in study based on inclusion and exclusion criteria. Audiovisual reaction time was estimated in the participants by audiovisual reaction time apparatus.

Result: Audiovisual reaction time was found to be significantly increased ($p < 0.001$) in students immediately after playing action video games.

Conclusion: Thus, this study concludes that audiovisual reaction time is prolonged immediately after playing action video games on smart phone in students.

Keywords: Action Video Games, Visual Reaction Time, Auditory reaction time, Attentional Skills

Introduction

The number of smartphone users in India has increased to 239 million by the end of 2015 and tremendous increase is expected about 702 million by 2020. [1]

Smart phone is a multitasking gadget which not only ensures communication, but also ensures entertainment in the form of games and music. [2] Mobile games are

video games played by single-player or multiple players. They are available online via a mobile device, and are popular when downloaded for free. [3]

In 21st century although various reports have documented the beneficial effects of playing video games they did not specify the types of mobile game used for the study. [4] Now a day there are various types available such as brain games, action games, and adventure games. Depending on the type of game, there could be a difference in responsiveness. [4,5]

Few studies have stated that 'action' video games promote the perceptual and attentional abilities. [5] On the contrary few studies have proved that some games cause frustrating experience and trigger the highest

urge to continue playing. Furthermore, smartphone gaming content and patterns of use (i.e., frequency of smartphone use on weekdays and weekend days) is also related to problematic smartphone use. [6]

Students pursuing professional course in medical college have more academic pressure and longer educational years than other college students. [7,8] Along with academics they have to face daily stressors of life, family matters and patient-related workload in both undergraduate and postgraduate students in both males and females. [7] It has been observed that in females pursuing professional course perceived stress score was directly correlated with menstrual problems. [9] Computer and mobile games provide a way for medical undergraduate students to relax. [10] The video game time of medical students and the factors influencing this time may differ from those influencing students of other majors. It has been observed that students play the games during day time whenever they get time, even in between the two consecutive lectures. The concept of game disorder has progressed and is now officially included in the ICD-11. (International Classification of Diseases-11) Gaming disorder is a pattern of gaming behavior (“digital-gaming” or “video-gaming”) characterized by impaired control over gaming. [11]

Reaction time is a reliable indicator to assess the processing capability of CNS and sensory motor performance in response to an external stimulus. [12] Its determination is one of the important methods to study a person’s central information processing speed and coordinated peripheral movement response.

Most of the studies [5,6] done to assess effect of playing mobile games have not documented immediate effect of playing the game on audiovisual reaction time. Thus the present study was planned to study immediate effect of playing action games (on smart phones) on audio-visual reaction time in students pursuing professional course.

Material Method

This was a cross sectional observational study and was carried out in the Physiology department, in a local medical college. After ethical committee approval the volunteers were briefed about the study protocol and a written informed consent was obtained from them.

Undergraduate students (n=100) in the age group of 18 to 23 years were included in the study. They were divided into Control group (n=50) and study group subjects (n=50). The auditory and visual reaction time was recorded before and after 10 minutes of playing the action game on smart phone in one sitting on the same day in study group subjects. Control group were asked to sit quietly in room and readings were taken after 10 minutes. The readings were taken between 11 a.m. and 12 noon in a quiet secluded room. They were asked to take light breakfast in morning. It was ensured that they did not have caffeine before coming for the experiment as it has a direct effect on the reaction time.

Volunteers in the age group of 18-23 years were included in this study. A written questionnaire which included duration in years and number of hours per day was filled by the students. Students playing smartphone gaming for 2-3 years and a minimum time of 3-4 hours per day were included in the study. (self-reported data)

On the other hand, volunteers who were non-alcoholics and non-smokers, those who were suffering from color blindness, acute or chronic cardiorespiratory illness, having any kind of hearing disabilities or with any physical deformity and taking any medication affecting the cognitive performance were excluded from this study.

Audio-visual reaction time:

Reaction time was recorded by using the Reaction Time Apparatus by Anand Agency Pune. The apparatus consisted of a source of stimulus, response key and the time recording device. The response was given by the test subject by pressing a key with his index finger. Time taken by the test subject to give a response was displayed with an accuracy of 1 millisecond and was recorded as his reaction time. [12]

The stimuli were in the form of a visual stimulus (green light or a red light) or an auditory stimulus (tone or click). The volunteer was informed about the type of stimulus that was produced in front of him/her, beforehand. The volunteer responded to the stimulus, as soon as he/she saw or heard it, by pressing both the buttons, placed on the either side of the surface of the apparatus. In this process, a reading was recorded and shown on the screen. This was the reaction time of the

individual, which was noted down. Three readings of each stimuli were taken, before and after playing the action game and their respective fastest reaction time for each stimuli was recorded. The fore period was also changed randomly before selecting the type of stimulus, which was totally unknown to the volunteer. [13,14]

Hence, this study was helpful in knowing whether audiovisual reaction time was affected immediately after playing action games on smart phone.

Statistical analysis- Data was represented in the form of mean + SD. Comparison was done in control and

study group subjects by unpaired 't' test. Comparison of auditory and visual reaction time values before and after playing action game on smart phone by students in study group subjects was done by paired 't' test.

Results

Mean age of students was 19.6 ± 0.2 years. Control group and study group subjects were involved for the duration of 2.12 ± 0.43 hours and 3 ± 0.64 hours daily in smart phone gaming. Statistically significant increase in auditory and visual reaction time was observed in study group subjects before and immediately after playing action games on smart phones.

Table no 1: Comparison of audio visual reaction time in control group subjects

Parameter	Control group (n=50) Before and after sitting quietly		p value
	Before	After	
High pitched sound (mean \pm SD) ms	0.198 \pm 0.070	0.201 \pm 0.075	>0.05
Low pitched sound (mean \pm SD) ms	0.187 \pm 0.042	0.185 \pm 0.052	>0.05
Red light (mean \pm SD) ms	0.256 \pm 0.052	0.254 \pm 0.063	>0.05
Green light (mean \pm SD) ms	0.234 \pm 0.174	0.236 \pm 0.183	>0.05

p>0.05 statistically not significant

Table no 2: Comparison of auditory reaction time in study group subjects before and after playing action games

Parameter	Study group (n=50) playing action game		p value
	Before	After	
High pitched sound (mean \pm SD) ms	0.201 \pm 0.075	0.292 \pm 0.116	< 0.001*
Low pitched sound (mean \pm SD) ms	0.185 \pm 0.052	0.300 \pm 0.183	< 0.001*

p< 0.001* statistically highly significant

Table no 3: Comparison of visual reaction time in study group subjects before and after playing action games

Parameter	Study group (n=50) playing action game		p value
	Before	After	
Red light (mean ± SD) ms	0.254±0.063	0.292±0.116	< 0.001*
Green light (mean ± SD) ms	0.236±0.183	0.300±0.183	< 0.001*

p< 0.001* statistically highly significant

Discussion

The present study was aimed to observe immediate effect of playing action video games on audio-visual reaction time in undergraduate medical students.

As observed in Table-1 statistically significant difference was not observed in control group subjects before and after sitting quietly in room for 10 minutes. Table no 2 and Table no 3 shows statistically significant increase in auditory and visual reaction time in study group subjects before and after playing action games. This might be due to decreased concentration and alertness. It has been observed that mental fatigue occurs after playing action games.^[15] (Reed and Antonova, 2007).

Study done by Sushil Chandra et al ^[16] observed that training in action video games improved reaction time, processing speed and reduced stress level. Also progressive attainment of skills i.e. hand eye co-ordination in psychomotor domain was observed in the study. This study has highlighted positive effects of playing action video games such as modifying visual selective attention, leading to improvement in basic cognitive skills.

The results of present study are not consistent with the earlier findings. ^[16] This might be due to the reason that earlier studies have not recorded the reaction time immediately after playing action video games on smart phone. They have studied overall effect and have compared with the control group who did not play

similar type of games.

An increase in reaction time indicates a reduced sensorimotor performance and could be due to decreased information processing ability of the central nervous system. It might be due to reduced performance in the speed and accuracy task due to diverted mind. ^[14]

King et al^[17] identified that graphics and presentation causes motivation to play videogames leading to digital fatigue. Also number of actions per unit of time to achieve the greatest reward while playing action video games make the students engrossed for the time being.

The focus of the volunteers is always on relatively fast tasks requiring decisions between just two alternatives. All these causes digital fatigue leading to increased reaction time. It has been observed that while playing games on smart phone volunteers feel anxious about their performance.^[18]

In a professional college if students play such type of games in between free time during the lectures their attention towards teaching will be affected eventually losing the interest in studies. So it's of utmost importance to make students aware about the side effects and encouraging them to play such games for fun during leisure time beyond teaching hours.

Conclusion: Increased reaction time immediately after playing action video game indicates decreased responsiveness of the students. Full concentration for a particular time period on the game ultimately decreased

alertness due to digital fatigue.

Conflict of Interest: The authors declare no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Type: Original Research

Evaluation of Serum Uric Acid Levels in Psoriasis Vulgaris

Apurav Kaushik¹, Aneet Mahendra², Sanjeev Gupta³, Suvarna Prasad⁴, Rohit Singla⁵

¹PG Resident, ²Professor, ³Professor and Head, ⁴Professor and Head, ⁵Assistant Professor, Dept. of Dermatology, Venereology and Leprology, MMIMSR, Mullana, Ambala (Haryana)

Abstract

Aims and Objectives: To estimate and compare the Serum Uric Acid levels in Psoriasis Vulgaris patients and healthy controls and to find out any association between the Serum Uric Acid levels and severity of the psoriasis vulgaris.

Methodology: Forty patients with clinically diagnosed Psoriasis Vulgaris were taken and assessed for Serum Uric Acid levels. Forty age, sex and BMI matched controls were taken and findings of both cases and controls were compared.

Results: Out of 40 cases, the prevalence of hyperuricemia in Psoriasis Vulgaris patients in our study was 17.5% compared to 10% in controls. Increased SUA levels were associated with higher PASI score and higher BSA involvement. Psoriasis and PASI were found to be independent predictors of hyperuricemia.

Conclusion: Serum uric acid levels offer to be a valuable biomarker in the evaluation of Psoriasis Vulgaris and its management.

Keyword: chronic inflammation, hyperuricemia, psoriasis vulgaris, uric acid

Introduction

Psoriasis is chronic, non-contagious condition of the skin marked by chronic inflammation and hyper proliferation of skin cells leading to formation of erythematous, well defined plaques with silvery white dry loose scales all over the body, usually over extensor aspects. Psoriasis is associated with increased risk of cardiovascular disease¹ and Hyperuricemia itself is an independent factor for cardiovascular disease.² Psoriasis is also associated with higher risk of obesity and alcohol consumption which may further increase Uric Acid levels.³ Uric acid crystals are strong stimulators of innate immunity.⁴ Thus, hyperuricemia might not just be a consequence of hyper metabolism of purines but also may be a factor in perpetuating the disease. Hyperuricemia appears to be an independent risk factor for psoriatic

arthritis.⁵ Uric acid as a factor might be able to predict the disease activity as well as be useful in monitoring the disease. Thus, it may be an important biomarker in managing psoriasis as well as its complications such as psoriatic arthritis.

Materials and Method

Forty patients of either sex with clinically diagnosed Psoriasis Vulgaris attending the Out Patient department(OPD) at Maharishi Markandeshwar Institute of Medical Sciences and Research (MMDU),Mullana, Ambala (Haryana) were enrolled in the study. The control group comprised of Age, Sex and BMI matched 40 individuals attending the OPD. The participation was totally voluntary and a written, informed consent was taken in a language understandable to the patient.

Inclusion Criteria:

- a) Patients with clinically diagnosed psoriasis vulgaris.
- b) Patients of either sex of age 18 years or older.

Corresponding Author

Dr Aneet Mahendra,

Email: draneetmahendra@yahoo.com

c) Patients willing to participate in study.

Exclusion Criteria:

a) Patients less than 18 years of age.

b) Pregnant and lactating females.

e) Patients taking any drugs known to affect SUA level, including diuretics, allopurinol, alcohol, losartan, estrogens, glucocorticoids, salicylates, levodopa, theophylline, pyrazinamide, ethambutol and cyclosporine.

d) Patients with history of gout, diabetes mellitus, chronic liver or renal diseases.

e) Patients who are on methotrexate or have taken methotrexate in the past 3 months.

A total of 80 patients attending the Dermatology OPD of either sex above the age of 18 years with clinically diagnosed Psoriasis vulgaris were enrolled in the study. Cases were clinically diagnosed psoriasis patients and selected after they met inclusion and exclusion criteria.

Controls were patients with other dermatological complaints, which do not have any proven association with derangements of serum uric acid levels and attendants of patients visiting the Hospital. Controls were age, sex and BMI matched before enrolment into the study.

A detailed medical history along with thorough dermatological and systemic examination was done. The severity of psoriasis vulgaris was assessed by

using PASI scale.

Blood samples were collected from cases and controls after an overnight fast, and Serum Uric acid were analysed by Uricase method/kit method (Transasia) as per manufacturers protocol, using Erba Manheim (EM 360) analyser. The results were interpreted as

Normal Serum uric acid level (in males) = 3.4-7.0 mg/dL

Normal Serum uric acid level (in females) = 2.4-5.7 mg/dL

Hyperuricemia (in males) = >7.0 mg/dL

Hyperuricemia (in females) = >5.7 mg/dL

After all the data was collected, it was tabulated and analysed using appropriate statistical tests/methods. The level of significance used was 0.05 for the corresponding degree of freedom. A P-value > 0.05 was not considered as statistically significant and a P-value < 0.05 was considered statistically significant with value < 0.001 as highly significant.

Results

This study included 80 individuals (40 psoriatic patients and 40 controls) with male to female ratio of 3.4:1 (31 males and 9 females in each group). The mean age among the cases was 41.45 years and the mean BMI was 25.73 kg/m². Descriptive characteristics of study population are reported in table 1. No statistical difference was observed between age of the patient and SUA levels. (p=0.9)

Table 1: Cases distribution according to Age and Gender

Age (In Years)	Males		Females		Total	Percentage(%)
	Number	Percentage	Number	Percentage		
18-30	8	25.81	2	22.22	10	25
31-40	6	19.35	4	44.44	10	25
41-50	12	38.71	1	11.11	13	32.5
51-60	5	16.13	2	22.22	7	17.5
TOTAL	31	100	9	100	40	100

Mean SUA level of the cases was higher (5.46 mg/dl) as compared to controls (4.64 mg/dl) p=0.011. Among males, mean SUA was 5.62±1.47 mg/dl in cases and 4.75±1.15 mg/dl in controls. Among females, mean SUA was 4.89±1.48 mg/dl in cases and 4.26±1.78 mg/dl in controls.

Table 2: Clinical characteristics of participants in the study

Clinical characteristics	Cases	Controls	P value
Age(years)	41.45±11.126	41.05	Matched
Sex (Male/Female)	31/9	31/9	Matched
BMI(kg/m ²)	25.73	25.55±1.96	Matched
Serum Uric Acid(mg/dl)	5.46±1.49	4.64±1.31	0.011

Table 3: Distribution of patients of Psoriasis according to individual parameters

Parameters	NO. OF INDIVIDUALS	PERCENTAGE	Mean SUA (mg/dl)	Standard deviation	P value
Males	31	77.5	5.62	1.47	0.012
Females	9	22.5	4.89	1.48	0.423
Joint Involvement yes	12	30	6.04	1.34	0.104
Joint Involvement no	28	70	5.21	1.50	
Nail involvement yes	15	37.5	5.4	1.40	0.85
Nail involvement no	25	62.5	5.49	1.56	
BSA 0-5	25	62.5	5.08	1.55	0.086
BSA 5-10	8	20	5.89	1.22	
BSA >10	7	17.5	6.34	1.12	
PASI 0-5	8	22	4.4	0.76	<0.001
PASI 5-10	23	57.5	5.19	1.38	
PASI >10	9	22.5	7.09	0.82	

Mean body surface area involvement was 4.79%. SUA of the patients showed an increasing trend as BSA increased but this difference was not found to be statistically significant ($p=0.086$). For severity assessment PASI score was calculated.

Mean PASI score was 6.95, higher SUA was observed in patients with severe PASI score. The

relation between PASI score and SUA level was found to be statistically highly significant. ($p<0.001$). In the present study, 30% of the patients had history of joint involvement. Patients with joint involvement had higher SUA but this difference was found to be statistically not significant ($p=0.104$).

Table 4: Multivariate linear regression for hyperuricemia

Model 1 : Predictors of Hyperuricemia among participants in the study(N=80)			
Characteristic	Beta	t value	Significance(p)
Age	0.020	0.191	0.85
Sex	0.119	1.057	0.29
BMI	0.194	1.718	0.09
Psoriasis	0.278	2.646	0.01
Model:2 Predictors of Hyperuricemia in Psoriasis patients(N=40)			
Age	0.094	0.773	0.445
Sex	0.126	1.024	0.313
BSA	0.198	1.248	0.220
PASI	0.353	2.282	0.021

Multivariate linear regression analysis was done which revealed that both Psoriasis ($p=0.01$) and PASI ($p=0.021$) were independent predictors of hyperuricemia.

Discussion

Psoriasis is one of the longest standing skin disease known to mankind. It is known to affect 2-3% of the population worldwide. It primarily involves skin and joints. Lately, it is being recognised as a multisystem inflammatory disorder due to the various co-morbidities associated with Psoriasis. Plaque Psoriasis (Psoriasis vulgaris) is the most common variant and presents as well defined erythematous, indurated, scaly plaques particularly over extensor aspects.

Psoriasis is a disease characterized by epidermal hyperplasia. This hyper-proliferation of keratinocytes requires increased rate of DNA formation. Consequently,

DNA degradation also occurs at much higher rate. This increased cell turnover leads to increased rate of purine formation and metabolism as purines are a fundamental part of DNA. Uric acid is an organic compound that is endogenously formed as a product of metabolic breakdown of purines. The increased degradation of purines may be reflected as higher levels of Serum Uric Acid in Psoriasis patients. Increased SUA levels may further be a risk factor for gout⁶, renal disease⁷, hypertension^{8,9} and cardiovascular diseases.²

In the present study, male patients had higher mean SUA (5.62 mg/dl) than male controls (4.76 mg/dl) and this difference was found to be statistically significant ($p=0.012$). This was in accordance with the study

conducted by Guiet al.¹⁰, Chand et al.¹¹ and Baumann et al.¹² In our study, female patients had higher mean SUA (4.89 mg/dl) as compared to females in the control group (4.26 mg/dl) and this was found to be statistically not significant. ($p=0.423$). This was in accordance with the study conducted by Chand et al.¹¹ and Baumann et al.¹² and they reported this difference to be statistically significant.

In our study, the SUA levels were observed to be higher among cases (mean SUA=5.46±1.49 mg/dl) as compared to controls (mean SUA=4.64±1.31). The difference between SUA levels of cases and controls was found to be statistically significant. ($p=0.011$) This was in accordance with the study conducted by Gisondiet al.¹³, Yilmaz et al.¹⁴, Khan et al.¹⁵, while contrasting results were reported by Agravatt et al.¹⁶ and Nicolae et al.¹⁷ The higher SUA levels among patients with Psoriasis can be explained by increased rate of purine metabolism, due to the rapid epidermal turnover, leading to accumulation of uric acid which is the end product of purine degradation.

Several studies have shown that hyperuricemia is an important risk factor for gout, renal disease (uric acid nephropathy, renal insufficiency etc.), hypertension and cardiovascular diseases. The increased hyperuricemia among psoriasis patients may increase the risk of many comorbidities in psoriasis patients. Various studies have reported increased prevalence of hyperuricemia among psoriasis patients. In 2015, Lai et al.¹⁸ conducted a study and found hyperuricemia in 17.17% of psoriasis patients as compared to 13.1 in controls. Similarly, Guiet al.¹⁰ found increased prevalence of hyperuricemia in psoriasis patients (31.6%) as compared to controls (17%). Our study has also reported increased hyperuricemia in psoriasis vulgaris patients (17.5% in cases and 10% in controls). The increased hyperuricemia among psoriasis patients may increase the risk of many comorbidities in psoriasis patients.

SUA levels have been known to be higher in various diseases affecting the joints. As psoriasis has been known to primarily involve skin and joints, it is expected that SUA levels may be higher in patients with joint involvement. Psoriatic arthritis is a seronegative inflammatory arthritis, which occurs in up to 40% of patients with moderate to severe psoriasis.¹⁹ Once

considered to be a mild disease, psoriatic arthritis is now considered to be a debilitating disease requiring targeted treatment with frequent monitoring and follow-up care.²⁰ Various studies conducted earlier have shown higher SUA levels in Psoriatic arthritis. In 2017, Collazo et al.²¹ reported higher SUA levels in psoriatic patients with joint manifestations but this was found to be statistically not significant. In our study also, higher SUA levels were present in patients with joint involvement but this difference was found to be statistically not significant. Thus, SUA levels can be a valuable tool in early diagnosis of psoriatic arthritis. Early intervention in such cases would prevent further complications.

Extent of body surface area involvement has been evaluated in some of the earlier studies to indicate presence of hyperuricemia. In 2011, Kwon et al.²² reported the relation between extent of BSA involvement and SUA level to be statistically highly significant. In 2017, Collazo et al.²¹ reported this relation to be statistically not significant. In our study, higher BSA involvement was associated with higher SUA level but this relation was found to be statistically not significant ($p=0.086$).

Increase in SUA levels in psoriasis patients has been attributed to the increased proliferation and rapid turnover of epidermal cells. To assess the impact of disease severity, PASI scale was used. Increased SUA levels were observed in patients with higher PASI score and this difference was found to be statistically highly significant ($p<0.001$). Our study shows higher the severity of psoriasis, higher are the SUA levels. Many of the earlier studies conducted by Kwon et al.²² ($p<0.05$) and Collazo et al.²¹ ($p<0.01$) have shown similar results. Multivariate linear regression model was also applied among Psoriasis patients which revealed that PASI score was an independent predictor of raised Serum Uric Acid levels. Similar results were observed in the studies by Kwon et al.²² and Gisondi et al.¹³ whereas contrasting results were reported by Gui et al.¹⁰. The raised SUA levels could be due to rapid epidermal turnover (with increased rate of purine metabolism). Hyperuricemia has been shown to be important risk factor for various other diseases such as renal disease (uric acid nephropathy, renal insufficiency etc.), hypertension and cardiovascular diseases⁽²³⁾ and may increase the risk of complications in Psoriasis patients.

Conclusion

Psoriasis is primarily a dermatological disease; it has been associated with many systemic abnormalities manifesting as comorbidities. Overall hyperuricemia was more prevalent in psoriatic patients. The SUA levels were significantly higher among Psoriasis patients as compared to the control group. Patients with higher SUA levels also had higher prevalence of joint involvement, higher extent of BSA involvement and higher severity (PASI) of Psoriasis. Psoriasis and PASI score being independent predictors of hyperuricemia show that Psoriatic patients are at increased risk of hyperuricemia and might develop subsequent complications (eg. Renal disease, Cardiovascular diseases etc.). Identifying hyperuricemic Psoriatic patients and treating them accordingly could help in applying various measures in order to prevent or manage the comorbidities and complications. Serum uric acid level offers to be a valuable biomarker in the assessment and monitoring of Psoriasis Vulgaris. It can be a useful prognostic indicator for various complications such as Psoriatic arthritis. Therefore, evaluation of SUA can be instrumental for a dermatologist in management of Psoriasis. This may help in intervening early and preventing complications and comorbidities associated with Psoriasis.

Limitations

As the present study was a cross sectional type, it cannot be ascertained how many patients with high SUA levels developed comorbidities in the future. Larger scale studies are required to ensure appropriate generalization of the findings of the study. Metabolic syndrome was not assessed in the study. It is unknown that drugs lowering SUA level will help in reducing the severity and complications of Psoriasis.

Abstract

Background and objective: Reverse osmosis technique is an adequate method for treating ground water for reducing the burden of abnormal levels of fluorides. The method protects the general population from diseases associated with high fluoride levels in the body. The objective of the present study was to assess the suitability and sustainability of reverse osmosis technology for community de-fluoridation of water used for cooking and drinking purposes in Kaiwara village, Karnataka.

Methodology: This interventional study was conducted between July 2012 and June 2014 at Kaiwara village, Karnataka using reverse osmosis technique for de-fluoridation of water used for drinking and cooking. Complete chemical analysis of water was done before intervention, and processed water supplying the village was tested every six months after intervention for about two years. The variation in chemical concentrations of various components were analysed.

Results: The mean baseline level of fluoride in untreated water was 2.075 mg/dl (above the safety limit), which dropped to 0.08 mg/dl at the end of first six months following the intervention, 0.042 mg/dl in 12 months, 0.1 mg/dl at 18 months and 0.01 mg/dl at 24 months after intervention, which were all below the safety limits for India in the treated water. The mean total dissolved solids in the water was 542.25 mg/dl in the untreated water, which dropped to zero after the first six months, remained at zero in the next six months, rose to 120 mg/dl at 18 months and then dropped to 70 mg/dl at 24 months in the treated water. The observed values were reduced significantly.

Discussion: The study concluded that it is possible to set up a community de-fluoridation plant using reverse osmosis technique at Kaiwara village, Karnataka which is economically sustainable and acceptable by local population.

Introduction

Water as we know, is one among the most important components for all forms of life and safe drinking water is the primary requirement for every human being. There is scarcity in the availability of portable water as natural sources or industrial wastes may contaminate water. One such contaminant is fluoride.¹

Fluorosis is one among the severe health problems faced by the public in India. Two-third of the states in India are fluoride endemic,² while approximately 25

million people are currently affected, and 66 million people are at risk of developing fluorosis.³

Over the last few years, domestic purification techniques came into use to minimise both inorganic and organic pollutants in water thereby maintaining the quality of water supplied to the urban society.⁴ There are various basic types of water purification systems that can be used alone or in combination, e.g., reverse osmosis, cation exchange softening, oxidation, filtration, activated carbon, disinfection, distillation, anion exchange etc.^{4,5}

Fluoride concentration present at low levels (< 0.5 ppm) in drinking water could cause lack of formation of dental enamel, dental caries and reduced bone mineralisation whereas high fluoride levels in drinking water could lead to adverse health effects ranging from mild dental fluorosis to crippling skeletal fluorosis, depending upon level of fluoride present and its duration of exposure.^{6,7}

Karnataka is among the fluoride endemic states in India.⁸ In Karnataka, districts endemic for fluorosis are Belgaum, Raichur, Bijapur, Gulbarga (districts in northern Karnataka) as well as Tumkur, Mandya, Mysore, Chitradurga, Shimogga, Chikmagalur, Bangalore-rural and Kolar (districts of southern and central Karnataka).⁹ Kaiwara village now comes under Chikkaballapur district but used to be part of Kolar district previously, forming a part of the fluoride belt bordering Andhra Pradesh. The weather conditions in Kaiwara village are like that of Chikkaballapur district.⁹

Results from some of the exploratory bore wells in Chikkaballapur region have recorded the concentration of fluoride to 2 ppm and above.¹⁰ As Kaiwara has no alternate source of water, it is dependent solely on ground water through bore wells for its water supply which have unacceptable levels of fluoride. The present study aimed to study the acceptability and sustainability of reverse osmosis technology for community defluoridation of water used for drinking and cooking purposes in Kaiwara village, Karnataka.¹⁰

Methodology

The present interventional study was conducted between July 2012 and June 2014 at Kaiwara village, Karnataka. The study was approved by the Ethical Review Board. Having gone through a number of studies on comparison of different methods for fluoride removal,¹¹ the Council for Scientific and Industrial Research Government¹² offered a 40,000 litres capacity reverse osmosis unit custom made for community defluoridation to pilot in the village, and report the feasibility of operating and sustaining such a technology within a village which can be replicated anywhere else in rural India.

Installation of the reverse osmosis plant was done in a plot granted by the Kaiwara Gram Panchayath that was

identified next to the main water tank of Kaiwara village which had a storage capacity of 100,000 litres of water. The Zilla Panchayath was approached for the electricity connection required for running the Reverse Osmosis plant (3Phase and 10KVA) from Kaiwara village. It was proposed that a sum of Rs 5/- would be collected for 25 litres of processed water from each household who were willing to purchase the processed water from January 1, 2012 for cooking and drinking purposes. 99.4% of heads of the families were willing to contribute and 89.8% of the heads of the family expressed acceptance for de-fluoridation of water in the village. The money collected by selling the processed water was used to run and maintain the R O plant. The cost of Rs 5/- per household was calculated considering Rs 3/- towards electricity and water charges for running of the R O Plant, maintenance charges for the R O Plant (filter replacement, pump repair etc) and salaries for the watch man, plant operator and electrician. Rs 2/- was further collected towards payment for the water distribution vehicle maintenance and petrol for the running of the vehicle as well as salary for the water distributor.

A road map of Kaiwara was prepared and 20 spots for water collection were identified in five areas of the village, which were less than 100 meters from the farthest house from the identified point (usual water collection points included). A vehicle with a 1000 litres tank fixed to it, which could be sealed from the top after filling with processed water and fitted with four taps, was used for the transport and distribution of the processed water to the collection point at a fixed time each day. Complete chemical analysis of untreated and processed water was made before intervention and processed water was tested every six months after intervention for about two years and the mean concentration levels before and after the intervention were compared.

Results

The opinion given for all four samples of water after complete chemical analysis (Table 1) was that the water was found to be unfit for potable purpose, as all the four samples showed excess of fluoride. The mean baseline levels of fluoride in untreated water were found to be 2.075 mg/dl and the mean total dissolved solids in untreated water was found to be 542.25 mg/dl.

Samples of the Feed, Product and Reject water obtained from the reverse osmosis plant and tested which will form a baseline data for our reverse osmosis process (refer Table 2).

The water sample after the intervention was submitted to Public Health Institute Bangalore for complete chemical analysis (Table 3) and was found to be useful for potable purposes. It was observed that the mean fluoride levels in the water which was 2.705 mg/dl in the untreated water, clearly above acceptable limits for India (0.5 mg/dl to 0.9 mg/dl) dropped to 0.08 mg/dl after the first six months, 0.042 mg/dl in the next six months, 0.1 mg/dl in the next six months and 0.01 mg/dl in the last six months which were all below the safety limits for India in the treated water. The fluoride levels

in the processed water were found to be significantly reduced.

Also, it was observed that the mean total dissolved solids in the untreated water which was 542.25 mg/dl in the untreated water which dropped to zero after the first six months, remained at zero in the next six months, rose to 120 mg/dl at 18 months and then dropped to 70 mg/dl at 24 months in the treated water. The total dissolved solid in processed water was significantly reduced.

The changes in the various parameters seen in the four reports are because at different times of the year, the conditions in bore wells supplying the main village tank also change, depending on the availability of water in the various bore wells.

Table 1: Complete chemical analysis of baseline water available at Kaiwara village

Component measured	Concentration in Chamundashwari Hill Tank	Concentration in Chikkaballapur Tank	Concentration in Vivekananda Tank	Concentration in Main Bore-well

Discussion

Fluoride is one of the normal constituents in groundwater in this region. The concentration of fluoride is variable, and it depends on the source of water. Provision of safe drinking water with optimal fluoride levels is the solution to protect against diseases associated with abnormal fluoride content in water used for drinking and cooking. In this study, reverse osmosis technology was applied for community de-fluoridation of water in Kaiwara village, Karnataka.

In this study, it was also observed that the mean fluoride levels in the water which was 2.705 mg/dl in the untreated water which is clearly above acceptable limits for India (0.5 mg/dl to 0.9 mg/dl) dropped to 0.08 after the first 6 months, 0.042 mg/dl in the next six months, 0.1 mg/dl in the next six months and 0.01 in the last six month which are all below the safety limits for India in the treated water. This reduction in fluoride levels in water was found to be significant. This is in accordance with the study conducted by Prabhakar et. al.¹³ in which there was statistical significance in the reduction of fluoride levels by reverse osmosis technique.

In the present study, it was observed that the mean total dissolved solids in the water which was 542.25 mg/dl in the untreated water was dropped to zero after the six months, zero in the next six months, 120 mg/dl in the next six months and then 70 mg/dl in the last six months in the treated water. This reduction in total dissolved solid in water was found to be significant. This is in accordance with the study conducted by Do-Hyung Kim et.al.¹⁴ where there was reduction in the concentration of total dissolved salts by reverse osmosis technique which was significant.

From the current study, we concluded that it is possible to set up, operate and sustain a community de-fluoridation plant using reverse osmosis technology. The economic feasibility of using a technology like reverse osmosis for community defluoridation has been proved through the reverse osmosis technique-based intervention in Kaiwara village. This has been a self-sustaining and effective model for community de-fluoridation of water used for drinking and cooking purposes in Kaiwara village. The intervention has been self-sustaining for the past four years. This has been confirmed by the fact that there are already three reverse

osmosis plants in Kaiwara village and five other reverse osmosis plants in the surrounding villages following our model today.

Effect of 810nm Diode Laser on Post-operative Pain Adjunct to Periodontal Flap Surgery

Arvind Nagaraj¹, Mamatha Shetty², Srikala Bhandary²

¹Post graduate, Department of Periodontics, ²Reader, Department of Periodontics, AB Shetty Dental College, Mangalore

Abstract

Introduction: Surgical lasers have been used in periodontal therapy. The anti-pain mechanism of low-level laser is not yet clear however, numerous studies have pointed out the physiological changes from light interference with various cells as the cause. Low-level laser can also modify the inflammatory process in a dose-related mechanism; and thus, it can reduce the inflammatory pain.²

Methodology: A sample of 10 systemically healthy subjects aged 30-60 years diagnosed with chronic periodontitis having a probing pocket depth ≥ 5 mm and clinical attachment loss ≥ 4 mm bilaterally in the region of the maxillary first premolar, second premolar and first molar were recruited from the out-patient, Department of Periodontics, A.B.Shetty Memorial Institute of Dental Sciences. The subjects were blinded as to which surgical site received the laser therapy following conventional periodontal flap surgery (Test Group). The subjects were recalled one week after scaling and root planing for the periodontal flap surgery. At the baseline visit, the contralateral surgical sites were randomly assigned to the control group or the test groups using a coin-flip.

In the test group, following the removal of soft deposits through scaling and root planing, the laser probe of 0.8W CW diode was used in a light contact, sweeping mode to cover the entire inner surface of the flap. Ablation was carried out from base of the flap to its coronal portion. **Results-**Median pain score did not differ significantly between the test and the control at 0 day, 1day, 2day and 5 day ($P > 0.05$), day7 ($P = 0.087$). Friedman test showed overall there was significant difference in pain score from 0 day to day7 test. Pain score differs significantly from day 0 to day7 ($P < 0.05$), day1 to day7 ($P < 0.05$), day2 to day7 ($P < 0.05$) except day5 to day7 ($P > 0.05$) within test group.

Conclusion-Lasers currently have a variety of uses in dentistry, although low-level lasers have been found beneficial in reducing the pain response after periodontal surgery in present study, but studies with larger sample are required to see significant association.

Key words- Diode laser, periodontal flap, pain response

Introduction

Periodontal surgery is a plastic surgical procedure designed to restore and regenerate normal form and function to lost and damaged periodontal structures.

Generally, surgery is indicated when the periodontal pocket persists even after the non-surgical procedures of Phase I treatment. The purpose of surgical pocket therapy is to eliminate the pathological changes in the pocket walls in order to create a stable, easily maintainable state

and if possible, to promote periodontal regeneration.

Surgical lasers have been used in periodontal therapy. Based on the type of the laser, power setting and wavelength, it can be used to excise the epithelium of the periodontal pocket during scaling and root planing and periodontal surgery, to eliminate calculus, granulation tissue and bone during resective and regenerative surgery, in the management of post-operative pain, enhanced coagulation and as a bactericidal agent.¹

Pain control following any surgical procedure is an essential part of periodontal treatment. This pain could be due to tissue trauma and the release of inflammatory mediators, which reaches its highest following the cessation of local anesthesia. Low-level Laser Therapy has been suggested as a pain-control protocol. The anti-pain mechanism of low-level laser is not yet clear, however, numerous studies have pointed out the physiological changes from light interference with various cells as the cause. The offered mechanisms include: stability of the lipid double membrane and its proteins, the enhancement of revival system and the increase in ATP production. Low-level laser can also modify the inflammatory process in a dose-related mechanism; and thus it can reduce the inflammatory pain.²

Hence, a study was planned to assess the postoperative pain and healing following conventional periodontal surgery without the use of a diode laser and comparing it with the use of an 810nm diode laser adjunct to periodontal flap surgery for the treatment of chronic periodontitis.

Material and Method

The study was a randomized, single masked split-mouth study. Ethical clearance was obtained from the institution ethics committee. A sample of 10 systemically healthy subjects aged 30-60 years diagnosed with chronic periodontitis having a probing pocket depth ≥ 5 mm and clinical attachment loss ≥ 4 mm bilaterally in the region of the maxillary first premolar, second premolar and first molar were recruited from the out-patient, Department of Periodontics, A.B.Shetty Memorial Institute of Dental Sciences. Subjects were excluded if they were smokers, were pregnant or gave history of long term steroidal and/or antimicrobial therapy.

One operator was enrolled to treat all subjects. The subjects were blinded as to which surgical site received the laser therapy following conventional periodontal flap surgery (Test Group). Clinical parameters such as clinical attachment loss, pocket depth, bleeding on probing, plaque index and gingival index were recorded at baseline followed by oral prophylaxis.

The subjects were recalled after one week to undergo subgingival scaling and root planing. Oral hygiene

instructions were reinforced after each appointment.

The subjects were recalled one week after scaling and root planing for the periodontal flap surgery. At the baseline visit, the contralateral surgical sites were randomly assigned to the control group or the test groups using a coin-flip.

In the test group, following the removal of soft deposits through scaling and root planing, the laser probe of 0.8W CW diode was used in a light contact, sweeping mode to cover the entire inner surface of the flap. Ablation was carried out from base of the flap to its coronal portion. Care was taken to avoid any laser contact to the root surface or the alveolar bone by placing a periosteal retractor between the hard and soft tissue. Ablation debris on the fiber was cleaned using damp, sterile gauze. Each flap was treated for 30 seconds amounting to possibly 1 minute per tooth. The control group received only the conventional periodontal surgery and a sham application of the diode. The surgical procedures were carried out one week apart. The periodontal flap was sutured with an interrupted suture using 3-0 black silk suture in all patients. Surgeries performed on all patients were virtually identical. All procedures were completed within a 1-hour time frame.^{1,3,4}

Oral hygiene instructions were reinforced and each subject was prescribed the use of a 0.2% Chlorhexidine mouthwash twice daily and Dolo 650 (650mg Paracetamol) as required (8 hourly and not more than 3 times/day) for the management of pain following each surgical procedure.

The post-operative tissue oedema seen in both the groups was assessed clinically after one week. Post-operative pain and discomfort was assessed using both, the visual analog case on Day 0, Day 3, Day 5 and Day 7, and, the number and frequency of painkillers taken post-operatively.¹

Results

The 10 subjects sample comprised of 5 females and 5 males in the age range of 42-57 years. Descriptive statistics such as median, interquartile range were calculated. Mann Whitney test was used to compare the scores between the groups. Friedman and Wilcoxon

Sign Rank Test was used to compare the scores within the groups. $P < 0.05$ is considered to be statistically significant. IBM SPSS Statistics for Windows, Version 22.0. Armonk, NY: IBM Corp was used for statistical analysis.

Table 1: Pain score between test and control- Mann Whitney test

		Median	Interquartile Range [Q1, Q3]	P
Day0 Pain Score	pain response test	4.00	2.75,5.25	0.669
	pain response control	4.00	3.00,5.50

	pain response control	3.00	2.00,4.50	
Day2 Pain Score	pain response test	1.50	1.00,2.00	0.266
	pain response control	2.50	1.00,3.00	
Day5 Pain Score	pain response test	0.00	0.00,1.00	0.259
	pain response control	1.00	0.00,1.00	
Day7 Pain Score	pain response test	0.00	0.00,0.00	0.087
	pain response control	0.00	0.00,1.00	

Median pain score did not differ significantly between the test and the control at 0 day, 1day , 2day and 5 day ($P > 0.05$) ,day7 ($P = 0.087$)

Table 2 Median pain scores (Interquartile range) within the test group

	N	Median	Interquartile Range [Q1, Q3]
Day0 Pain Score	10	4.00	2.75,5.25
Day1 Pain Score	10	2.00	1.75,3.50
Day2 Pain Score	10	1.50	1.00,2.00
Day5 Pain Score	10	.00	0.00,1.00
Day7 Pain Score	10	.00	0.00,0.00

Friedman test- chi square=37.665 , $P < 0.001$ sig

Friedman test showed overall there was significant difference in pain score from 0 day to day7, but to find which

group differs significantly we use wilcoxon sign rank test

Table 3 Median pain scores (Interquartile range) within the control group

	N	Median	Interquartile Range [Q1, Q3]
Day0 Pain Score	10	4.00	3,5.50
Day1 Pain Score	10	3.00	2,4.50
Day2 Pain Score	10	2.50	1,3.00
Day5 Pain Score	10	1.00	0,1.00
Day7 Pain Score	10	0.00	0,1.00

Friedman test- chi square=37.871 P <0.001 sig

Table 4 Wilcoxon Signed Ranks Test within control group

	Day1 - Day0 Pain Score	Day2 - Day0 Pain Score	Day5 - Day0 Pain Score	Day7 - Day0 Pain Score	Day2 - Day1 Pain Score	Day5 - Day1 Pain Score	Day7 - Day1 Pain Score	Day5 - Day2 Pain Score	Day7 - Day2 Pain Score	Day7 - Day5 Pain Score
P	0.015	0.007	0.005	0.005	0.008	0.004	0.004	0.006	0.004	0.046

Pain score differs significantly from day 0 to day7 (P<0.05), day1 to day7 (P<0.05), day2 to day7 (P<0.05) and day5 to day7 (P>0.05) within control group

Table 5 Wilcoxon Signed Ranks Test- within test group

	Day1 - Day0 Painkillers	Day2 - Day0 Painkillers	Day5 - Day0 Painkillers	Day7 - Day0 Painkillers	Day2 - Day1 Painkillers	Day5 - Day1 Painkillers	Day7 - Day1 Painkillers	Day5 - Day2 Painkillers	Day7 - Day2 Painkillers	Day7 - Day5 Painkillers
P	.480	.059	.006	.004	.102	.017	.011	.023	.014	.317

Median pain killers used did not differ significantly between 0 day to day1, day0 to day2, day1 to day2 and day 5 to day7 (P>0.05). It differed significantly from day0 to day5, day 0 to day7, day1 to day5, day1 to day7, day2 to day5 and day2 to day7 (P<0.05) within the test group.

Discussion

This study found that diode laser use did not lead to postoperative complications or to impair tissue response, indicating that this type of laser has no detrimental effects when used in conjunction with periodontal flap surgery. Also, this study found that the postoperative pain and tissue oedema were reduced with the use of the diode laser. As the optimal dosage and treatment schedule has not been determined, it is difficult to evaluate the efficiency of LLLT. As a result, studies have encountered a wide range of clinical findings attributable to the differences in experimental and assessment methods and irradiation conditions.^{5,6,7,8}

Despite the proposed benefit of LLLT, there are very few clinical studies using LLLT in gingival surgery, which makes comparing the results of the current study with previous reports difficult. Human randomized controlled clinical studies that analyzed periodontal healing response using LLLT are available.

The pain scales used in this study are subjective and highly dependent on individual experience. However, the patient served as both the control and the test. Patients were unaware of which site actually received laser treatment to reduce the 'placebo effect of laser treatment'. The subjective measure of the pain using the scale found differences between the control sites and the test sites. However the differences in pain and the number of painkillers taken did not show a statistically significant difference.

The mechanism of LLLT involves photoreceptors in the electron transport chain within the membrane of cell mitochondria. Absorption of light creates a short-term activation of respiratory chain components, promoting ATP production and activation of nucleic acid synthesis.⁹

LLLT has an additional effect on fibroblasts by promoting proliferation and increasing cell numbers, secretion of growth factors, and differentiation of fibroblasts into myofibroblasts. During wound healing the inflammatory response and synthesis of specific extracellular matrix molecules by fibroblasts; angiogenesis, reepithelialization and remodeling are regulated by growth factors including transforming growth factor-beta1 (TGF- β 1) and basic fibroblast growth factor (bFGF). TGF- β 1 plays an important role

in wound healing by stimulating fibroblast proliferation, increasing the synthesis of extracellular matrix molecules and inhibitors of matrix metalloproteinases (MMPs), and inhibiting MMP synthesis. bFGF is a potent mitogen and chemo attractant for fibroblasts and endothelial cells and induces a predominantly angiogenic response in the wound and activates the neutral proteases in both epithelial cells and fibroblasts.^{10,11}

Conclusion

Lasers currently have a variety of uses in dentistry, and some low-level lasers have been found beneficial in in vitro studies. However, clinical outcomes in vivo application of low-level lasers is still unclear, although this study found postoperative pain and tissue oedema were reduced with the use of the diode laser. To assess whether lasers provide additional benefits to periodontal treatment, studies with larger sample size are needed to be done.

A Cross Sectional Study on Middle Finger Tip Pinch, Ring Finger Tip Pinch, Little Finger Tip Pinch Strengths : The Correlations with Anthropometric Variables in North Indian Population

Ashish Jacob¹, Vishal Verma², Reena Singla³

¹M.Sc Student, Department of Anatomy, MMIMSR, MMDU, Mullana- Ambala, ²Asstt. Professor Department of Anatomy, MMIMSR, MMDU, Mullana- Ambala, ³Professor, Department of Anatomy, MMIMSR, MMDU, Mullana- Ambala

Abstract

Introduction: Pinch strength in addition to handgrip strength is considered an important factor in the assessment of proper hand muscle function. Various parameters like nutritional status, physical activities and muscle pathologies can affect the overall gripping capabilities of the fingers. The unique abilities of opposition in human hand is because of the distinct articular surfaces in the miniature bones and intrinsic muscles of the hand. Due to fine neuromuscular coordination and sensory perception in the digits, firm grasping abilities and in the hand pinches have developed. These grasps can be very useful for sensory and motor capabilities of the hand specially in sports like cricket, baseball and volleyball.

AIM: To generate data for middle finger tip pinch, ring finger tip pinch, little finger tip pinch strengths and to evaluate their correlations with other anthropometric indices.

Materials and Methods: Four hundred and fifty healthy young adult individuals were selected for the study. A pinch gauze was used to measure pinch grip strengths in both the sides. Pearson's correlation test and independent t-tests were used. SPSS Version 20 was used for statistical analysis.

Result: Mean age of the population was 22 years and all the subjects were males. Pinch grip strength in all the pinches were found to be greater in dominant side than non dominant side ($p < 0.001$). There was significant association between middle finger tip pinch and anthropometric indices. No statistically significant correlation of little finger tip pinch with waist circumference, waist to hip ratio and BMI was observed.

Conclusion: The analysis provides normative data for pinch grip strengths and their correlation with other anthropometric indices in adult North Indian population.

Keywords : Pinch grip strength, BMI, Indian population

Introduction

Sports activities need high level of forearm and hand muscle strength¹. Tip pinch is stated to be a positioning pinch useful in daily life activities needed for fine motor skills instead of hand grip and pinch strengths². Dental surgeons are at an increased risk of musculoskeletal

disorders due to repetitive hand function, pinch force and sustained hand postures. Various factors can affect pinch strength like hand dominance, height, body weight, age, finger strength etc³. Salam FA conducted a study to evaluate the grip and pinch strengths of these professionals⁴.

In the field of dentistry, the management of patient by dental surgeons is done in an inflexible work posture because of which musculoskeletal disorders tend to develop quiet early in their carrier. During periodontal scaling, high pinch force is applied; development of muscular fatigue is quiet common and this affects the pinch strengths. Pinch grip hence becomes an important index in hand therapy evaluations. Pinch force is also affected by general weakness, nutritional status, physical activities, muscle disabilities, decrease of cognitive measures .

Studies concerning pinch strength of middle finger tip pinch, ring finger tip pinch and little finger tip pinch are lacking. It is stated that the muscle of obese individual have fatty infiltration and alteration in the distribution of type I and type II muscle fibres which also enhances muscle strength and endurance⁵. Waist to height ratio is an useful parameter for discriminating hypertension, diabetes and dyslipidemia in both the genders. It is found to be more precise measure of body fat distribution⁶. Waist- hip ratio (WHR) above 0.9 for males and 0.85 for females or a BMI above 30 is a possible indicator of obesity and other more serious health conditions according to World Health Organization (WHO)⁷.

In fast pitch of baseball the index and middle finger tips are used in the perpendicular seam of baseball, the thumb lies underneath the baseball resting on the smooth leather⁸. That is why the role of pinch strength in such sports is important.

Daily life activities like insertion and removal of a key or the Automated Teller Machine (ATM) Card, operating clothes with zipper, insertion or removal of a plug, eatables requiring the insertion of prongs of a fork, operating a remote control or holding a pen all need good pinch strength⁹.

Considering the relevance of these parameters in sports and day to day life activities the study was conducted to establish the correlation of anthropometric

indices.

Present study will be helpful to establish the relationship between BMI and other anthropometric indices on pinch grip strengths and role of physical activities and fitness on overall health of medical students for their better performance in academics and sports.

Material and Method

Participants:

This cross sectional study was conducted on four hundred fifty young healthy adult North Indian males, in the age group of 18-26 years. The participants were medical students of MMIMSR, MMDU , Mullana, Ambala, Haryana. The study was conducted from Mar 2017 to Feb 2019 .

The subjects with any neuromuscular and musculoskeletal impairment of upper limb or any cardio-systemic illness after taking adequate history were excluded from the study. Prior informed consent were taken from the participants. The study was approved (Project No. IEC-1132) by Institute Research And Ethics Committee.

Measurements:

A pinch gauze (Saehan Corp. Masan, Korea, ModelNo.SH5005) was used to assess middle finger tip pinch, ring finger tip pinch & little finger tip pinch on both dominant and non dominant sides. Subjects were asked to sit with shoulders adducted, elbow flexed to 90 ° forearm in neutral position, wrist between 0 ° to 30 ° of extension and 0 ° to 15 ° ulnar deviation. Pinch measurements were performed with wrist, forearm, elbow, shoulders in neutral position. Height was measured in metres using stadiometer. Heels, buttocks, shoulders were in contiguity with flat rigid surface or wall during the assessment and head was in easeful, upright position.

Weight of subjects were measured in kilograms with help of electronic weighing scale (unicare). Subject was asked to stand freely, barefooted on the weighing scale with equally distributed weight with empty pockets.

Subjects were directed to nip the pinch gauze by pressing the tip of the pollex with the tip of the middle

finger , ring finger, little fingertip pinch respectively for measuring the three tip pinches as shown in Fig. 1

Fig.1

Waist circumference was measured in centimetres by using the elastic measuring tape under the recommended guidelines of WHO. The subject stood erect, abdomen relaxed , arms by the sides and with normal respiration. Assessment was done after the end of normal expiration and practice repeated test trails .

Hip circumference was measured in centimetres by using a measuring tape. Measurement was done keeping the measuring tape parallel to the floor. Waist to hip ratio was measured by using the formula $WHR = WC(cm) / HC(cm)$. Waist to height ratio was measured by using the formula $WHTR = WC (CM) / HEIGHT(cm)$. BMI was measured by using the formula $BMI = weight(kg) /$

$height(m^2)$.

Statistical Analysis

Difference between dominant and non dominant handgrip strength were compared using Independent T Test, Pearson's test .The relationship between pinch strength of dominant and non dominant side and anthropometric indices for analyzing , statistical analysis were done using SPSS version 20. P value <0.05 was considered statistically significant.

Results

A total of 67% of participants were right handed and

26% were left handed. Pinch strength of three pinches in dominant side were greater than non dominant side under the study as observed from table no. 1.

Positive correlation of Thumb middle finger tip pinch was found with all the variables. Significant association was observed with all the anthropometric indices except age, waist to hip ratio as seen in table no 2.

Negative correlation of ring finger tip pinch was found with age and significant association was observed

with all the anthropometric indices except age, waist to hip ratio, waist to height ratio & BMI as observed from table no.3.

Negative correlation of little finger tip pinch was observed with age and waist to hip ratio. Significant association was found with all the anthropometric indices except age, waist to hip ratio, waist to height ratio and BMI as observed from table no.4.

Table no 1: Baseline data of pinch grip strengths in the study population

Variables	Handedness	Mean ± SD
Thumb middle finger tip pinch	Right hand	11.68±3.14
	Left hand	11.18±3.13
Thumb ring finger tip pinch	Right hand	8.88±3.17
	Left hand	8.49±2.67
Thumb little finger tip pinch	Right hand	5.38±2.21
	Left hand	5.13±2.12

Discussion

There was a significant association in case of thumb middle tip pinch and ring finger tip pinch with BMI, but not significant in case of little finger tip pinch. Middle finger tip pinch as well as little finger tip pinch showed negative correlation with waist to hip ratio. Ring finger tip pinch had very less positive correlation with waist to hip ratio (r value Right side = .001 and Left side = .037) in the current study.

It was found that the pinch strengths were high in male participants^{10,11,12}. Longer fingers and larger hand span have stronger pinch strengths and a significantly reduced risk of mortality rate¹¹. Present study findings are in coherence with these findings. Low to moderate correlation is reported between pinch strength and age¹³. This was also observed in the present study. It was observed that average pinch strength peaked between 35 and 44 yrs in men¹⁴. One study done on different medical professional groups established that dentists have maximum pinch strength among all the groups considered¹⁵. It was also found that pinch strength declines with rising age and was higher in dominant hand^{16,17}. The trend of pinch strength variation according to age was not analyzed in the present study but it was found to be higher in dominant right handed individuals. Positive association of pinch strength with BMI is proved by another study where subjects with normal BMI had significantly higher grip strength than overweight and obese group¹⁸.

Previously no study was conducted to find out the correlation between middle tip pinch, ring finger tip pinch, little finger tip pinch strengths with other anthropometric variables.

Limitations: The population under study is limited to medical students only, so results cannot be generalized over larger populations belonging to different professions or geographical locations for external validation. Although it was planned to include participants up to 26 years of age but very few above 23 years participated in the study.

Conclusions

This study showed that there is a positive correlation

of pinch strengths with anthropometric indices such as weight and height. Future studies should be performed to evaluate the risk factors for reduced pinch strengths which can directly or indirectly affects the health of the individual. These factors should be considered while giving training to sports personnel for their better performance.

Management Practices among Diabetes Population in Rural Area of North India

Ashok K¹, T. Bano², S.K. Garg³, G. Singh⁴

¹PG3rd Dept of Community Medicine, LLRM Medical College, Meerut; ²Professor Dept of Community Medicine, LLRM Medical College, Meerut; ³HOD & professor Dept of Community Medicine, LLRM Medical College, Meerut; ⁴Associate Professor Dept of Community Medicine, LLRM Medical College, Meerut

Abstract

Background and Objective- Diabetes is the serious public health problem in all the countries but majorly in developing countries. The prevalence of diabetes is rapidly rising in rural population. The characteristics symptoms are excessive thirst, polyuria, polyphagia, purities, and otherwise unexplained weight loss, or may be asymptomatic till complications present themselves ⁽¹⁾. Medication, exercise and yoga are holistic approach for controlled and prevention of diabetes and its complication in diabetic population.

Aims & Objectives –

1. To study the signs & symptoms of diabetes in rural population
2. To study management practices among rural diabetics populations

Study Design- A cross-sectional study.

Material & Method- By taking the prevalence of diabetes mellitus 13% in persons age 30 years & above by various studies & relative precision 20% the sample size come out to be 642, total subjects studied were 700 for uniform coverage in villages selected by systematic random sampling, fasting blood sugar was done to estimate the prevalence of diabetes. Rest of the information was collected on Predesigned and pretested questionnaire.

Results- the prevalence of diabetes were found to be 11.7% in persons aged 30 years & above in rural population of Meerut. A comprehensive approach to prevention of diabetes mellitus will require active participation of all sections of the community including health services to change the determinants of associated risk factors with diabetes mellitus. **Conclusions-** the diabetes mellitus is a significant health problem in rural population. Medication, exercise and yoga are holistic approach for controlled and prevention of diabetes and its complication in diabetic population.

Key words- Diabetes Mellitus, rural Population, Fasting blood sugar, yoga, exercise, medication

Introduction

Diabetes mellitus is a chronic non communicable disease and characterized by chronic hyperglycemia with disturbances of carbohydrate, fat, proteins metabolism due to defect in insulin secretion, insulin action or both ⁽²⁾.

Non communicable diseases are increasing among the adult population in both developed and developing

countries. Diabetes is the serious public health problem in all the countries but majorly in developing countries ⁽⁴⁾. This is an important cause of disability and death not only in our country but also throughout the world ⁽²⁾.

The prevalence of diabetes is showing an upward trend in most countries. According to the 6th edition of International Diabetes Federation Diabetes Atlas, it is estimated that there are currently 387 million people with

diabetes worldwide and this number is set to increase to 592 million by the year 2035. China has the largest number of people with diabetes in the world (98 million) followed by India with (65 million). These figures of India are predicted to increase to 109 million by 2035. ⁽³⁾

The characteristics symptoms are excessive thirst, polyuria, polyphagia, prurities, and other unexplained weight loss, or may be asymptomatic till complications present themselves ¹

The prevalence of diabetes is rapidly rising in rural population. The prevalence of diabetes in rural Andhra Pradesh is 13.2%. The large number of individuals with poorly controlled diabetes, particularly in rural areas is worrying as this could potentially lead to development of chronic complications in this segment of population, as here diabetic care is currently not available, accessible, or affordable. ⁽⁵⁾

Material & Method

A cross-sectional study was conducted in the rural population Machhara block of district Meerut. There are 47 villages covering the 158188 population in Machhara block. The population wise list of all villages was obtained from Community Health Centre, Machhara.

Sampling size: Prevalence of diabetes mellitus in various studies in rural population was found to be 13% among persons aged 30 years and above. Therefore by taking the prevalence of diabetes 13% with 95% confidence level and relative precision of 20%, the sample size calculated was 642. A sample of 700 individuals above 30 years of age was taken for uniform coverage from 10 villages selected by systematic random sampling technique.

Period of study: The study was carried out from June 2014 to 31 May 2015.

Study population: The present study was conducted in a Rural Population of 30 years & above who belongs to Machhara block, Meerut.

Methods: This study was conducted by house to house visit in the selected villages. A population wise

list of all the villages covered under Community Health Centre, Machhara was obtained and divided by number of villages to be studied for obtaining the sample interval. Then random number was drawn from random number table and the village corresponding to that number was selected as first village and then subsequent villages were identified by adding the sample interval. Thus 10 villages were selected by cluster sampling. For selection of houses in the villages investigator went to the centre of the village along with ASHA and village Pradhan and the pencil was dropped and the direction of pencil pointing towards the house was chosen as first house and the next nearest houses were visited continuously without leaving a single house until sample size of 70 persons aged 30 and above was completed in each selected village. Two house visits were done in each family. First to collect the information pertaining to socio-demographic characteristics and other factors associated with diabetes on pre-designed and pretested proforma. And then second visit was done on next day early morning for doing fasting blood sugar of study subject by glucometer. In case any study subject unavailable on first visit, his/her information was collected on second visit along with fasting blood sugar test. However, if any person found unavailable on both the visits or showed non co-operative attitude was excluded from the study & another subject was included in the study from next house in continuation.

Statistical analysis- the data was checked thoroughly for its consistency and analyzed using Epi-info. Chi-square test was used to determine the statistical significance of association between diabetes mellitus and management of diabetes mellitus.

Results

In the present study 700 study subjects of aged 30 years & above were studied to know the prevalence of diabetes mellitus, and a total 82 cases of diabetes mellitus were found among the study population accounting for the diabetes prevalence rate of 11.7% in study population.

Table 1: Distribution of presence of symptom of diabetes mellitus

Symptom Of Diabetes Mellitus	Diabetes	
	Mellitus Status	
	Number	Percentage%
Increase frequency of micturation	73	89.0
Presence of ants at the place of micturation	64	78.0
Increased thirst or increase in water intake	77	93.9
Increased appetite	59	71.9
Feeling off and on numbness in some part of body	51	62.1
Feeling of reduced eye-sight	23	28.0
Becoming ill more often than other	29	35.3
Wound or other infection taking more time than normal time to heal	17	20.7
Feeling of tingling sensation in some part of body	33	40.2
Feeling of reduced efficacy of doing work or weakness	79	96.3
Feeling on and off pain/cramp in some part of body more usually in lower limb	47	57.3
Base	82	

Symptoms associated with diabetes mellitus in diabetics have been classified in table 25. Reduced efficiency of doing work(weakness) was the most common symptoms (96.3%) followed by increased thirst(93.9%), increased micturation(89.0%), presence of ants at the place of micturation(78.0%), increased appetite (71.9%). Other symptoms were numbness(62.1%),cramp in lower limb(57.0%),tingling sensation(40.2%),more illness(35.3%).reduced eye sight(28.0%)and wound taking more time to heal as compared to normal time(20.7%).

Table 2: Distribution of Treatment compliance in relation of Blood sugar status among known diabetics

		STATUS OF BLOOD SUGAR							
STATUS OF TREATMENT	Controlled (<126mg/dl)			Uncontrolled (≥126mg/dl)			TOTAL		
	Number	percentage%	Number	percentage%	Number	percentage%			
Taking									
Regular	18	78.3	05	21.7	23	39.0			
Treatment									
Taking									
Irregular	02	06.9	27	93.1	29	49.2			
Treatment									
Taking No	0	0	07	100	7	11.8			
Treatment									
Total	20	33.9	39	66.1	59	100			
X ² =33.10	df = 1	(P <0.01)							

For calculation of χ^2 categories Taking Irregular Treatment and not Taking Treatment were pooled together

One can see that 39% of known diabetics were taking regular treatment, out of them 78.3% had controlled blood sugar (<126mg/dl) , 49.2% of known diabetics were taking irregular treatment and majority of them (93.1%) had uncontrolled blood sugar (≥126mg/dl) .11.8% known diabetics were not taking any treatment and all of them (100%) had uncontrolled blood sugar (≥126mg/dl).The treatment outcome of diabetes mellitus was found to be statistically associated with treatment compliance (P<0.01).

Table 3: Distribution of Known Diabetics according to exercise and yoga Practices

Exercise And Yoga Practices	Controlled Blood Sugar (<126Mg/Dl)		Uncontrolled Blood Sugar (>126Mg/Dl)		Total	
	Number	Percentage%	Number	Percentage%	Number	Percentage%
Exercise Only	6	27.3	16	72.7	22	37.3
Yoga Only	5	29.4	12	70.6	17	28.8
Both Exercise and Yoga	8	72.7	3	27.3	11	18.6
None	1	11.1	8	88.9	9	15.3
Total	20	33.5	39	66.5	59	100

Table 3 clearly shows that 72.7% people practicing both exercise and yoga were having blood sugar control while only 27.3% doing exercise and 29.4% doing yoga alone had controlled blood sugar. This implies that those practicing both yoga and exercise are having better control of diabetes as compared to those practicing none of them. This difference in Blood sugar status in relation to Exercise and Yoga Practices was found to be statistically significant ($P < 0.05$)

Table 4: Impact of duration of exercise, yoga and both on blood sugar level among known diabetics

DURATION OF YOGA/EXERCISE	CONTROLLED (<126 Mg/Dl)		UNCONTROLLED (≥ 126 Mg/Dl)		TOTAL	
	Number	percentage %	Number	percentage %	Number	percentage%
<30 minute/day	4	14.8	23	85.2	27	54.0
≥ 30 minute/day	15	65.2	8	34.8	23	46.0
Total	19	38.0	31	62.0	50	100
X ² = 13.39,	df = 01,		(P<0.001)			

Table 4 clearly shows that diabetics patients practicing yoga , exercise or both more than 30 minutes (65.2%) had better blood sugar controlled as compared to diabetics patients practices yoga, exercise or both less than 30 minutes(14.8). This difference in proportion of blood sugar control in relation to duration of exercise/yoga was found

to be statistically significant ($p < 0.001$)

Discussion

Present study revealed that most common presenting symptom among the diabetics was weakness (96.3%), followed by increased thirst (93.6%), polyuria (89.0%) and, increased frequency micturation (89.0%), ant present at the place of micturation (78.0%), increased appetite (71.9%), numbness and tingling (62.1%), paincramps (57.3%), frequent illness (35.3%) delayed healing (20.7%), and similar findings were also observed by Bajaj et al (1984)⁽⁶⁾.

In the present study prevalence of diabetes mellitus was 11.7% out of which 71.9% were known case and 28.1% were unknown case of diabetes mellitus. Among the known cases 39.0% were taking regular medical treatment 49.2% were taking irregular treatment and 11.8% were not taking any treatment. Chow et al (2006)⁽⁷⁾ reported the prevalence of diabetes in rural Andhra Pradesh as 13.2%, of which 6.4% were known and 6.8% were previously undiagnosed. Out of those with known diabetes, 67% were taking oral hypoglycaemic therapy, 3% were using insulin, and 46% were taking blood pressure-lowering agents.

Hu YH, et al (1997)⁽⁸⁾, Qiao Qet al (2003)⁽⁹⁾, Weinstein AR et al (2004)⁽¹⁰⁾ and Sigal RJ et al (1999) found similar fact in their study noted that walking briskly for at least 2.5 h/wk (i.e., 30 min/day for 5 days/wk) was associated with a 25% reduction in diabetes over 8 yr of follow-up among those reporting no vigorous exercise. Study by Divakar MV et al (1978)⁽¹¹⁾, Sahay BK et al (1984)⁽¹²⁾ and, Sahay BK et al (1994)⁽¹³⁾ showed the role of yoga in the control of diabetes mellitus with significant fall in the blood sugar level soon after the practice of Pranayam.

Present study found the positive correlation of controlled diabetes mellitus with practices and time duration of exercise, yoga and both. It was seen that blood sugar is better controlled in diabetics' person doing exercise, yoga, or both more than 30 minute per day as compared to those doing less than 30 minute per day or nothing.

3Role of Pre Operative Peritoneal Lavage in Patients of Perforation Peritonitis

Ashutosh Bawa¹, Ram Gopal Sharma², Kapil Sindhu³, Piyush K. Sinha⁴,
Ashish K Chaudhary⁵, Minal Panwar⁶

¹Junior Resident, Dept. of Surgery, MMIMSR Mullana Ambala, ²Professor, Dept. of Surgery, MMIMSR Mullana Ambala, ³Assistant Professor, Dept. of Surgery, MMIMSR, Mullana Ambala, ^{4,5}Senior Resident, Dept. of Surgery, MMIMSR Mullana Ambala, ⁶Assistant Professor, Dept. of Pediatrics, MMIMSR, Mullana Ambala

Abstract

Background- Perforation peritonitis is amongst the most common emergency condition in surgical practice and is a common cause of mortality in tropical countries like ours. Factors contributing to the high mortality rate include advanced age, late presentation, septicaemia, comorbidities and delay in the treatment. Previous literature has shown peritoneal drainage does improve morbidity and mortality. Not much literature is available on role of NS in pre-operative peritoneal lavage. **Aims and Objectives** - To assess and compare the morbidity, mortality and final outcomes of the patients who were given peritoneal lavage pre operatively with patients who were not given peritoneal lavage in the pre-operative period. **Material and Method-** 60 Patients, with generalised perforation peritonitis; reporting in MMIMSR, MMDU, Mullana, Ambala (Haryana); were included in this Randomised control study and divided into two groups. Group I (study group) underwent pre-operative peritoneal lavage under local anaesthesia and group II (control group) without pre-operative peritoneal lavage. The Mannheim's peritonitis index (MPI) of the patients was calculated and was used to estimate the probable outcome/prognosis of the patient. The haemodynamic parameters and vitals of the patient were recorded just before surgery, before induction of anaesthesia as well as at the end of procedure. On discharge the duration of stay of each patient, complication, suture site infection, recovery period were recorded and analysed using the appropriate statistical tests. **Results-** The ratio of male: female population in the study was found to be 5:1. 26 patients had MPI score of >25, 22 patients had scores between 15-25 and 12 patients had score of <15. In the study group after giving peritoneal lavage 80% (24/30) patients were stable while 20% (6/30) were unstable just before surgery, while in the control group 63.3% (19/30) were stable while 37.7% (11/30) were unstable. Only 20 cases (33.3%) required the ventilatory support later. 48 cases were discharged after recovery whereas 12 cases (20 %) expired. Favourable outcomes were seen in 93.3% (28 cases) of the lavage group and only 6.7 % cases expired. **Conclusion-** The pre-operative percutaneous peritoneal aspiration of the fluid and peritoneal irrigation and drainage in patients with advanced stage of perforation peritonitis documented by their high MPI score before definitive surgical source control is associated with a significant improvement in the pre-operative pulse rate and blood pressure, a decrease in the overall mortality and deep seated wound infection and dehiscence.

Keyword: MPI, Perforation Peritonitis, Patient, Haemodynamics, Peritoneal lavage

Introduction

Peritonitis is the most common emergency in general surgery and a serious life threatening condition all over the world, India is no exception to it. Peritonitis may be primary or secondary, but general management

is the same in both conditions. Majority of the patients present late, with purulent peritonitis and septicaemia. In the developing countries like India the perforations of proximal gastrointestinal tract is more common than the distal gastrointestinal tract.^[1, 2]

Although phenomenon of self- healing has been claimed to be efficient in 50% of patients yet a large number of patients require definitive treatment. [3, 4] Mortality of the patients of perforation peritonitis was as high as 90% in the early twentieth century. The mortality in such patients is still high despite advances in surgical technique, radiographic imaging, antibiotics and resuscitation therapy. The peritoneal cavity contamination leads to cascade of infection, sepsis, multi system organ failure and death if not treated in timely manner. [5, 6] Laparotomy is the gold standard for the definitive management of perforation peritonitis. In the event of high risk status of patient and non-improvement in general condition despite various intensive resuscitative protocols, the immediate laparotomy under general anaesthesia is not advisable. [7]

Co-morbidities further worsen the chances of survival and lead towards bad prognosis in spite of doing the management according to the focussed plan.[8] Factors contributing to the high mortality rate include advanced age, late presentation, septicaemia, comorbidities and delay in the treatment.[9] Majority of the patients are generally referred from the peripheral centres or a private practitioner as a result of which the patient presents late to the tertiary centre i.e. the perforation-operation(PO) interval time is higher.[10] In the event of high risk of patients and non-improvement in the vitals of the patient have led to delay in the surgical exploratory laparotomy under General anaesthesia (GA).[11] Thus resuscitation in such patients helps in the possibility of increasing the perforation operation interval time and final outcome of exploratory laparotomy in view of morbidity and mortality. On evaluating, it is generally found that the patients are resuscitated by Ryle's tube aspiration, intravenous fluid, and catheterisation by Foley's catheter and injectable antibiotics. [12]

Sepsis source control through percutaneous peritoneal drainage is not new. S. Paterson- Brown and H.A.F. Dudley stated that "in a circumstance of severe abdominal distension, peritoneal aspirate should be considered in order to permit the escape of gas and exudate, thereby providing an initial guide to the diagnosis in addition to relieving the cardiopulmonary effect of distension." Along with this they stated that "if the patient's condition still prevents operation, treatment may begin by running a litre of normal saline over

a period of an hour and then recovering it by gravity drainage." [13]

Aims and Objectives

1. To assess the outcome of the patient who was given peritoneal lavage pre-operatively.
2. To compare mortality and morbidity with patients who are not given peritoneal lavage pre operatively.

Material and Method

This study was conducted in MMIMSR Mullana, Ambala, Haryana (India), with the approval of ethical committee of the university. A written and informed consent was obtained from the patients. A Quantitative Research Approach with Random Control Trial was conducted on the patients of gastro intestinal perforation peritonitis, presenting to and operated upon in the Department of General Surgery of MMIMSR, Mullana, and Ambala (India) **Study Duration** September 2017 – June 2019 (2 years). **Population:** 60 patients were included in this study and divided into two groups equally and random sampling technique (Lottery Method). *Group I* included preoperative peritoneal lavage under local anaesthesia and *Group II* (control group) without preoperative intra-peritoneal lavage.

Inclusion Criteria: Patient's included who were diagnosed as a case of perforation peritonitis, presenting in emergency in various units of Department of Surgery who are willing to participate and of age > 18 years.

Exclusion Criteria: The patients not giving consent or did not undergo definitive surgery. Patients in whom bowel perforation was not found at the time of definitive surgery were excluded. Gall bladder perforation and patients with Spontaneous Bacterial peritonitis (SBP) were also not included in the study.

Method of Data Collection/ Procedure/ Intervention

Patients who came to emergency with complain of acute abdomen with clear suspicion of perforation peritonitis were admitted and evaluated in the following ways.

1. Accurate history was taken with respect to: Pain, Vomiting, Abdominal distension, Bowel and

bladder disturbance

2. Vital signs of the patient were recorded and based on the criteria of shock patients' vitals were tagged as "Stable" and "unstable".

3. Thorough clinical examination was done for the evidence of abdominal tenderness, guarding, rigidity, obliteration of liver dullness and peristaltic sounds.

4. Based on the history and clinical examination, provisional clinical diagnosis was made.

5. The Mannheim's peritonitis index (MPI) of the patients was calculated and used to estimate the probable outcome/prognosis of the patient. Data was recorded in proformas for analysis.

In conjunction with the conservative methods, pre-operative intraperitoneal lavage was performed under local anaesthesia through a 1-2 cm long midline vertical incision below or above the umbilicus/ in the right or left iliac fossa in 30 out of 60 patients selected in random manner.

Results

Table I: Distribution of patients' haemodynamics on admission between our two study groups

PRE OPERATIVE PERITONEAL LAVAGE						Total
		No	No	Yes	Yes	
Haemodynamics On Admission	Stable	13	43.3%	7	23.3%	20
	Unstable	17	56.7%	23	76.7%	40
Total		30	100%	30	100%	60

Table II: Distribution of patients in the two study groups on the basis of Mannheim's peritonitis index

Pre Operative Peritoneal Lavage						Total
		No	No	Yes	Yes	
MPI	<15	6	20.0%	6	20%	12
	15-25	13	43.3%	9	30%	22
	> 25	11	36.7%	15	50%	26
Total		30	100%	30	100%	60

Table III: Change in the haemodynamics of the patient on admission and before surgery.

Pre operative peritoneal lavage	unstable haemodynamics		Change	Chi square	P value
	On admission	Before surgery			
Yes	23	15	8	3.65	0.0002
No	17	19	-2		

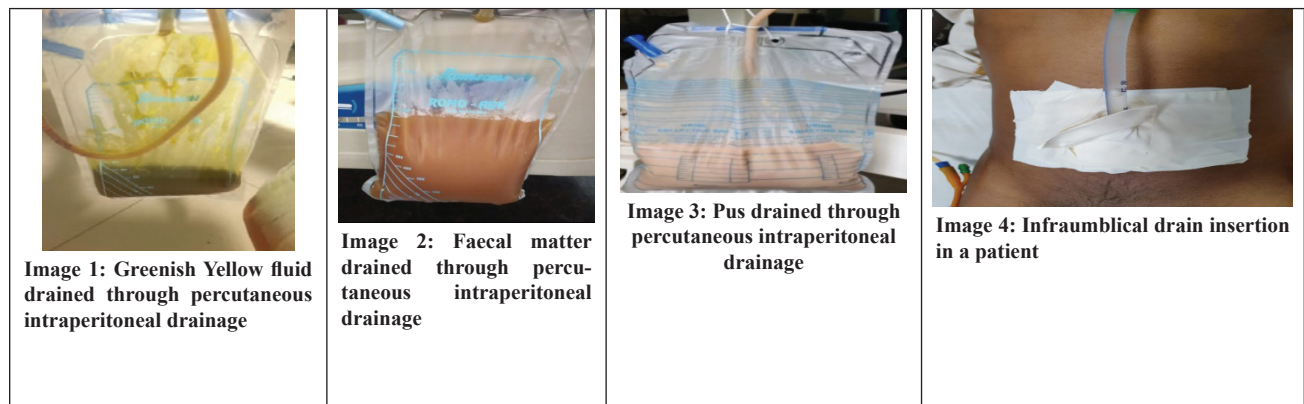

Upon recording the haemodynamic conditions on admission and before surgery, it was found that there were 23 patients with unstable haemodynamics and 15 upon resuscitation before surgery. Whereas, 17 patients presented with unstable haemodynamics and 19 ended up in unstable haemodynamics before surgery. The comparison has been done in the table III.

Table IV: Final outcomes in both the study groups

PRE OPERATIVE PERITONEAL LAVAGE						Total	Chi-square value	p-value
		NO	NO	YES	YES			
FINAL OUTCOME	Discharged	20	66.7%	28	93.3%	48	6.667	0.021
	Expired	10	33.3%	2	6.7%	12		
Total		30	100.0%	30	100%	60		

As shown in table IV, both the study groups were compared on the basis of final outcomes. Favourable outcomes were seen in 93.3% (28 cases) of the lavage group and only 6.7 % cases expired whereas in control group (cases in which peritoneal lavage was not performed, 20 cases (66.7 %) recovered and were discharged, and 10 patients (33.3%) cases expired.

Chi square test was applied and value came out to be 6.667. P value calculated at 95% confidence interval was 0.021 which was significant (<0.05).

Discussion

The patients were evaluated upon admission and depending upon the history, through clinical examination, radiological and laboratory findings were given probable diagnosis. In the present study of 60 patients, pre operatively 56 patients (93.3%) were diagnosed as perforation peritonitis, 2 (3.33%) were diagnosed as intestinal obstruction and 1 (1.7%) each as appendicular perforation and blunt trauma abdomen.

Out of total 60 cases, only 4 cases (6.7%) reported to the hospital within first 24 hours of commencement of the symptoms whereas rest (93.3%) reported later i.e. more than 24 hours of onset of symptoms. The data is consistent with study of Prabhu VV et al [12] where the mean of PO interval was 42.12 hours. In the other study done by Jhobta RS et al [14] around 47% cases reported in the first 24 hours and 53% cases reported after 24 hours. On admission, 60 patients in our study was analysed as per Mannheim’s Peritonitis Index (MPI)

and divided the patients into three groups based on score <15, 15-25, >25. In total there were 12 patients with MPI <15, 22 with MPI score 15-25 and 26 patients with MPI score >25. Due to late presentation and old age, maximum (26) patients had MPI of more than 25. The final outcomes of the patients were noted. 8.3% patients with MPI <15 expired, 13.6% of the patient with MPI 15-25 expired and 30.7% of total patients with MPI>25 couldn't survive. The incidence was similar to various studies which define mortality in MPI <15, 15-25, >25 as 4%, 14% and 50% respectively. [15] Out of 6 patients with MPI <15 and who were given peritoneal lavage pre operatively, there was no mortality whereas out of 6 patients with MPI <15 and no peritoneal lavage, 1 expired. In group of patients with MPI 15-25, 3 out of 13 patients expired, who were not given peritoneal lavage whereas there was 0 mortality out of 9 patients. The significant results were found in comparing the mortality in patients with MPI >25 between two groups. Out of 11 patients in control group, there were 6 mortalities and there were only 2 mortalities out of 15 patients who were given pre-operative peritoneal lavage.

In the study it was observed that in study group with pre-operative peritoneal lavage 15 patients were stable and 15 patients were with unstable haemodynamics before surgery whereas in the control group, 19 patients were still having unstable haemodynamics before surgery and 11 were stable pre operatively. Upon recording the haemodynamic conditions on admission and before surgery, it was found that there were 23 patients with unstable haemodynamics and 15 were still unstable after resuscitation before surgery in patients who were given pre-operative peritoneal lavage. Whereas, 17 patients presented with unstable haemodynamics and 19 ended up in unstable haemodynamics before surgery in the control group. On comparing the change in the haemodynamics and effect of resuscitation, it was noted that pre-operative peritoneal lavage had significant effect on resuscitation leading to stabilisation of haemodynamics of the patient over due time.

Conclusion

The pre-operative percutaneous peritoneal aspiration of the fluid and peritoneal irrigation and drainage in patients with advanced stage of perforation peritonitis documented by their high MPI score before definitive

surgical source control is associated with a significant improvement in the pre-operative pulse rate and blood pressure, decrease in the operation time, decrease in the incidence of post-operative ventilator support, decrease in the incidence of deep seated wound infection, dehiscence and overall mortality.

Nutritional Assessment Using 24 Hour Dietary Recall Method, Anthropometry and Clinical Assessment among Young Adults Studying in a Private Medical College, Thrissur, Kerala

Albin John¹, Navya C J², Vidhu M Joshy³

¹Medical Student, ²Associate Professor, ³Statistician, Amala Institute of Medical Sciences, Thrissur, Kerala, India

Abstract

Introduction: The three common methods for assessment of nutritional status are 24 hour dietary recall method, anthropometry and clinical assessment. **Objectives:** To assess the nutritional status of young adults using 24 hour dietary recall method, anthropometric measurements and using clinical assessments and to correlate between nutritional status obtained by these methods. **Methodology:** A cross sectional study was conducted on all the students of an MBBS batch in a private medical college. There were 100 students in total and each student was interviewed on 3 non-consecutive days (2 week days and 1 weekend day) in a dietary cycle using questionnaire for nutritional assessment to collect data. **Results:** Males were 30% and females 70% in proportion, with a mean age the study population was 21.69 ranging from 20 to 23. The mean of required calories per day was 2741.79 ± 528.65 . 84% of study population was consuming above the required calorie level and 16% were consuming below the required calorie level. The mean BMI was found to be 22.32 ± 3.58 kg/m². Body mass index of majority (51%) was found to be normal; 11% was underweight, 20% was overweight and 18% was obese according to modified Asian WHO classification. Waist hip ratio of 38% of total study population was found to be above the limits. On examination no clinical sign of vitamin or mineral deficiencies or excess were found in the study population. Average calorie intake was positively correlated with body mass index. Pearson Correlation Coefficient (r) value was found to be 0.536 and p value was 0.0001. This was statistically significant. **Conclusion:** As average calorie intake estimated using 24 hour dietary recall increased, body mass index increased.

Key words: Nutritional assessment, 24 hour dietary recall method, anthropometric assessment, clinical assessment, young adults, cross sectional study

Introduction

Emerging evidence demonstrates that overweight and obesity are increasing in the developing world. Three quarters of the obese population worldwide are projected to be in non-industrialised countries by the year 2025. [1] The state of being overweight coexists with under nutrition in developing countries. [2] The prevalence of non-communicable diseases such as hypertension, cardiovascular diseases, and type 2 diabetes is becoming a public health concern. In this

context periodic assessment of nutrition is important as dietary intake has been linked to important health outcomes, including several of the leading causes of death (e.g., cardiovascular disease, cancer, diabetes). [3] Three main methods used to assess nutrition are 24 hour dietary recall method, anthropometry and clinical assessment.

24 hr recall method (questionnaire method) is a method of dietary assessment of nutritional status. It is a relatively easy method based on the recall capabilities of the individual over a period of the past 24 hour and is fairly accurate.

Anthropometry and clinical signs are methods of direct assessment of nutritional status.

Nutritional anthropometry is simple, quick to do, easy to reproduce and objective method for measurement of human body at various ages and levels of nutritional status. It is based on the principle that appropriate measurements should reflect any morphological variation occurring due to a significant functional physiological change. In some cases it identifies even subclinical changes resulting from nutritional variations.

Assessment of nutritional status using clinical signs is a widely practised method which is based on the examination for changes believed to be related to inadequate or excessive nutritional intake that can be observed in superficial tissues or in organs close to the surface.^[4]

The method used to assess nutritional status can vary depending upon the people who is assessing it. The nutritional status obtained using 24 hour dietary recall method, anthropometry and clinical assessment are to be correlated with each other to check whether the result obtained by each of these method are the same. This is important as the further management of nutritional excess or deficiency of the person depends on the result of these studies.

Method

A cross sectional study was conducted from June 2019 to September 2019 among all the students of 2016 MBBS batch of Amala institute of medical sciences, Thrissur.

Twenty four hour dietary recall was taken on three non-consecutive days (two weekdays and one weekend) in a dietary cycle by interviewing each participant using a questionnaire for nutritional assessment without prior announcement regarding the date of interview. This was done to ensure that participants were not making any alteration to their habitual diet during the study period. Participants were asked about all details including type of food, estimated portion size in terms of standardized quantities like 5 ml spoon, 15ml spoon, 200ml bowl and brand of food and beverages consumed for the previous 24 hours. For foods and beverages consumed from outside, participants were asked to recall as much detail as possible about them. All information collected during the interview was recorded in questionnaire.

A digital scale was used to assess the weight. Individuals were requested to remove shoes and heavy cloths prior to weighing. Height was measured by requesting the subjects to stand with their scapula, buttocks and heels resting against a wall, the neck was told to be kept in a natural non stretched position, the heels are supposed to be touching each other, the toe tips are to form a 45° angle and the head has to be held straight with the inferior orbital border in the same horizontal plane as the external auditory canal (Frankfort's plane). Body Mass (BMI) was estimated by dividing weight (kg) by square of height in meter (m²). Individuals were classified according to modified Asian WHO scale.

Waist to hip ratio (WHR) was estimated by dividing waist circumference by hip circumference. ^[5] The threshold WHR is ≤ 0.85 for women and ≤ 1.00 for men ^[6], above which superior distribution of adipose tissue was considered.

The clinical signs suggestive of vitamin and mineral deficiencies or excess were examined.

The clinical signs suggestive of thiamine deficiency are bounding pulse, warm extremities, peripheral oedema, and progressive peripheral neuropathy. The sluggish tendon jerks, anaesthesia of the skin (especially over tibia), Muscle wasting was checked. Confusion, low levels of consciousness and poor coordination (encephalopathy) was also noted.

Clinical signs indicative of riboflavin deficiency are cheilosis, angular stomatitis, magenta tongue, nasolabial seborrhoea and genital (scrotal or vulval) dermatosis.

Deficiency of nicotinic acid causes dermatitis (skin exposed to sunlight gets inflamed, that progresses to pigmentation, cracking and peeling.),diarrhoea (accompanied by scarlet tongue),dementia(present as mild confusion and disorientation to mania and psychosis.).

Dietary folate deficiency maybe accompanied by depression, insomnia, forgetfulness, irritability and dementia.

Deficiency of cyanocobalamin causes malabsorption. Neurological symptoms characterized by loss of sensation and motor power in the lower limbs (due to degeneration of myelin) would also be seen.

Ascorbic acid deficiency would be manifested as spongy and bleeding gums, perifollicular haemorrhages in the skin and poor wound healing. Fatigue and muscle weakness would also be seen.

Signs and symptoms of vitamin A deficiency are dryness, itching, redness of conjunctiva, night blindness (inability to see in dim light), Bitot's spots; corneal xerosis; keratomalacia; dry rough itchy skin; rash; dry brittle hair and nails, loss of acuity of senses: smell and taste, loss of appetite, fatigue, poor growth, low immunity: increased vulnerability to infections. Vitamin A toxicity would be characterized by dry lips (cheilitis), dryness of nasal mucosa and eyes, erythema, scaling, peeling of skin, hair loss, nail fragility, hip fractures (Bone abnormalities).

Deficiency of vitamin D would be characterized by skeletal deformities, bone pain and weakness.

Vitamin E deficiency would be characterised by reduced tendon reflexes, loss of touch and pain sensation, unsteady gait, loss of coordination and impaired eye movement.

Deficiency of vitamin K would be characterized by bleeding tendencies.

Deficiency of calcium levels would produce tetany, characterized by twitching of muscles of face, hand and feet. Cardiac arrhythmias would also be seen. Long term calcium deficiency would manifest as stunted skeletal growth.

Sodium deficiency would manifest as muscle cramps and severe dehydration.

Cardiac arrhythmias and muscle weakness are indicative of potassium deficiency.

Magnesium deficiency would be manifested as apathy and muscular weakness.

Anaemia indicates iron deficiency.

Deficiency of iodine manifests as hypothyroidism characterised by lethargy, poor cold tolerance, bradycardia, and myxoedema.

Fluoride toxicity is manifested as mottled enamel.

Deficiency of zinc is characterized by growth

retardation, delayed sexual maturation. Zinc deficiency may present as a tetrad of symptoms comprising of neuro-psychiatric changes, dermal lesions, diarrhoea and alopecia (Acro-dermatitis Enteropathica).

Copper deficiency usually presents as chronic diarrhoea.

Selenium deficiency is associated with coronary artery disease and Kashin Beck syndrome.^[4]

The data collected by interview and examination was entered in Microsoft excel and analysed using SPSS version 23 software

Results

The whole 100 students of 2016 MBBS batch of Amala institute of medical sciences responded to the study. The mean age was 21.69 ranging from 20 to 23. The study population consists of 30 males and 70 females.

A large proportion of the study subjects were Christians (66%) and then followed by Hindus (22%) and Muslims (12%). Most of the subjects were hostellers (92%) and only few were day scholars (8%).

Table 1: Occupational categories of father's of the study subjects

	Frequency	Percentage
Professional	83	83
Teacher	8	8
Skilled worker	5	5
Unemployed or retired	4	4

Table 2: Occupational categories mothers of the study subjects

	Frequency	Percentage
Professional	24	24
Clerk	1	1
Teacher	19	19
Home maker	53	53
Unemployed or retired	3	3

Mean monthly income of both the parents of study subjects was 95650 ± 85793.43 Indian Rupees.

The mean of required calories per day of the study population was 2741.79 ± 528.65 . Consumption of calorie above the required level was found in 84% of study population and 16% were consuming below the required calorie level.

The mean of required protein per day of the study population was 60.58 ± 13.16 . Overconsumption of protein was found in 83% of study population and 17% were consuming below the required protein level.

The mean BMI was found to be 22.32 ± 3.58 kg/m². Almost half of the study population were in the normal BMI range (51%). 11% of the subjects were underweight, 20% were overweight and 18% of the subjects were undernourished.

Table 3: Nutritional status according to BMI

	Frequency	Percentage
Underweight	11	11
Normal	51	51
Overweight	20	20
Obese	18	18

Average calorie intake was positively correlated with body mass index. Pearson Correlation Coefficient (r) value was found to be 0.536 and p value was 0.0001. This was statistically significant.

Table 4: Average calorie consumption according to BMI categories

BMI	Average calorie/day		P value
	Mean	Standard deviation	
Underweight	2474.73	818.44	.0001
Normal	3691.79	816.99	
Overweight	4157.45	475.61	
Obese	4336.05	317.73	

The mean waist hip ratio in males was found to be 0.89 ± 0.0566 and in females it was noted to be 0.87 ± 0.0562 .

About one third of the study population (62%) was having waist hip ratio within normal limits. This included 33% females and 29% males. 38% of the study population (37% females and 1% males) had waist hip ratio above normal limits.

On examination no clinical sign of vitamin or mineral deficiencies or excess were found in the study

population.

Discussion

The studies on correlation between nutritional status obtained by 24 hour dietary recall method, anthropometry and clinical assessment are scarce.

The mean of required calories per day of the study population was 2741.79 ± 528.65 . Consumption of calorie above the required level was found in 84% of study population and 16% were consuming below the required calorie level.

The mean of required protein per day of the study population was 60.58 ± 13.16 . Overconsumption of protein was found in 83% of study population and 17% were consuming below the required protein level.

The mean BMI was found to be 22.32 ± 3.58 kg/m². Almost half of the study population were in the normal BMI range (51%). 11% of the subjects were underweight, 20% were overweight and 18% of the subjects were undernourished.

Average calorie intake was positively correlated with body mass index.

The mean waist hip ratio in males was found to be 0.89 ± 0.0566 and in females it was noted to be 0.87 ± 0.0562 .

About one third of the study population (62%) was having waist hip ratio within normal limits. This included 33% females and 29% males. 38% of the study population (37% females and 1% males) had waist hip ratio above normal limits.

On examination no clinical sign of vitamin or mineral deficiencies or excess were found in the study population.

Conclusion

Average calorie intake of the study population estimated using 24 hour dietary recall method was positively correlated with body mass index. As average calorie intake estimated using 24 hour dietary increased, body mass index increased. The mean of required calories per day of the study population was 2741.79 ± 528.65 . The mean of required protein per day of the study population was 60.58 ± 13.16 . The mean BMI of the study population was found to be 22.32 ± 3.58 kg/m². The mean waist hip ratio in males was found to be 0.89 ± 0.0566 and in females it was 0.87 ± 0.0562 . Nutritional status assessed using 24 hour dietary recall method, anthropometry and clinical assessment are giving identical results of

the study population, and they can be used to assess nutritional status of individuals.

Slow Learners and Low Achievers Can be in the Limelight with the Toppers- A Ray of Hope for Zero Rejection-a Qualitative Analysis

P Anitha¹, G.Denish Dhivyan²

¹Assistant Professor, Social work Department, Holy Cross College, Trichy, ²Assistant Professor, PG & Research Department of Commerce, Bishop Heber, College, Trichy

Abstract

Slow learner is who may have poor language skill in writing and communicating. They run into poor judging skills and illogical reason to the theory classes. Slow learners always can't get along with the same age mate companionship, but show proficiency in particular task which might not be the curriculum relevance. They always expect to have novel way of transferring the details to teach the old concepts. On the other hand learning disability experiences physical retardation to speak, write and calculate, inadequate motor skill to coordinate and cooperate the live class room activities. The academic institution unfailingly stumble on such individuals who want to do a regular stream of graduation. If the college can tailor the curriculum to feed such expatriates, inclusive growth and human rights will be flagged to raise the institution profile to a prominent culmination among the horizons. The study administered to underpin the postulation was a qualitative analysis made among the low achievers of 300 adolescent college students in Tiruchirappalli, who were desperately forgotten by the college tutors and the mentors sharing their plight of reality they are in and the Pandora dream they hold back to become in reality. The focussed group discussion and the findings make intelligible explanation about the essential modified curriculum which will be a ray of hope to all poor scorers and the learning disabled, a regular college education leaving Zero rejection

Key words: Academic Inclusion, Zero Rejection, Adolescent College students,

Introduction or Background

¹“Small minds are concerned with the extraordinary, great minds with the ordinary.” small mind can manifest the great and extraordinary output while great minds are tuned to think in the regular pattern as the majority fashioned to think. Academic arena always have a struggle for the aspiring and under aspiring individuals. ⁷The SDG goal for the 2030 states Zero Rejection as one of the prominent goal along with quality education with gender parity.

Methods or Materials

²Focus group come in numerous shapes and sizes the methodology adopted for the study was based on which stated that a minimum of 10-12 participants to be included in a single group. The method also mandated that the nature of the group should be based on its

homogeneity because composing a group with highly different characteristics will decrease the quality of data. ²Further emphasized that the focused group should comprise of the essential elements and the researcher tried to incorporate the same model adhering to the methodology in conducting FGD's.

Selection Criteria

⁴The researcher selected 24 respondents with low rating. As denoted, the presented procedure is called 'sampled Group' and does not require a Specific sampling structure but rather focus on the researchers' convenience. Informed consent for the participants willing to participate in the research process was also systematically done while adhering to the ethics and norms of research.

Conative Model in a focused Group Discussion:

⁵Conative is a term coined by Mary Goodyear 2013, and this term refers to a style or approach to focused group discussion in qualitative research that is interpretative and based on the humanistic approach. Its primary objective is to achieve understanding of a topic or issue in the respondent's own terms. ⁴The researcher adopted this model using a set of structured interview questionnaires depicted in the focused group scripts with an objective to portray and achieve an understanding pertaining to the factors that led to the respondents having a low rating in achievement motivation.

Group I

Group Discussion- Outcome

Though the respondents' hesitated to initiate the conversation after the sentence completion test; they started spontaneously volunteering in the discussion when their individual contribution was disclosed without their names. Every respondent manifested that society is "WE" and "WE" alone. "If I am ok why should we blame society". "Society should be positive to the youngsters". Few others expressed that society means it defines only for the upper class and the son/daughter of the highly occupied personnel. Law, police station and educational institutions are working impartial. "Society demotivates us all"

Most of the respondents say that once their parents felt their son/daughter is grown up, total responsibilities are displaced and they totally go uncared. "My mother never cares even I come home by 3 am", "I rule and my rules only at home". Girls mutually say they get total freedom to move around, but there are times when phones are checked and bags are raided. Respondents strongly enforces that parents/teachers should not treat/guide their children by their own bitter experiences but rather they have to look upon the contextual scenarios also.

Respondents' felt that colleges are more syllabus and semester driven but not teaching what life is. We as young college students forget to represent our teachers as the best friend. They always look up on us with inquisitive eyes if they come across any mistake we commit.

"The girl whom I love madly, left me like this"

"My parents will never ask me where you are going. They will let me go free"

"I am a good dancer but fear of myself itself the problem"

"No money so I am deprived of extracurricular activities"

What made them to go so uncared of self and about the future?," the immediate response is that friends and their social gang made them to do many risk taking adventurous and cinematic behaviours.

"I practiced and quit all types of drugs but still I consume brown sugar and alcohol"

"When I was with my friends I can even murder"

"As Friends we always motivate each other to have an affair to avoid boredom"

"I regret for my friendship"

They also said that each of them spend a lot of money to maintain their friendship and their specific existence. To accompany the techno trends of Social networks all the respondents' need to spend money for mobile data, not only for the self but also for their girlfriends and boyfriends too. They comment that Social networks and pornographies, parties and outings have made them hold a low self-esteem and they hold a low spirit, yet the respondents do it all voluntarily to seek and reveal their identity.

Irrespective of their economic class, all the respondents make up their appearance as an upper middle class boy or girl, for example they spend on latest out fits, trending with branded accessories, high-end mobile phones, bike, and other gadgets. Every respondent accepted that they mint excessive money from their parents more, other than fees, and spend for parties and get-togethers. While expressing their views some were regretting for their ill-mannered behaviour, but some felt that there is pleasure in such activities.

Willingly knowing all the ill effects and evils, the respondents verbalize that:

"I use brown sugar and stuff"

“I drink alcohol and stay night out”

“Though not possible in my family to have a boyfriend I’m having one”

“I never tasted alcohol but now I’m an alcoholic and mentally depressed because of love failure”

Closing/Summary

The core discussion of the above FGD clearly reveals the present situation of the respondents’ who attended the FGD. As this group discussion focused not to teach about a guide or a manual but to learn the reason behind the low rates in quantitative analysis.

Being vigorously active, they bring in lot of mess, always procrastinate, and work lethargically on their own pace. They always wish the society to keep their world undisturbed because, they say and see lot of pit falls in adult planning and adult politics. They advocate their world to be serene and they request others not to spoil the peace they enjoy. Though they achieved nothing in this young age yet they are beautiful as they are honest in accepting their inabilities.

Most of the respondents’ wanted their professors to be a helping hand to guide and to direct, but not a yardstick to measure on what they are, and what they were incapable of, but they needed light to have a good future.

Not many of the respondents were satisfied by the parenting methods they experienced. They individually grumble that either of the parents were highly vigilant while the other is totally least bothered about anything, while the boy children say that they were given too much of freedom and trust and they were ignored in turn they lacked monitoring. None of them were guilty for what they possess; their emotional instability and social inadequacy.

Group II

Group discussion- Outcome

The discussion initiated by the moderator and inquired from the group, the reason for latent emotionality’s and abnormal range of emotional expressions. Almost all the group members unanimously stated that the nurturing pattern since their childhood was weird, that their

parents were solely responsible for such unfavourable emotional outlet now colouring their adolescent stage “*I always want to be in good emotional climate, but my mother will never allow me to live a life of my choice*”.

The Painful ventilation is that “The only everlasting villain is my father who sees me as a doll to dance for his tunes”. Every group member tagged themselves with the same statement, “If we were allowed to socialize blissfully we would have matured socially by this time”.

They also revealed that, the respondents true desires were not recognized when they were schooling, so now they preferred to do whatever they want, because of the age, and development of autonomy in their hand.

Probing the respondents further, they shared that they are happily living their life with friends, outings and chatting, which keeps their mind fresh. They were able to trend out, freak out, the way they want. Motivation in achieving was far somewhere in their lifespan and they stated that this is the age meant for mere recognizing and identifying what they love.

“I chose fine arts club in my college and never attend classes”

“I prefer to bunk class and stay with old friends for drugs/ alcohol/ movie”

“I love to bunk and move out but I do the same stuff in mobile phones”.

All the respondents’ curiously ventilated that it is very difficult to receive money for tuition fees, so to fulfill the individuals need to dress, drive, hangout, they will demand excess money as fees, or go for part-time jobs, indulge in any work that offers instant payment. Somewhere happily for the unapproved causes. Sharing their own experience of stealing money from the wrong sources. The members all have an impression that each of them having their ego wrapped with shame, hurt and lack of resources along with biased parenting. The only motive at this age was to flourish their own desires than their parental will and wish they have for their daughters/ and sons.

The respondents stated, that “*My home taught me to suppress my desire rather to race for achieving that*”. The other says, “*My father often says all your desires/*

wish/ambition is “ok” for high socio economic class sons and not for us”, and majority accepted this. The family taught us to wish a desire, which is nominal for a lower middle class family. When the moderator asked for explaining the way, they made their life. They said as follows:

“I earned and bought a costly bike and happily riding that in pride”

“I selected a dance floor qualified myself a dancer and now I am a choreographer”

“I am what I am; living happily in hostel hiding myself from family and nauseating rules”

The moderator re-caped the discussion and posted the reason for lower/poor academic performances. Without any hesitation, group members confront that:

“Teachers are not teaching they are working for a corporate target” “Academics are tertiary to me”

“College is to make friends and I am done with that”.

These verbatim capsules with molecules of negative parenting, inadequate economy, unstable mood and wrong decisions, negative peer pressures as reasons for going astray. The moderator led the discussion based on the fact of achievement motivation among them. They shared the feeling of conviction that they need to achieve and they have lot motivation owned in their personality.

Thus, the discussion totally revealed the language and amicableness of all employees were not to a great extent. The moderator concluded the group discussion and highlighted the major findings in order to ensure the validity on the statements made. The key findings revealed that the psychological and sociological developments rely on the childhood experiences and the kind of parenting style adopted in their respective houses.

Closing/summary

The moderator concluded the group discussion by revising the key points discussed and addressed in the group discussions. The major findings revealed that they were under the pressure of achieving the development

standards what media has portrayed.

When addressed about their college life they revealed that they expected the institution to be a thrust for the needy but in reality they found that colleges were giving preferences to the higher socio economic class, high proficiency and language and the rest were ignored. Most of the respondents stated that the priority of the college was to check the student’s punctuality and complete the syllabus. They also stated that there was a different way of approach depending on the student’s ability. They expected colleges to be a platform to unbiased learning and growing. By doing so, if the respondent’s family failed to develop their children psychologically and socially adaptive, the college will bring up the inmates psychologically and socially equipped apart from academics.

Findings

Convergent findings:

³Similar thought process were perceived as convergent findings. The common thought shred was, that parents were irresponsible, being conventional that suppressed their emotional and social maturity contextually. All were aggressive with uncontrolled emotions in some way or the other. All the group members were having poor academic records and lack of attendance the reason they state for this back logs were friends circle. Bunking classes for jolly trips or not just staying away from classes but also loitering inside the campus. Partying out is a way of defending their damaged ego and displacing the same with lot of friends, social media, and related socialization. All the three groups inevitably explained that the parenting style was not the sort they desired for. The real want of the hour to them was mere recognition and social attention from their parents and teachers, which they were deprived off.

Divergent findings:

Majority of the respondents from group 1 inferred that a family handling their adolescent child brings in many success and failure stories. They all have a wounded ego and end up in wrong relationships because of the blind trust parents have on their kids. Parents are either not vigilant or over vigilant, which fails poor in the development of an individual. While the other two

groups surmise that controlled parenting has resulted in unpleasant childhood and it has also affected their emotional and social stability. Majority of the respondents from Group 1 and 2 have records of indulging in malicious acts and remanded in police stations and still narrating the same without any conviction. While the third group appears to be athletic and allured in nature and have no evidence of drug abuse, no love affair, but contemplate that society, and family are the nurturing environment and that they can join them at any time. Most of the respondents were academically on a low profile, the reasons are contradictory and divergent in nature.

Conclusion and Suggestion

The under achievers or the low scorers are neither disabled to learning nor incapable to comprehend, but a modified approach in education's programmed instruction can be a scope to revitalize their position in academic zones. Academic achievement motivation is every body's desire to be the start line of the race but not all have the same spirit to follow the old fashioned or regular mannered structure to be the achievers. Sugar can be the single ingredient desired to be mandatory in all the sweets but now sugar has many alternatives to match the tastes of the cravers who are diabetic too. Updated trends are the only example to set our mind to start one of a kind of a research. Academics achievement motivation is a flavor that brings wonder depending on the factor that induces or reduces success, so which is the main feature to draw such flavor is the developmental stage or the age group that plays the key music.

- Home is the prime learning institution which ponders the effect by various factor by quality parenting and adequate emotional and social maturity.

- A child with adequate parenting can develop a matured emotions and matured social

- School or college is the secondary home

- If home failed to sow, the learning centers has to be the nurturing source.

- Outcome based education and customized ranking pattern can be ensured

- Drill on the wholesome education and peel out the convention mod of education

- Perceive adolescents with the fullest cognitive potential and not on the behavior manifested.

- The college can also affirm various extra curricular, industrial startups and incubation centre to receive contribution variedly across intellectual domain

Funding Source: Self

Conflict of Ineterest: Nil

Ethical Clearance Committee: The ethical board comprises of the respective college Dean of student affairs, Dean of Research and Development and the three college Principles met in a common consensus and acknowledged the research questions and the intention of the FGD were well discussed and the verbal consent was received by the team in person and the researcher was allowed to proceed with the same.

Perception of the Visually Impaired Students Towards Inclusive Education in Mainstream Higher Educational Institutions (with Special Reference to Multimodal Material Preparation Center, Bharathiar University - Coimbatore)

Sowdeswari. D¹, Chandramathi. R¹, F. X. Lovelina Little Flower²

¹PhD Scholar, ²Professor and Head Department of Social Work, Bharathiar University

Abstract

Leading a dignified life is not only a desire but also a fundamental right of any Human being. With Disability being an important global problem across the world, the Persons with disability struggle to lead a dignified life in the society. Despite advancement in Science and Technology, the issue of disability still remains a challenge and demands rapid intervention strategies to curb the barriers that curtail the development of individuals with disability and the nation at large. The aim of this study is to know the perception of the visually impaired students towards Inclusive Education in mainstream higher educational institutions. The evident based case study method of study design is used, where the Multimodal Material Preparation Centre of the Bharathiar University, Coimbatore on the whole is taken as the unit of analysis for the study. This study investigates the concerns of the visually impaired students studying in the Bharathiar University based on the in depth interview conducted with the students of various mainstreams of higher education who are making use of the material preparation centre of the University. The findings of the study reveal the overall perception of the visually impaired students towards Inclusive Education in all the aspects of availability, accessibility and affordability of education, where it becomes the evident study. Thus this study implicates greater scope for social work practice and further research in this area of Inclusive Education which will create a positive inclusive society.

Key Words: *Inclusive Higher Education, Visually Impaired students, Multimodal Material Preparation Centre, Inclusive Society*

Introduction

“You have a responsibility to make inclusion a daily thought, so we can get rid of the word ‘inclusion.’”

-Theodore Melfi

Persons with disabilities constitute a significant proportion of the minority population in the world. There are several types of disabilities, including intellectual and physical disabilities. Though an intellectual disability is different than a physical disability, such as visual impairment, students receiving special education services for any disability share common experiences. All students identified with a disability in the educational setting are considered to have significant impairment emotionally, intellectually, or physically that requires

them to be provided with extra resources and assistance to achieve in the academic setting.^[1]

Vision Impairment

Vision Impairment can occur at any age group. Visual impaired people are those who suffer from the impaired conditions, difficulties and deficiencies present in their visual organs which make them different from people with normal vision to extent of requiring special provisions. Visual condition of them remains the same throughout their life. Some conditions might cause vision problem only for the shorter period of time whereas other conditions might get worse over time resulting in poor vision or blindness when they grow older. When one can't see all the things that one should be able to

see in their age it is regarded as the low vision. These visual conditions include low vision, blurred vision, or the loss of side vision or may not be able to see and identify the colours. Visual impairment typically calls for the change in life style and solid support system . In the various forms of disability vision impairment has the highest range of difficulty, problems and risks because without vision the world becomes dark and one cannot see what is happening around the world . Without vision it is strange situation and time for the children where they will be very much eager and interested to know what is happening around them as they can feel the environment with their other senses of hearing , smelling , touching etc. So it makes the visually impaired people to feel for their disability which affects their mental health as they start thinking negatively about their life.

Inclusive Education

Inclusive Education is an approach towards educating the children with disability and learning difficulties with that of normal ones within the same classroom, regardless of their strengths or weaknesses in any area, and seeks to maximize the potential of all students.^[2]

Providing all students in general education classes with high-quality instructions, intervention, and support is a hallmark of inclusive education. It is one of the most effective ways to promote an inclusive and tolerant society, constructed on the basis of human values and morals.^[3]

Inclusive education is education that has everybody, with non-disabled and Disabled people (including those with “special educational needs”) learning together in mainstream schools, colleges and universities. This means the system should adapt to incorporate Disabled individuals –The education system should recognize that it creates barriers for Disabled learners, for instance if parts of the school are inaccessible.

Disabled pupils and students might need variations and support to access the information.

Such adaptation and support will make disabled students more independent and it in-turn improves their psycho-social condition and their quality of life. Comparing to the special schools, the inclusive

education in mainstream schools is more preferable for the children with disability as it helps them to have a better quality education as like normal people without any discrimination.

Visually impaired students in the Inclusive education cope up with their studies with the special reading aids in the accessible way. In today’s technology world the availability, accessibility and affordability for the education for the students with disability in this inclusive society is in positive way comparing to the past but still there lies a gap between all the areas for bringing in and creating a positive reach to the inclusive society.

Multimodal Material Preparation Centre for Persons with Disabled

Multimodal Material Preparation Centre for Persons with Disability has been established in the Bharathiar University since July 2013. The resource center is being supported and facilitated by Department of Social work. The center has advanced softwares installed in computers for those with low vision, locomotor disabilities, cerebral palsy, and visual and hearing impairment. Examples: JAWS Pro Talking Software, PacMate 20 Cell Braille Display, Index Basic D Braille Embosser and Duxbury DBT Win Braille Translation Software. It is open to all the students from all institutions on working days from 10a.m. to 5p.m. at free of cost. This study be the pathway for the theme of Inclusive society where this centre in Inclusive educational institution be the successful model for supporting the differently abled students by providing all the required special aids for their education in the easily available, accessible and affordable way. As like this centre all the educational institutions should make a start for strengthening the inclusive education with all the available resources in the accessible and affordable way for all the mainstreams of educational field. Though differently abled people forms the minority group this should not paves the way for discrimination. For this Inclusive society only be the key factor for ending all forms of discrimination with the differently abled people and it enhances the quality of life of them in this inclusive normal world.

Importance of the Study

The growing body of analysis has shown that student

do higher academically once in comprehensive settings and Inclusion provides opportunities to develop relationships.

Higher education provides individuals with a chance to mirror on the crucial social, economic, cultural, moral and spiritual issues facing humanity. It contributes to national development through dissemination of specialised information and skills.^[5]

Research Methodology

Study Materials And Methods:

The aim of this study is to know the perception of the visually impaired students towards inclusive education in mainstream higher educational institutions.

The evidence based case study design was used which provides the in depth knowledge about the perceptions, concerns and experience of the visually impaired students about the availability, accessibility and affordability of education in the inclusive society.

Study Questions:

What are the perceptions of the visually impaired students towards inclusive education?

How the Multi model preparation centre be the supportive system for providing quality inclusive education to the visually impaired students?

Tools For Data Collection:

The Multimodal Material Preparation Centre on the whole is taken as the unit of analysis for the study. The case study approach was adopted to know about the centre on the whole of its importance, provisions and its supportive system for providing special educational aids to the visually impaired students in the available, accessible and affordable way. This study had been done with the MMPC educational trainer.

The in depth case study had been conducted with 6 visually impaired students who are making use of the MMPC through interview schedule.

Sources of Datacollection:

Primary Data:

The case study had been conducted with the

educational trainer and visually impaired students through interview schedule.

Secondary Data:

Secondary data is collected through Review of literature ,Internet articles , journals , news papers.

Limitations Of The Study:

This study focuses only the visually impaired students and not the other form of disabled students.

This study takes the visually impaired students only who are visiting the MMPC and not the others.

Findings

The findings of the study reveals as,

The socio demographic factors of the 6 respondents are, all the selected visually impaired students are male, doing their PG degree in Bharathiar University, staying in hostels and have limited family support, they are from rural area, they had their school education in special schools and college education in inclusive setting, they do their education by receiving various scholarships.

The perception of the respondents towards Inclusive education are,

The visually impaired students have positive attitude towards inclusive education where they come out of their limited circle of their special zone and able to be with the normal people and adopt themselves to lead their life in this normal world.

In their perception the Multimodal Material Preparation Centre is very useful and be the greater supportive system for being under inclusive education where this centre provides all the special alternative educational aids for coping up with the general educational curriculum and syllabus.

From the experience of their education from schooling to the college , in schooling they were in special blind schools were they were in their own limited circle where they felt very low and discriminated from the society, but when they came into contact with the mainstreams of inclusive educational setting it improved their quality of life in educational aspects and they had good psycho social condition and felt positive about

their life.

The Inclusive education improved their psychological status and developed their adjustmental, inter personal skills.

In the availability aspects of education the visually impaired students felt that because of this centre within the university make us available with all the required materials for studying with the available special educational aids and by the support of the trainer at the centre. All the new technologies are made available in the centre for meeting up with the special educational needs which removes their barrier for studying in inclusive field.

The availability of such centres within the university is very essential and useful where the visually impaired students easily making use whenever they are in need of it. It reduces their efforts for searching the reading materials outside and saves lot of time where they can relaxly concentrate in their studies without any issues.

In the accessibility aspects such supportive centre within the university are in greater accessible way where the students can make use of it as and when they required.

The trainer in the centre helps students in recording and scanning reading materials and also teaches the students to make use of the reading software in the system where these all forms and be the easy accessible ways for the visually impaired student's education.

The students also felt that such supportive centres are needed in all the educational institutions as by which it only provides fulfilled inclusive education. From their previous college and school experience the supportive centres are not available in all the institutions and the students need to go to common centre in one place and meet up with their educational needs even if they were in inclusive education. So such institutions without any supportive centres provides inaccessible situations to the students.

The University provides disable friendly infrastructures and environment which acts as an adaptation mechanism, making the entire university accessible for the differently abled students .

In the affordability aspects as the MMPC is for free of cost it be easily affordable to the visually impaired students. The students also prefer such affordable way where they can continue their education from their lower economic status.

All the available new technologies for meeting with special educational aids are very costly for the individual to make use of it. So making it available in the educational institution at the free of cost is very useful for the students as they felt very beneficial.

Thus by having in depth interview form of case study with 6 visually impaired students who are making use of the MMPC in the university revealed their perception towards inclusive education with their own individual experiences. On the whole the students showed positive feeling towards inclusive education with supportive centres to meet up with their alternative educational special needs.

Discussion

From this evidence based study, it is very clear and understandable that the education with all the available, accessible and affordable aspects in the inclusive society shows positive attitudes towards the visually impaired students only if they properly reach their hands.

The inclusive education for the differently abled people be the facilitating factors in the psychological, social, environmental and educational aspects. yet there be the certain barriers such as adaptation mechanism and supportive system for making them available in the inclusive settings.

For overcoming such barriers the supportive centres as like in Bharatyar university the Multimodal Material Preparation Centre be the key factor.

As the available, accessible and affordable aspects in this centre are easily and properly in reaching hands to the students their perceptions towards inclusive education is in positive way. But this perception change in negative way with those students where those three aspects be difficult for reaching out with the students. So they will show negative attitude towards Inclusive education.

Like this supportive centres all the educational institutions should take step for starting up

In order to providing a better quality inclusive education.

For adaptation mechanism the educational institutions should form and build a differently abled friendly infrastructures and environment.

Though it is able to provide education in this inclusive society in the available, accessible and affordable way most of the institutions are not coming forward to provide such inclusive education. So such supportive centres, systems and adaptation mechanism needs to be strengthened in this developing stage for making such minority groups noted and treated as alike.

If all the educational institutions are ready to provide such form of good and proper inclusive education then it will be more beneficial to the differently abled students to perform well in their educational field and to have a bright future.

Suggestions:

- Strengthening of aids and supportive centers in all the educational institutions is very essential for creating Inclusive setting.
- Proper training is to be provided to the teachers about the SE aids and technologies.
- Awareness about the available technologies and aids is to be created among differently abled people.
- Awareness of the importance of Inclusive education is also to be created among teachers, students without disabilities and their parents.

The inclusive education brings in holistic development to the differently abled students where it improves their psychosocial condition and enhances their quality of life.

Through this study it is evident that the visually impaired students shows positive perception towards inclusive education in the mainstreaming higher

educational institution where the three aspects of availability, accessibility and affordability are in most favourable way.

Conclusion

Thus this study be the pathway for creating and strengthening supportive centres for providing quality inclusive education. This Multimodal Material Preparation Centre be the key factor for providing inclusive education in available, accessible and affordable way. The minority group of differently abled people should have equal opportunities in all the fields of this challenging inclusive society.

Thus this study implicates greater scope for social work practice and further research in this area of Inclusive education which will create a positive inclusive society.

Conflict of Interest Statement: The authors declare that there is no conflict of interest.

The Impact of Inclusive Education on Children with Mild Intellectual Disability in Promoting Social Skills and Peer Positive Attitudes in Trichy District

G.Sasikala¹, P. Swarnakumari²

¹Assistant Professor, ²Associate Professor, P.G & Research Department of Rehabilitation Science, Holy Cross College (Autonomous), Tiruchirappalli, Tamil Nadu, India

Abstract

Background: Social skills and social status are important aspects of development that are likely to be influenced by an individual's ability to solve social problems appropriately. An important area of development for children with mild intellectual disability is the development of social skills and social relationships. When children with disabilities are mainstreamed into general education classroom, they learn to play and interact appropriately with children of their own age. Inclusion provides opportunities for socialization and friendships to develop. Inclusion help children with disabilities decrease their aggressive and non complaint behaviour. The study aims to explore the social skills and peer interaction of children with mild intellectual disability which is considered as the most important factors of social outcomes. Finally, the study is objectively proposed to find out how the children with mild intellectual disability self rated themselves as well as the teachers and parents rating of social skills of children with mild intellectual disability in inclusive education programmes.

Materials and Method: In the inclusive education set up, 200 Children with intellectual disability and their teachers, parents and also the children without disability (peers) and their parents in the rural and urban areas of Trichy District were chosen for the study. The data was collected through SOCIAL SKILLS RATING SYSTEM (SSRS)-Gresham & Elliott, 1990). Obtained data were transcribed and analyzed using Descriptive and Differential analysis.

Findings: The statistical procedure showed that children with intellectual disability in inclusive education have average social skills. Since interpersonal contact was associated with positive attitudes towards children with mild intellectual disabled children, interventions should be directed towards promoting interpersonal relationships in order to build an inclusive society.

Conclusion: It is essential to build an inclusive society through an inclusive approach. Success of inclusion demands effective collaboration and meaningful cooperation from all stakeholders associated with education of children.

Key Words: *Social Skills, Inclusive Education, Peer Attitude, Children with mild intellectual disability.*

Introduction

Inclusion is a different way of providing education to all students not just another option in the Special Education Program. It is an approach to education where students with special needs including disabilities are educated in neighborhood schools in age-appropriate regular classroom settings with non-disabled peers.

They are provided with supports and instruction that assures their participation with their peers, while also meeting their individual strengths and needs. The focus is on giving every child the help she /he needs to learn. Inclusion denies the utilization of special schools or classrooms to separate students with disabilities from students without disabilities.

Education is the most prominent means to socialization. The main purposes of elementary education are to develop social skills among children since it is more important as academics. An author ⁽¹⁾ observed that socialization is the child's ability to relate positively to people in society in a manner appropriate to his or her age. Elementary education is the fundamental right. Everyone has the "right to education" states the Universal Declaration of Human Rights (1948). A study ⁽²⁾ found social skills as the cognitive functions use to communicate and interact with each other, both verbally and non-verbally, through gestures, body language and personal appearance.

Children who continuously exhibit social skill deficits experience both short and long term negative consequences and these negative consequences may lead to severe problems later in life. Researchers have indicated that social skill deficits in early childhood are relatively more stable over time related to poor academic performance and may be predictive of social adjustment problems and serious psychopathology in adolescence. Inclusion helps students understand the importance of working together and fosters a sense of tolerance and empathy among the students manifested in most of research.

Materials and Method

Aim of the Study

- To describe the socio demographic background of children with mild intellectual disability.
- To describe the socio demographic background of the teachers of mild intellectual disability.
- To describe the socio demographic background of the parents of mild intellectual disability.
- To describe the socio demographic background of non disabled peers of mild intellectual disability.
- To describe the socio demographic background of the parents of children without disability.
- To study the social skills in mild intellectual disability with regard to cooperation, assertion, self-control, responsibility and empathy.

- To study the problem behaviour in mild intellectual disability with regard to externalizing, internalizing factors.
- To study the academic competence of children with mild intellectual disability.
- To study the attitude of normal children (non-disabled peers) towards children with mild intellectual disability.
- To study the attitude of parents of children without disability towards children with mild intellectual disability.
- To drive a set of guidelines and training booklet for teachers and parents to equip Mild intellectual disability with adequate social skills.

The researcher selected 400 children with mild intellectual disability (200 rural & 200 urban) in inclusive schools of Trichy district by Purposive random sampling technique. 400 regular Teachers and 400 parents of children with intellectual disability have been invited to be the informants in the study. The teachers are teaching 6th, 7th and 8th std in the formal curriculum, as some of them had experience of teaching children with mild intellectual disability in the formal curriculum.

Data collection was done through standardized research tool and self designed Questionnaires to the sample of 400 Mild intellectually disabled children of both urban and rural areas selected by purposive random sampling. Literature survey and analysis of journals helped in determining the suitable tool for data collection. The 400 inclusive teachers and 400 parents of Mild intellectual disability children were also interviewed and administered through standardized tools to get the information and the progress reports of the respondents were also made use of.

The researcher administered the Student form of Social Skill Rating System (SSRF-SF) to the children with mild mental intellectual disability. The researcher interacted with each and every child by explaining the items in Tamil. According to the manual a SRSS rating form typically can be completed in 15-25 minutes; respondents are required to have at minimum grade three reading level. Out of 400 children, 68.5% of children

with mild intellectual disability studying in 7th and 8th need some assistance in reading and understanding the item, 31.5% of (studying in 6th std) children need full assistance where the researcher interacted with every child and collected their responses. So, it took 30-45 minutes to complete the rating scale.

The regular teachers who are handling the children with mild intellectual disability completed the Teacher form of Social Skill Rating System (SSRF-TF) in classroom by assessing the social skills of each student separately. The parents of mild intellectual disability completed the Parent form of Social Skill Rating System (SSRF-PF).

The SSRS assesses children's positive social skills, using a 30-item scale for teachers, and a 39-item scale for parents. Parents and teachers rated the frequency with which children displayed positive social behaviors at home and at school, respectively (e.g., "makes friends

easily" and "volunteers to help peers with classroom tasks") on a 3-point Likert scale ("never", "sometimes", or "often").

Results and Discussion

The table-1 reveals the overall mean, standard deviation and ranges of children, teacher and parent SSRS ratings of social skills, problem behaviour and academic competence of 400 mild intellectually disabled children. In all the subscales cooperation, assertion and self-control teacher rated significantly higher than the parents. This is because majority of the respondents (teachers) had increased experience of teaching in inclusive classroom and basic knowledge about children with disability especially intellectually disabled children. It is also clear that teachers in the inclusive classroom have a broader understanding on the overall social skills of children with mild intellectual disability.

Table -1: Descriptive Analysis Between Social Skills

Sub Scale	Parent	Teacher	Children
Co operation	9.66(4.38)	10.34(4.43)	9.75(4.76)
Assertion	9.44(4.10)	10.09(4.43)	9.56(4.36)
Empathy	--	--	9.70(4.92)
Self control	9.35(4.12)	10.44(4.56)	8.92(4.68)
Responsibility	9.91(4.16)	---	--
Overall Social Skills	38.36(15.249)	29.67(12.668)	
Problem behaviour Externalizing	5.41(2.50)	4.82(2.82)	--
Problem behaviour Internalizing	5.24(2.25)	4.74(2.83)	--
Overall Behaviour	10.65(4.292)	9.61(5.352)	--
Academic Competence		21.01(7.60)	--

Means and Standard Deviations of SSRS for 400 children with Mild Intellectual Disabled

A Study⁽³⁾, Differences between teacher and parent rating on cooperation, assertion, self –control and responsibility of social skills can be interpret as because parents and teachers observe different aspects of the child’s behaviour, it is reasonable that their information is not equal ,but can be seen as completing . Parents’ reports, in fact, may improve and deepen a teachers’ understanding of a child.

The respondents (children with intellectual disability) rated themselves higher on the subscales cooperation, assertion than the parents and teachers rating. In the self-control subscale items like ignore other children when they tease, disagree with adults without fighting or arguing, accept punishment from adults, controlling the temper when people are angry etc .The children rated themselves lesser than the parents. But the teachers rated higher the self control subscale items politely refuses unreasonable requests from others, responds appropriately to teasing ,when hit or pushed by other children ,speaks in an appropriate tone or voice at home of their children with intellectual disability. This difference in rating is due to the children sees themselves lower in mingling with their peers.

An author⁽⁴⁾The peers in school, being the closet on par, play an important role in the lives of children with disabilities. Acceptance by peers provides a much greater challenge for children with disabilities. Children with disabilities are often an easy target for being teased and bullied by their non –disabled peers. The children commonly reflected that they wanted to be accepted and have more friends in the class who understand them and involve them in their talks and play.

The parents sees their children with intellectual disability have higher responsibility on subscale items like shows concern for friends and relatives of his/her own, follow household rules, informs you before going out with friends, say nice things about himself/herself etc higher .

This is due to Parents’ ratings provide a wider range of information, because they observe their children in a variety of settings across a long period of time. At times, however parents are not familiar with the purpose of the assessment and also may not have experience with various types of deviant behaviors.

The children with intellectual disability rated themselves higher in the empathy subscale includes items like say nice things to others, ask friends for help, smile, wave and nod at others, tell other people when they have done something well etc.

Research suggests that there is an important link between student social skill development and academic development. In a study found that⁽⁵⁾Children’s academic skill development and their social skill development often are closely related. Research has demonstrated that social behaviors in the classroom predict academic achievement have found that most children who have social adjustment problems also experience problems in academic areas, such as reading skills⁽⁶⁾.Students with higher social functioning exhibit less problem behaviors in the classroom and more academic competence.

Discussion

The objectives of this study were to analyze the social skills strength, deficit and acquisition among children with mild intellectual disabled in inclusive education. The study also aims to study the attitude of the peers and parents of children without disability towards children with mild intellectual disabled.

Based on the findings of the research the children with mild intellectual disability are lagging behind their normal peers when building social skills. There are several steps that can be taken to ensure students with special needs are offered an opportunity to create social interactions with peers. The regular teacher has to play an interactive role in order to promote social inclusion.

Research has also found that inclusive education practice has a positive contribution on students’ peer relations and social skills .When provided with inclusive education during the early years of their life, children are likely to have shared interactions with peers and adults. This promotes growth, the positive change, and their desire to learn. “Children become open to learning and change, and with their flexible point of view they are able to empathize with their peers have special educational needs, they develop tolerance and understanding towards their peers with special educational needs during inclusion”.

Ethical Clearance: This study was undertaken

with the consent from the participating children, their teachers and families. The children with mild intellectual disabilities were the main respondents for the study. The institutional research and review body explicitly approved the conduct of this research.

COVID-19 as a Conscious Organism: A Novel Understanding of the SARS-CoV-2 as a Natural Evolution of the SARS Virus

Asima Tripathy¹, Rajat Kumar Pradhan²

¹Post Graduate Department of Zoology and Microbiology, ²Post Graduate Department of Physics, Bhadrak Autonomous College, Bhadrak, Higher Education Department (Govt. of Odisha)

Abstract

The RNA virus SARS-COV-2 that has led to the outbreak of the worst ever pandemic has one particular enhanced virulence factor, the spike protein in the Receptor Binding Domain (RBD). We discuss its evolution from earlier strains of respiratory infection causing viruses in terms of increased incubation period and symptomatic width. We propose that any disease can be considered as an evolving conscious organism having its own teleological evolutionary pathway, the pathogens, vectors and hosts being merely the vehicles of its transmission, and not its causes. In this perspective even if it is the result of some sinister design by genetic modification in laboratory, it still can be considered as its natural evolution only, in which the scientists themselves became its extended evolution and transmission vehicles, which made it defy the existing medical knowledge, methods, resources and efforts. In an expanded scheme the pathogens like SARS COV-2 are to be considered as predator species for their human hosts. We conclude that only with conscious awareness of expression of emotions keeping reasonable restrictions on oneself mankind can ever hope to address such pandemics.

Key words: COVID-19, SARS-CoV-2, SARS, virulence enhancement, consciousness, teleological natural evolution.

Introduction

There has been an ongoing debate on whether the SARS-CoV-2 was a bioengineered product of a biological weapons development laboratory in Wuhan, China or whether it was a natural evolution from the earlier strain SARS virus^[1]. The common characteristic that grants the family of coronaviruses their lethality is their being RNA viruses. They specialize in attaching to the host cell's ribosome to replicate without any need for

penetrating into the mitochondria or nucleus. We propose that even if it is a bioengineered product it can still be seen as a product of natural evolution. The question that we pose is: Of all the viral strains available, why did the researchers fall for the SARS virus for engineering? The SARS virus itself was not bioengineered by researchers but had highly developed, naturally endowed virulence factors. This points to some deeper underlying truths about diseases and their appearance as part of natural evolution.

Table:1: Progressive width and severity of symptoms from respiratory viral infections

Sl. No.	Disease	Symptoms	Incubation period
1	Allergy	Dry cough and Sneezing	1 sec -- 24 hrs
2	Common Cold	Cough with mucous, Sneezing and Nasal discharge	1 -- 3 days
3	Flu	Cough with mucous, Sneezing, Nasal discharge, Body ache, Fatigue and Low fever	1-- 4 days

Cont... Table:1: Progressive width and severity of symptoms from respiratory viral infections

4	Swine flu (H1N1)	Fever, cough, sore throat, chills, body ache	1-7 days
5	Avian flu(H5N1)	Cough, fever, sore throat, headache, muscle pains, shortness of breath	2-8days
6	SARS	High fever, chills, headache, pneumonia, hypoxia	2-10 days
7	COVID -19	Dry cough, Sneezing, Sore throat, Body pain, Fatigue, Oppressed breathing and High fever	1—14 days

Table 2: Pathogenic genus of the Corona viruses, Hosts and symptoms

Sl.No	Genus	Host	Symptoms
1.	Alpha	Human	Mild respiratory tract infection
		Pig	Mild respiratory tract infection, Diarrhoea, Vomiting
		Dog	Diarrhoea
		Camel	Asymptomatic
		Cat	Fever and Serositis
2.	Beta	Human	Pneumonia, Mild respiratory infection, Severe acute respiratory syndrome
		Cow	Diarrhoea
		Horse	Fever, anorexia
		Mouse	Pneumonia and Severe Lung injuries
3.	Gamma	Whale	Pulmonary disease, Acute liver failure
		Chicken	Severe respiratory disease
4.	Delta	Bulbul	Respiratory disease
		Sparrow	

It is clear from Tables-1 and 2 that SARS-CoV-2 is a mutation of SARS virus to enhance incubation period and the capacity to create fluid accumulation in alveolar edema leading hypoxia.

Action of Hydroxychloroquine on SARS CoV-2

In order to penetrate cells by membrane fusion and uncoating the SARS COV-2 requires its surface spike proteins to be activated by lysosomal proteases which attach to the angiotensin converting enzyme 2 (ACE-2) receptors in the outer tissue layers of lungs, heart, kidneys and intestines of humans. Hydroxychloroquine used as an antiporozoan in malaria treatment is weakly basic in character which increases the pH of

the endolysosome thereby inactivating the lysosomal proteases. This is how Hydroxychloroquine proves beneficial in treatment of COVID-19.

We take the example of malaria as an epidemic to bring into focus certain hitherto unexplored and unthought of aspects of diseases.

Malaria as a typical example

In case of malaria, does the Plasmodium parasite consciously work on the vector to instruct it to transmit the sporozoite into the human bloodstream so that its lifecycle can be completed^[2]? Does the mosquito vector get some release by transmitting sporozoites into the human bloodstream from its salivary apparatus^[3]?

The human being tries its best not to get infected with malaria and struggles hard by taking all precautions not to be bitten by the mosquito. The vector undergoes great struggle in its physiological and biochemical level to carry sporozoite and the vector struggles hard to evade the parasite growth in its body^[4]. And finally, the parasite must not have wished to follow such a complicated life cycle to complete its process of multiplication. Thus in this whole cycle, the Parasite, the Vector and the host are all consciously engaged in evading the whole process. Still, the process continues to occur in a very systematic manner and thus ensures:

1. The successful reproductive fitness of the parasite.
2. Vectorial capacity in the mosquito vector with assured sporozoite transmission.
3. The successful proliferation of “malaria” as if it were a conscious being.

Our view of an organism as a physiological unit is rather restrictive in its scope and content and we need to cross that barrier to better appreciate the existence and evolution of diseases alongside that of species. We don't as yet have any understanding of what makes an organism an organism: that is, how does an organism behave as a coordinated whole with lot of autonomous processes incessantly going on to maintain and sustain itself as such, without its conscious agency? We have, in earlier works, proposed about the organism being essentially a set of psychic impressions beyond space-time, which awaken to become instincts and then get activated as urges leading to manifestation in the physical plane as the morphological structure of the organism^[5-7]. In the psychic dimension, therefore, the disease can exist in a progressively grosser form as a set of impressions or instincts or urges, in that order, which have been necessitated by certain past experiences stored in the memory of certain species as essential ingredients of their existence and evolution. Such a set of impressions/instincts/urges is itself recognizable as the subtle form of the disease-organism and as a precursor to the appearance of the corresponding organisms as its pathogenic vehicles with their continuously evolving pathogenicity.

Disease as a conscious being

We find that even with so much of scientific and technological advancement, the most aware and technology-enabled human is not yet able to get rid of malaria. Whatever precaution one may take, all the ideas fail when we confront the fact that a ‘single bite of the infected vector can cause malaria in the human’. And, the human being therefore, cannot avoid being infected. It clearly indicates that the conscious mechanism that plays a role in the form of ‘**malarial disease**’ is teleological and the whole design is due to conscious mechanism of the disease-organism called ‘**MALARIA**’, which succeeds to manifest finally without fail^[5]. The struggle in all the three levels of the parasite, the vector and the host is seemingly conscious too, as it is designed by the final unfailing conscious mechanism of the teleological evolution^[8].

Similarly, the modes of pathogenic transmission through very fundamental, normal and unavoidable survival modes such as respiration or intake of food and drink point to the fact of there being a tremendously intelligent design by the disease-organism to spread unfaithfully. The SARS-CoV-2, for example, has a dangerously high rate of spread by modes of mutual contact, inhalation or ingestion to other individuals from a single infected individual. It spread more dangerously faster than the proverbial *wildfire* to infect whole continents! Risk factor for it is far more than any other pandemic in known human history.

The first necessity for the existence of such pandemic generating pathogens is as population regulators since they perform the role of predators for the species they prey upon or infect. The exact mode of transmission has to be unfailing to ensure their functional success. Evolutionary mechanisms come into full play once the tussle between the host-prey and the disease-predator starts and at the physiological level it appears as the ever-evolving war between the disease-transmitting pathogens and the antibodies generated in the host-system^[9].

Endemic or Pandemic- Virulence Enhancement is the goal

The pathogens such as viruses and bacteria, the vectors such as mosquitoes, bats, pangolins, humans etc.

are merely the vehicles of transmission of the disease and not the causes thereof. A disease in the form of an endemic can be seen as the subtler form of an organism which is manifest through the network of Parasite, Vector and Host with the sole purpose of spreading to ever larger dimensions with much stronger virulence factors. The urge to spread by infection and transmission appears as the viral genome with ever evolving virulence factors. This perspective is applicable to all viral and bacterial epidemics and can help us understand them at a deeper level and enable us to develop effective mechanisms against them. One particular virulence factor, the spike protein in the Receptor Binding Domain (RBD) became more potently manifest in the SARS-CoV-2 causing the worst ever pandemic COVID-19^[1]. The increased virulence seen here is same as with other pathogens, whether it is drug resistance in the pathogen, insecticide resistance in vector and immunoglobulins or antibodies in the host. They are for their conscious evolutionary advantages only^[10, 11]. Re-emergence of the importance of Chloroquine drug which was stopped to be employed for malaria intervention due to Plasmodium drug resistance for around a decade, is also to be taken into account as its conscious evolution to re-materialize as a chemotherapeutic agent of further more crucial importance and it was well anticipated too^[12]. Similarly, in case of cancer, nature selects some cells that can develop aggression and resistance as the vehicles of the transmission and manifestation of the oncovirus^[13,14,15,16,17].

Conclusion

Our proposal indicates several levels of tackling the phenomenon of diseases, starting from the core psychic domain to the level of chemical interventions or medicines as a therapeutic strategy. Certain undesirable habits of instinctive mutual contact among individuals which in case of humans is inherited, imposed and practiced by way of modes of greeting or other conformatory socio-cultural norms. It is through these contacts that the pandemic like COVID-19 has spread so fast and so successfully. There are many other lessons to be learnt following this line of approach that we have advocated here.

Implications for Human Evolution:

We have recently proposed the viral origins of life, its

evolution and ultimate dissolution through *The Cancer Principle*^[13,14,15,16,17]. SARS CoV 2 being an RNA virus predates the known onco viruses (DNA viruses and has emerged as a predator for humans vindicating our proposal of ubiquitousness of Prey Predator Relationship in nature⁹. From this point we as a species have only two possibilities of evolution; (1). We may develop antibodies naturally or artificially through vaccination against such viruses. (2). If we fail to develop antibodies then it will be a permanent acceptance of such pandemic viruses as the predator species for humans. The first alternative will lead to competitive evolution while the second is some kind of capping on evolution^[18].

The researchers who fell into the trap of developing it further into the SARS virus were obviously prey to such enticing and intensifiable virulence factors available in it. The SARS virus, the researchers, the funding agencies all together form components of the widespread virulence enhancement network of the SARS virus. Therefore, seen in this perspective, SARS-Cov-2, even if it is a bioengineered product, is apt to be called a natural evolution of the SARS virus^[19]. If HIV warned mankind on unrestrained expression of passion, SARS CoV-2 has cautioned us on unrestrained expression of emotion. Seen from this angle, it has deeper penetration than HIV to the inner layer of emotion that often is a precursor to the expression of passion. One may wonder, what will be the next evolution of virulence and to which unavoidable mode of transmission it will adapt. As of now, medical science is completely undone, with only one choice of control of the spread of COVID 19 - 'to be conscious'. We have to be eternally vigilant to be safe from infection. Social distancing has to be the order of the day everywhere and for all times and for everyone. It is not that we were unaware of viral and bacterial transmission of infections through contact. Still because of the treatability low risk factors associated, we could take the liberty of continuing with our old ways and habits of unrestricted mutual contact and sharing and what not. Now we have to be cautious and conscious every moment of our interaction with others keeping in mind the increased severity and the risk factors of COVID-19.

Diseases can be somewhat broadly classified as per their occurrence and endemicity in different sections of human society. For example most of the life style

diseases (LSD) such as diabetes, obesity, High BP, hypertension etc. are mostly diseases of the rich and the affluent, while the diseases such as low BP, hepatic, pulmonary and enteric diseases are mostly characteristic of the poor. HIV-AIDS and COVID-19 are diseases of the unaware or unconscious lot and tend to point out to humanity its dangerous ways of social culture. A pandemic of such order has certainly great lessons for raising the consciousness level of humanity, even if we succeed in eventually dealing with it effectively through vaccination or medication. Truly, nothing in science makes sense except in the light of 'consciousness'^[20].

Knowledge, Awareness and Attitudes About Hepatitis B Infection and Its Vaccine among Health Care Workers at a Tertiary Care Centre in Eastern India

Ayaskanta Singh¹, Bijayalaxmi Balirasingh², Pratishya Bhatt³, Jimmy Narayan¹

¹Associate Professor Department of Gastroenterology, I M S & SUM HOSPITAL, Bhubaneswar, Odisha, India, ²Staff Nurse, PBSSC NURSING, I M S & SUM HOSPITAL, Bhubaneswar, Odisha, India, ³Research Scholar, I M S & SUM HOSPITAL, Bhubaneswar, Odisha, India

Abstract

Background: Hepatitis B virus (HBV) infection is a major health problem worldwide. The aim was to assess the knowledge, awareness and attitudes about HBV infection and its vaccine among HCWs at a tertiary care centre in eastern India.

Method: The study was carried out among 210 numbers of randomly selected HCWs of IMS and SUM Hospital. Answer to questionnaire about different aspects of HBV infection and its vaccine were assessed.

Results: Majority of the participants were females (90%) and within the age group 15-25. A large majority (> 95 %) of the participants were aware of HBV infection and vaccination and all these persons have been vaccinated against HBV. Most of the health care workers (> 90 %) were aware that hepatitis B spread through infected blood, infected razors and vertical transmission. When asked that if one is vaccinated against HBV & gets a needle prick injury, only 5% correctly said that nothing needs to be done if one is adequately vaccinated. When asked if one is not vaccinated & gets needle prick from a HBV infected person, then majority (89 %) of the HCWs said one need to take HBV immunoglobulin alone. The participants had another question which was whether there is the need for booster dose after completion of vaccination, only 37% of the HCWs correctly.

Conclusion: There is very good awareness and knowledge regarding HBV infection and its vaccine among the HCWs. This is probably due the practice of universal and free vaccination that the hospital follows.

Keywords: - HBV, KAP, HCW, Community Practice, Vaccination, Needle Prick

Introduction

Hepatitis B virus (HBV) can cause chronic hepatitis which can lead to cirrhosis of liver and hepatocellular malignancy and liver failure in a significant number of patients.¹ Worldwide, approximately 2 billion people have been infected with HBV.² India lies in the intermediate endemic zone, the prevalence of the virus being around 2-8%.³ HBV is 50–100 times more infectious than HIV.⁴ The HBV is present in high concentration in blood, serum, saliva, semen, vaginal fluid and most of body fluids. Vertical transmission from mothers to neonates, transmission through unsafe sex, unsafe injections and body fluids like blood remains the

most common route of infection for hepatitis B virus.^{5,6} Another important route of entry includes accidental inoculation of minute quantities of blood during the surgical and dental procedures.⁶ Health care workers (HCWs) are at high risk for HBV infection as compared to normal population. Various studies have shown that HCWs had a prevalence of HBV infection approximately 10 times greater than the general population.⁶ HCWs do not recognize all exposures to potentially infectious blood or body fluids. Few studies published from India have shown that the awareness of HBV infection and its vaccine in the community is believed to be very poor.⁷ The objective of the study was to assess the knowledge,

awareness and attitudes about HBV infection and its vaccine among HCWs at a tertiary care centre in Eastern India.

Materials and Method

This was a cross sectional study which was conducted at a medical college, IMS and SUM hospital, Bhubaneswar during the month of November 2018. Two hundred ten health care workers (HCWs) of the hospital were randomly selected and included in the study. These health care workers were mostly nurses, pharmacists and laboratory physicians. Doctors and students were excluded. The age, gender and qualifications of the HCWs were noted. All these HCWs were subjected to a predesigned questionnaire [containing 15 questions] on hepatitis B infection and its vaccine (Image 1). Verbal informed consent was obtained from the participants and strict confidentiality maintained.

HCWs, who had a history of HBV infection, unlikely to come in contact with blood/body fluid, and those who did not agree to participate were excluded from the study. Effectively vaccinated subjects were defined as those who had received three doses of hepatitis B vaccine according to the schedule (0, 1 and 6 months).

Results

Two hundred ten randomly selected HCWs were included in the study. Majority of the participants were females (90%) and within the age group ¹⁵⁻²⁵. All the 210 (100%) selected HCWs were aware of hepatitis B infection. A good number of the health care workers (97%) were aware of Hepatitis B vaccine. When these health care workers were inquired regarding the source of awareness for HBV infection, most of the participants (76%) said that it is because of medical training and 21% of the participants knew about HBV infection from mass media communication (television and radio). When

asked about the route of HBV spread, a large number of participants (95 %) said that HBV infection can spread through infected blood and most (93%) of the participants identified correctly that HBV can spread through infected razors. A good number of participants (88%) identified that HBV infection can have vertical transmission from mother to fetus. Almost everyone (97%) were aware that HBV can affect the liver. About 2/3rd of the participants (63%) correctly said that the virus can lead to acute liver failure, cirrhosis and hepatocellular carcinoma. According to the present survey, most (88%) participants said that HBV infected patients can lead normal life with family members. When asked what percentage of acute HBV infection spontaneously resolves in adults, the opinion was divided among the participants. One third (35%) said that the infection can resolve in only 20 % of cases; while only 16% said that acute hepatitis B spontaneously resolves in more than 90 % of adults. The HCWs were then inquired regarding the post exposure prophylaxis (PEP) following needle stick injury with an infected patient. When asked that if one is vaccinated against HBV & gets a needle prick injury, 52% of the participants said that HBV immunoglobulin needs to be given, 38% said vaccination is required and 5 % said anti-viral drugs needs to be started. Only 5% said that nothing needs to be done as PEP if one is adequately vaccinated. When asked if one is not vaccinated & gets needle prick from a HBV infected person, then majority (89 %) of the HCWs said one need to take Hb immunoglobulin. The participants had another question which was whether there is the need for booster dose after completion of vaccination, 74(37%) correctly said that there was no need of taking booster dose again, while a similar percentage (36%) said that there is a need of booster dose after five years. When asked about vaccination status, around 188(94%) of the participants replied that they were effectively vaccinated while the rest did not.

Image 1 – Questionnaire for HBV awareness

Questionnaire for the study -

1. Are you aware about Hepatitis B (HBV) infection?
Yes No
2. Hep-B can be prevented through the following?
Vaccine, Tablets. Not preventable, Universal precautions.
3. Are you aware regarding Hepatitis B Vaccination?
Yes No
4. Source of awareness?
Reading Newspaper, b. Watching TV c. Listening to radio, d. Medical training.
5. How Can HBV spread among relatives by sharing?
Utensils, Razor, Bed linens, Comb Touching
6. If one who is adequately vaccinated gets pricked needle one should go for?
Vaccine. Hb immunoglobulin. Drugs. None.
7. One who is not vaccinated & gets needle prick from a positive (+) person then one needs to take?
Only Vaccine. Hb immunoglobulin + Vaccine. Drugs. None.
8. Which organ will be affected in HBV infection?
Pancreas. Liver Kidney. Stomach.
9. Through which HBV infection spread from one person to another?
Blood Sneeze Water Street food.
10. Is that need for Booster dose after complete of vaccination?
5years. 2years. Not needed. Once a time.
11. Can HBV infection spread from mother to fetus & Newborn?
Yes . No.
12. HBV infection results in
a. Cirrhosis. b. Liver cancer. c. Acute liver failure. D. All of the above.
13. Acute HBV infection in adult spontaneously resolves in _____ % of patient?
85%. 90%. 20%. 95%.
14. Can a Hepatitis B patient lead a normal life with his/her family member?
Yes No
15. Are you vaccinated?
Yes No

Table 1: Comparison of studies from various parts of the world regarding HBV awareness among health care workers and others

Region	Authors	Number	Types	Whether aware of HBV?	Whether aware of HBV vaccination	Whether vaccinated?
United Kingdom	Ogden et al8	649+224	Medical and dental students		99.2%	99%
Saudi Arabia	Paul T et al9	126	Dentists	100%	100%	85.7%

Cont... Table 1: Comparison of studies from various parts of the world regarding HBV awareness among health care workers and others

India	Sukriti et al10	2162	HCWs	~	~	55%

India	Rathi et al18	161	Medical students(1st&2nd year)	~	96%	40%
Present study		210	Nurses and pharmacists	100%	97%	97%

Discussion

It was seen that most of the participants were females, with male: female ratio of 9:1. This is because most of the participants were nurses and lady pharmacists. In the present study, it was observed that 100% staffs are aware of Hepatitis B virus and 97% were aware of Hepatitis-B vaccination. Table 1 shows the various studies done from different parts of the world and also from India done on the knowledge and awareness about the virus and its vaccine among health care workers.⁸⁻¹⁸ This study has included only the nurses and pharmacists. Still surprisingly the awareness about HBV infection and its vaccine is almost 100%. This is probably due to the fact that the hospital follows an universal and free vaccination against hepatitis B. In fact when these HCWs were asked regarding the source of knowledge, majority replied they were taught about HBV during their medical training and also during time of vaccination. Similar favourable

and 100 percent results have been seen among medical and dental students of Dungee, United Kingdom.⁸ The policy of that college also calls for universal vaccination. There are various KAP studies from India on medical students, doctors and dentist regarding hepatitis B and its vaccination. [Table 1] A study from Odisha, albeit done two decades back, has shown that the vaccination status was abysmal 2% among nursing students while it is comparatively higher among medical and dental students (~ 80 %) ¹⁹ A study from northern India showed that only 56% of the HCWs were adequately vaccinated.¹⁰ Another study from Chhattisgarh showed that both awareness and vaccination status among the first year students is very low (only 18% are vaccinated). However the awareness and vaccination status increases among the final year year students.²⁰

Previous studies have shown that HBV infected patients are discriminated, just like HIV patients, not only by health care providers but also family members.²¹ However in this study, it is commendable that around 90 % of the HCWs agree that these HBV patients can lead a normal life with his family members and that the infection does not spread by touching or eating together. Similarly around 90% of the health workers know that HBV infection can have vertical transmission from mother to child. This study shows that there is some ignorance and confusion regarding post exposure prophylaxis (PEP) against hepatitis B and regarding the need for booster dose. The good thing that the study illustrates is that most of the health care workers have heard of HBV immunoglobulin and vaccine as PEP. The study also shows that the most of the health care workers are not aware that there is no need of a booster dose of HBV vaccine.

There are few limitations of the study. Only a randomly selected 210 HCWs were enrolled in the study, whose opinion may not represent the whole community as a whole. Second limitation is that the all the information was self-reported which may not reflect accurate knowledge.

Conclusion

Almost 95 % were vaccinated adequately against HBV infection and this practise of free and universal vaccination at the hospital is the probably the reason of very high awareness about HBV infection among the HCWs. There is also good knowledge regarding different aspects of HBV infection.

Systematic Review on Quality of Life among Migraine Sufferers

B.Jayabharathi¹, K.Silambuselvi²

¹Professor , ²Assistant Professor, SRM College of Nursing, SRM IST, Kattankulathur Chennai

Abstract

Migraine is a neurologic disorder characterized by a cycle of attacks, including headache, separated by attack-free periods. Increasingly, episodic migraine is recognized as a disorder that may escalate to chronic migraine, with a frequency of 15 or more attacks per month. Migraine exacts a toll on the quality of life (QoL) of affected individuals, their families, and their workplace. The objectives of the study were to review the related studies and to understand the evidences regarding the quality of life among migraine sufferers. This article presents the review of literature relating to the studies carried out by various researchers in the area of quality of life among patients with migraine.

Keywords: *Quality of life , Migraine, sufferers*

Introduction

Migraine is a neurologic disorder characterized by a cycle of attacks, including headache, separated by attack-free periods. Increasingly, episodic migraine is recognized as a disorder that may escalate to chronic migraine, with a frequency of 15 or more attacks per month. Migraine exacts a toll on the quality of life (QoL) of affected individuals, their families, and their workplace. Migraine adversely affects a patient's QoL during an attack, but also has an impact between attacks. This burden on the patient manifests itself as worry in anticipation of the next painful attack and concern over its possible adverse impact on future plans or activities. The high prevalence of migraine, 12% in industrialized countries and approximately 28 million people in the United States, is considered a low estimate. Patients with disruptive migraines frequently overuse self-prescribed medications or may postpone a visit to a physician, which

delays accurate diagnosis and appropriate treatment for migraine. An extensive literature search of migraine reviewed its associated disability and reduced QoL during, and especially between, attacks. Nevertheless, patients with frequent and recurring migraines, who suffer a reduced QoL, continue to be under recognized and undertreated.¹

Aim of the Review: The aim of the this study was to identify the evidences on quality of life among migraine sufferers.

Objectives of the Review

- To review the related studies regarding the quality of life among migraine sufferers
- To understand the evidences of on quality of life among migraine sufferers

Materials and Method

Quantitative approach and descriptive design was used for this review. The need for the study was identified , the review was done by using different search strategies , adopting the interfaces and databases .The collected data was noted for clarity and used in this study.

Eligibility Criteria: The review was done to identify the relevant articles that describe the quality of

Corresponding Author :

life among migraine sufferers.

Inclusion Criteria:

- Studies related to assessment of quality of life among migraine sufferers
- Literatures published in English language
- Literatures published in the year 2013-2018

Exclusion Criteria:

- Studies with inadequate information on the research methodology
- Studies related to the effectiveness of intervention on quality of life among patients with migraine

Literature Search Strategies and Data Source

To gain an understanding regarding the quality of life among migraine sufferers, the author performed a systematic search of literature mainly from electronic databases such as MEDLINE, Pubmed, EBSCO Host, Science Direct, Wiley Online Library, CINAHL, Google Scholar. The review was restricted from 2013 to 2018. Reviews were mainly collected by using the following keywords; quality of life & Migraine .

Data Analysis

The data analysis comprised of three stages;

- Developing a preliminary synthesis of studies
- Exploring the studies based on the various objectives
- Summarizing the findings: The following data were extracted and tabulated as Author, year of publication, methodology, instruments/ techniques, sample size, setting, tool utilized and major findings

Results

The articles included in the review were published in the time period of 2013-2018, which are discussed as follows:

The study conducted by **Kartavya Sharma, etal²**, 2013 among newly diagnosed migraine patients in Headache clinic of a tertiary referral center. The

findings revealed that Migraineurs were significantly impaired in all subscales of the SF-36 compared to controls, with greatest impairments in role physical, general health, and role emotional subscales. Prevalence of clinically significant anxiety (48%) and depressive (41%) symptoms in patients was higher than in healthy controls. HRQoL is significantly reduced in Indian migraine patients compared to healthy controls. The study done by **Raggi A ,etal³** 2013 , revealed that, migraine frequency and intensity were almost stable over 3 months, and an evident trend toward improvement was found in disability and in some health-related quality of life aspects, particularly in the social activity domain. Our results clearly indicate that continuity of care has a positive impact on patients' health status and functioning, also in stable patients already on anti-migraine therapy, and that the use of patient-oriented outcome measures is a viable way to capture such improvements.

Sulmaz Ghahramani, etal⁴ 2014 studied 100 Patients with migraine treated with both propranolol and topiramate. the results showed that, after treatment, the highest score belonged to physical problem and the lowest one was emotional problem. Men had significantly higher scores in body pain compared to women (P = 0.039). Combined migraine prophylaxis with propranolol and topiramate improved HRQOL in migraine sufferers in this study. Another study by **Kim SY, Park SP⁵**, 2014 evaluated the contribution of headache chronicity to QOL in relation to clinical, psychiatric, and psychosocial variables in patients with migraine. Among 251 eligible patients, 183 (72.9%) had episodic migraine (EM) and 68 (27.1%) had chronic migraine (CM). Patients with CM had more serious clinical, psychiatric, and poor QOL than did patients with EM. Chronic migraine appears to impair QOL directly as well as indirectly by provoking disability and depression.

Shaik MM, etal⁶ , 2015, conducted a study to measure QOL among migraine sufferers in comparison with healthy controls. Females with migraines had significantly lower total WHOQOL-BREF scores than did healthy controls . Similarly, physical health and psychological health scores were significantly lower than those for healthy controls. The present study showed that migraine sufferers experienced significantly lower QOL than the control group from a similar population.

Cha MJ⁷, 2017, conducted a study among 186 CM patients. The stress group had more patients with poor outcomes of acute treatment than the reference group. High levels of stress were reported by 42.5% of patients with CM. Another study by **Al-Hashel JY**⁸, 2017 aimed to measure the prevalence of migraine and to assess its burden in Kuwait. A total of 15,523 subjects were identified; of whom 3588 (23%) were diagnosed as episodic migraine and 845 (5.4%) as chronic headache. Prevalence of episodic migraine was 31.71% in female versus 14.88% in males ($P < 0.01$) with a mean age of 34.56 ± 10.17 years. Migraine in Kuwait is highly prevalent and it has a significant impact on activity of daily living, schooling/employment and social occasions of patients. Accurate diagnosis, effective abortive and preventive treatments of migraine are paramount to improve quality of life and as well as cost saving.

Sumit Singh, etal⁹, 2017 done a study among 705 Migraine patients in 10 Centres. They used HRQoL using Migraine Specific Quality of life (MSQ) and Migraine Disability Assessment Scores (MIDAS) questionnaire. Hypertension (7.0%) was the highest comorbid illness associated with migraine. Majority of patients had pulsating, bilateral attacks for the duration of 4h to 72 h. Paracetamol (47.1%) and propranolol (50.9%) was most commonly prescribed drugs for acute attack and prophylaxis, respectively. Cardiovascular diseases, diabetes mellitus and anxiety were common comorbidities associated with migraine.

Benz T etal¹⁰, 2017, conducted a pilot study and found that moderate to high levels of pain and self-reported disability owing to headache were observed, whereas physical function on the SF-36 was not different from the expected level of the norm. Mental health was substantially affected in several dimensions, which had been described to reduce the ability to cope with pain. MOH patients seem to have high expectations of functionality, low symptomatology, and intact well-being.

Hanson LL, etal¹¹, 2018, reported that Visual quality of life is significantly adversely affected in migraine sufferers. In fact, patients with chronic migraine may have visual quality of life impacts that are as significant as those associated with other common neuro-ophthalmic disorders. Future studies of the overall

disease burden in patients with migraine should include an evaluation of the effects on visual functioning.

Discussion

The total review articles included in the study are 10, in time period of 2013-2018. The methodology utilized was cross-sectional quantitative survey in most of the studies (8 out of 10), one was longitudinal observational study with a 3-month follow-up and 2 was Interventional study. Participants were recruited from different settings, including headache clinic (6), hospitals (2), headache program (2). The samples of the study were patients with migraine. Majority of the subjects were diagnosed by Short Form-36, Migraine Disability Assessment Score, World Health Organization Disability Assessment Schedule, second version, Migraine-Specific Quality of Life (MSQoL), Malay version of the World Health Organization QOL Brief (WHOQOL-BREF) questionnaire. Studies were done in various countries across the world which includes Germany, Italy, India, USA, Kuwait, Korea(2), Malaysia, Iran. Sample size in all studies varied from 71 to 4433. The results of all studies showed that, quality of life was significantly reduced in migraine patients.

Conclusion

The present study showed that migraine sufferers experienced significantly lower QOL. Clinically significant association was found with migraine and anxiety and depressive symptoms. Accurate diagnosis and preventive measures for migraine are very important to improve quality of life of migraine sufferers.

Limitations

- Most of the studies were from foreign countries
- Only 10 studies were taken for this review

Conflicts of Interest: Nil

Source of Funding: Self Funded

Ethical Consideration: The research title was approved by research committee of SRM college of Nursing, SRM IST, Kattankulathur, Kancheepuram district.

Protective Role of Royal Jelly and Honey against Cisplatin Induced Sperm Function Parameters in Male Rats

Bhalchandra Baburao Waykar ¹, Yahya Ali Alqadhi ²

¹Professor, ²Ph. D Researcher, Department of Zoology, Dr. Babasaheb Ambedkar Marathwada University, Aurangabad-431001, Maharashtra, India

Abstract

Background: Cisplatin is one of the cytotoxic agents in the treatment of cancer and has side effects on sperm function.

Objective: This study aims to investigate the ameliorative role of dietary bee honey and royal jelly against *cisplatin*-induced alterations in sperm function parameters in male wistar albino rat.

Methods: Male wistar albino rats of same age and weight were randomly divided into four groups; G, I: control group which was given 0.9% saline, G: II: *cisplatin* (7 mg/kg/d) was injected intraperitoneally for 15 d, G, III bee honey with royal jelly (500 mg/kg/d of honey and 100 mg/kg/d of royal jelly) fed orally daily for 15 d, G, IV: *cisplatin* (7 mg/kg/d) was injected intraperitoneally and honey (500 mg/kg/d) and royal Jelly (100 mg/kg/d) fed orally daily for 15 d. The sperm function parameters like sperm count, sperm viability, sperm motility, weight of epididymis and testis were measured by using a hemocytometer under the microscope at 100X magnification.

Results: *Cisplatin* treated rats revealed a significant decrease in sperm count, sperm viability, sperm motility, weight of epididymis and testis as compared to control group. Royal jelly and honey treated group of rats revealed a significant increase in all sperm function parameters compared to control group. Dietary bee honey with royal jelly along with *cisplatin*-treated rats revealed significant increase as compared to animals treated with *cisplatin* (G, II).

Conclusion: Bee honey and royal jelly could be used as dietary preventive natural products against *cisplatin*-induced sperm function parameters alterations during the treatment of cancer.

Keywords: *Wister albino Rats, sperm function parameters, Cisplatin, Honey, Royal jelly, Role, Testicular damage.*

Introduction

The infertility is a disease of the reproductive system defined by the failure to achieve a clinical pregnancy after 12 months or more of regular unprotected sexual intercourse ¹. There are many reasons that cause infertility including cisplatin treatment. Cisplatin is anticancer chemotherapy drug used against several human cancers ². Despite the fact of its effective anti-cancer action, it exerts many unwanted adverse effects, including spermiotoxicity ³.

Honey and royal jelly are natural dietary substance has been previously investigated to ameliorate the

toxic side effects of different substance, through its antioxidant, free radical scavenging and anti peroxidative activity ⁴. Royal jelly has been associated with positive effects on human fertility, where it is effective on premenopausal symptoms, osteoporosis, improving hormonal equilibrium and fertility in women and men by increasing ovules and sperm quality ⁵.

The aim of the present study was to investigate the ameliorative role of honey and royal jelly against cisplatin induced alterations in sperm function parameters in male Wister albino rat.

Materials and Method

Animals: Healthy male wistar albino rats weighing 200-250gm (10-12 week age) were obtained from the animal house of R. C. Patel Institute of Pharmaceutical Education and Research, Shirpur-India. All animal experiments were approved by the Institutional Animal Ethics Committee (IAEC) of RCPIPER, Shirpur (Reg No. -651/PO/ReBi/S/02/CPCSEA). All the experimental procedures were carried out in accordance with the guidelines of the committee for the purpose of control and supervision of experiments on animal (CPCSEA).

Housing Conditions: The rats were housed in standard plastic cages. The bedding material of the cages was changed every day. Maximum of 3 rats housed per polypropylene cage having size of 32 X 11cm with stainless steel grill top mesh having facility for holding food palate and a water bottle. The rats were allowed free access to food, diet and water throughout the experimental period. All animals were housed in an air conditioned room at a temperature range between 22 -25°C, relative humidity in between 30% -60% and with a 12 hour light-dark cycle.

Chemicals: Cisplatin was purchased from Cipla Ltd company- Goa, India. Honey and royal jelly collected directly from the *Apis mellifera* colonies located in the university campus, Dr. B.A.M.U, Aurangabad,(M.S) India. Food pallet was purchased from Nutrivet Life sciences, Pune, Maharashtra, India. All other chemicals used in the experiment were of analytical grade.

Preparation of Royal Jelly and Honey:

500mg of honey and 100mg of royal jelly were dissolved in distilled water and administered through an intragastric tube through the mouth. The doses were weighed on digital scales where each dose relies on the relevant animal's weight, in which every single gram of the experimental rat should receive 0.5mg of honey and 0.1mg of royal jelly.

Preparation of Cisplatin:

Cisplatin was taken (7mg/kg/day) of the bottle and inject the rat's intraperiton. Also the dose is relied on animal weight in which every single gram of the target animal should receive 0.007 mg of cisplatin for 15 days, and the injection intraperitonally.

Experimental Design:

For the study, 24 adult male wister albino rats of 10-12 week age and with 200-250g weight randomly divided into 4 groups; each group consisting 6 rats (n=6) and they were treated for 15 days as below:

Group I (Control): 0.9% (10ml/kg/day) saline solution was administered for 15 days.

Group II (Cisplatin): Cisplatin (7mg/kg/day) intraperitoneal injection for 15 days ⁶.

Group III (honey+ royal jelly): Honey (500mg/kg/day) +Royal jelly (100mg/kg/day) orally administered for 15 days ⁷.

Group IV (Cisplatin+honey+royal jelly): 7 mg/kg/day of cisplatin injected intraperitoneally while honey (500mg/kg/day) and royal jelly (100mg/kg/day) were orally fed through an intragastric tube for 15 days.

Estimation of total sperm count:

The epididymal sperm count was determined by hemocytometry (Neubauer chamber) and the method described in the ⁸. 5 micro liter aliquot of epididymal sperms was diluted with 95 micro liter of diluent (0.35% formalin containing 5% NaHCOR3R and 0.25% trypan blue). With the widened micropipette tip, 0.5 ml of this suspension was diluted up to 10 ml with saline. A few drops of the diluted sperm suspension as a sample, was transferred into a Neubauer's improved counting chamber (depth 0.1 mm) and allowed to stand for 5 min. The sperm heads was counted and expressed as million/ml of suspension

Estimation of total sperm motility:

10 microliters of semen was placed on a glass slide and covered with a lamella. Using a light microscope with a magnification of 400×, the number of sperm with rapid progressive forward movement (RPFM), slowly progressive forward movement (SPFM), Non-progressive motility (NPM) and motionless (ML) sperm cells were counted in several microscopic field of vision and percentage of motile and Immobile sperm cells was obtained ⁹.

Determination of sperm viability:

Sperm viability was evaluated as follows. 20µl of 0.05% eosin Y and nigrosin were added into an equal volume of the sperm suspension. After 2 minutes of incubation at room temperature, slides were seen by light microscope with magnification of 400×. Dead sperm cells were appeared pink and live sperm cells were unstained. In each sample 400 sperm cells were counted and viability percentages was calculated ¹⁰.

Results

Effect of administration of cisplatin (G, II), honey and royal jelly (G, III), and the combined administration of cisplatin with honey and royal jelly (G, IV) on sperm function parameters of male wistar albino rats were evaluated in comparison with control (G, I) and obtained results were summarized in table 1.

The results are demonstrated that cisplatin administrated rats (G, II), exhibits significant decrease

in the values of sperm count, sperm viability, sperm motility, weight of epididymis and testis compare to control. The percentage decreased were 54.7 %, 81.9 %, 70.8% and 32.8 %, 31.25 %, respectively.

In the present study, it was observed that oral supplementation of honey and royal jelly to rat (G, III), caused non-significant increase in the values of sperm function parameters like sperm count, sperm viability, sperm motility, weight of epididymis and testis as compare to control. The percentages of values increased were 8.2 %, 2.7 %, 2.7 %, 4.4 %, 6.25 % respectively.

Combined administration of cisplatin along with honey and royal jelly to rat (G, IV), caused significant increase in the values of sperm function parameters like sperm count, sperm viability, sperm motility, weight of epididymis and testis compare to animal administrated with cisplatin (G, II). The percentage increased were 60.60 %, 284.61 %, 119.04, 13.33.8% and 27.27 %, respectively.

Table 1: Effect of royal jelly and honey on cisplatin-induced changes on sperm function parameters in male Wistar albino rats

Group	(G, I) Control	(G, II) Cisplatin	(G, III) Honey and royal jelly	(G, IV) Cisplatin with honey and royal jelly
Sperm Count (103 /cmm)	7.30 ± 0.29	3.30 ± 0.42***a # (- 54.7 %)	7.90 ± 0.83NSa # (+8.2 %)	5.30 ± 0.42**b w (+60.60 %)
Sperm Viability (Live sperms / 100 sperms)	72.00 ± 1.2	13.00 ± 0.60***a # (-81.9 %)	74.00 ± 1.2 NSa # (+2.7 %)	50.00 ± 3.5***b w (+284.61 %)
Sperm Motility (Motility Sperm / 100 sperms)	72.00±0.88	21.00±2.3***a # (-70.8%)	74.00±2.9 NSa # (+2.7 %)	46.00±1.8 ***b w (+119.04 %)
Epididymis Weight (gm)	0.67 ± 0.037	0.45 ± 0.037**a # (-32.8 %)	0.70 ± 0.043NSa # (+4.4 %)	0.51 ± 0.034*b w (+13.33.8%)

1. Mean ± indicate S.E.M. of three observations

2. # (+) or (-) indicate percent variation over respective control (G, I) rats

3. w (+) or (-) indicate percent variation over cisplatin injected (G, II) rats

4. Values are significant at * $P < 0.001$, ** $P < 0.01$, *** $P < 0.05$, NS –Non significant

5. a = $P < 0.001$, ** $P < 0.01$, *** $P < 0.05$ values compared with respective control rats

6. b = $P < 0.001$, ** $P < 0.01$, *** $P < 0.05$ values compared with respective cisplatin injected rats

Discussion

In the present study the decrease in the sperm count, motility and viability was attributed due to cisplatin induced oxidative damages to testis. Cisplatin induces generation of free radicals that leads to degeneration of leydig and sertoli cells. Oxidative stress impairs male fertility by changing the cell function like sperm motility¹¹, increase in DNA damage by induction of gene mutations, DNA denaturation, base pair oxidation and DNA fragmentation. Therefore, poor sperm count, motility and viability may be associated with oxidative stress and DNA fragmentation¹². Cisplatin is known to induce apoptotic germ cell loss and also sloughing of seminiferous epithelium¹³ which severely affects sperm count. Therefore, the reduction in the sperm count, motility and viability of sperm may indicate cisplatin-induced testicular and epididymal toxicity. So, these results may refer degenerative changes and hypofunction of testis¹⁴ which causing to azoospermia.

The decrease in the epididymis and testis weights of rats was attributed due to oxidative damage to testis induced by cisplatin¹⁵. This suggests that testis and epididymis are vulnerable targets to cisplatin in rats. Reduction in the testis weight along with disrupted spermatogenesis is a well-known side effect of cisplatin-based chemotherapy¹⁶. It is accepted that the weight of the testis largely depends on the mass of differentiated spermatogenic cells which has been used as a crude measure of the damage to spermatogenesis¹⁷.

In the present study, it was observed that oral supplementation of honey and royal jelly to rat (G, III), caused non-significant increase in the values of sperm function parameters like sperm count, sperm viability, sperm motility, weight of epididymis and testis as compare to control. However, these observations may

be attributed to the antioxidant properties of honey and royal jelly.

In combined administration of cisplatin along with honey and royal jelly to rat (G, IV), leads to significant increase in the values of sperm function parameters like sperm count, sperm viability, sperm motility, weight of epididymis and testis as compare to cisplatin administered rats (G, II) (table 1 and fig 1, 2, 3, 4). Results indicate that honey and royal jelly ameliorated the cisplatin induced toxicity. Similar results were reported by many authors¹⁸. Royal jelly has been associated with positive effects on human fertility, where it is effective on premenopausal symptoms, osteoporosis, improving hormonal equilibrium and fertility in women and men by increasing ovules and sperm quality¹⁹.

In the present study it was observed that in combined administration of cisplatin along with honey and royal jelly to rat (G, IV), caused significant increase in the values of sperm function parameters like sperm count, sperm viability, sperm motility, weight of epididymis and testis as compare to cisplatin administered rats this might be due to antioxidant properties of honey and royal jelly. Several studies have shown that honey contains flavonoids, phenolic acids, some enzymes (e.g. glucose oxidase, catalase), ascorbic acid, carotenoid-like substances, organic acids, amino acids and proteins²⁰. Many of these compounds have been shown to be cytoprotective by scavenging superoxide anion, hydroxyl radical, hydrogen peroxides, other reactive oxygen species (ROS) and reducing lipid peroxidation²¹. The amino acid content of both honey and royal jelly may play a role as well by enhancing acrosome reaction, sperm motility, or improving fertilization²¹ and enhancing sperm motility by the short-chain fatty acids specific of royal jelly, especially 10-hydroxy-2-decenoic acid²².

Honey and royal jelly also significantly enhanced semen motility and count and this is can be interpreted by the increase in testosterone level which is responsible for motility of the sperms. Moreover royal jelly enhances the production of seminal fluid from secondary sex organs, which play the major role in the motility and viability of the sperm during the nutritional supply; in addition zinc content of royal jelly could play a role in enhancement of sperm motility.

Conclusion

In conclusion, the present study clearly indicated that the cisplatin treatment caused impairment of sperm function parameters. Treatment with honey and royal jelly protect and restore the normal condition of sperm function parameters caused by cisplatin. The protective effect of honey and royal jelly is attributed to beneficial biological properties of its components, has been determined to exhibit antioxidant capacity and its ability to inhibit oxidative stress by ROS neutralization as well as the chemical composition and physiological functions of its proteins and vitamins.

Organ Donation: Awareness, Attitudes and Beliefs among Undergraduate Medical Students

Bharani P.Jada¹, Meghana Kankanla², Ravi Kumar Jonnalagadda³

¹Assistant Professor ²Third year Medical Student ³Professor & HOD, Department of Community Medicine, Dr. Pinnamaneni Siddhartha Institute of Medical Science & Research Foundation

Abstract

Background: To save and extend lives, Organ Donation (OD) and Organ Transplantation (OT) have become the only hope. Knowledge and attitude of health care providers towards OD plays a major role in promoting this concept among population. Objectives: To understand the awareness about OD among medical students and to assess their attitudes & beliefs towards it. Material & Methods: A cross-sectional study was conducted among 494 medical students of Dr. Pinnamaneni Siddhartha Institute of Medical Science and Research foundation. Data was collected by using predesigned pilot tested self administered questionnaire. Results: 74.2 % students could give the correct definition of OD. Internet was a source of information for 25.7 %. 94.7 % of the students felt that OD is necessary to save lives. 75.1 % students responded that OD involves risk. 97.2 % students approve OD. Fear of surgery is the main (42.9%) cause of refusal among 56 students. Religious beliefs of 56.7 % students are for OD and 24.4 % believed that OD advances premature termination of treatment. 17.6 % believed OD encourages euthanasia. Discussion: Although it was found that majority of the medical students were aware of certain aspects of OD, there exists significant gaps like knowledge about organ registry and OD card. Still there are beliefs in the budding doctors that OD encourages premature termination of treatment. Conclusion: These gaps are to be met by introducing OD topics in various levels of their curriculum along with social and ethical aspects. The outcome of this appraisal shows the necessity for more debate on OD to prepare future healthcare professionals.

Keywords: Organ Donation, Awareness, Attitude, Beliefs

Introduction

In India, 500,000 people die every year because of non-availability of organs; 200,000 due to liver disease, 50,000 due to heart disease. 150,000 people await a kidney transplant but only 5,000 get one. 1,000,000 people suffer from corneal blindness and await transplant. Around 9.5 million deaths occur annually of which nearly 0.1 million deaths are due to organ failure. Though India has a population of 1.2 billion, organ donation rate is only 0.08 persons per million which is very insignificant when compared to the rest of the world.⁽¹⁾

To save and extend lives, OD and OT became the only hope ^(2, 3). OT is the most preferred treatment modality for end-stage organ disease and organ failures ⁽¹⁾. Many organs such as cornea, kidney, and liver are commonly transplanted to human recipients. However,

the need for the transplants is high and the gap between organs available for transplantation and the number of patients waiting for a transplant is widening globally⁽²⁾. There is a worldwide shortage of donor organs in comparison to the need for transplantation ⁽⁴⁾.

The shortage in organ supply is due to lack of awareness ⁽⁵⁾ among public, myths and misconceptions surrounding OD due to religious and cultural barriers leading to hesitancy in donation of human organs. There is a significant relation between public attitude towards OD and availability of such organs ^(6,7). It is identified that there is reluctance of family members to donate organs due to fear of surgery leading to loss to health ⁽⁸⁾. The prerequisites for the success of a transplantation program include awareness, positive attitude of the public toward OD and consent by relatives for OD in the event of brain death⁽⁴⁾.

In India, Transplantation of Human Organs Act, was passed in 1994 in order to regulate the removal, storage, and transplantation of human organs for therapeutic purposes. It also aimed at prevention of commercial dealings in human organs. The amendment to the act was passed by the parliament in 2011, and the rules were notified in 2014⁽¹⁾. As per the Transplantation of Human Organs (Amendment) Act 2011, the National Organ and Tissue Transplant Organization (NOTTO), a national level organization was set up under Directorate General of Health Services, Ministry of Health and Family Welfare, Government of India. The Standard Operative Guidelines, IEC Materials and Operational guidelines are available in the website (<https://notto.gov.in/awareness.htm>).

Knowledge and attitude of health care providers towards OD plays a major role in promoting the concept among population⁽⁹⁾. Studies have shown that health care providers including medical students lack adequate knowledge about OD⁽¹⁰⁾. The “Jeevandaan” programme (deceased donor program) of the Government of Andhra Pradesh has been facilitating organ distribution. By 2013 however, only 246 organs could be retrieved. The shortage of OD is the major limiting factor in the transplant program, in spite of improvement in graft and patient survival rate⁽⁶⁾.

The present study helps to identify the awareness, attitude and beliefs of medical students regarding OD.

Materials and Method

This is a cross sectional descriptive study, conducted from June 2017 to September 2017 at the Dr. Pinnamaneni Siddhartha institute of Medical Sciences & Research Foundation, Chinnoutapalli, Krishna district of Andhra Pradesh. Ethical approval was obtained from the Institution Ethical Committee (IEC) of the institution and 521 medical students from 1st year to final year were given the pre designed, pilot tested, self-administered questionnaire consisting of questions regarding socio demographic data, awareness, attitudes and beliefs on OD. Informed consent was taken from each participant. The questionnaire was distributed to the students in the lecture galleries and they were instructed not to

discuss the questions among themselves. Anonymity and confidentiality of respondents were maintained and participation was voluntary. 494 students completed the questionnaire with a response rate of 94.8 %. Only completed questionnaires were utilized for the study. The data obtained was entered in MS excel and analyzed. The results are presented as proportions and as tables.

Results

Majority (83 %) of the students were in the age group of 18 to 21 years. 67.2 % were females. The majority (87.9%) are Hindus. Nearly 66 % belong to OC category. 31.4 % students were from first year. 78.8 % participants came from urban areas and 82.6 % from nuclear families.

Regarding awareness, all students heard about OD and 99.2 % were aware of OT. 74.2 % were able to give correct definition of OD. The major (25.7 %) source of information is internet. 84.2 % responded that organs can be donated from live, dead & brain dead persons. 94.7 % participants felt that OD saves life. 75.1 % responded that OD involves risk. Major risks stated were organ rejection, infection, weakness, bleeding and pain. (Table 1)

Concerning attitude, 65.6 % did not know about OD register, and most of them (80.3 %) had no idea where to obtain the OD Card. Many students are comfortable in talking & thinking about OD and many approve it. 88.7 % agree to donate organs. However 8.7% were willing to donate when they are alive. 23 students said that they would donate in special circumstances. Causes of refusal of OD were fear of surgery, no belief in health system, religious beliefs and concern for commercialism. (Table 2)

Regarding beliefs, 56.7 % responded that their religious beliefs allowed for OD. However 91.3% believed that there would be misuse of OD. 24.4 % students believed that due to OD there would be premature termination of treatment in a dying person in order to facilitate OD. 17.6 % believed that OD encourages euthanasia. (Table 3)

Table 2: Attitude regarding OD

Attitude	Response	Frequency	Percentage
Heard about OD register	Yes	170	34.4
	No	324	65.6
Source of obtaining OD card	Yes	97	19.7
	No	397	80.3
Comfortable while talking or thinking	Yes	451	91.3
	No	43	8.7
Approve OD & OT	Ye	480	97.2
	No	14	2.8
Agree to donate organs	Yes	438	88.7
	No	56	11.3
If yes, willing to donate as live donor (n=438)	Yes	38	8.7
	No	400	91.3
As a live donor, will you donate irrespective of situation (n=38)	Yes	15	39.5
	No	23	60.5
If no, causes of refusal (n=56)	Religious	10	17.9
	Commercialism	9	16.1
	Surgery fear	24	42.9
	No belief in health system	13	23.2
Family's consent	Yes	313	63.4
	No	181	36.6
If your loved one needs transplant	Check for donor	109	22
	Donate mine	385	78
Acceptance, if hospital approached for OD of deceased family member	Yes	321	65.1
	No	173	34.9

Table 3: Beliefs regarding OD

Beliefs	Response	Frequency	Percentage
Religion agrees OD	Yes	280	56.7
	No	40	8.1
	Don't Know	174	35.2
Misuse of organs	Yes	451	91.3
	No	20	4
	Don't know	23	4.7
OD encourages premature termination of treatment	Yes	120	24.4
	No	55	11.2
	Don't Know	317	64.4
OD encourages Euthanasia	Yes	87	17.6
	No	195	39.5
	Don't Know	212	42.9
Need effective laws	Yes	407	82.4
	No	87	17.6

Discussion

OD and transplantation are the most important treatment modalities of many end organ diseases. Medical students should have sufficient knowledge regarding OD so that they can bring awareness and behavior change in the community. Studies show that health professionals can positively influence the opinions and attitudes of patients and their relatives, leading to higher rates of organ procurement^(11, 12). It is therefore important to determine the level of knowledge among medical students and their attitude towards OD.

The important questions to be answered in this appraisal are; Do medical students have enough knowledge about OD? What is their attitude towards OD? And what are their beliefs regarding OD?

Regarding the sample of students in the current study, the demographic details of age and sex are similar to studies by Prince Alex et al⁽¹²⁾, Karini D et al⁽¹³⁾ and

Shreya Agarwal⁽¹⁴⁾. A study by Sindhu et al in the AFMC had a higher male population. Hamed Het al⁽¹⁶⁾ in their study had 60 % participants from urban background. The study by Karini D et al⁽¹³⁾ had almost the same percentage of first year medical students (27.8%).

In our study, 100 % participants heard about OD as seen in other studies⁽¹⁴⁾. Like in other studies done in India⁽¹³⁾, a majority of medical students in the current study defined OD correctly. The source of information for majority of them was internet while elsewhere it was television⁽¹⁵⁾. Most of the students responded that organs can be donated from live, dead & brain dead persons but in Shreya Agarwal's study only brain dead patients were considered as potential donors for OD by the majority⁽¹⁴⁾. Awareness about the OD register was seen in only a small number of the students, but when compared to a study in Malaysia 77.7% were aware of the OD registry⁽¹⁷⁾.

All students approved the concept of OD as seen in another study from South India ⁽¹⁸⁾. A study from UK showed that attitude to OD was overwhelmingly positive in nearly two thirds of the students. A good number of students in this study agreed to donate their organs. However, only a small number are willing to donate when they are alive. Most of the students are agreed to OD after their demise as was also seen in a study by Vinay KV et al ⁽²⁰⁾. Not all are willing to donate organs irrespective of the situation. Some students specified that they would donate only in special situations. Similar result from Egypt study showed that a good number of students were willing to donate to any recipient while some were selective ⁽¹⁶⁾. Three fourths of the participants said that they would donate organs of their own when their loved needed them while one fourth of them look for donor. However in a study by Vinay KV et al ⁽²⁰⁾ almost half the number of students in each year of MBBS were ready to donate their organs to their family members.

Causes of refusal of OD in this study were fear of surgery, no belief in health system, religious beliefs and commercialization of transplantation procedures. The causes of refusal seen in an Egyptian study by Hamed H et al ⁽¹⁶⁾ were familial refusal (13%) religious prohibition (19%) fear of commercialism (27%), fear of surgery (10%) and lack of confidence in the health care system (31%).

Regarding donating an organ from their own deceased family member, in this study, 65.1 % of subjects are willing which is similar to the study by Karini Det al ⁽¹³⁾. Concerning beliefs of students, a good number of subjects said that their religious beliefs are in agreement with OD as seen in a similar study ⁽¹⁸⁾. However in agreement to the above study, a third of the students were ignorant of any religious connotations regarding OD. A study by Shreya Agarwal et al ⁽¹⁴⁾ states that only 14.2% students cited religious beliefs as the reason to refuse OD.

The current study showed that a majority of students believed that there would be a misuse of organs as seen in a study by Karini D et al ⁽¹³⁾ study. Most students maintained that there should be effective laws and a regulatory body to govern OD and the similar finding was seen in a study by Sucharita ST et al ⁽¹⁸⁾.

Conclusion

Majority of undergraduate students were aware of OD in a broad manner. However awareness on issues like Organ registry and OD card was lacking. There is a need for lectures, seminars and workshops to be included in the MBBS curriculum regarding the physiology of OD and transplantation, related pathology, immunology, pharmacology and the relevant medical and surgical details. There is also a need to include student centered group discussions on the social and ethical aspects of OD. The misconceptions about OD in these budding doctors need to be addressed. The results of this study show the necessity of more debate and knowledge to prepare the next generation of healthcare professionals about transplants and OD.

Acknowledgement: The authors are grateful to Indian Council of Medical Research (ICMR) for their grant under STS programme for the study (Grant number: 2017-00992) and to the students of Dr.PSIMS &RF for their participation in the study.

Ethical Clearance: Ethical approval (**Certificate No. 201/UG/2017**) was obtained from Institutional ethical committee (IEC) of Institutional Research Cell (IRC) of Dr.Pinnamaneni Siddhartha Medical Science and Research Foundation (**ECR/804/Inst/AP/2016**).

Internet use and Physical Health Problems in School Going Students

Bhuvan Kumar Singh¹, Mohan Patil²

¹Junior Resident Doctor, Department of paediatrics, D. Y. Patil Medical College Hospital And Research Institute, Kolhapur, Maharashtra, (India), ²Professor, Department of paediatrics, D. Y. Patil medical college hospital and research institute, Kolhapur, Maharashtra, (India)

Abstract

Background: The Internet and mobile phone is becoming increasingly important and essential to the educational and social lives of adolescents and have become an integral part of their lives. Misuse or excessive use of the internet can cause mental and physical health issues in adolescents. 35% of internet users in India are adolescents. Hence, this study was conducted to evaluate internet use and physical health problems in school going adolescents.

Method: The cross-sectional study was conducted on 1600 school students (14-16 year of age) of Kolhapur city, Maharashtra. A semi-structured questionnaire with questions pertaining to internet use and associated health issues was used for data collection. Data was analysed using R Studio V 1.2.5001.

Results: Most of the students (48.1%) use the internet for 1-2 hours every day, 2-6 days a week and the phone was the common mode of internet use (48%). A significant association was observed between internet usage time and complications such as headache, neck pain, eye dryness, eye redness, thumb pain, backache, numbness in the finger, and disturbed sleep (P = 0.0004). A significant association was noted between the mode of internet usage and wrist pain (P= 0.004).

Conclusion: A number of physical health complications were found to be associated with internet usage with the mode of internet also playing a significant role.

Keywords: Adolescent, back pain, cell phone, headache, internet, neck pain

Introduction

The internet in this era is easily available to almost everybody and is widely used for work and leisure.¹ Unique features and benefits of the internet such as highly engaging and motivating virtual components, portability and multitasking makes it a very attractive tool, easily and quickly accessed through laptops and mobile phones. Among the younger population, the internet is a prevalent

mode of communication and networking.^{2,3} Adolescents utilize the internet for information searching, sharing personal information, social media and recreational activities and it is incorporated in their daily lives.⁴ However, misuse of the internet among adolescents has become a major health concern the world over.^{5,6}

The use of the internet can cause disturbed mental and physical conditions of adolescents.⁷ Several studies have demonstrated that individuals can become addicted to online activities, in particular those with psychological and emotional problems such as depression, anxiety, loneliness, distraction and lack of sleep.^{6,8-10} Moreover, misuse or excessive use of the internet can lead to physical health issues such as dry eye, carpal tunnel syndrome, repetitive motion injury, wrist pain, neck pain,

Corresponding author

backache, shoulder pain, headache, and numbness and pain in fingers.¹ The debate of risks versus benefits of the internet, in particular on its physical and psychosocial impact on vulnerable populations like adolescents is one that requires constant evaluation given that the internet and its contents are constantly changing. On this premise, the study aimed to evaluate the internet use and its related physical health problems among school going students.

Material and Method

The cross-sectional study was carried out from December 2017 to September 2019, after obtaining ethical approval from the Institutional Ethics Committee on 1600 school going students of Kolhapur city, India. Samples were selected based on a simple random sampling technique. Students in the age group of 14-16 years who use the internet were included in the study sample. Students who don't use the internet, who have mental or psychiatric disorder, ophthalmic problems and migraine prior to the use of internet were excluded. Informed consent was obtained before initiation of the study.

A semi-structured questionnaire was used to collect the data. It consists of a structured proforma to obtain

information about education qualification and status, the purpose of using the internet, time of the day when the internet was accessed the most, duration of use of internet per day, height weight and BMI of the participant and health-related problems associated with internet usage such as headache, thumb pain, backache, numbness in finger, wrist pain, disturbed sleep, neck pain, eye dryness, and eye redness. Completed questionnaires were collected, the data tabulated and the results statistically analysed.

Statistical Analysis

Data was analysed using R Studio V 1.2.5001. Categorical variables were expressed in frequency and percentage and the continuous variable was expressed in mean \pm standard deviation. A chi-square test was used to find the association between the variables. $P < 0.05$ was considered as statistically significant.

Results

The average age of the 1600 students was 15.19 ± 0.83 years and 57.43% of the students were male. Most of the students use the internet 1-2 hours daily and 2-6 days of the week and the mobile phone was the common mode of internet use (table 1).

Table 1. Daily, weekly and mode of internet used by students

Usage of internet	Frequency	Percentage (%)
Per week (days)		
0-1	486	30.4
2-6	770	48.1
Every day	344	21.5
Daily (hours)		
<1	307	19.18
1-2	771	48.18
2-3	401	25.06
3-4	110	6.90
>4	11	0.68
Mode of use		
Computer	745	46.6
Phone	768	48
Both	87	5.4

Headache (30.1%), backache (26.3%), disturbed sleep (28.6%), and thumb pain (25.9%) were the commonly observed complications in the students (figure 1).

Figure 1. Frequency distribution of different complications observed

A significant association was observed between internet usage time and complications such as headache, neck pain, eye dryness, eye redness, thumb pain, backache, numbness in the finger, and disturbed sleep ($P = 0.0004$). The number of health-related problems was found associated with duration of internet use ($P 0.0004$), also a significant association was noted between mode of internet usage and wrist pain ($P 0.004$).

Discussion

The Internet is increasingly important to adolescents for educational and social activity. Easy availability of the internet and mobile phones gives young people access to the internet at any time and place, thus posing the risk of the internet competing for priority space in their personal and academic lives.¹¹ Obsessive, excessive use of the internet may lead to impaired physical and mental health of adolescent students.^{8,12} The study was aimed to evaluate internet use and physical health problems in school going students. The use of the internet for 2 to 6-days per week was seen in 48.1% of students while 30.4% and 21.5% of the students were using the internet <2 days and every day of the week respectively. Similar results were observed in the study of Tan et al.¹¹ The study by Bhatiya et. al showed 60.43% of students were spending <2 hours for internet use and 2-4 hour use was

observed in 26.33% of students.¹³ In the study, most of the students (48.18%) were found to be spending 1-2 hours daily on the internet whereas, <1 hour and 2-3 hours daily use was observed in 19.18% and 25.06% of students respectively. Internet use depends on developmental, gender, and social characteristics of adolescents. As age progresses from childhood to early adolescence, general internet usage increases and then levels off, perhaps due to increasing academic work in high school.¹⁴ Data shows that 20% of African students reported spending 2 hours per day online while the values are at 42% and 40% in Chinese and American students respectively. Literature shows that internet addiction among African students was far more prevalent when compared with Chinese or American students despite limited access to the web implying that ease of access and availability were not strong determining factors for use and addiction.¹⁵

It is evidenced that excess internet use can cause musculoskeletal pain.^{12,16,17} This is possibly due to remaining in a fixed position over long periods; subsequently, more pressure is exerted on the part of the body involved such as the muscles, discs and tendons or may be due to poor postural habits.¹⁸ In the study, headache (30.1%), neck pain (15.3%), wrist pain (21.9%), numbness in finger (19.8%), back pain (26.3%), and

thumb pain (25.9%) was observed in the students. The study of Bohany T. et al showed complications such as headache (46%) neck/shoulder pain (41.3%), back pain (42%), wrist pain (16%) in participants.¹³ Similarly, the study by Yang G. et al and Park S. Et al. showed similar observations.^{18,19} Sleep problems, depressive symptoms, and eyesight problems were commonly reported with the use of internet and phones.²⁰⁻²³ The study showed disturbed sleep in 19.6% students and eye redness, eye dryness was seen in 19.6% of students. Similar results were observed in the study of Bener et al.¹ A significant association was found between internet use and physical health complications which is similar to the findings of Yang G. et al.¹⁸ Repetitive stress injury or repetitive strain injury are the conditions affecting the muscular and nervous system caused by doing the same task in the same position for long durations.^{24,25} The mode of internet use (computer or mobile phone) for long duration in same posture can cause musculoskeletal injury.^{12,26} Similarly, wrist pain was found associated with the mode of internet use which is may be due to prolonged gripping of the phone with the wrist pronated and extended (P 0.004).¹⁸ No similar data was found similar to these findings. Excessive use of the internet has also been linked to poor academic performance.²⁷ Students in the age group of 14-16 years are frequently found in the 10th grade and declining exam pass percentages in this group and its possible association with internet use must be reflected upon and studied.

Conclusion

This study provides an overview of the pattern of internet use and its association with physical health problems among adolescents. The study is limited by the fact that internet addiction among the students was not evaluated, reporting bias by students may be present due to self-reporting, and psychological effects were not evaluated. These pave way for further research in the arena.

Clinical Profile of Dengue Fever and Associated Expanded Dengue Syndrome in a Tertiary Care Hospital

Bimal K Agrawal¹, Robin Gahlawat², Manu Mathew³, Gaurav Aggarwal⁴, Usha Agrawal⁵

¹Professor of Medicine, ²Senior resident, Department of Medicine, ³Resident, Department of Medicine, ⁴Senior resident, Department of Cardiology, M M institute of Medical Sciences & Research, Maharishi Markandeshwar(Deemed to be university) Mullana, India, ⁵Scientist F, ICMR-National Institute of Pathology, New Delhi

Abstract

Background: The worldwide epidemiology of dengue fever (DF) and dengue hemorrhagic fever (DHF) is changing fast. The Indian encounter with this disease is fascinating and captivating. In recent years the disease has distorted its course exhibiting in a severe form as DHF, dengue shock syndrome (DSS) and Expanded Dengue Syndrome.

Methods: The present study is an observational prospective study conducted in a single unit of the department of Medicine of a tertiary care hospital. Institutional ethics committee approval was obtained prior to enrolment of any patient.

Results: The work presented in this study expands the knowledge base of dengue clinical profile and management. Fever, thrombocytopenia, raised transaminases were the common findings in the 150 patients studied. Hemorrhagic manifestations were observed in 20 patients who had required platelet transfusion.

Conclusion: Dengue fever is always the foremost of these arboviral infections with significant impact on socioeconomic and healthcare cost for the patient. The clinical picture can be non-specific viral prodrome to classical dengue fever to life threatening dengue shock syndrome(DSS)/dengue haemorrhagic fever(DHF). Early diagnosing and with aggressive management particularly for DHF and DSS remains the cornerstone strategy for good outcomes.

Keywords: *pericholecystic oedema, raised transaminases, myocarditis*

Introduction

Dengue viral infections have been endemic in tropical and sub-tropical areas which were previously considered as non-endemic to dengue virus. The main areas are Asia, Americas, and the Caribbean. Typically, transmission of dengue virus peaks near the equator

during the annual rainy season. Dengue virus is a small single stranded RNA virus belonging to family Flaviviridae; genus Flavivirus, with approximately 4 billion human beings spreading 128 nations at risk of DENV infection.

Material and Method

We conducted a study in a tertiary care centre situated in north India in a single unit of the department of medicine for one and a half year. Blood samples from 150 clinically suspected and serologically positive cases of dengue infection (according to WHO criteria) were taken after receiving approval from the Institutional Ethics Committee. The informed written consent was

Email-onlybimal@gmail.com

taken from each participant before enrolment into the study. The dengue seromarkers used in this study were NS1 antigen, IgM and IgG antibodies. The method which was employed in the study was a Rapid immunochromatographic test (card test). All patients with confirmed serology (IgM positive alone or both IgM and IgG) or NS1 antigen positive dengue fever patients were enrolled. The other requisite tests were done for each of the dengue patients. In addition to these specific markers, age, gender, fever duration, clinical manifestations and laboratorial parameters were recorded for each patient.

Results

The demographic data and the results of haematological parameters, transaminases, renal function tests has been shown in table 1. The patients of the age group below 18 had been excluded as the study had been conducted in the department of Medicine.

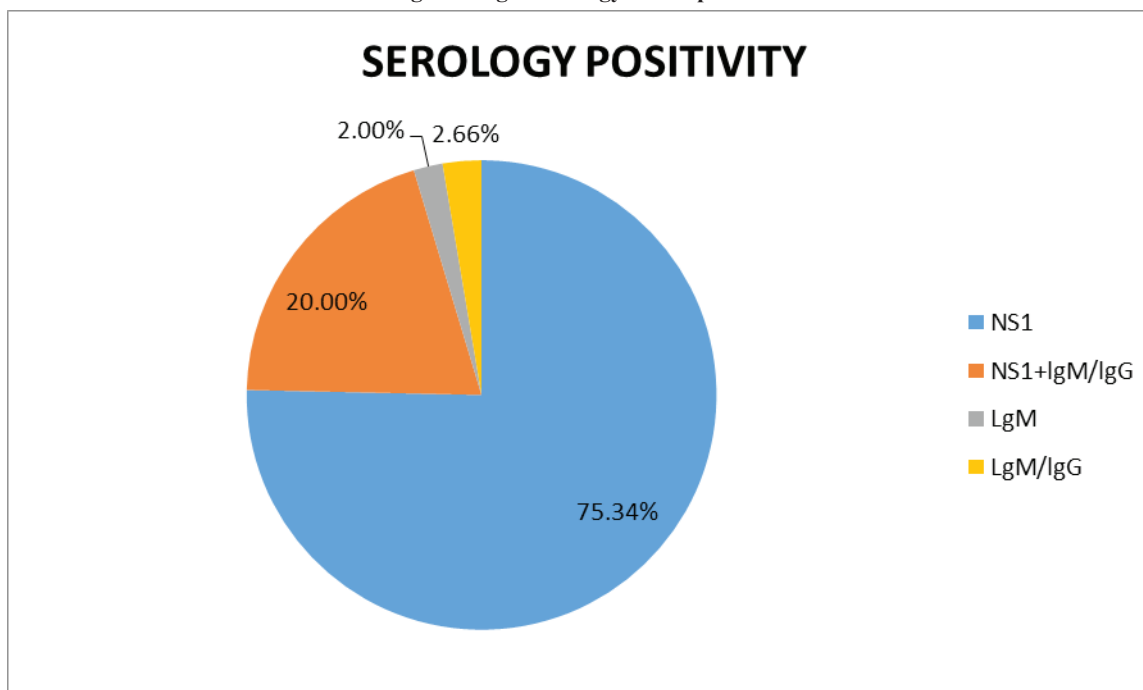

TABLE 1: DEMOGRAPHIC DATA OF 150 PATIENTS

	Mean \pm Std dev	Median	Min-Max
Age	35.03 \pm 13.75	30	18-80
Hb%(gm/dl)	13.53 \pm 2.02	13.6	8.1-17.7
PCV%	39.43 \pm 5.13	39.3	25.4-52
WBC(cells/cu.mm)	5354.67 \pm 2990.76	4950	1400-24000
Platelet count(cells/cu.mm)	50793.33 \pm 37616.27	40000	6000-200000
Serum Bilirubin(mg/dl)	0.85 \pm 1.5	0.54	0.13-15
SGOT(IU/L)	345.81 \pm 1212.81	90	17-12000
SGPT(IU/L)	222.39 \pm 737.68	86.5	14-7600
Urea(mg/dl)	32.5 \pm 23.52	28	12-160
Creatinine (mg/dl)	0.97 \pm 0.65	0.84	0.31-6.8

Out of 150 cases studied melena was seen in 8(5%), ecchymosis in 7(5%), hematemesis in 5(3%). Dengue serology revealed NS1 positivity in 143 (95.34%) patients and out of those 143 patients, 113 were exclusively NS1 positive and the rest 30 were associated with IgM or IgG or both. Three (2%) patients were exclusively IgM positive and 4 (2.66%) were both IgM/IgG positive.(Fig 1) In this study of one fifty patients 120 (80%) had dengue

fever and 20(13%) were diagnosed as DHF, 10(7%) had Dengue Shock Syndrome. Albuminuria was present in 54(36%) of the patients and 29(19%) patients had RBC in urine. Out of 150 patients, myocarditis was present in 7(4.67%) of the patients. Out of 150 patients, 107 patients (71.33%) had gall bladder involvement in the form of gallbladder wall thickening or pericholecystic oedema, 43(28.67%), had no involvement.

Fig 1- Dengue serology of 150 patients

Discussion

Despite dengue's enormous global impact there is still no licensed therapeutic to combat the toll of the disease on patients and overburdened health systems in the tropical world. There is a pressing need for a therapeutic that can shorten the duration of illness and reduce the risk of disease progression. Clinical trials have been conducted in dengue that have used different approaches to influence the disease outcome. These include attempts to reduce dengue viraemia or modulate the host response to dengue infection. Unfortunately, to date, these attempts have not demonstrated a clinical benefit. However, in 2016 a vaccine to prevent dengue fever (Dengvaxia) became commercially available in some countries. WHO in 2018 september had updated its recommendations for the use of this vaccine and substantiate that seronegative vaccine recipients have an excess risk of severe dengue compared with those of seronegative individuals who are unvaccinated .

Gastrointestinal complaints:

We had 70 (46.67%) of patients with abdominal pain. Fifty one(34%) of our patients experienced nausea and vomiting and loose stools were seen in 2 (1.33%) of the patients. Hepatomegaly was observed in 15 (10%) of our patients. Enlarged spleen was palpable in 7 (4.67%)

of our patients.

Ultra-sonographic findings:

Acalculous cholecystitis has been documented in many case reports of dengue fever. In ultrasound examination an asymptomatic gall bladder wall oedema can be an alternate marker of dengue during epidemic before arrival of laboratory investigations report. The main pathology behind this is plasma leakage which results in deposition of fluids in various organs (gallbladder, pleural effusion, and ascites). Thickening of wall of gallbladder, a positive Murphy's sign, pericholecystic collection of fluid with no stones in the gallbladder along with raised alkaline phosphate values are the features. In our study gall bladder wall thickening or pericholecystic oedema was seen in 107 (71.33%), pleural effusion in 13 (8.67%) and ascites in 5 (3.33%) of our patients. A study done by Santosh et al found that out of sero-positive 96 cases of dengue, 66.7% patients had oedematous gallbladder wall thickening, 64.5% patients were having ascites, 50% patients were found to have pleural effusion.¹ In a study done by Parmar et al demonstrated distinct patterns of gall bladder wall thickening in dengue fever patient. and suggested that honeycombing pattern may predict severity of the disease.²

Serology and laboratorial parameters:

We confirmed a diagnosis of dengue fever with NS1, IgM and IgG rapid immunochromatographic tests and included patients who were NS1 antigen positive or IgM positive alone or both IgM/IgG positive. The seromarker NS1 antigen which is a highly sensitive dengue marker for dengue infections is detected from the first day of fever and it was done within first 3 days of presentation of fever. This is in accordance with a study conducted by Hang et al.³

From the above it can be said that a large number of cases would be missed if NS1 antigen is not included in the test panel for dengue virus infection detection. Those who are exclusively NS1 positives could be offered appropriate supportive therapy, thus avoiding any irrational use of antibiotics. The patients and their attendants could be briefed regarding the basics of vector biology and provided with mosquito nets during viraemic phase to further prevent the spread of infection to others. The dengue specific antibodies appear only by third to fifth day of fever in primary dengue infection. Even in most secondary infections, both IgM and IgG type antibodies cannot be recorded before the third day. Both in primary and secondary dengue infection there is always a window period, when only antibodies are detected. Moreover, the utility of antibody relies mainly on the rising titres especially in endemic areas. The seromarker NS1 antigen which is a highly sensitive dengue marker for dengue infections is detected from the first day of fever⁴

Platelet transfusion:

A total of 20 patients (13.33%) received platelet transfusion in our study group. The indication being severe thrombocytopenia, bleeding manifestations such as hematemesis or malena. Kulkarni et al⁵ in her study 118(51%) out of 232 patients received single unit platelet transfusion with platelet counts between 20,000 and 1,00,000 cells/mm³ and 64(27.5%) with platelet of <20,000 cells/mm³ received multiple platelet transfusions. They concluded that 51% of platelet transfusions were inappropriate and more effective when it is given with a platelet count of <20,000cells/mm³.

David C Lye et al⁶ in their open-label, randomised, superiority trial in five hospitals in Singapore and

Malaysia involving 372 patients concluded that that prophylactic platelet transfusion was not superior to supportive care in the prevention of bleeding in adult patients with dengue as it is associated with risk of transfusion related adverse effects. Our study was in line with that, 20 patients who received platelet transfusion, 8 were those who had malena, 5 were having hematemesis and 7 had ecchymosis with severe thrombocytopenia. Out of which 17 recovered and 3 deaths occurred.

Urine Albumin:

Increased urinary excretion of protein in patients infected by dengue virus is thought to be a hallmark of vascular endothelial cells defect and plasma leakage associated with complicated forms of dengue and is considered a possible prognostic marker⁷ Proteinuria has been reported in up to 74% of patients with dengue haemorrhagic fever (DHF)⁸ and cases of self-limiting nephrotic-range proteinuria in patients with DHF presenting no manifestations of renal damage have been described. In our study 54 (36%) out of 150 patients were having albuminuria detected by dipstick in urine specimens. Andries et al observed that decreasing proteinuria is a sign of improvement.⁹

Myocarditis:

Dengue myocarditis has spectrum from mild case of only ECG changes to severe case of myocarditis induced acute heart failure (cardiogenic shock). There is no conclusive pathogenic mechanism for dengue myocarditis. Direct viral invasion of cardiomyocytes, myocardial oedema from local capillary leakage, overwhelming cytokine effect, coronary hypo perfusion and intracellular calcium homeostasis disruption have just partly explained the pathophysiology.¹⁰

Our 7 (4.67%) patients presented with myocarditis in form of sinus bradycardia, arrhythmia and shock with evidence of electrocardiographic abnormalities, abnormal cardiac biomarkers (elevated CPK MB).

If viral myocarditis was a primary event thought in our patients, it would be difficult to differentiate it from other causes of such manifestations like plasma leakage, shock occurring in Dengue fever thus, separating secondary cardiac effects from primary cardiac involvement is difficult, and this may have led to under-

reporting of cardiac involvement in the past.

Dengue virus induced myocarditis is underreported but it may be an important cause of the mortality in Dengue fever. Because of its nonspecific clinical features and variable electrocardiographic (ECG) and echocardiographic (2D ECHO) findings it requires a high degree of clinical suspicion by the treating physician. Awareness is important for this entity to prevent the high mortality.

Expanded dengue syndromes:

The World Health Organization (WHO) has coined the term expanded dengue to describe the cases which do not fall into the category of either dengue haemorrhagic fever or dengue shock syndrome. Unusual manifestations of patients with severe organ involvement such as liver, kidneys, brain or heart associated with dengue infection have been increasingly reported in dengue haemorrhagic fever (DHF) and also in dengue patients who do not have evidence of plasma leakage.

Neurological involvement in dengue fever is heterogeneous. Intra-cerebral haemorrhage, encephalitis, aseptic meningitis and acute disseminated encephalomyelitis are seen due to neuro-virulent effect of dengue viruses and serotypes 2 and 3 have been isolated from the CSF of dengue patients.¹¹

One patient in our study presented with monoparesis of right arm with associated NS1 positive dengue fever. All other causes of nervous system involvement were ruled out in this patient; hence dengue remained the only culprit. Patient's right arm weakness resolved within 10 days of resolution of fever. There are numerous other organ system involvements seen in expanded dengue syndromes.¹² One of the patient had associated hypoparathyroidism and had presented with hypocalcemic tetany which the authors had presented earlier as a case report.¹³

In our study 7 patients with unusual manifestations of severe multi organ involvement such as liver, kidneys, brain or heart associated with dengue infection were reported to be in DSS leading on to the mortality of 5. These unusual manifestations might be associated with other coinfections or co-morbid conditions or due to complications of prolonged periods of shock and can

be clubbed under the expanded dengue syndrome. They may be potentially serious and may result in increased rates of morbidity and mortality in dengue fever, which can be preventable with prompt diagnosis and judicious management. Therefore, we should be aware of these atypical manifestations.

Conclusion

Our study focused on the clinical profile of dengue fever in correlation with the blood parameters. It was concluded in this study that fever with headache along with thrombocytopenia, decreased TLC count and raised serum transaminases levels should raise a strong suspicion of Dengue fever for which screening and confirmation must be done. This study supports the concept that in comparison to IgM and IgG antibodies for dengue fever, NS1 antigen testing is an effective tool for diagnosis of dengue infection particularly in early diagnosis of dengue infection when antibodies are not at a detectable level. Detection of all three parameters NS1 antigen, IgM, IgG antibodies simultaneously gives more information regarding the primary and secondary infection. In this study immunochromatographic test was used in the diagnosis of dengue infection which is a cheap, prompt and accepted standard test method for dengue diagnosis which notably holds its place in our country with an ever-increasing number of dengue patients. In our study gall bladder wall thickening or pericholecystic oedema was seen in 107 (71%) patients thus showing a direct relationship of ultrasonographic findings with dengue fever. Hence showing the use of advanced radiology in future diagnosis of severity of dengue fever. Our study highlighted the ever-perpetuating spectrum of dengue expanded syndromes in form of renal involvement, myocarditis, monoparesis, hepatic dysfunction and severe multi organ system involvement.

Ethical Clearance- Ethical approval was taken from the Institutional Ethics Committee before initiating the study.

Attitude of Medical Students Towards Dissection on Human Cadaver: A Study on the Students of a Medical College of Eastern India

Biswa Bhusan Mohanty¹, Gyanaranjan Nayak¹, B. Shanta Kumari², Sujita Pradhan³,
Sitansu Kumar Panda⁴

¹Associate Professor, ²Assistant Professor, ³Tutor, ⁴Professor, Department of Anatomy, IMS & SUM Hospital, SOA University

Background : Dissection of cadaver is an integral part of anatomy. It is a vital component in order to understand the relations of structures and to have an orientation on the subject. With the advent of modern technologies and equipments like synthetic cadavers, virtual dissection table and lack of adequate number of cadavers, the importance of dissection seems to be compromised among students.

Aim and Objective: This study was conducted to find out the attitude of MBBS students towards cadaveric dissection. It focused on the emotional and psychological aspect on the tender minds of students.

Material and Method: The study included 1st year MBBS students. It was conducted after 3 months of their exposure to the course. A formatted questionnaire was given to them. The questionnaire included some general information about the students, some questions regarding their feeling towards cadaveric dissection. The questions were to be answered in Yes or No.

Discussion and Conclusion : The response of the students was tabulated and analyzed. The data revealed that only 21.58% students preferred for dissection. Majority of students don't perform dissection. The most frequent cause of it was smell of formaldehyde (38.85%) and lack of adequate number of cadavers (15.11%). There are other factors too which expels them from dissecting the cadaver. Many other angles were explored and discussed.

Key words: Attitude, dissection, cadaver, psychological

Introduction

Anatomy is one of the first, most basic, and a major part of the MBBS curriculum. It is very necessary for students to have a clear understanding of clinical sciences. The provision of learning gross anatomy has an emotional as well as intellectual approach to

medical education. Cadaveric dissection is the key stone of learning anatomy. It helps the MBBS students to acquire adequate information, orientation, about the 3-dimensional architecture of human body. Cadaver dissection also plays a very important role and acts as a building block that provides essential knowledge required for the duration of the future studies of the MBBS students. Many students express a cocktail of emotional reactions, different types of feelings when they come across the cadaver for the first time. To study these effects, many studies have been conducted by various researchers. Many studies have shown a positive attitude of students, however some studies also reported adverse effects too. The present study is done to estimate the effect of dissection on the tender minds of first year MBBS students.

Aim of the Study

- To study the psychological effect of dissection while doing it on cadavers.
- Attitude of students towards dissection.
- To know about the preference of students towards cadaveric dissection as compared to modern amenities available.

Material and Method

This is a cross sectional study. The study was conducted on 1st yr. MBBS students of IMS & SUM Hospital, Bhubaneswar. It included 278 students. Purpose of the study was explained to the students. Formal consent of the students was taken. Formal permission was taken from ethical committee of the institution. Name of the students was not recorded to have a free opinion. The students were given a formatted questionnaire after 3 months of commencement of course. The answers were analyzed and tabulated.

Questionnaire

- Name -
- Age - Sex - Religion -
- Dissection done = Yes/No

- Reason for not performing dissection
- Fear/ Smell of formaldehyde/ Anxiety/ Laziness/ Not interested/lack of cadavers/others
- Have you ever seen dead bodies before? Yes/No
- Were you shocked to see the dead body for first time? Yes/No
- Did you get nightmare about the body? Yes/No
- Did you find dissection exciting? Yes/No
- Do you prepare mentally for dissection of cadaver? Yes/No
- Did you experience the formalin odour after your first encounter with cadaver, even when away from college? Yes/No
- Does cadaver dissection made anatomy easier to understand? Yes/No
- Should cadaver dissection be replaced by plastic models? Yes/No
- Do you feel dissection by yourself is more helpful than demonstration of prosected parts? Yes/No
- Is dissection essential for anatomy? Yes/No

Table 1: Religion

Hindu	260 (94%)
Muslim	12 (4%)
Christian	6 (2%)
Others	0

Table 2: Dissection performance

Yes	60 (21.58%)
No	218 (78.41%)

Table 3: Reasons for not doing dissection

Fear	38 (13.66%)
Smell of formaldehyde	108 (38.85%)
Anxiety	30 (10.79%)
Laziness	24 (8.63%)
Not interested	36 (12.95%)
Lack of adequate no. of cadavers	42 (15.11%)

Table 4: Response to the questionnaire

	Yes	No
Have you ever seen dead bodies before?	88 (31.65%)	190 (68.34%)
Were you shocked to see the dead body for first time?	50 (17.98%)	228 (82.01%)
Did you get nightmare about the body?	66 (23.74%)	212 (76.26%)
Did you find dissection exciting?	190 (68.34%)	88 (31.65%)
Do you prepare mentally for dissection of cadaver?	30 (10.79%)	248 (89.21%)
Did you experience the formalin odour after your first encounter with cadaver, even when away from college?	136 (48.92%)	142 (51.08%)
Does cadaver dissection made anatomy easier to understand?	240 (86.33%)	38 (13.67%)
Should cadaver dissection be replaced by plastic models?	88 (31.65%)	190 (68.34%)
Do you feel dissection by yourself is more helpful than demonstration of prosected parts?	214 (76.98%)	64 (23.02%)
Is dissection essential for anatomy?	124 (44.6%)	154 (55.39%)

Graph 1: Graph depicting percentage of students according to their religion

Graph 2: Graph depicting different factors preventing students from doing dissection

Discussion

The study reveals that only 21.58% of students have done dissection while a large no. of them are not dissecting. A study done by Sharma et al.¹ showed that 35% of students were dissecting. So, the results are not very contrasting. There were so many causes that expel the students from doing the dissection. Most prevalent

cause was smell of formaldehyde (38.85%) as it causes irritation and gives unpleasant odour. The study of Sharma and Gupta et al.¹ showed the same result. But in that case, the prevalence was 50.7%. This is a factor that students have to accept and get habituated to it. Because, formalin is the most common and most effective chemical to preserve the cadaver. Study of Nirmalya Saha *et al*²

showed that about 64% of the students experienced the formalin odour even when away from the college. In this case, about 48.92% students feel that. Monika Lalit *et al*¹¹ reported that 52.17% students experienced the formalin odor even when they are away from the college. Next factor was lack of adequate no. of cadavers. So, maximum students don't get a chance to dissect. With increase no. of colleges and increased no. of seats in each college, the demand for cadavers is shooting high. Public awareness and body donation programmes must be more aggressive in order to fulfill our needs. Other less common factors are anxiety, laziness and fear. To overcome this, the students need a proper counseling and motivation. They must learn first the importance of dissection preferably during orientation programme. 32% of students have previously seen the dead bodies, so they are not really shocked to see it for first time. They are mentally prepared for it. Parker¹³ reported that students with prior exposure with a dead body were better equipped to deal with issues surrounding death and are more aware of medical uncertainties. Other less common factors are anxiety (10.79%), laziness (8.63%) and fear (13.66%). Sharma *et al*.¹ found that anxiety and tremors of the hand was experienced by 13.84% of the students which was quite embarrassing. Also, Abu Hijleh *et al*⁹ reported that 46.5% of the students expressed some level of fear before dissections. To overcome this, the students need a proper counseling and motivation. They must learn first the importance of dissection preferably during orientation programme. 68.34% of students found human dissection very exciting. Studies done by Izunya *et al*.⁴, 2010, Mulu *et al*.⁵, 2010, Oyeyipo and Falana⁷, 2012 and by Rajkumari *et al*.³, 2008, Kemeir¹⁰, 2012, Khan and Mirza⁶, 2013 revealed that 85% students were very excited with their dissection experience. They also accept (86.33%) that dissecting the cadaver helps them to learn and remember the subject in a better way as it creates a visual and motor experience, but the study of Izunya *et al*.⁴ gives a different picture. Still 31.65% students believe that cadaveric dissection can be replaced by plastic models. Because unlike cadavers, in plastic models, the relation is not distorted with time. They can also be used time and again. This gives ample opportunity to most of the students to see the relations properly. Those students who can't perform dissection due to lack of cadavers, it can be solved by synthetic models. So, we believe,

though plastic models should not replace dissection, but they should be there as a helping hand. With the availability of virtual study table, the radiological study, the cross sectional views are at our reach. Still students prefer dissection to demonstration of dissected specimen as it gives a better three dimensional approach. The same fact was observed by the study done by Rajkumari and Singh *et al*.³ 2010

Conclusion

So, students should be more motivated and they should be counseled properly about the importance of cadaveric dissection. Though there are other modalities available, but cadaveric dissection is irreplaceable. It gives a visuo-motor and psycho-motor impact on the subject. Cadaver acquisition procedures should be more streamlined, so that "lack of cadavers issue" is solved.

Physical Therapy Approach in Conjunction with Dry Needling on Health Related Quality of Life in Patients with Temporomandibular Disorder: A Randomized Control Trial

Biswajit Kanungo¹, Ramesh Chandra Patra¹, Patitapaban Mohanty², Parul Bawa¹

¹Assistant Professor, Lovely Professional University Phagwara Punjab, India, ²Associate Professor, Swami Vivekanand National Institute of Rehabilitation Training and Research, Odisha, India

Abstract

Introduction: Temporomandibular disorders (TMD) are one of the commonest musculoskeletal problems in physical therapy practice. This is not only a problem of temporomandibular joint but also affect the whole nervous system. The main purpose of this study was to assess the effectiveness of physical therapy approach on quality of life in TMD patients. **Methods:** The design of the study was randomized control trail where 200 subjects with both the gender, aged between 18 to 50 years who were clinically diagnose with TMD in the Department of Physiotherapy, Lovely Professional University, Punjab. India. After preliminary assessment all the subjects were assigned into two groups namely control group and experimental group. For outcome measurement short form of health related questionnaire (SF-36) was used to assess quality of life. In this study control group was received normal home based exercise and experimental group was received physical therapy approach which consists of dry needling, muscular inhibition in combination with home based exercise. **Results:** The experimental group to whom physical therapy protocol was applied associated with dry needling was shown significant increased scores in all the domains of the questionnaire. In control group where conventional physiotherapy was applied and improvement shown only in the domain of pain but not in the other parameters in comparison with experimental group. The level significant level was considered as $P < 0.05$ for the analysis of data. **Conclusion:** The results of this study claimed that the application of a physical therapy protocol in association with dry needling was able to improve the health related quality of life in patients with temporomandibular disorders.

Keywords: Health related Quality of Life, Physical Therapy, Dry Needling, Temporomandibular Disorders.

Introduction

Now day's temporomandibular disorders (TMD) have turned into a one of the commonest problem among physical therapist as well as for dentist. [1] TMD is a cervico-canio-madibular dysfunction which not only affects the Temporomandibular joint but also affect the central nervous system. [2] The aetiology of this condition is considering "biomechanical, neuromuscular and biopsychosocial" and the condition can aggravate with emotional stress, bad posture, bad position of teeth, tooth loss, and various extrinsic and intrinsic changes of the structural components of the Temporomandibular joint. [3, 4, 5]

The main sign symptoms of TMD patients include pain in temporomandibular joint and/or muscle with or without reduced range of motion of temporomandibular joint. The symptoms included with TMD may lead a patient to changes their lifestyle due to problem in talking, impeding their ability to partake in discussing, problem in eating. This may be the responsible for the low quality of life. [6, 7, 8, 9] The American Academy of Craniomandibular Disorders (AACD) revealed that physical therapy helps to reduce neuromusculoskeletal pain, and restore the normal range of motion through alter the sensory input and reducing inflammation, coordinating and strengthening the muscular activity, and promoting repair and regeneration of the tissues. [10] A study conducted by Oliveira et al., and the result of the

study proposed that temporomandibular joint pain may impact negatively in patients with TMD. [3]

Quality of life is a broad, subjective, productive and polysomic concept which has been the subject of numerous studies in the Health area, especially directed towards people with chronic diseases, such as TMD. It is defined by the individual as an internal experience of satisfaction and well-being in their living process. [11, 12] As per the existing studies it is clear that the TMD condition is a multidimensional condition where all the components are involved. Therefore the treatment strategies require a broad multidisciplinary approach. Physical therapy in conjunction with dry needling having a vital role in the rehabilitation of these patients, since it provides pain relief, rehabilitates the neuromuscular system and restores the mandibular rest position and muscle coordination, therefore improving quality of life. [10, 13] Therefore, the main purpose of this research was to evaluate the effectiveness of a multimodal physiotherapy approach on health related quality of life in patient with TMD.

Materials and Method

The design of the study was randomized control trial where 200 subjects with both the gender, aged between 18 to 50 years who were clinically diagnose with TMD were participated in this study. All the data were obtained from the Department of Physiotherapy, Lovely Professional University, Punjab. India. After preliminary assessment they were randomly divided into two groups by using lottery method namely control group (100 subjects) and experimental group (100 subjects). Control group was received conventional physiotherapy with normal home based exercise and experimental group was received physical therapy approach made of muscular inhibition technique, dry needling and home based exercise which sets out the principles for human research protocol. [14] The study was approved by the Institutional Research Ethics Committee of the Lovely Professional University (LPU/IEC/2019/01/05) and the clinical trial registration number of the study is CTRI/2019/06/019858. All the subjects were informed about the study and written consent form was signed by the participant.

The participants were included for the study, pain and positive three finger test with limited MMO of less than 30mm (but not necessarily painful) clearly originating in

the TMJ. Those who are suffering any dental problem, headache, hypertension, diabetes, asthma, epilepsy, and trauma and surgery to the maxillofacial area were excluded from the study.

For outcome measurement short form of health related questionnaire (SF-36) was used to assess quality of life. [15] The data was collected before starting the intervention and after four weeks of treatment protocol. The SF-36 is a generic instrument composed of 36 questions and divided into eight domains: “functional capacity, limitations due to physical aspects, pain, general health status, vitality, social aspects, emotional aspects, and mental health,” with these dimensions representing basic human values relevant to the assessment of the quality of life of the general population.

Intervention

The dry needling and muscle inhibition technique were given to the experimental group where dry needling was performed on masseter, temporalis and sub-occipital muscle for first weeks for three session the in the second week muscle inhibition technique were performed for medial and lateral pterygoid, masseter, temporalis, as well as for sub-occipital muscle. Before using the dry needling the skin surfaces was cleaned by saline water the a plastic guided 40mm acupuncture needle was insert in to the tender point of the muscle and for muscle inhibition technique, ischemic sustained pressure applied on the muscle for 5-10 second. In the 3rd and 4th weeks supervised exercise were performed. The conventional physiotherapy treatment protocol received by the control group was performed twice weekly for a total of eight sessions for 4 weeks with a duration of 10 minutes of ultrasound therapy. The Biomed brand ultrasound modality was used with the dosages of continuous mode of 3MHz with the intensity of 0.6 W/cm². [16]

Data Analysis

Data was analyzed by using SPSS version 16.0. Total 200 subject's data were analyzed. Within the group comparison pair t-test and between the group comparisons unpaired t-test was used. Level of significance for this study was fixed at 5% (P<0.05).

Results

In the descriptive demographic data, no significant difference was found [Table-1]. There was a significant change in the experimental group for all the parameters of quality of life after the intervention [Table-2] but in the control group only changes found in the pain domain [Table-3]. When the post intervention data were compared between the groups, it was found that in all the parameters of experimental group were significantly different than the control group.

Discussion

The result of the study showed that manual physical therapy is effective against TMD. The main purpose of this study was to evaluate the effectiveness of manual physical therapy in conjunction with dry needling to improve quality of life in patients with TMD. In this study experimental group was shown a significant improvement in all the parameter of SF-36. The result showed that there is a significant improvement in quality of life in all domains for experimental group as compare with control group. In the control group very minimal amount of improvement shown in health related quality of life for all the parameters except the domain of pain. It is because; the study found that therapeutic ultrasound has a healing effect which can effect on the pain reduction. [24] Where in experimental group, improvement shown in physical functioning 28 points, role of limitations due to physical health 50 points, role of limitations due to emotional health 51 points, energy 35 points, emotional well-being 22 points, social life 23 points, bodily pain 39 points, general health 30 points.

A retrospective study conducted by Matta et, al. [17] and conclude that multidisciplinary approach is compulsory to treat the TMD patient. They also suggest that physical modalities only can reduce the symptoms for promoting a better quality of outcome interdisciplinary approach is required. Another similar study was done by Felício et, al. in 2008, where SF-36

questionnaire was used and shown that physical therapy approach is capable to improve the quality of life in patient with TMD. [18]

Study suggested that the relaxed, gentle and gradual stimulus of the fascia and the Ruffini endings within caused the subsequent instigation of the parasympathetic nervous system, which, in turn, caused a reduction in blood pressure. [19] Kim et al. [20] observed a decrease in stress hormone (known as a cortisol) levels following self-myofascial release and it was attributed to the suppression of the sympathetic nervous system through relaxation of the fascia. Hence, it can be assumed that the relaxation of the fascia can cause instigation of the parasympathetic nervous system and decrease blood pressure and pulse rate. In addition, MFR stimulate the mechanoreceptor which creates the balance of the autonomic nervous system mechanoreceptors [21] and another author said that stretching of the deep fascia surrounding the internal organs, causing a release of neurotransmitters which can affect the cardiovascular system. [22]

It is observed that multidimensional treatment approach for multifactorial disease is still lacking in physical therapy practice for the TMD management. [23, 24] Because in the physical therapy practice only some traditional manual therapy technique like mobilization, manipulation etc. but very less study with weak methodology found that multidisciplinary approach.

The present study was a multidimensional approach where improvement has shown in all the parameters. In this context, in control group also shown reduction of pain domain, therefore ultrasound can be effective modalities to reduce pain in patient with TMD, especially for those who are suffering acute TMD with persistent pain.

Conclusion

The results of the study showed that manual physical therapy in conjunction with dry needling treatment is beneficial to improve quality of life in patients with TMD. It was concluded that the dry needling can be a part of a physical therapy management protocol for better management of patients with TMD.

Current Radiographic Practices and Radiation Dose Evaluation

Chanchal Kaushik¹, Inderjeet Singh Sandhu², AK Srivastava³, Mansi Chitkara²

¹Assistant Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, ²Professor, Chitkara University Institute of Engineering & Technology, Chitkara University, Punjab, India, ³Medical Physicist cum RSO, Department of Radiology, University College of Medical Sciences, Delhi, India

Abstract

To investigate the current radiographic practices in a public tertiary care teaching hospital in digital radiography set-up, the study aimed to calculate the entrance surface air kerma (ESAK), kerma area product (PKA), and effective doses in chest PA, and AP digital radiographic examinations. Chest radiography is the most common examination performed worldwide. Due to the frequency of these examinations, its contribution to the collective dose is considerable. Also, various international authorities have recommended guidelines for local dose surveys for radiation protection and optimization. IAEA recommended protocol was used to calculate the patient doses. The 3rd quartile values of ESAK and PKA obtained are 0.17 mGy and 0.27 Gy cm^2 for chest PA; 0.38mGy and 0.21 Gy cm^2 for chest AP. The estimated mean effective doses are 0.017 (ED from ESAK), 0.037 (ED from PKA) for chest PA and 0.041 (ED from ESAK), 0.028 (ED from PKA) for chest AP. The results obtained are compared with ESAK, PKA, and effective dose values of previously published literature. The estimated doses could be used as a baseline value for setting up of future local diagnostic reference levels (LDRLs) and for optimization of patient doses in diagnostic radiology.

Keywords: Radiation dose, Chest X-ray, Kerma area product, entrance surface air kerma, effective dose, digital radiography, diagnostic reference levels.

Introduction

Ionizing radiation from medical X-ray exposures contributes largely to the public exposures from man-made radiation sources. X-rays serve as a valuable tool for diagnosis in medicine.¹ However, a major concern remains the radiation risk from these exposures. Benefits from these exposures must outweigh the associated

risks. Therefore it is crucial to justify and optimize each exposure without limiting the diagnostic information from the radiographs. Internationally many efforts are taken for radiation protection.² Dose surveys and patient dose monitoring is recommended by various national and international authorities and organizations such as Atomic Energy Regulatory Board (AERB), European Commission (EC), National Radiological Protection Board (NRPB), International Commission on Radiological Protection (ICRP), and International Atomic Energy Agency (IAEA). They have proposed guidelines and regulations for radiation protection of patients. They have also recommended the establishment of diagnostic reference levels (DRLs) for patient dose management.³⁻⁷ DRLs can be described as an investigation level or a dose quantity intended to identify abnormally high radiation doses during radiological examinations. These guidance levels represent a state of practice and are not expected to exceed the national

diagnostic reference levels (NDRLs).⁸ Dosimetric measurements in diagnostic radiology are done by quantities namely KAP (kerma area product, PKA) and ESAK (entrance surface air kerma).⁹ The replacement of the film-screen system with the digital system has increased rapidly in Indian hospitals and diagnostic medical imaging centers. However, studies aiming to investigate local radiographic practices in digital radiography are limited.^{10, 11} Features associated with DR like post-processing and large dynamic range can influence the contrast and density of image and can result in overexposures without the knowledge of the operator.^{12, 13} Present study aims to examine the current state of radiographic practice in chest digital radiographic examinations in a public teaching hospital in Delhi, India. Chest radiographic examinations are the most commonly done diagnostic X-ray examination and contribute considerably to the collective dose.^{14, 15} ESAK and PKA were calculated in adult patients undergoing chest PA and AP radiographic examinations and effective doses (ED) were estimated from appropriate conversion coefficients. Obtained ESAK, PKA, and ED values were compared with corresponding international and national values published in the literature.

Method

71 adult patients (42 men and 29 women) who underwent chest PA and chest AP radiographic examinations participated in the study over a period of 2 months (November-December 2019). Radiation dose calculation was performed following the IAEA recommended protocol and weight criterion of (70 ±10) kg was applied while enrolling patients.¹⁶ Ethical approval was obtained from the institutional ethical committee (approval no: ECR/296/Indt/PB/2019/ISFCP/46). Pregnant patients were excluded. Patient's age, sex, weight, height, type of examination along with tube voltage (kVp), tube current (mA), exposure time (s), mAs, focus to detector distance (FDD) and patient thickness was recorded. Focus to skin distance (FSD) was obtained by subtracting patient thickness (t_p) and t_b (bucky thickness of 5 cm approximately) from the FDD (equation 1).¹³ Patient thickness (t_p) was measured with a caliper scale (least count of 0.1 cm) in the center of the X-ray beam. Patient radiation doses were calculated and effective doses were estimated in chest radiographic examinations.

$$FSD = d_{FDD} - t_p - t_b \quad (1)$$

Estimates of ESAK, PKA and, Effective dose

The ESAK was determined (equation 2) from the tube output and recorded exposure factors during the X-ray examinations as described in international protocols.

$$ESAK = OT \times (\text{mGy/mAs}) \times \text{mAs} \times (100/FSD)^2 \times \text{BSF} \quad (2)$$

Where, ESAK corresponds to entrance surface air kerma, OT is tube output in mGy/mAs, mAs is tube current x exposure time, FSD is the patient thickness and BSF is the backscatter factor. Appropriate backscatter factors can be found in the IAEA Technical Report Series No. 457.¹⁶ Once the ESAK was determined, the effective dose (equation 3) per radiological projection was evaluated using conversion coefficients from UK HPA -012 which were obtained using tissue weighting factors from ICRP -103.¹⁷

$$E \text{ (mSv)} = CC_{ESAK} \text{ (mSv/mGy)} \times ESAK \text{ (mGy)} \quad (3)$$

Where CC_{ESAK} corresponds to ESAK to an effective dose conversion coefficient.

Kerma area product measurements were carried with the use of a calibrated KAP meter, attached to the surface of X-ray tube collimator.¹⁸ An effective dose from P_{KA} was determined from equation (4).

$$E \text{ (mSv)} = P_{KA} \text{ (Gy. cm}^2\text{)} \times CC_{P_{KA}} \text{ (mSvGy}^{-1}\text{ cm}^{-2}\text{)} \quad (4)$$

Estimation of effective doses was done based on recorded P_{KA} using appropriate conversion coefficients (P_{KA} to effective dose), published by Wall et al. (0.16 mSv/Gycm²).¹⁹ Descriptive statistics of the collected data were performed in SPSS statistics 23.0 for windows. The results were compared with corresponding ESAK, P_{KA} , and effective dose values published in the literature.

Results

Patient demographic information and technical parameters are presented in table 1. FDD used for chest PA was 180cm and chest AP was 100 cm. Field size came out to be 32.15*35.64 cm² for chest PA and

29.96*34.5 cm² for chest AP. For chest PA the mAs ranged from 1.07-4.55 and for chest AP the mAs ranged from 0.81-1.97. The linear relationship observed between mAs and ESAK is presented in figure 1 with R² values. Table 2: Presents ESAK, PKA, and effective dose values obtained in this study (mean ±SD, median, 25th, and 75th percentile values). Table 3 presents a comparison between 3rd quartile values of P_{KA} and ESAK values for digital radiography obtained in this study with published dose reference levels (LDRLs and NDRLs). Table 4: Comparison between obtained effective doses in this study with published dose reference levels (LDRLs and NDRLs).

Discussion

Dose surveys help in understanding the current practices in radiographic examinations, its comparison with other hospitals, the scope of dose optimization, and ultimately patient dose reduction. It is observed that the ESAK values of chest PA are lower with the earlier studies of LDRL values reported by Suliman in Oman, LDRLs reported by Bhupendra et al and Satish et al in India and, Macro et al in Brazil and comparable with UK 2010.^{10-13, 20} For chest PA, the percentage decrease of radiation dose is found to be 15%, 56%, 60% 29% with Suliman, Bhupendra et al, Satish et al, and Marco et al respectively.^{10,11,13,20} The LDRLs reported by Suliman and Bhupendra et al are in digital radiography.^{10,13} The study by Macro et al is in film-screen radiography, a study by Satish et al presented DRLs via a dose survey of mixed type of X-ray machines, i.e. 64% conventional, 31% computed, and 5% digital radiography. Lower doses of the present study are due to practicing high kVp and low mAs technique in digital radiography. Observed kVp in chest PA is 120 and mAs is 2.35. Increased filtration is another reason for lower doses along with the inclusion of patients with weight range close to reference patients, as reported by Metaxas et al in Greece.²²

The P_{KA} (3rd quartile) values for chest PA in the present study came out to be 0.27 Gy cm^2 , which is comparable and higher than UK 2010, and two studies in Greece by Metaxas et al.^{12, 22, 23} This difference can be attributed to the difference in technology of radiography systems on which data was collected, different patient demographics and different radiographic techniques adopted by radiographers. Also, this study presents LDRLs in a single hospital only. A higher kVp, mAs, and filtration were observed in UK 2010 in comparison with the present study.¹² For chest PA, a high kVp low mAs (120 kVp, 2.3 mAs) technique and increased filtration were used, but still, the P_{KA} doses were significantly higher than UK 2010, this difference can be attributed towards radiographic practices with digital radiography, with decreased use of collimating field of view and resulting in larger exposed areas.²⁴ The observed ESAK of chest AP came out to be 0.38, which is nearly double that of UK- 2010 (034).¹² PKA came out to be 0.21 which is 40% higher than UK 2010. The observed higher values chest PA and AP shows the need for further optimization of radiation doses.^{12,}

¹⁵ The results of this study provide baseline values for dose optimization in digital radiography and show that regular monitoring of patient radiation doses should be encouraged for radiation protection of patients.

Conclusion

The study aimed to calculate the ESAK, PKA, and effective dose values in chest PA, and AP digital radiographic examinations. The results obtained are compared with ESAK, PKA, and effective dose values of previously published literature. Dose surveys for common radiological investigations will help in improving examination techniques. The estimated doses could be used as a baseline value for future LDRLs and for investigating radiographic practices to further help in the optimization of patient doses in diagnostic radiology.

Family Interaction Pattern in Wive's of Alcohol Dependents

Chinnu Sebastian¹, Suja M.K²

¹PhD Scholar, ²Associate Professor Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Abstract

Introduction: Alcoholism is a disease which affects the individual and their family hence it is known as a family disease. Alcoholism reflects on the family bonds and it often leads to the complete breakdown of the entire family. The most affected persons are the wives of alcoholics because of their commonly nature and the intimacy in their relationships. The spouses of alcoholics facing severe domestic, financial and emotional violence which leads major psychological problems like anxiety, depression and poor self-esteem. Family interaction pattern (FIP) is defined as methods by which members of the family relate to each other through various mechanisms binding them in the bond of family.

Aim: This research work has made an attempt to study the Family interaction pattern in wive's of alcohol dependents. This study to measure the level of family interaction pattern and significant factors associated with wive's of alcohol dependents of Kottayam district of Kerala, India. **Result:** Nearly half of the respondents (37%) have medium level of Family interaction pattern. 33% have high family interaction pattern and 30% have low level of family interaction pattern. The study reveals that FIP Score has significant difference with the variables like age, area of residence, education and duration of drinking habit in spouses. The post hoc test indicates that respondents between the age group of 31-40 years, rural area of residence, educated below 10th standard and above 10 years of drinking habit in spouses have better FIP. Religion, type of family, occupation and family monthly income has no significance. **Conclusion:** This study inspires in realizing the mental, social, marital and family relation among wive's of alcoholics and it will be a great help in promoting family counselling programmes in de- addiction centres.

Key words: Alcoholism, Alcohol dependents, Wives, Family interaction pattern.

Introduction

Alcoholism is one of the major health and social problems around the world, which results in 3.3 million deaths in every year (WHO, 2018)¹. Alcohol consumption is the world's third largest risk factor for several disease and disability in the world today. Since India has the second largest population in the world the magnitude of the problem of "Alcoholism" is also very

high in India, and as per WHO 33% of India's population is alcoholics. It is also seen an annual rise in the number of people who use alcohol (WHO, 2010)². Alcoholism is a major cause of mental, social, family and health problems in Kerala. The state of Kerala has the highest per capita alcohol consumption in India, at over 8 litres per person per year³.

Alcohol addiction can be considered as a family problem and this contributes to the increased stress in the family. Family failure and breakage due to alcoholism is a serious pervasive social issue. Alcohol is connected with domestic violence, low satisfaction in the relations, relationship conflicts, under care of children, legal and economic issues, disrupted family interaction etc. and some also results in physical and psychological illness⁴. Researcher observed that the

actual sufferers are the members of family who depends upon the alcoholic, particularly the spouse. The wives of alcoholics often shows many mental and physical problems, their social involvement will be very low and low level of marital satisfaction. Even these people have very bad communication level also⁵. The spouses of alcoholics have psychological issues in various adaptive and maladaptive coping mechanisms, to restore the equilibrium and to relieve stress.

Family is the basic and fundamental part in the society. And several families contribute to form a society. The health of a nation can be measured only in terms of health of a family. Addiction affects mostly the spouse in the family as the family income is spent on liquor and the spouse is compelled to manage family finance and needs. There exist fear and uncertainty which leads to lack of self-esteem and self-confidence. Spouses of alcohol dependent person may have feelings of guilt, shame, anger, fear, grief, avoidance of social contacts and isolation due to the presence of an alcohol dependent in the family. They are often subjected to moderate to severe form of harassment. Conflict and tense atmosphere arises when they confront the drinking behaviour of their alcohol abusing family member. The problems that arise as a result of alcohol abuse is numerous, which includes long absences from home, destroying house hold and domestic items, no communication, isolation, domestic violence etc. these people are least bothered of the happenings in their family.

Alcoholism of husband results in the change in the interaction patterns of the wife and causes an alteration the complexion of family environment by financial resources of the family which intern results in the dysfunction of several other areas. The heavy stress experienced by wife in dealing with the pressure of her husband will always influence their marital life negatively. Almost all of the alcoholic dependents and their spouses agree that the main factor of marital happiness is related to family interaction and interpersonal relationship⁶.

Family interaction patterns are defined as those socio-psychological transactions occurring in the family as system to evolve processes for decision making, emotional expression, personal views, assigning tasks and social status, enabling the family members to

contribute to the growth of the family by generating morphogenesis at emotional, intellectual, and social levels by manipulation of external and internal milieu of the family as a whole. From the evolutionary point of view, every family has patterns of leadership, communication, role, reinforcement, cohesiveness and social support constituting its functioning.

Reinforcement: process adopted by the family to enable the members to imbibe socially approved behaviour. Social support system: manipulation of internal and external social milieu of the family for its existence and growth. Role: socio culturally prescribed and ascribed tasks to be performed by different family members according to their age and sex. Communication: Communication within the family is extremely important because it enables members to express their needs, wants, and concerns to each other. Cohesiveness: processes adopted by the family for a firm degree of mutual trust and interpersonal commitment. Leadership: A family member engaged in decision making through consensus for growth of the family, as a system is the leader of the family⁷.

The researcher visited various De-addiction centres in Kottayam district, Kerala and interacted with the spouse of alcoholics during the Al-anon programme (Al-anon group is a worldwide fellowship that offers a programme of recovery for the families and friends of alcoholics, whether or not the alcoholic recognizes the existence of a drinking problem or seeks help)⁸ and family counselling. The interaction with spouses and discussion with family counsellors of the de-addiction centres helped the researcher to find out the family interaction pattern of the respondents. Researcher came to know that the impact of alcoholism on marital family functioning and influences the family interaction.

Methodology

This paper is based on standardized scale and the data was collected with an interview schedule from wives of alcoholic attending family counselling and Al-anon meeting in a De-addiction centre of Kottayam district of Kerala. An interview schedule was used to collect data. Family interaction Pattern Scale (FIPS) developed by Bhatti et al (1986) is used for the study. The research is descriptive in nature. Census method used to collect the samples. The researcher collected data's from all

the respondents who were willing to participate in the study during the period of data collection (July 2019 – December 2019). The criterion for selection of the respondents was the wives living with the alcoholics who are under treatment at de-addiction centres in Kottayam District. 200 respondents were included in the study.

Major Findings:

The simple percentage of socio demographic data reveals the following information. It is seen that 30% of the respondents are in the 20-30 years age group. Nearly half of the respondents (49%) are Christian. More than half of the respondents (55%) are from rural area. More than half of the respondents (56%) are from nuclear family. Nearly half of the respondents (29%) have Under Graduate education. Nearly half of the respondents (29%) are unemployed spouses (housewives). Majority of the respondents (64%) have family monthly income above Rs.20000. Half of the respondents (50%) have

above 10 years of drinking habit in spouses. **Level of Family interaction pattern**

Nearly half of the respondents (37%) have medium level of Family interaction pattern. 33% have high family interaction pattern and 30% have low level of family interaction pattern.

Evidences show that severe alcoholism leads to marital problems and family conflict, and negative emotions and interpersonal interactions often lead to relapses among alcoholics. Stress from family and other relations will motivate them for more drinking. Family members of the alcoholic have medium level of communication as either of the spouses, children or parents is afraid to talk to each other. This is mainly due to the violent nature of the alcoholic where the family members limit their communication so as to avoid problems.

Factors affecting the Family interaction pattern

Table No. 1: ANOVA Test to compare Family Interaction Pattern (FIP) and Socio demographic profile

S.No.	Variables	F -value	Table value	Significant/Not
1	Age	4.230	3.883	**
2	Religion	0.196	3.048	NS
3	Area of residence	4.052	3.048	*
4	Type of family	0.946	3.042	NS
5	Education	3.482	3.113	**
6	Occupation	0.662	2.418	NS
7	Family monthly income	0.915	3.042	NS
8	Duration of habit in spouse	4.144	3.883	**

NS-Not significant, * -Significant at 5% level, ** -Significant at 1% level

1) FIP Score has significant difference with age. The post hoc test indicates that respondents are between the age group of 31-40 years have better FIP.

This study revealed that the family interaction pattern is more significant in spouses of alcoholics with age groups of 31-40 years than other age group.

It is because couple's given more concentration to their young children and when the child grown to teenage or above they leaves the home for studies, job.

2) FIP Score has significant difference with Area of residence. The post hoc test indicates that respondents who are from rural area of residence have better FIP.

The National Family Health Survey 2015-16(NFHS-4) reveals that the consumption of alcohol is higher in rural area than urban area in Kerala⁹. The study revealed that the FIP is significant in rural area than urban and sub urban areas. The significance is due to the influence of social support and interaction among the neighbours is higher in rural area than urban and sub urban areas. The women in the rural areas are gathering together once in a week for the “Kudumbashree Meeting” (a poverty eradication mission by Government of Kerala) which help them to share their problems with the peer group and find the solutions for the same.

There is a need of detailed study among the rural populations, mainly family centered people in order to have in-depth knowledge. On their particular needs and to contribute more to adopt public health measures for preventing these issues and promoting health and psychological rehabilitation. The problem of excessive alcohol consumption is a major cause of public health concern both in urban and rural areas.

3) FIP Score has significant difference with education. The post hoc test indicates that respondents were educated up to 0-9 standard (below 10th standard) has better FIP.

The FIP is higher in respondents below 10th standard education than the educated wives. As most of the respondents are from rural area, the culture of the society is more family oriented. The less educated respondents are more flexible to adjust with alcoholic habit of their spouses than the educated respondents. Hence the FIP is higher in this category. Some of the high income individuals are not highly educated. They are into business and earn lakhs of rupees and hence were found to lead a comfortable life with the satisfaction given by money¹⁰.

4) FIP Score has significant difference with Duration of habit in spouses. The post hoc test indicates that respondents whose husband's are drinking above 10 years have better FIP.

Analysis of the research shows that the FIP is higher in wives of alcoholics whose spouse's drinks alcohol for more than 10 years. On interaction with the respondents the researcher identified that most of the respondent's spouses who drinks alcohol for more than 10years have

more responsibility towards the family and spouses gives mental support to the alcoholics as they were adjusted with habit of the spouses. This helped them to reduce domestic violence and quarrels among them.

Discussion and Conclusion

Family education and family therapy will lead to solve the problem to a certain extent and other important is to educate the community. Adjustmental problem of wives of alcoholics affect their future generation. Mass media- information should be given about the ill effect of alcoholism. Family counselling or 12 steps therapy (AI-anon) will help the wives to recover from adjustmental problem, marital dissatisfaction and family interaction. De-addiction centres suggest a need to study the stress perceived by spouses of alcoholics and these centres recognized spouse of alcoholic's as an important components in the development of personality, marital conflict, maintenance relationship and treatment of psychological problems. Changes in the attitude and behaviour of the wives of alcoholics can be bought through various therapies like individual, family, musical, occupational etc. and also methods like yoga, meditation and relaxation techniques may contribute to their psychological improvement.

Conclusion

Nearly half of the respondents (37%) have medium level of Family interaction pattern. The study reveals that FIP Score has significant difference with age, area of residence, education and duration of drinking habit in spouses. The post hoc test indicates that respondents between the age group of 31-40 years, rural area of residence, below 10th standard education and above 10 years of drinking habit in spouses have better FIP.

Researcher observed that the social consequences of the wives of alcoholics at the individual level significantly impact on personal life, work related area and family relationship. They experience physical, social, economical and psychological problems like socially isolated, lost status in the society, anxiety, depression, loneliness, worthlessness, fear of being rejected etc. because of their husband's drinking. So many negative social consequences like very low self-esteem, disturbed family, social problems, recreational problems etc. are reported from the wives of alcohol

dependents. It is the responsibility of social workers to use social work intervention techniques and methods (psychotherapy for couples & family members, group therapy, counselling etc.) for improving their self esteem and better family interaction pattern.

- Marital satisfaction and stability is negatively affected because of excessive drinking.

- Discordant alcohol consumption is a prime factor in marital dissatisfaction.

- Treatment for the couples for alcoholism has given better outcome and greater satisfaction in marital life. This has also resulted in less partner violence.

- After family therapy, the openness, warmth, support and relationships became more effective and sharing of responsibilities is seen in the family.

- Practising problem-solving skills and additional behavioural skills help the couples to cope up with relapse episodes¹¹.

A retrospective study to assess the trends of Sexually Transmitted Infections among the patients attending Skin and STD OPD KIMS, Hubli

Dattatraya D Bant¹, Shiv Kumar²

¹Professor and Head, Department of Community Medicine, Karnataka Institute of Medical Sciences, Hubballi, Karnataka

Abstract

Background & Objectives: Sexually transmitted infections are on focus since the advent of HIV, as they contribute to the spread of the disease. To simplify the detection of STIs at the community level syndromic approach has been introduced. There is a shift in the trend of aetiology from bacterial to Viral. However the information available on these changing trends is very limited. The present retrospective study was conducted to study the trends of sexually transmitted infections in KIMS, Hubli.

Method: A retrospective study where data was collected from the previous records of patients attending Skin and STD OPD, KIMS Hubli. The data was entered in MS Excel and analysed using SPSS software.

Results: The study showed that prevalence of STI is highest in the age group of 25-44 years (56.54%), and among females (11.2%) with vaginal discharge being the most common presenting complaint (38.7%). The prevalence of HIV among patients attending skin & STD OPD, KIMS, Hubli was found to be 5.04% during the year 2012

Conclusion: The average prevalence of STI is 5.36% during years 2008-2012. There is an increase in the detection of HIV positive status among the patients attending skin & STD OPD, through the years.

Keywords: Sexually transmitted infections, trends, retrospective study

Introduction

Every year there are over 340 million new cases of sexually transmitted infections, 75–85% of them occurring in developing countries according to WHO.¹ 40 million new cases occur each year in India.¹

The sufferings of majority of women who had RTI are mainly because of complications like infertility,

pelvic inflammatory disease and cervical cancer.¹

With the advent of HIV, STDs have become one of the major public health problems.²

There is a huge impact of STDs on health and economics of a nation. HIV pandemic has forced to focus on the prevention of these diseases as they are the key factors in HIV transmission.³

Bacterial infections like syphilis and gonorrhoea were dominating in India during 1960s and 1970s. With the spread of HIV and the changing life style and behaviour have led to a rise in viral infections.⁴

The socio-demographic and clinical knowledge in STI population can contribute to the necessary changes in the improvement of already existing preventive

programs.⁵

This retrospective study was carried out to determine the changing trends of STIs among the patients attending skin and STD OPD KIMS, HUBLI.

Methodology

The study was started with orientation to records maintained in skin and STD OPD, KIMS, Hubli. The records were maintained on monthly basis with entries of all cases attending with complaints of STI for whom various laboratory examinations were done for the diagnosis of STI.

Entries were made under the following headings:

- Name of the STD clinic/hospital.
- Reporting period- month and year.
- No. of patients availed STI services in the month.

- STI syndromic diagnosis.
- Details of other services provided to patients with STI complaints in this month.
- STI service provision HRGs in the month.
- ANC syphilis screening in the month.
- Laboratory diagnosis in the month.

The records from January 2008 to June 2012 were retrieved and data was collected and recorded systematically for all the patients of STI attending skin and STD OPD during this period.

The data was segregated and analysed. Various demographic factors were studied; the information was tabulated and interpreted. The data was presented as frequencies and percentages.

Results

Table 1: Table showing the total number of patients attending the skin and STD OPD for STIs at KIMS, Hubli

Year	Gender/ Total	No. of cases
2008	Male	10026
	Female	6371
	Total	16397
2009	Male	8544
	Female	5489
	Total	14033
2010	Male	6024
	Female	4630
	Total	10654
2011	Male	7158
	Female	5172
	Total	12330
2012	Male	3423
	Female	2354
	Total	5777

The above table shows the total number of STI cases attending Skin and STD OPD

Table 2: Prevalence Of STI among patients attending skin & STD OPD, KIMS, Hubli

Years	2008	2009	2010	2011	2012
Male	50	97	73	37	87
%	0.5	1.1	1.21	0.52	2.54
Female	43	59	699	517	686
%	0.67	1.07	15.1	10	29.14
Total	93	156	772	554	773
%	0.57	1.11	7.25	4.49	13.38

From the above table we can see that the prevalence of STI has gradually increased over a period of time to 13.38% in 2012.

Table 3: Table showing the difference in the STI trends according to age and gender

Age group	Years	Male	%	Female	%	Total	%
Less than 20 years	2009	5	3.2	0	0	5	3.2
	2010	1	0.13	57	7.38	58	7.51
	2011	0	0	13	2.33	13	2.33
	2012	1	0.13	36	4.65	37	4.78
20-24 years	2009	14	8.97	3	1.92	17	10.89
	2010	5	0.64	98	12.69	103	13.34
	2011	3	0.54	85	15.34	88	15.88
	2012	18	2.32	116	15	134	17.32
25-44 years	2009	56	35.85	46	29.48	102	65.38
	2010	51	6.61	367	47.54	418	54.15
	2011	26	4.69	294	53.06	320	57.75
	2012	40	5.17	415	53.68	455	58.85
More than 44 years	2009	22	14.1	10	6.41	32	20.51
	2010	18	2.33	143	18.52	161	20.85
	2011	12	2.16	106	19.13	118	21.23
	2012	28	3.62	119	15.39	147	19.01

From the data in the above table, we can see that majority of the patients of STIs were in the age group of 25-44 years in all the four years and in all the years females were the majority except for the year 2009 where males were more in number when compared to females (Table 3).

Table 4: Table showing the trends of Genital Herpetic Ulcer and Genital Non Herpetic Ulcer from 2008-2012

Lesion	Year	2008	2009	2010	2011	2012
Genital Herpetic Ulcer	Male	16	58	44	24	11
	%	17.2	37.17	5.7	4.33	1.42
	Female	16	20	30	18	5
	%	17.2	12.82	3.88	3.24	0.64
	Total	32	78	74	37	16
	%	34.4	49.99	9.58	6.67	2.06
Genital Non Herpetic Ulcer	Male	6	12	3	11	0
	%	6.45	7.69	0.38	1.98	0
	female	2	4	0	5	1
	%	2.15	2.56	0	0.9	0
	total	8	16	3	16	1
	%	8.6	10.25	0.38	2.88	0

Genital Herpetic ulcer was equal in both males and females during the year 2008 and after that more males were detected and the maximum number of cases detected was during the year 2009. Genital non herpetic ulcer was more common in males and in 2012 there was only one case. (Table 4)

Table 5: Symptomatology of the patients attending Skin and STD OPD, KIMS HUBLI.

Symptom	Years	2008	2009	2010	2011	2012
Lower abdomen Pain	Male	0	0	0	0	0
	%	0	0	0	0	0
	Female	0	0	244	177	129
	%	0	0	31.6	31.95	16.68
	Total	0	0	244	177	129
	%	0	0	31.6	31.95	16.68

Cont... Table 5: Symptomatology of the patients attending Skin and STD OPD, KIMS HUBLI.

Inguinal Bubo	Male	0	3	0	2	1
	%	0	1.92	0	0.36	0.13
	Female	2	0	0	0	0
	%	2.15	0	0	0	0
	Total	2	3	0	2	1
	%	2.15	1.92	0	0.36	0.13
Genital wart	Male	5	3	5	1	0
	%	5.37	1.92	0.64	0.18	0
	Female	3	6	0	0	1
	%	3.22	3.84	0	0	0.13
	Total	8	9	5	1	1
	%	8.6	5.76	0.64	0.18	0.13

Lower abdomen pain was the most common symptom among females during the years 2010 to 2012 (Table 5)

Table 6: Prevalence of HIV among patients attending skin & STD OPD, KIMS, Hubli

Year	2008	2009	2010	2011	2012
Male	0	7	6	4	12
%	0	4.48	0.77	0.72	1.54
Female	0	14	11	0	27
%	0	8.97	1.42	0	3.49
Total	0	21	17	4	39
%	0	13.46	2.19	0.72	5.04

5% of the total patients with STIs were found to be positive for HIV during the year 2012 which was 13.5% during the year 2009 (Table 6).

Discussion

In this study, we found that the prevalence of STI among the patients attending SKIN AND STI OPD, KIMS, Hubli is 5.36% during the study period JAN 2008 TO JUNE 2012. STI prevalence during each year is

- Ø 2008- 0.57%
- Ø 2009-1.11%
- Ø 2010-7.25%
- Ø 2011-4.49%
- Ø 2012-13.39%

The prevalence of STI is more in the age group 25 – 44 years (56.54%) which is different from a study conducted by Dr. V K Jain where 54 % of the patients with STI were 21-30 years.³

The prevalence of STI is high in females (11.2%) than males (1.17%) in contrast to the previous study made by Dr. V K Jain, et al. where the male:female ratio was found to be 5:1.³

And one more study conducted by T S Chandragupta et.al. was also in contrary to our study where majority were males and were in third decade of their life.⁶

In our present study, vaginal discharge is the most common syndrome with a prevalence of 53.68% in 2012 which was about 23.66% in 2008 which is similar to a study conducted by Sangeetha S Balamurugan (32.77%).¹

The second most common syndrome was lower abdominal pain with a prevalence of 26.7% in accordance with the similar study made by Sangeeta S Balamurugan (23.48 %).¹

The third most common STD was genital ulcer herpetic with prevalence about 20.54%.

The next in the list was AIDS with prevalence of 5.3%.

The next to follow were non herpetic genital ulcer (4.42%) and genital warts (3.06%).

There is a change in the trend of STIs as we can see a gradual rise in the cases of many viral infections with

increase in the detection of STIs by the health workers because of syndromic approach, many studies also show a similar trend of increasing Viral STIs.^{7,8}

More studies should be conducted to note the changes in the trends during the course of time to help in the improvement of the existing strategies followed.

Conclusion

In the retrospective study conducted the total prevalence of STI is found to be 5.36% and STIs are more prevalent in the age group of 25- 44 years. STIs are more prevalent among females than males with vaginal discharge being the most common syndrome.

Limitations

1. Data about socio economic status, religion and marital status was not available and could not differentiate between urban and rural population.
2. The population under the study could not be defined exactly since the hospital caters for a very large population from various regions of North Karnataka.
3. The results cannot be generalised to the community.

Recommendations

1. To conduct prospective studies to find out the trends of STIs, at community level.
2. To strengthen awareness about transmission of disease among the people more so among females.
3. To create awareness among people about the preventive measures.
4. Health campaigns should be conducted regularly by public health workers.
5. Promotion of female literacy.
6. Early diagnosis and prompt treatment must be encouraged.

Acknowledgement: The authors would like to thank the head of the department of Dermatology and Medical Records Department KIMS, Hubli for their cooperation in the conduct of the study.

Assessment of Safety Practices of Pesticide Use among the Farmers in Adargunchi and Noolvi, Karnataka - A Cross Sectional Study

Dattatraya D Bant¹, Laxmikant Lokare², Tewe U Kapfo³

¹HOD and Professor, ²Associate Professor, ³Post Graduate, Department of Community Medicine, Karnataka Institute of Medical Sciences, Hubballi, Karnataka

Abstract

Background: Modern agricultural practices reveal an increase in the use of pesticides and fertilizers to meet the food demand of increasing population which results in more exposure of pesticide residues. Many of the pesticides have been associated with health and environmental hazards. Thus, understanding farmer's knowledge of pesticides and safety practices is vital to provide valuable information aimed at preventing or reducing the health hazards associated with it.

Objectives : To assess the awareness of the safety practices related to pesticide among the farmers and to identify the health problems associated with it.

Method: A cross sectional study was conducted among 150 farmers in Adargunchi and Noolvi of Dharwad district, Karnataka, in the month May and June 2014. A pretested, semi-structured questionnaire was used to collect data.

Results: 93% were not aware of the harmful effects of pesticide. 78% did not undergo any practical training related to pesticides. 70% did not take any precautions nor use any protective equipment. 59% suffered from one or the other ailment due to exposure to pesticides and only 5% have sought medical care.

Conclusion: Overall awareness of agricultural workers on pesticide was inadequate. The findings of the study emphasize the need to educate agricultural workers regarding safe and adequate use of pesticides to prevent health hazards.

Key Words: *Farmers, Awareness, Pesticides, Herbicides, Agricultural workers.*

Introduction

Pesticides are substances or mixtures of substances that are mainly used in agriculture or in public health protection programs in order to protect plants from pests, weeds or diseases, and humans from vector-

borne diseases, such as malaria, dengue fever, and schistosomiasis. Some of the typical examples includes; Insecticides, fungicides, herbicides, rodenticides, and plant growth regulators^(1, 2, 3).

India is largest manufacturer of basic pesticides in Asia and ranks 12th globally. The production of pesticides started in India in 1952 with the establishment of a plant for the production of BHC near Calcutta, and India is now the second largest manufacturer of pesticides in Asia after China⁽⁴⁾. The pattern of pesticide usage in India differed from that for the world in general where in India, 76% of the pesticide used is insecticide, as against 44% globally. The main use of pesticides in India is for

Corresponding author:

Email: tewekapfo@gmail.com

cotton crops (45%), followed by paddy and wheat. The use of herbicides and fungicides is correspondingly less heavy (4, 5).

Because of the widespread use of agricultural chemicals in food production, people are exposed to low levels of pesticide residues. Many of the pesticides have been associated with health and environmental hazards (1, 2, 6-8), and the agricultural use of certain pesticides has been abandoned (2). Evidence also suggests that children are particularly susceptible to adverse effects from exposure to pesticides including neurodevelopment defects (9). No segment of the population is completely protected against exposure to pesticides and the potentially serious health effects, though a disproportionate burden is shouldered by the people of developing countries and by high risk groups in each country (1). The world-wide deaths and chronic diseases due to pesticide poisoning number about 1 million per year (10). The high occupational, accidental, or intentional exposure to pesticides can result in hospitalization and death (1, 11). Thus, understanding farmer's knowledge of pesticides and safety practices is vital to provide valuable information aimed at preventing or reducing the health hazards associated with pesticides. This study aims to study the awareness of the safety practices related to pesticides among the farmer and to identify the health problems associated with exposure to pesticides.

Objectives

To assess the awareness of the safety practices related to pesticides among the farmers

To identify the health problems associated with exposure to pesticides.

Method

This was a cross sectional study of conducted among the farmers in Adargunchi and Noolvi of Dharwad district, Karnataka, in the month May and June 2014. Convenient sampling method was used to collect the data and the total sample size included was 150.

Inclusion criteria – Labourers and Farmers exposed to pesticide who have given consent to participate in the study.

Data collection: The participants were briefed about the purpose of the study and informed written consent was taken and data was collected by in depth interview method with a pre-determined, pre-tested questionnaire in English and was asked in local language (Kannada) and details regarding pesticide usage, precautions taken, and health problems during exposure and awareness about harmful health effects of pesticides.

Data Analysis: The data collected was entered in Microsoft Excel and later analyzed using SPSS version 20. Chi-Square test was applied as test of significance and p-value of <0.05 was considered statistically significant.

Results

Table 1. Socio-demographic factors

Variables		No. of farmers	Percentage
Locality	Adargunchi	54	35.3
	Noolvi	96	0.7
Gender	Male	139	92.7
	Female	11	7.3
Religion	Hindu	135	90.0
	Muslim	15	10.0
Education	Literate	76	50.7
	Illiterate	74	49.3
Duration of farming	<5 years	5	3.4
	5 - 10 years	12	8.0
	>10 years	133	88.7

93% of the participants were males, about half of them (51.7%) were literate and 88% were BPL card holders. 89% of the study participants were cultivating for more than 10 years.

Table 2. Practices of the farmers

Variables		No. of farmers	Percentage
Practical training attended	Yes	33	22.0
	No	117	78.0
Method of usage	Mixed	95	63.3
	Separately	41	27.3
	Both	14	9.3
Storage at safe place	Yes	148	98.7
	No	2	1.3
Printed instruction followed	Yes	102	68.0
	No	48	32.0
Increased usage compared to previous years	Yes	87	58.0
	No	31	20.7
	Not considerably	32	21.3
Equipment used	Manual placement	2	1.3
	Sprayer	5	3.3
	Trigger pump	143	95.3
Frequency of usage per year	1	33	22.0
	2	77	51.3
	3	19	12.7
	4	17	11.3
	≥5	4	2.7
Visits in the field after application of pesticides	After few hours	77	51
	After few days	54	36
	After a week	19	13
Precautions taken during application	Yes	45	30.0
	No	105	70.0

78% of them were not practically trained. 64% mixed different pesticides and used, 41% uses separately and 14% uses both at a time. Almost all of them (99%) store the pesticides in a safe place. 68% of them follow printed instruction. 58% were opined that pesticide usage has been increased as compared to that of previous year. 95% of them use trigger pump for pesticides applications. 51% of used twice a year and few reported using ≥ 4 times a year. 51% goes to field immediately after the application and 70% do not take any precautionary measures while applying the pesticides (Table 2).

Most of the farmers use only masks and many of them did not use any kinds of personal protective devices (PPD) during application (Table 3). Majority of them (93%) were not aware of the harmful effects of pesticide. About 59% reported suffering from pesticide exposure on the day of exposure or on the next day. Majority (46%) had general health problems viz., headache malaise, fatigue etc. (Fig. 3) and 2% were hospitalized. Only 7% were aware of the harmful health effects of pesticide treated product consumption and only 5% of them have sought medical care.

Table 3. Types of PPD use during pesticides applications

Types of PPD*	No. of farmers	Percentage
Respirator	1	0.7
Mask	44	29.3
Boots	2	1.3
Gloves	11	7.3
Shield	3	2
Resistant clothing	2	1.3

* Personal protective devices

Figure 1. Self reported health problems due to exposures of pesticides

Majority (46%) of the participant complaints of general health problems viz., headache malaise, fatigue etc. after exposure to pesticides.

Table 4: Relation between literacy and health problems with precautions taken

Variables		Precautions		p- value
		Yes (%)	No (%)	
Literacy	Literate	27 (18%)	49 (32.7%)	>0.05
	Illiterate	18 (12%)	56 (37.3%)	
Health problems	Yes	34 (22.7%)	54 (36%)	<0.05
	No	11 (7.3%)	51 (34%)	

Those who were literate have better precautionary measures as compared to illiterate and but it not was found to be statistically significant (Table 4). Precautionary measures and health problems were found to be statistically associated ($p < 0.05$).

Table 5: Association between duration of cultivation with eye and dermal problems

Duration of cultivation	Eye problem		Dermal problem	
	Yes (%)	No (%)	Yes (%)	No (%)
< 5 years	2 (1.3)	3 (2%)	3 (2%)	2 (1.3%)
5 to 10 years	6 (4%)	6 (4%)	3 (2%)	9 6%
>10 years	44 (29.3%)	89 (59.3)	37 (24.7%)	96 (64%)
p-value	>0.05		> 0.05	

As the duration of cultivation increases the health problems increases as well i.e eye problems and skin problems but it was not found to be statistically significant ($p > 0.05$).

Discussion

This study was conducted in Adargunchi and Noolviof Dharwad District of Karnataka with the aimed to assess the awareness of the safety practices related to pesticides among the farmers and to identify the health problems associated with it. In our study 93% of

the farmers were males 89% of them were cultivating for more than 10 years. Whereas in the similar study conducted by Strong et.al study 73.5 were male, 62.5 were cultivating for more than 10 years and in the Mohanty K M et.al study, all the participants were male (12,13).

In our study 68% were not aware of the harmful effects of pesticide and 7% were aware of the harmful health effects of pesticide treated product consumption. Whereas in the study conducted by Strong et.al, 91.9% were aware about the harmful effects of pesticides⁽¹²⁾.

In our study, 29.3% used masks, 7.3 used gloves, 2% used gloves, 1.3% used boots and resistant clothes and 0.7% used respirator pesticides application. In the study conducted by Strong et.al, 41.2% used protective boots, 38.4% gloves, 82% hat and 22.7% protective lenses always during the application of the pesticides. And in the study conducted by Mohanty K M et.al, 40% to 70% were not using any protective equipment during pesticide spraying^(12, 13).

46% of the respondents reported having general health problems such as headache, fatigue and malaise after exposure to pesticides. 35% reported eye problems such as burning, itching and watering. 28% reported skin problems such as itching, redness and 27% reported gastrointestinal symptoms such as loss of appetite, vomiting and diarrhoea. 2% reported of being hospitalized after exposure to pesticides. There were very few cases which manifested neurological symptoms and no reported cases of poisoning, respiratory, cardiac and renal problems. Only 5% of them have sought medical care.

Conclusion

93% were not aware of the harmful effects of pesticide. 78% did not undergo any practical training related to pesticides. 70% did not take any precautions nor use any protective equipment. 59% suffered from one or the other ailment due to exposure to pesticides and only 5% of them have sought medical care. Safety measures taken by farmers were not satisfactory and overall awareness of agricultural workers on pesticide was inadequate. The findings of the study emphasize the need to educate agricultural workers regarding safe and adequate use of pesticides to prevent health hazards.

Limitation

The study had some limitations. Firstly, the data was based on self report and evaluation was only based on questionnaire and didn't include any form of medical examination, therefore subject to bias. Secondly, the

farmers in Adargunchi and Noolvi grow mainly cotton, for which they use pesticides less frequently i.e., 1-2 times/year. So the results might not be generalizable.

Recommendation

Proper training in pesticide handling and education on the hazards of pesticide exposure would diminish substantially the health hazards currently facing by farmers. Continuous emphasis on the importance of protective equipment is essential for changing wrong habits of farmers which can be hazardous for their health. The farmers should be encouraged for periodic medical check-up to minimize the adverse health effects of the pesticides.

Acknowledgement: The authors would like to thank all the farmers in Adargunchi and Noolvi who had participated in the study for their co-operation and all the staff of Community Medicine Department KIMS, Hubli for extending their help in smooth conduct of this study.

Abstract

Introduction: Human immunodeficiency virus infection and acquired immune deficiency syndrome (HIV/AIDS) is a spectrum of conditions caused by infection with the human immunodeficiency virus. The purpose of this study is to obtain data on the prevalence of HIV in the cancer population and vice versa at a major tertiary cancer in Bathinda and as the HIV population is also growing, the proportion, epidemiology and demographic profile of HIV in cancer patients need to be evaluated. **Aims & Objectives:-** To estimate the proportion of HIV infection among cancer patients visiting tertiary care hospital in District Bathinda and to study the demographic profile of patients suffering from HIV and cancer as primary outcome and to study the epidemiology of cancer among HIV-infected people as secondary outcome. **Materials and Method:-** Descriptive cross sectional study in cancer patients coming to tertiary care cancer hospital in Bathinda. **Results & Conclusion:-** In our hospital based study, we observed low proportion of HIV (0.28%) as well as HIV+ Cancer patients(0.23%). In cancer patients burden of HIV-infection will have implications for current and future cancer risk.

Keywords: Malignancy. non-AIDS defining cancers, AIDS defining cancers.

Introduction

Human immunodeficiency virus infection and acquired immune deficiency syndrome (HIV/AIDS) is a spectrum of conditions caused by infection with the human immunodeficiency virus (HIV)⁽¹⁾ HIV affects the person's immune system and this state of immunosuppression with compromised immune system makes it harder for the body to fight infections. As the infection progresses, it further interferes with the immune system and reduces the body's ability to fight viral infections thus leading to ^(2,3,4) high risk of developing cancer as compared to uninfected people of the same age ^(5,6,7) in their lifetime. HIV allows cancer cells to spread faster than in someone without HIV. People with AIDS are 19 times more likely to be diagnosed with anal cancer, 3 times with liver cancer, 2 times likely to be diagnosed with lung cancer, 2 times as likely to be

diagnosed with oral cavity/pharynx cancer and about 8 times more likely to be diagnosed with Hodgkin lymphoma compared with the general population. Collectively all these malignancies are called "non-AIDS-defining cancers" ^(1,2). HIV infection increases the risk of cancer and also increases the mortality in cancer patients ^(8,9). The poor cancer survival rate of HIV-infected people may be due to weakened immune system, cancer being more advanced at diagnosis and also delay in cancer treatment. As cancer risk increases with age, people living with HIV/AIDS are at an increased risk of developing cancer. The aim of this study is to obtain data on the prevalence of HIV in the cancer population and vice versa at a major tertiary cancer in Bathinda and as the HIV population is also growing, the proportion, epidemiology and demographic profile of HIV in cancer patients need to be evaluated.

Aims and Objectives

1. To estimate the proportion of HIV infection among cancer patients visiting tertiary care hospital in District Bathinda.
2. To Study the demographic profile of patients suffering from HIV and cancer.
3. To study the epidemiology of cancer among HIV-infected people

Materials and Method

Study design : Descriptive cross sectional study

Study Population: Cancer patients coming to tertiary care cancer hospital in Bathinda.

Study Period: 3 years from 01.01.16 to 31.12.19.

Sample Size: All the patients who were confirmed Histo-Pathologically for Cancer

A. INCLUSION CRITERIA: Patients confirmed Histo-Pathologically for Cancer were tested for HIV and other marker

B. EXCLUSION CRITERIA: Patients who came to OPD but did not took intervention from our Hospital

This descriptive study was carried out in a teaching cancer hospital in Bathinda (Punjab), India. Demographic and geographical data of the HIV patients with cancer admitted to our hospital was collected for a period of 4 years from 01.01.16 to 31.12.19.

Data

Data from this study were obtained from the cancer patients who visited ACI, Bathinda for treatment. The status of HIV infection was determined by the ELISA. This checkup has become routine for any cancer patient visiting our Hospital. The proportion has been determined according to the number of patients who visited ACI, Bathinda. Social characteristics (age, gender, marital status, tobacco and alcohol consumption, education, and body mass index) were reviewed

Analysis: Analysis was done on Microsoft Excel.

Table 1: Showing year wise distribution of cancer patients examined for HIV

Year of Diagnosis	Total Number of Samples	HIV Positive	HIV Postive with Cancer
2016	140	0	0
2017	356	0	0
2018	734	1	1
2019	879	5	4
TOTAL	2109	6	5

Table 2: showing age wise distribution of HIV positive patients

Age	HIV Postive with Cancer
30-40YRS	0
41-50YRS	2
51-60YRS	2
60-70YRS	1
TOTAL	5

Table:3: Showing sex distribution of HIV positive patients

Sex	HIV Postive with Cancer
Male	1
Female	4
Total	5

Discussion

Our study is a hospital based study in which we observed 0.28% of HIV among the samples received and 5 cases(0.23%) had HIV+ Cancer as out of 2109 received. 6 were reported HIV positive and out of this 6 cases reported only 5 had HIV+ Cancer .In our based study, we observed low proportion of HIV (0.28%) as well as HIV+ Cancer(0.23%) in cancer patients. Studies in this regards showed a high Proportion (2.1%) of the HIV infection in patients with cancer in surgical oncology unit^(10,11). In a report from Maharashtra proportion of HIV was 1.2%⁽¹¹⁾. As cancer risk increases with age the burden of cancer people infected with HIV has shifted to higher age group. 5 cases which were reported, 4 were in the age group of 45-55 years and 1 was more than 60 years. With the introduction of antiretroviral therapy mortality among HIV-infected individuals has reduced and the projected life expectancy in these patients is almost similar to that observed in the general population^[12].

The female gender was more predominant out of HIV+ Cancer patients as out of 5 cases reported, 4 were female and 1 was male. Similar finding has already been reported by several authors^[13] All these females patients were from rural background and were uneducated. Most likely reason for delayed presentation is lack of awareness, improper health care facilities, faith in quacks & drug abuse.

In this study, non-AIDS defining cancers were more frequent than AIDS defining cancers. Breast cancer was the most common of non-AIDS defining cancers in our study as 3 females had carcinoma breast and 1 had carcinoma ovary. Studies done by other authors like Yanik et al⁽¹⁴⁾ in sub-Saharan Africa^[13] Uganda^[13] and South Africa^[15] also supported the same fact.

Earlier in developed countries the number of AIDS defining cancers KS and NHL were more but recently one US study, focused on people with AIDS, stated that the number of cases of KS and NHL has declined and non-AIDS-defining cancer increased over time⁽¹²⁾ and lung cancer is the most common of non-AIDS defining cancers^[16,17]. This estimated changes in the cancer burden was largely because of growth and aging of the HIV population due to antiretroviral therapy as supported by authors.

Conclusions

Even though Proportion of HIV+ Cancer (0.23%) is low in our study and universal screening of patients with newly diagnosed cancer for hepatitis B virus (HBV), hepatitis C virus (HCV) and HIV is not routine in oncology practice. But surely the burden of HIV-infected cancer patients will have implications for current and future cancer risk and the total burden of cases. Long term studies with large number of population needs to be done to reach to any definite conclusion and to know the exact burden of HIV in cancer patients and also to determine whether HIV changes the risk factors.Public health interventions and creation of integrated oncology and infectious diseases working groups for clinical research should be encouraged as prevention will be an important tool against these problems.

Effect of Two Connector Designs on the Fracture Resistance of All-Ceramic Core Materials for Fixed Dental Prostheses: An In-Vitro Study

Deepanshu Sharma¹, Sumit Aggarwal², Chandan K Kusum³, Arshi Mishra⁴,

¹Postgraduate Student (JR3), Department of Prosthodontics, Crown and Bridge, ²Reader, Department of Prosthodontics, Crown and Bridge, ³Reader, Department of Prosthodontics, Crown and Bridge, Subharti Medical College, Swami Vivekanand Subharti University, Meerut, ⁴BDS, New Horizon Dental College and Research Institute, Bilaspur, Chhattisgarh

Abstract

Background: The aim of this study was to test the difference in fracture resistance of 3 ceramic core materials used for simulated 3-unit all-ceramic FPDs with 2 fabrication techniques (lost-wax/heat-pressing and CAD/CAM methods) and 2 connector designs (round and sharp).

Material and method: The present in vitro study was conducted in the Department of Prosthodontics and Crown & Bridge, Subharti Dental College & Hospital, Meerut, Uttar Pradesh. For the purpose of this study, 3 all ceramic core materials were selected viz. Yttrium-tetragonal zirconia polycrystals, Milled Lithium disilicate glass ceramic and Lost-wax/heat-pressed lithium disilicate glass ceramic. A total of 10 rectangular bars of dimensions 30 mm (L) x 5 mm (W) x 5 mm (H) from each material were manufactured. Of these 10 bars, 5 bars were fabricated with sharp notch connector and 5 bars were fabricated with round notch connector. The dimensions of all specimens were measured and verified individually by an electronic caliper with an accuracy of 0.05 mm. The radius of each connector was measured with a measuring tool.

Results: The failure load was more in Press-R in comparison to Press-S and the difference was found to be statistically significant. The FS was more in CAD-R in comparison to CAD-S and the difference was found to be statistically significant.

Conclusion: The round connector design in yttrium stabilized zirconia and heat pressed lithium disilicate both may be considered to be the all-ceramic core material of choice for FDP's as they have highest failure load and flexural strength.

Keywords: FPD, Flexural strength, Failure load

Introduction

Esthetically driven dental treatment, biocompatibility, and improved mechanical properties

have contributed to the use of all-ceramic materials, not only in single unit restorations, but also for fixed partial dentures (FPDs). Recent research on dental ceramics has focused on the development of microstructurally refined, tougher, and stronger ceramic materials to enhance service life. Because of their potential for accurate margins and minimal shrinkage, hot pressable ceramic materials have been introduced for the fabrication of anterior and posterior 3-unit fixed partial dentures (FPDs)^{1,2}.

The shape of an FPD is not uniform. In particular, the connector area has a narrow constriction for biologic and esthetic reasons, and these sites in 3-unit FPDs represent stress concentrations relative to the average stress levels within other areas of the prosthesis. The stress distribution in a ceramic prosthesis can be affected by a change in contour of the prosthesis components; this effect may be more significant at locations with an abrupt change of contour. This stress-raising effect may be much more significant in a brittle material, such as a ceramic that contains many small flaws and cracks in a variety of sizes and orientations. These factors may be more critical in posterior FPDs, where connector height is usually limited by short clinical molar crowns and because higher loads are produced in posterior areas^{3,4}.

Framework design, especially connector geometry, affects the strength of all-ceramic materials. The shorter the connector occluso-gingivally, the higher the stress concentration. Smoother, less angled connectors showed lower stress levels. As the radius at the gingival embrasure increased from 0.25 to 0.9 mm, the mean failure load increased by 140%. The radius of curvature at the occlusal embrasure has only a minor effect on the fracture susceptibility of 3-unit FPDs. Evidence is lacking with respect to how connector design affects these new ceramic materials. It is also unclear how connector design and fabrication techniques affect the strength of this materials⁵.

The purpose of this study was to test the difference in fracture resistance of 3 ceramic core materials used for simulated 3-unit all-ceramic FPDs with 2 fabrication techniques (lost-wax/heat-pressing and CAD/CAM methods) and 2 connector designs (round and sharp).

Material and Method

The present in vitro study was conducted in the Department of Prosthodontics and Crown & Bridge, Subharti Dental College & Hospital, Swami Vivekanand Subharti University, Meerut, Uttar Pradesh. For the purpose of this study, 3 all ceramic core materials were selected viz. Yttrium-tetragonal zirconia polycrystals (IPS e.max Zir CAD, Ivoclar Vivadent, Schaan, Liechtenstein), Milled Lithium disilicate glass ceramic (IPS e.max CAD, Ivoclar Vivadent, Schaan, Liechtenstein) and Lost-wax/heat-pressed lithium disilicate glass ceramic (IPS e.max Press,

Ivoclar Vivadent, Schaan, Liechtenstein). A total of 10 rectangular bars of dimensions 30 mm (L) x 5 mm (W) x 5 mm (H) from each material were manufactured. Of these 10 bars, 5 bars were fabricated with sharp notch connector and 5 bars were fabricated with round notch connector.

Preparation of master bar with different connectors:

Two master bars of dimension 30x5x5 mm were prepared by milling a ZirCAD block. On one of these bar a sharp notch (0.60±0.15-mm radius of curvature) were created. On the other bar a round notch (0.60±0.15-mm radius of curvature) was prepared manually, to define a central pontic of 10±0.10 mm in length. These master bars were again scanned to mill 10 specimen of each material.

Fabrication of zirconia specimens: Using the .stl file of scanned master bars, 5 samples having sharp connector notch and 5 samples having round notch were milled from pre sintered Yttrium-tetragonal zirconia polycrystals blocks. Anticipating a 20-25% postsinter shrinkage, the rectangular bars in this group were cut oversized from the block with a slow-speed saw (Hyperdent, Germany).

Fabrication of milled lithium disilicate specimens:

Using the .stl file of scanned master bars, 5 samples having sharp connector notch and 5 samples having round notch were milled from Lithium disilicate glass ceramic. As the crystallization process does not produce dimensional changes, all specimens were prepared from the ceramic blocks to the final desired size of 30 mm x 5 mm x 5 mm, in the same manner as for the ZirCAD group but in a wet milling machine (Roboice, Istanbul, Turkey). All 10 bars were crystallized following the manufacturer's instructions.

Fabrication of heat pressed lithium disilicate specimens:

Using .stl file of master bar of sharp connector notch and round connector notch 5 specimen of each connector design were milled on the inlay wax block. The milled specimens were heat pressed after lost wax technique under manufacturer's recommendation and a total 10 bars were prepared

The dimensions of all specimens were measured and verified individually by an electronic caliper (D & W, Istanbul, Turkey) with an accuracy of 0.05 mm. The radius of each connector was measured with a measuring

tool (Dial Caliper, Germany). A 3-point bending test was performed in a universal testing machine (Digital Tensile Testing Machine, Shambhu Nath & Sons, Uttam Nagar, New Delhi, India) with a loading speed of 0.1 mm/min until the maximum failure load was reached. The data were recorded and the failure load was registered in newton and flexural strength was recorded as newton per millimeter square (N/mm²).

Statistical Analysis

The data was analysed using SPSS software version 24. Anova test was used to compare the statistical difference between the groups.

Results

Zirconia, milled lithium disilicate, and heat pressed lithium disilicate specimens were further subdivided into sharp and round design. Thus the present study comprised of 6 groups ZirCAD-S, ZirCAD-R, CAD-S, CAD-R, Press-S and Press-R. The failure load was more in ZirCAD-R in comparison to ZirCAD-S and the difference was found to be statistically significant. CAD-S and CAD-R failure load ranged from 263 N-387 N (mean \pm SD 299 \pm 53.21 N) and from 285 N-455 N (mean \pm SD 392.2 \pm 71.01N) respectively. The failure load was more in CAD-R in comparison to CAD-S and the difference was found to be statistically significant. The failure load of Press-S and Press-R ranged from 289 N to 1157 N (mean \pm SD 707.2 \pm 385.19 N) and from 540 N to 1927 N (mean \pm SD 1090.8 \pm 514.29 N) respectively. The failure load was more in Press-R in comparison to Press-S and the difference was found to be statistically significant (Table 1,2).

The Flexural strength of ZirCAD-S and ZirCAD-R ranged from 243 N/mm² to 405 N/mm² (mean FS 242.2 \pm 79.19) and 162 N/mm² to 336 N/mm² (mean FS 337.4 \pm 67.25) respectively. The FS was more in ZirCAD-R in comparison to ZirCAD-S and the difference was found to be statistically significant. CAD-S and CAD-R FS ranged from 63 N/mm² to 100 N/mm² (mean FS 67.8 \pm 10.85) and 58 N/mm² to 85 N/mm² (mean FS 86.4 \pm 15.57) respectively. The FS was more in CAD-R in comparison to CAD-S and the difference was found to be statistically significant. The FS of Press-S and Press-R was ranged from 119 N/mm² to 426 N/mm² (FS 160.2 \pm 80.01 N/mm²) and 71 N/

mm² to 256 N/mm² and (mean FS 241 \pm 113.81 N/mm²) respectively. The FS was more in Press-R in comparison to Press-S and the difference was found to be statistically significant (Table 3,4).

Discussion

In the present study, 3 all ceramic core materials Yttrium stabilized zirconia, milled lithium disilicate, and heat pressed lithium disilicate were selected and a total of 30 rectangular bars were manufactured through CAD/CAM and heat press technique with 2 connector design sharp and round. When compared statistically, mean failure load of ZirCAD-S was significantly more than that of CAD-S. This can be explained as zirconia polycrystal materials exhibit mechanical properties superior to other machinable all-ceramic materials available. In a study done by Rodrigo Alessandri et al⁶ and Ricardo Fabian Fonzar et al⁷ they concluded that milled lithium disilicate possessed lower fracture resistance than zirconia based materials. Our study also suggests these results.

Mean failure load (MFL) of Press-S was more than CAD-S but the difference was not significant. Alec Willard and Tien-Min Gabriel Chu⁸ in 2018 suggested that the sharp connector design in milled lithium disilicate plays an important role in crack propagation, here in our study the same reason appears to be the reason for Press-S group to show marginally better results than CAD-S in terms of MFL.

Between ZirCAD-R and CAD-R mean failure load of ZirCAD-R was found to be higher which was statistically significant. With 550 Mpa the strength of lithium disilicate is much lower than the strength of zirconia which is 900 Mpa. When force is applied directly to the long axis of a ceramic FDP connector, compressive stresses develop on the occlusal aspect, while tensile stress develop on the gingival aspect; such stresses contribute to the propagation of microcracks located at the gingival surface, leading to fracture. Michaela Pantea et al⁹ have suggested that Increasing the dimensions of the connector may decrease this effect.

When mean failure load of ZirCAD-S and ZirCAD-R was compared, ZirCAD-R possessed higher failure load. According to study by Hamza et al¹⁰, strength of the yttrium stabilised zirconia -based ceramics is affected

by the connector dimension and design. In accordance with this study, our result also affirms the fact that round connector design may withstand forces better than the sharp design.

When mean failure load of CAD-S and CAD-R was compared, the difference was statistically significant which can be explained by the fact that round connector design in CAD exhibits 77% higher fracture resistance than their corresponding sharp connector groups. The same however was not found with press group suggesting the fact that connector design affect only milled all ceramic in our case yttria stabilised zirconia and milled lithium disilicate not heat pressed lithium disilicate. This finding is however contrary to the study done by Fleming et al¹¹ where milled and heat pressed lithium disilicate were compared.

Our study suggests that round connector design of zirconia bridge has better mechanical properties studied, when compared to all other study materials. However when esthetics is of utmost concern, pressable ceramics with round connector should be preferred.

Conclusion

It can be concluded from the present study that structural reliability and strength of industrially prepared ceramic blocks are negatively affected by the milling procedure. The sharper the milling bur configuration used, the greater the potential for defects and flaws induced in the ceramic. This lessens the ability of these materials to withstand catastrophic forces. The round connector design in yttrium stabilized zirconia and heat pressed lithium disilicate both may be considered to be the all-ceramic core material of choice for FDP's as they have highest failure load and flexural strength.

Clinical Significance Versus Statistical Significance with Regards Gingival Scores in Herbal and Chlorhexidine Mouthwash Clinical Trials- A Systematic Review

Deepika Dagar¹, Pradnya Kakodkar², Sahana Hegde Shetiya³

¹Public Health Dentist, ²Dy Director, Dr D Y Patil Vidyapeeth, Pune, ³Prof and HOD, Dr D Y Patil Vidyapeeth, Pune, Department of Public Health Dentistry

Abstract

Purpose: Does clinical significance match with the statistical significance with respect to gingival score when herbal mouthwash is used in comparison to the chlorhexidine mouthwash?

Material and Method: A systematic search of literature was conducted on two databases (PubMed and Google Scholar) for the studies published from 1st January 2006 to 31st December 2018. Cross-references were checked. Hand searching was done in the library. Studies were included if they were done among healthy, non hospitalized humans and compared chlorhexidine with herbal mouthwash for the gingivitis score. Clinical significance was ascertained based on Loe and Sillness (1967) Gingival index interpretation.

Results: A total of 22 unique clinical trials were identified and 24 estimates which used Gingival index as outcome assessor. 18 estimates showed matching between clinical significance and statistical significance in the chlorhexidine group while in herbal group it was found only in 15 estimates. As per Thirthalli J, Rajkumar RP criteria none of the studies showed clinical significance.

Conclusion: Statistical significance does not always mean clinical significance. Researchers should modify their study design to focus on clinical significance along with statistical significance.

Keywords: *Clinical significance, statistical significance, herbal mouthwash, chlorhexidine .*

Introduction

Gingivitis is a worldwide phenomenon reaching to high epidemic proportions.¹ Microbial plaque plays an important role in development of gingivitis.² It can be controlled by using mechanical plaque control measures like toothbrush, dental floss, interdental brush etc. In addition, chemical control such as mouthwashes can also be used. Mouthwashes have the ability to reach those areas where mechanical plaque control cannot reach. Many agents such as bis-biguanides,

essential oils, quaternary ammonium compounds, antibiotics and antiseptics have been used as mouth washes. Chlorhexidine (bis-biguanide) is well known and well studied chemical agent to control gingivitis. It is commonly used in two concentrations 0.2% and 0.12%, which can be with or without alcohol, and literature shows that there is no difference in their efficacy with regards the two different concentrations.³ There are some side effects such as staining of teeth and loss of taste sensation which restricts its use for long duration. To overcome this side effect many other alternative mouthwashes are being researched for. Herbal products have been used since ancient times, and in last 2 decades it has become mainstream for research because of its natural ingredients and less expensive prescriptions.⁴ Herbal mouthwashes available over the counter indicates they are in demand by the people.

In a clinical trial, when two interventions are compared and statistical significance is obtained for the outcome variable, the null hypothesis is rejected and thus it is concluded that one treatment procedure is better than the other.¹ However, a statistically significant reduction in symptom ratings may or may not represent a clinically meaningful treatment response or the magnitude of the difference.^{5,6} The p value of <0.05 tells us that there is difference between the groups but does not necessarily tell us how much clinically significant difference.

Statistical significant deals with the numbers, while according to LeFort, results will be called clinically significant if the newer modality is better enough to make a real difference in the people's life, effect of the treatment will last for a longer time, it is cost effective and it is easy to implement.⁷

The aim of this study was to compile all the clinical studies conducted, comparing herbal mouthwash against Chlorhexidine and to evaluate if statistical significance matches with the clinical significance with regards gingival scores.

One of the reasons to undertake this study was that the authors, researchers and readers should be able to appreciate the difference between statistically significant clinically relevant data and statistically significant clinically insignificant data.

Material and Method

Literature Search :

The electronic search was initially conducted on the MEDLINE via PUBMED database with the following search strategy "Gingivitis (tw)* AND Chlorhexidine (tw)* AND herbal (tw)* AND mouthwash (tw)*", "Gingival inflammation (tw)* AND chlorhexidine (tw)* AND natural product (tw)* AND mouthrinse (tw)*", "Gingival inflammation* OR gingivitis* AND chlorhexidine* AND natural product* OR herbal* AND mouthrinse* OR mouthwash*. In addition, Google Scholar was also searched. We also manually searched the reference lists of eligible studies to ensure identification of relevant published and unpublished studies. We also contacted study authors to provide full text articles. Search was conducted for the article during the period of January 1st 2006 to December 31st 2018

Eligibility criteria: All the studies reporting randomized control trials for herbal and chlorhexidine mouthwashes used for anti-gingivitis regimen; studies conducted in humans; studies considering Loe and Sillness (1967) gingival index as an outcome assessor and papers written in English language only and where there is a possibility to translate the foreign language to English. Case reports, Letter to the editor abstracts and narrative reviews were excluded.

Two reviewers (DD and PK) independently performed the first stage of screening by titles of all the identified studies. Round 2 included screening by the abstracts. Round 3 was full text assessment.

Data extraction

A standardized, pre-piloted form was used to extract data from the included studies for evidence synthesis. One review author (DD) extracted data independently and second author (PK) cross checked the data. Discrepancy if any, was identified and resolved through discussion with a third author (SHS) where necessary. The extracted data included the following: Study ID, author name, year of publication, sample size, intervention group, comparison group, duration of the trial, index used, mean and standard deviation of the gingival baseline and end of trial scores, statistical significance as reported in the article and the clinical significance (calculated by the reviewers).

Clinical significance calculation:

It was ascertained based on Gingival index score interpretation⁸. The interpretation score mentioned is as follows: 0.0- No gingivitis ; 0.1-1.0 – Mild gingivitis ; 1.1 – 2.0 Moderate gingivitis ; 2.1 – 3.0 Severe gingivitis.

At the end of the trial, in both the study and control group, if the baseline score moved up from higher interpretation grade to lower, it was considered as clinically significant. For e.g. before intervention the base line score was 1.3 (moderate gingivitis) and post intervention the end score was 0.9 (mild gingivitis) , than this intra group comparison was considered as clinically significant. But if the baseline score and the end score remained in the same interpretation grade, it was not termed as clinically significant.

Thirhalli J and RajkumarRP⁹ proposed five criteria which were used to assess the clinical significance of the studies. The criteria were as follows: 1. What are the implications of the adverse effects profiles? 2. Are the outcome measures appropriate? 3. Are the effects of a treatment sustained? 4. Is the treatment cost effective? 5. Do the findings generalize to different context?

Results

A total of 22 articles unique clinical trials and 24 estimates were identified (Prisma Flow chart depicted as Fig 1).

The characteristics of experimental and control group mouthwashes are depicted in Table 1. There was a wide variation noted in the duration of the study period (Table 1). Four studies (XIX-XXII), were conducted for 30 days, four studies (XV-XVIII) were conducted for 4 weeks, eight studies (VII-XIV) were conducted for 21 days, two studies (V,VII) for 15 days, two studies were conducted for 14 days (III, IV), one study (II) was conducted for 7 days and one study (I) was conducted for 5 days.

Intra group comparison remarks (Table 1): The mean gingival score at baseline and end of trial in both experimental and control group were correctly reported in all the studies. In the herbal mouthwash group, there were seven studies which were statistically significant clinically not significant (I,IV-VIII,XIX), whereas 15 studies were clinical and statistically significant (II,III,IX-XVIII, XX-XXII). In the Chlorhexidine mouthwash group: six were statistically significant but not clinically significant (I,IV-VII,XIX) and 18 studies showed a clinical and statistical significance (II,III,VIII-

XXII).

Table 2 showed results of clinical significance as assessed by Thirhalli J and Rajkumar RP⁹ criteria. The studies considered in this review, reported adverse effects in four studies (II, XVI,XXII) with both chlorhexidine and herbal mouthwash. All the studies reported the outcome measurements and statistical significance. None of the studies carried out any follow up after the study was completed and also none of the studies mentioned the cost of the mouthwash in their paper and hence it cannot be commented whether the treatment was cost effective or not. The findings cannot be generalized to different context in any study. Overall, none of the study showed clinical significance.

Discussion

The aim of this review was to provide a comprehensive appraisal and differentiate between the statistical significance and clinical significance of the gingival score parameter in the clinical studies conducted using chlorhexidine and herbal mouthwashes among human participants. The results of this review showed that it is possible to have statistical significance without having clinical relevance. As per Thirthalli J and Rajkumar RP⁹ criteria all the studies considered in the review showed that there was statistical significance but were clinically insignificant. This review, concludes that the clinical trials have not been designed keeping in mind the clinical significance but it is oriented towards finding out the statistical significance only between the two groups to report which treatment is better than the other.

One of the reasons why statistical significance may be more popular among the researchers, authors and readers is because p value cut-off ($p < 0.05$) gives a simple YES/NO answer to differentiate between two groups, unlike the clinically significant result which needs calculation on multiple factors.

Greenstein G³¹ in his paper discusses that statistical significance testing as a method to infer that results of periodontal clinical trials are clinically meaningful, have shortcomings. He suggests that, what determines clinically significant results should be defined before initiating a study and statistical significance testing should be used to validate that findings did not occur by chance.

This paper recommends that the researchers clearly define parameters for clinical significance testing while designing the study and incorporate following important criteria's: Adverse effects, appropriate outcome measure, post intervention follow up, cost effectiveness and generalizability.

This review has few limitations. While calculating the clinical significance, only Gingival index was taken, hence we had to exclude other studies which have used other indices. Only those indices with interpretation remarks can be chosen.

Conclusion

Based on the factors used for assessing clinical significance, the present review concludes that statistical significance does not always match clinical significance. Researchers should modify their study design to focus on clinical significance along with statistical significance.

Impact of Two Grip Strengthening Exercise Protocols on Grip Strength of Non-Dominant Hand

Devika Sharma¹, Saurabh Sharma², Raj Kumar Meena³, Sanjai Kumar⁴, Sartaj Ahmad⁴

¹Assistant Professor, Jyoti Rao Phule Subharti College of Physiotherapy, Meerut(UP)., ²Associate Professor, Department of Community Medicine, Subharti Medical College, Meerut(UP)., ³Professor & Vice Principal(Physiotherapy), Kailash Institute of Nursing and Paramedical Science, Greater Noida(UP)., ⁴Professor & Head, Department of Physiotherapy, Shri Dev Suman Subharti Medical College, Dheradoon(UK), ⁵Associate Professor (Sociology), Department of Community Medicine, Subharti Medical College, Meerut(UP).

Abstract

Introduction: Power grip is commonly used as an index to assess impairment and treatment outcomes of hand. There is very less literature available on effect of strengthening exercises on non dominant hand in normal individuals. This study is planned with a vision to get an exercise protocol which can improve the hand grip strength of non dominant hand significantly in both genders.

Methodology: Study sample was extracted from all the students of Subharti College of physiotherapy. 30 male subjects and 30 female subjects between 18-25 years were selected randomly. These individuals were then distributed randomly in two groups keeping in mind the equal distribution of males and females in both the groups. Group A(control) was allocated for squeezing exercises alone for 6 weeks with periodicity of exercising 3 times a week. Group B(experiment) was advised the combination squeezing and hand gripper exercises for 6 weeks with periodicity of exercising 3 times a week.

Results: Increase in the mean grip strength of experimental group was statistically significant while of control group it was not. Increase in mean grip strength of males was statistically significant in experimental group while it was significant in control group while in females mean grip strength increased significantly in both experimental and control groups.

Conclusion: Combination of grip and squeezing exercises have a better impact on mean grip strength than squeezing exercise alone in non dominant hand in normal person. Findings can be used in sports like cricket, lawn tennis etc, where grip of nondominant hand is also important.

Key Words- Grip exercise, non dominant hand, squeezing exercise, gripping exercise

Introduction

The human hand has been characterized as a symbol of power, as an extension of intellect, as the seat of the

will. The hand and the wrist are the most active and intricate parts of the upper extremity because of this they are vulnerable to injury, which can lead to functional difficulties, and they do not respond well to serious trauma^[1]. Many daily activities involve interaction with objects that are grasped in the hand. The manipulative ability of human hand requires effective force and dexterity^[2]. Hand functionality is considered to be vital in most of the daily activities involving upper limb be it carrying loads, lifting objects, opening or closing doors to name a few. Most sports activities also require adequate grip strength to enhance performance and

prevent injuries. For routine daily activities of hand high activity of flexor musculature of forearm and hand is required^[3]. Power grip is a forceful act resulting in flexion of all finger joints. When thumb is used, it act as a stabilizer to the object held between the fingers and the palm. Power grip is commonly used as an index to assess impairment and treatment outcomes of hand function^[4]. Analysis of grip strength is an important index of hand rehabilitation program as because it assess the patient's initial limitation and can be compared with normal. Measurement of hand grip strength utility continues throughout the treatment process because it provides a quick reassessment^[5]. Hand grip strength is widely considered as an objective index of functionality of upper extremity which can be optimized with a reliable evaluation^[6,7]. It has been proved earlier that the population as a whole demonstrated significant differences between the dominant and non-dominant handgrip strength^[8]. Therapist often follows the 10% rule as general guidelines. This rule states that person's grip strength in dominant hand is 10% greater than that of non-dominant hand ^[9]. There is very less literature available on effect of strengthening exercises on non dominant hand in normal individuals. This study is planned with a vision to get an exercise protocol which can improve the hand grip strength of non dominant hand significantly in both genders. Non dominant hand strengthening is a very important part of rehabilitation process, because If, the injuries involving dominant hand loss also. The objective of study was to evaluate the effectiveness of squeezing exercise and combination of squeezing and hand gripper exercises for grip strengthening of non dominant hand in 18-25 years old students of both genders.

Methodology

Study sample was extracted from all the students of Subharti College of physiotherapy. 30 male subjects and 30 female subjects between 18-25 years were selected randomly.

Inclusion criteria includes Normal healthy individuals, Age group 18-25 years, Both males and females, Right hand dominant persons, not having any history of traumatic injury to non- dominant hand (left) since last 1 year, Not having any neurological deficit in Non- Dominant Hand. **Exclusion criteria includes** Age

below 18 years and above 25 years, Left hand dominant person, Unhealthy individuals, Having any history of traumatic injury to Non-dominant hand since last one year, Neurological deficit in non dominant hand. This device is the most widely reported and recommended measure of grip strength.

Photograph 1. Showing equipments used in study

These individuals were then distributed randomly in two groups keeping in mind the equal distribution of males and females in both the groups. Group A with 30 subjects was control group and Group B also having 30 subjects constituted experimental group.

Group A was allocated for squeezing exercises alone for 6 weeks with periodicity of exercising 3 times a week.

Group B was advised the combination squeezing and hand gripper exercises for 6 weeks with periodicity of exercising 3 times a week. Subjects were asked to sit on the chair with straight back, without armrest with the feet flat on the floor, shoulder adducted and neutrally rotated, elbow flexed at 90°, forearm in neutral position and wrist between 0° – 30° of extension and between 0°- 15° of ulnar deviation (As given by ASHT)^[10-13]. Then the handle of dynamometer was set at setting 3.8 cm apart^[14] and kept constant for all. Subjects were asked to hold the dynamometer in above said position and were instructed to squeeze to initiate the optimal handgrip strength. All the subjects were evaluated in same position and under the same protocol. Every subject was demonstrated and then was asked to initiate handgrip strength using dynamometer.

Exercise Protocol

1) General squeezing exercises with squeezing ball.

- a) Holding time-10 seconds.
 - b) Resting time-2 seconds
 - c) No. of repetition-10 times
 - d) Total duration-2 minutes
 - e) No of sitting-3 times a week for 6 weeks
- 2) Hand gripper exercises (20 kg weight)
- a) Holding time-2 seconds
 - b) Resting time-1 seconds
 - c) No. of repetition-10 times
 - d) Total duration- 30 second

- e) No of sitting-3 times a week for 6 weeks

All the analysis was obtained using SPSS 19. A base line data was taken at the beginning of the study (pre test values) and after the completion of the intervention (post test values) to analyze the difference between the two groups and group themselves, Mann-Whitney U-statistic was used. A level of 0.05 was used to determine the statistical significance.

Results

When the experimental and control groups were compared pre and post intervention, it was found that the increase in the mean grip strength of experimental group was statistically significant while of control group it was not (Table 1).

Table 1- Pre and post intervention comparison (total)

Parameter	Experimental group		Control group	
	Pre intervention	Post intervention	Pre intervention	Post intervention
Mean grip strength	20.15	25.40	21.150	23.400
Standard deviation	3.15	4.29	3.787	4.122
Standard error	.70	0.96	0.8469	0.9217
	Mann-Whitney U-statistic = 66.000 The two-tailed P value is 0.0003		Mann-Whitney U-statistic = 134.00 The two-tailed P value is 0.0762	

When the comparison was done among females of experimental and control group,pre and post intervention , it was found that increase in mean grip strength was statistically significant in both categories but experimental group had more significant difference than control group (Table 2).

Table 2. Pre and post intervention in females of experimental and control group.

Parameter	Experimental group		Control group	
	Pre intervention	Post intervention	Pre intervention	Post intervention
Mean grip strength	17.7	22.3	18.4	20.5
Standard deviation	1.2	1.7	1.8	1.5
Standard error	0.36	0.53	0.58	0.47
	Mann-Whitney U-statistic = 1.5 The two-tailed P value is 0.0003		Mann-Whitney U-statistic = 21.0 The two-tailed P value is 0.03	

When the comparison was done among males of experimental and control group, pre and post intervention, it was found that increase in mean grip strength was statistically significant in experimental group while it was significant in control group (Table 3).

Table-3. Pre and post intervention in males of experimental and control group.

Parameter	Experimental group		Control group	
	Pre intervention	Post intervention	Pre intervention	Post intervention
Mean grip strength	22.6	28.5	23.9	26.3
Standard deviation	2.5	3.8	3.18	3.8
Standard error	0.79	1.2	1.0	1.2
	Mann-Whitney U-statistic = 9.5 The two-tailed P value is 0.003		Mann-Whitney U-statistic = 1.5 The two-tailed P value is 0.17	

Discussion

Present study was aimed to compare the effect produced by squeezing exercises alone and combination of squeezing and grip strengthening exercises on non dominant hand.

Results of the study revealed that the increase in the strength after combination of exercises was significantly higher while the effect produced by squeezing exercise alone was not statistically significant. In control group only females had significantly increased mean grip strength after completion of protocol, in squeezing exercises, while males did not. The difference might be due to the fact that normal males in routine life bears this minimal amount of resistance in activity of daily living as driving bikes, playing cricket etc.

Hence the outcome expected from such exercise would not be significant, on the other hand females don't encounter such tasks daily, so even, this soft exercise was able to produce significant difference. This difference was also discussed by Vincent Wai-Shing Lau et al^[15] when they stated that It is recommended that when assessing the progress and outcome of hand rehabilitation, the occupation and demand level of hand use of the patient must be taken into consideration when using the uninjured hand for comparison. This fact was

also proved in different way by Paddy Jarit^[16] where they found that in young basketball players there was no significant difference in strength of dominant and non dominant hand since both the hands were used equally for same amount of resistance. Like the results of present study Mika Matsumura et al^[17], Matthew W. Rogerset et al^[18] & Hartwig Woldag et al^[19] also find the significant rise in grip strength after gripping exercises. Present study found that the males has higher grip strength than females which matches with the findings of Shu-Wen Wu et al^[20], R.E. Anakweet al^[21] & Esther Luna-Heredia et al^[22] who found that gender difference is present for grip strength and males had higher grip strength than females. Grip exercises are absolute necessity to improve the grip strength and limb exercises are not a substitute for grip strengthening this was also proves when Birgitta Langhammer et al^[23], Sandstedt et al^[24] and Suleyman Patlar^[25] did not notice any improvement in grip strength after routine limb exercises.

Acknowledgement-

Conflict of Interest- No

Conclusion

Combination of grip and squeezing exercises have a better impact on mean grip strength than squeezing

exercise alone in non dominant hand in normal person. Findings can be used in sports like cricket, lawn tennis etc , where grip of nondominant hand is also important.

Mental Distress among Students of a Private University of Delhi, NCR

Dhruva Nandi¹, Karunanidhi Kaur¹, Tanvi Yadav,¹ Udit Narayan Chhetri,¹ Neha Taneja,² Aanchal Anant Awasthi², Rajiv Janardhanan³

¹Postgraduate (MPH), Laboratory of Disease Dynamics & Molecular Epidemiology, ²Assistant Professor, Laboratory of Health Data Analytics & Visualization Environment, ³Professor & Head, Laboratory of Disease Dynamics & Molecular Epidemiology, Amity Institute of Public Health, Amity University, Noida, India

Abstract

Background: One of the emerging significant public health problems is mental distress which includes somatic symptoms such as anxiety and depression. In comparison to the general population, earlier studies reported higher mental distress among university students. Students having mental distress suffer from poor academic performance and other learning disabilities. Due to the dearth of literature on the burden of this problem in India, the present study was done to assess the prevalence of mental distress and its association with sociodemographic, personal and academic related variables among students of a private university of Delhi, NCR.

Methods & Materials: A cross-sectional observational study was done on 300 private university students of Delhi, NCR. We applied the Self Reporting Questionnaire (SRQ-20) for the assessment of mental distress. Descriptive and Chi-square statistics were done. p value <0.05 was considered statistically significant.

Result: The study participants were predominantly females 58.7%. It was also observed that 13% participants were unsatisfied with admission in the college, 17.3% were unsatisfied with their academic course and 16.3% were unsatisfied regarding coping up with course.

On bivariate analysis it was observed that level of course ($p<0.001$), history of parental conflict (<0.001), satisfaction with life (<0.001) showed higher statistically significant association with mental distress. Similarly, academic variables such as satisfaction with admission to college ($p<0.001$), satisfaction with academic course (<0.001), satisfaction with coping up with course (0.003) were also highly statistically significant.

Conclusion: It is noted that mental distress is common among university students and there is a need for attention, support and personalized counseling.

Keywords: *Mental distress, SRQ-20, university students.*

Introduction

Mental distress is defined as disturbance and unpleasant mental-emotional state such as fear, anxiety, depression, confusion and mood swings often impairing the ability to cope with day to day ability⁽¹⁾. Mental distress is becoming a common problem among university students accounting for nearly 12% of the global burden of disease⁽²⁾. By 2020, mental distress is

expected to become the second most important cause of disability in the world⁽²⁾. In recent years, due to strong competition and aspiration, this makes the students more vulnerable to developing mental distress. Hence the study was undertaken to find the prevalence of mental distress and its association with socio-demographic, personal and academic-related variables among students of a private university of Delhi, NCR.

Materials and Method

A cross-sectional study was conducted among 300 students of a private university of Delhi NCR. The study was conducted during mid-semester to ensure that no university examination or event might add extra pressure on students.

A self-constructed, pre-tested questionnaire was used to collect information on socio-demographic, personal and academic-related variables. Mental Distress was assessed using SRQ-20. It is an instrument having 20 questions for the respondents regarding the symptoms and difficulties faced which are significantly seen in the condition of neurotic disorder⁽³⁾ The questions are oriented concerning certain symptoms and problems that might cause difficulties to the participants in the last 30 days. Answers are based on yes & no which are scored as 1 & 0, 1 for yes that indicate symptoms were present during the past month and 0 for no indicates the symptoms were absent.

The maximum score is 20 and anyone with cutoff score ≥ 10 suffers from mental distress. It has been used in different countries and is available in many international languages as well⁽³⁾. Informed consent was taken from the study participants. Institutional ethical approval has been taken.

Inclusion criteria: Students who gave their informed consent to participate in the study.

Exclusion criteria: Those students diagnosed with any form of mental illness and currently on medication.

Data was analyzed using SPSS Version 23.0 (SPSS Inc., Chicago, IL, USA).

Result

Majority(48%) of study participants were between 16-20 years of age. 58.7% study participants were females. 90.7% of the participants belonged to general category. Out of 300 study participants, alcohol and smoking was reported in 27.3% and 27% of students respectively. With respect to academic related variables, 70.3% of the participants were satisfied with admission in college.

Figure 1 shows that out of a total of 300 students of a private university the overall prevalence of mental distress was 22%. Age, level of course, history of parental conflict, current mental status, satisfaction with life, satisfaction with academic course and fear regarding future life were the contributing factors regarding mental distress among student.

Bivariate analysis was applied to study the association between sociodemographic, personal and academic related variables with mental distress.

Table 3 shows that on applying bivariate analysis students, study participants between age 16-20years showed higher proportion of mental distress (n=47,32.6%) compared to students >20years (n=14, 10.3%) and this association was highly statistically significant. (p<0.001)

On studying the association between academic variables and mental distress, students who were unsatisfied with admission to college had higher mental distress (n=21,42%) than those who were satisfied with admission to college (n=41,18.8%) and this association was highly statistically significant. (p<0.001). (Table 3)

Discussion

Our study was conducted in the mid-semester, to ensure that the students were not under the influence of any college event or examination on joining the university, Our observations suggested that 22.3% of the university students sampled in this study were under distress.

A study carried out in different regions of India reflect diverse situations depending on the use of study instruments. Similar findings were observed in the Kolkata study, where the prevalence of mental distress

was found to be 14.5% among medical students⁽²⁾. A study done among medical under-graduate students in Bhubaneswar (Odisha) reported the prevalence of depression, anxiety and stress using DASS (Depression Anxiety Stress Scale) scale as 51.3%, 66.9%, and 53% respectively⁽¹¹⁾. A study in Jodhpur found that 57.98% of Medical students were depressed whilst 47.41% of the students suffered from anxiety⁽¹²⁾. A Delhi based study carried out using the Patient Health Questionnaire (PHQ-9) reported the prevalence of depressive and major depressive disorder to be 21.5% and 7.6% respectively⁽¹³⁾.

Similar findings have been reported from else where in the world as well. A study from Ethiopia reported the prevalence of mental distress using SRQ-20 (Self-Reporting Questionnaire) among university students to be 21.6%, (South-West Region) Studies from different North West Region from Ethiopia showed prevalence of mental distress as 40.09% and 11.7% (Addis Ababa, Ethiopia)⁽⁴⁾⁽⁶⁾⁽⁷⁾. A study from Ireland using GHQ (General Health Questionnaire) and LBQ (Lifestyle Behaviour Questionnaire) reported 41.9% of university student respondents being mentally distressed⁽⁸⁾. Another study from the University of Iceland using Symptoms Checklist – 90 Depression and Anxiety Subscale among female students showed 22.5% and 22.2% of depression and anxiety respectively⁽⁹⁾. A study from five faculties at Jazan University, Saudi Arabia found that 31% of undergraduate students were psychologically distressed based on the BSI-18 scale (Brief Symptom Inventory-18)¹⁰⁾.

The predictors such as history of parental conflict, level of study, satisfaction with life, satisfaction with course, and alcohol consumption were significantly ($p > 0.05$) associated with mental distress. Satisfaction with life was found to be strongly associated with mental distress in our study as well, Similar findings have also been reported by Canadian National Survey⁽¹⁵⁾, Ankara University⁽¹⁶⁾ and Mid-Atlantic university⁽¹⁸⁾.

Students start their professional journey based on their selected courses with high expectation and enthusiasm with a keen interest of gaining new information. As they progress with their courses this enthusiasm often gets dampened along with lack of satisfaction with course. This is significantly common in students with mental distress, a fact well supported

by a study in Turkish university, which showed that mental stress is strongly associated with the student course satisfaction⁽¹⁷⁾. A similar study done in Wollo university stated significant correlation of alcohol intake with mental distress⁽¹⁹⁾. In our study, although females showed higher proportion of mental distress (25.6%) when compared with males (17.7%), this association was not statistically significant. However a study done in University of Hargeisa, Somaliland showed statistically significant association between gender and mental distress.⁽²⁰⁾

Our observations revealed that inability to cope up with the course content was found to be significantly associated with mental distress, Similar findings have also been reported in studies conducted from Kolkata and New Delhi⁽²⁾⁽¹⁴⁾. Family history of mental illness, level of education and global satisfaction with life were other dominant risk factors associated with mental distress as observed in a study conducted among university students from New Delhi⁽¹⁴⁾. Risk factor identification observed in this study could be prospected as a potential risk factor for further studies⁽¹⁴⁾.

Limitation

The cross-sectional nature of the study and the use of the self-reporting method is a limitation of the study. Further, the study has been conducted in a single university and it limits the external validity of the findings. However, the research is not defeated its purpose.

Conclusion

Mental distress is common among university students they are either unaware of their situation or reluctant to seek help. But there is a need for care, assistance and counseling support which will provide further impetus for conducting multi-centric longitudinal studies for examining the causal hypothesis.

Evaluating the Pain Responses among Infants Receiving Rotavirus Vaccine Versus Oral Polio Vaccine Before the Administration of Pentavalent Vaccine with Inactivated Polio Vaccine: A Randomized Study

Divya Sri Mudundi¹, Apoorva AC², Juny Sebastian³, Mandyam Dhati Ravi⁴

¹Intern, JSS Medical College and Hospital, JSS Academy of Higher Education & Research, Mysuru, Karnataka, India, ²Intern, JSS Medical College and Hospital, JSS Academy of Higher Education & Research, Mysuru, Karnataka, India, ³Lecturer, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, Karnataka, India, ⁴Professor, Department of Pediatrics, JSS Medical College and Hospital, JSS Academy of Higher Education & Research, Mysuru, Karnataka, India

Abstract

Background: Vaccination is the most common painful interventions in infants. Non-pharmacological interventions to alleviate pain rely on the inhibition of pain signaling.

Objective: To compare the acute pain response of the infants receiving oral rotavirus vaccine versus oral polio vaccine before administration of injectable vaccines.

Method: This was a randomized control study conducted for a period of six months at the immunization center of a tertiary care teaching hospital. Children who are receiving rotavirus vaccine, inactivated polio vaccine (IPV), Pentavac® [Diphtheria+ Tetanus+wholecellpertussis(DTwP) + Hepatitis B (Hep B)+ Hemophilus Influenza B (HiB)] and oral polio vaccine (OPV) belong to the age group of 6 to 14 weeks visiting the study site for routine immunization were included in the study. The enrolled subjects were randomized into group A and group B using blocked randomization method. The responses of the infants were video graphed for 10seconds before and 30seconds after giving the vaccination. The recorded videos were coded and given to a research panel for scoring the pain response of infants on the basis of modified behavior pain scale (MBPS). The pain response scores were compared between the groups.

Results: Mean post vaccination MBPS in group A was 7.72 ± 1.01 and in group B was 7.88 ± 0.90 . There was no statistically significant difference in pain response was found between group A and Group B children ($P 0.55$).

Conclusion: Sequence of administration of oral polio vaccine and rotavirus vaccine did not impact the pain response following the administration of Pentavac® and inactivated polio vaccine among infants.

Key words: Inactivated Polio Vaccine, Pain Response, Pentavalent vaccine, Rotavirus vaccine, Sequence of vaccination

Introduction

Vaccination is the most common painful interventions in infants.¹ Newborns can perceive pain and respond to pain through facial expression, behavioral responses and physiological signals.^{2,3} Vaccination complications include increased behavioral and physiologic responses to pain, increased neural disorders, psychosocial problems, learning disorders,

poor adaptive behavior, future fear of injection, and long-term complications in brain development.⁴ With the increasing number of vaccines available, the number of injections a child gets has correspondingly increased. Clinicians have got important responsibility in eliminating pain and suffering when possible. There were many studies that described how to evaluate and treat acute pain in children using pharmacological and non-pharmacological interventions. pharmacological methods are most frequently used to prevent pain in infants. However, many analgesics have life threatening adverse effects and its use is questionable in infants. Opioids can have adverse effects including somnolence, and respiratory depression making it unsuitable for use in spontaneously breathing, opioid-naïve patients.⁵

Non-pharmacological interventions to alleviate pain rely on the inhibition of pain signaling. Pain arises from nociceptive transmission through small afferents to the spinal cord and then to higher brain nuclei and the cerebral cortex. Nociceptive signals are mediated by peripheral and central components that may facilitate or inhibit this input. Several neurotransmitters are involved in mediating nociceptive signals including substance P which facilitates transmission and endogenous opioid-based compounds that inhibit transmission.⁶ Non-pharmacological pain relief strategies are convenient, inexpensive and can be used without prescriptions, also are well tolerated by infants. Some of the non-pharmacological methods which proved to reduce pain are oral sucrose, breastfeeding, non-nutritive sucking, skin-skin contact, swaddling, cryotherapy, acupuncture, distraction, and music therapy.⁷⁻¹³ The present study was conducted to compare the acute pain response of the infants receiving oral rotavirus vaccine versus oral polio vaccine before the administration of injectable vaccines.

Material and Method

The study was planned based on the assumption that rotavirus vaccine blunts the pain response of injectable vaccines administered thereafter, as it is sweet in nature. This was a randomized control study conducted for a period of six months at the immunization center, department of Pediatrics, Jagadguru Shri Shivarathreeshwara hospital, Mysuru. The study site functions 7 days a week and receives vaccine supply through Expanded Program of Immunization.

Ethical clearance of the study was obtained from the Institutional Ethical committee before initiating the study. Children who are receiving rotavirus vaccine, inactivated polio vaccine (IPV) and Pentavac® [Diphtheria+ Tetanus+wholecellpertussis (DTwP) + Hepatitis B (Hep B)+ Hemophilus Influenza B (HiB)] and oral polio vaccine (OPV) vaccine belong to the age group of 6weeks to 14 weeks visiting the study site for routine immunization was the inclusion criteria. Parents or legally acceptable representatives who are unable to provide the informed consent were excluded from the study. The informed consent form was developed in local language as per the requirements of Indian Council of Medical Research (ICMR) Ethical Guidelines for biomedical research on human subjects. The enrolled subjects were randomized into group A and group B using block randomization method. Group A subjects received the vaccination in the order - rotavirus vaccine, Pentavac®, inactivated polio vaccine and oral polio vaccine. Group B subjects received vaccination in the order oral polio vaccine, Pentavac®, inactivated polio vaccine and rotavirus vaccine. A trained staff nurse who follows the standard immunization practice at the study site administered vaccines to all study participants. The responses of the infants were video graphed for 10 seconds before giving the vaccination and 30 seconds after giving the vaccination. The recorded videos were coded and given to a research panel for scoring the pain response of infants on the basis of modified behavior pain scale (MBPS). The research panel consisted of two clinical psychologists and two neonatologists. Panel members scored the pain response separately and the mean scores are considered for further analysis. Comparisons of mean scores of both the groups were done using independent sample t test.

Results

Study team approached 70 eligible children and explained the study procedures and enrolled 50 children with a response rate of 71.42%. Using blocked randomization technique, 25 children were enrolled to group A and 25 enrolled to group B. Boys were more enrolled into the study (58%) and 54% of the study population were enrolled at the age of 6 weeks. Demographic details of the study population are presented in Table I. The mean body weights of the enrolled children were 4.1 kilograms and 3.8 kilograms

for group A and group B respectively.

There was no larger difference in the scoring of various parameters in MBPS by the panelists. Neonatologists in the panel given same score for some parameters such as cry and movements in Group and Group B, which was 3 and 2.92 respectively. Even clinical psychologists gave almost similar score for cry (2.76 and 2.8) and movements (2.52 and 2.56) for group A and group B. Mean MBPS in-group A was 7.72 ± 1.01 with confidence interval of 0.19 to 1.40. Mean post vaccination in group B was 7.88 ± 0.90 with

confidence interval of 0.17 to 1.26. The differences in the mean of two groups were statistically not significant ($P 0.55$) implying that there is no difference in the pain response between 2 groups. The MBPS scoring of the study participants are depicted in Table 2. There were no immediate adverse events or complications observed following the vaccination in both groups. It was also observed that there was no statistically significant difference in the pain response of boys and girls and children belong to different age groups such as 6 weeks, 10 weeks and 14 weeks.

Table 1: Demographic details of the study population

Demographic details		Group A	Group B	Total (%)
Gender	Male	16	13	29 (58%)
	Female	9	12	21 (42%)
Age in weeks	6 weeks	13	14	27 (54%)
	10 weeks	11	9	20 (40%)
	14 weeks	1	2	03(06%)

P Value			0.55			

Discussion

There have been studies done on how to modify and reduce pain associated with immunization.¹⁴ Most of the studies are based on pharmacological ways of reducing pain.^{15,16} Modifying vaccination technique preferably order of vaccination has got many advantages. It is easy to implement, requires less time and cost effective compared to other methods of pain reduction such as pharmacological method. Studies have shown that giving something sweet like sucrose solution decrease the pain response to the injectable vaccine administration.^{17,18} A study proposed that sucrose

reduces pain only during the young infant period but not after 4 month of age.¹⁹ This is because endogenous opioids are released that are activated by sweet taste and blunts pain response.²⁰ Conversely, as polio is bitter in taste, increased bitter taste sensitivity may increase perception of injection pain.²¹ In contrast, vaccines like Diphtheria+Tetanus+Pertussis (DTP) vaccine and Hepatitis B vaccine have got differences in physical nature. DTP vaccine is more likely to cause pain when compared to Hepatitis B vaccine.

Present study enrolled 50 infants of age group one and half to three and half years, 25 in each group formed

the sample size. A similar study was done by Taddio *et al.*, done in 2015, enrolled 120 infants of age group 2-4 months and 60 infants received rotavirus vaccine first and the remaining received sucrose solution first to evaluate the vaccine injection pain.²² Present study aimed at finding the difference between pain response of two different oral vaccinations, rotavirus vaccine and oral polio vaccine which is sweet and bitter in taste respectively followed by intramuscular injections. Taddio *et al* noticed no significant difference in MBPS between the infants who received rotavirus vaccine initially (7.4) and infants received sucrose solution initially (7.7) with a p value of 0.3. Taddio *et al* concluded by saying that rotavirus vaccine did not differ from sucrose solution in reducing injection induced pain. The primary objective in the present study was to compare the acute pain response during immunization in the two groups. The mean post vaccination MBPS in the infants who received rotavirus vaccine initially was 7.72 ± 1.01 and the infant who received oral polio vaccine initially was 7.88 ± 0.90 . The differences between the groups were not significant ($P 0.55$).

The present study couldn't prove the proposed hypothesis sweet rotavirus vaccine decreases pain response among infants by changing the sequence of vaccination. It is possible that the amount to stimulate is not adequate to produce endogenous opioids as rotavirus vaccine is given in smaller amount. Therefore there was no decrease in pain perception related to sequence of vaccine administered before parenteral vaccination. The administration technique would not have any impact on the pain response among the infants as all the vaccinations in the study was administered by a trained staff nurse.

Conclusions

Sequence of administration of oral polio vaccine and rotavirus vaccine did not impact the pain response following the administration of intramuscular Pentavac® and inactivated polio vaccine among infants of age group 6 to 14 weeks. A larger study needs to be performed to verify results by enrolling a diverse infant population, and multiple nurses and physicians administering vaccines.

Menstrual Characteristics among the Nepali Adolescent Girls

Duka Devi Chhetri¹, Maibam Samson Singh²

¹Ph.D Scholar, ²Assistant Professor, Department of Anthropology, Sikkim University, Gangtok, Sikkim

Abstract

Background: Menarche is a milestone in a woman's life as it denotes the start of reproductive capacity. The experience of first menstruation is often horrifying and traumatic to an adolescent girl. Menstrual health has a close link with women's fecundity and other reproductive health risks. Women having appropriate knowledge regarding menstrual hygiene and safe practices are less vulnerable to RTI and its consequences. **Objectives:** The present study aims to find out menstrual characteristics and its association with socio-economic factor among a group of rural Nepali adolescent girls. **Materials and Method:** Data was collected from Nepali adolescent girls aged 10-16 years residing in the rural area of Sombaria village of West Sikkim. Data on age at menarche, menstrual characteristics and menstrual health were collected from 106 participants using structured schedule. **Results:** The mean age at menarche of the participants was 12.6±1.17 years. 76.6 percent of the participants have irregular periods. In present study, 85.8 percent of participants have premenstrual syndrome (PMS) like breast sore, legs cramps, mood swing and back pain. The heavy discharge and menstrual problems shows 30.1 percent and 69.8 percent respectively. **Conclusions:** The average age at menarche shows gradually increase with increasing the age of adolescent girls. Maximum numbers of participants show higher percentage of irregular period and premenstrual syndrome. The socioeconomic conditions especially the mother's education and family income did play an important role in determining the menstrual characteristics of the participants.

Keywords: Absorbents, menstruation, premenstrual, socioeconomic

Introduction

Menarche is a milestone in a woman's life as it denotes the start of reproductive capacity.¹ In general, menarche occurs between 11 and 15 years with a mean age of 13 years.² Onset of menstruation is an important aspect of reproductive health, which bothers many women on a regular basis due to their lack of knowledge of health aspect and cognitive immaturity.³ The experience of first menstruation is often horrifying and traumatic to an adolescent girl.⁴ Generally, menstrual characteristics include age at menarche, menstrual disorder, and irregularity in the menstrual cycle, premenstrual discomfort, menstrual discharge

etc.^{5,6,7,8} Age at menarche is affected by several factors such as general health and lifestyle, nutrition, physical activity, socioeconomic conditions, stress and genetic parameters.^{9,10,11} In India, poor menstrual hygienic practices lead to different kind of reproductive health issues.^{12,13} Women having appropriate knowledge regarding menstrual hygiene and safe practices are less vulnerable to RTI and its consequences.¹⁴ Proper hygienic practices such as the use of sanitary napkins and washing of genital area are essential during menstruation. Females of all age groups need to take care of their reproductive health by using soft and clean absorbents during their menstruation.¹⁵

Under this backdrop, the present study focuses on menstrual characteristics, socio-economic status of the family and issues related with menstrual health among the Nepali adolescent girls.

Materials and Method

The present study was conducted among the Nepali adolescent girls aged 10-16 years residing in the rural area of Sombaria village of West Sikkim. Among the different Nepali communities, the majority of populations are Limbus followed by others sub caste of Nepali like Chettri, Sharam Rai, Manger, Bhujel. Majority of people in the area depend upon agriculture to sustain their life.

Data were collected from 106 adolescent girls during the month of November and December, 2018. Data on the age at menarche, health and hygiene, use of sanitary pad, pre menstrual syndrome, menstrual health problems and other menstrual hygienic practices associated with menstruation were collected from each participant. Data on menstruation such as irregular period (menstrual cycle length beyond 30 days or below 28 days interval), excessive bleeding (bleeding for more than 7 days) were collected through recall method. Data on menstrual health problems like urinary tract infection, allergy rashes, excessive bleeding during and after menstruation period was collected through interview method. Data on various socio-economic conditions such as age, education, parent's education, parent's occupation, family income, family type, type of house, sanitary etc. were collected from each subject. The data on income was divided into three groups-high income group (above 75th percentile), middle income group (between 50th-75th percentile) and low income group (below 50th percentile). The educational qualification of the mother was divided as illiterate (those who did not go to school), primary (those who attained class I to class V), and secondary (those who studied up to class VI and above). Since the higher secondary and graduate educations are very negligible in number, it was clubbed together with secondary education. The data collected were analyzed using MS-Excel software.

Results

The average age at menarche in all the age group was 12.6±1.17 (Table 1). Table shows that 76.6 percent of adolescent girls have irregular periods, whereas, 27.3 percent have reported regular periods. Majority of participants (85.8%) had the problems of premenstrual syndromes. The frequency of breast soreness, leg cramp, mood swing, stomach pain and back pain was 28.3 percent, 23.5 percent, 15 percent, 9.4 percent and 9.4

percent respectively. Maximum numbers of girls were nervous (66.0%) on first period. This was followed by reaction of emotional (13.2%) and painful (11.3%). The heavy discharge and menstrual problems shows 30.1 percent and 69.8 percent respectively.

Table 2 shows that 79.2 percent of adolescent girls took regular bath during their menstruation. Using of sanitary pad (69.8%) as mode of absorbent reported higher among girls followed by using cloths (20.7%) and both (9.4%). The frequency of 23.5 percent of participants reported restriction during their periods. Mother shows the higher frequency (56.6%) who informs their daughter about the first menstruation followed by sisters (33.0%) and friends (10.3%).

Table 3 shows that the average bleeding days was found same in the age group 14-15 years and 16 years and above. The higher frequency of girls who missed school during menstruation was found in age group 16 year and above (41.1%). This was followed by adolescent girls who missed school from age group of 14-15 years (25.7%) and 12-13 years (17.1%). The frequency of adolescent girls who did not missed school was found 83.7 percent, 74.2 percent and 58.8 percent in the age group 12-13 years, 14-15 years and 16 years and above respectively. Furthermore, total of 72.6 percent of girls from the different age regularly go to the school during their menstruation. Whereas, (27.3%) of girls missed their school during menstruation.

Table 4 shows the higher frequency of urinary tract infection (6.3%) and excessive bleeding (36.1%) was found among adolescent girls belonging to lower income family. However, the higher frequency of allergy rashes (42.5%) was found among girls belongs to middle income family. This was followed by adolescent girls belong to low income family (29.7%) and high income family (16.6%). The frequency of urinary tract infection was found 2.1 percent among girls belong to middle income family. The frequency of excessive bleeding was found more or less the same between adolescent girls belong to high income family (25.0%) and middle income family (25.5%). The absence of any kind of menstrual problems was reported higher among adolescent girls belonging to higher income family (58.3%), followed by middle income family (29.7%) and low income family (27.6%).

Table 5 illustrated that the higher frequency of urinary tract infection (6.6%) found among adolescent girls whose mothers are illiterate. However, higher frequency of allergy rashes (44.4%) and excessive bleeding (37.5%) was found among girls whose mothers attained primary and secondary respectively. The urinary tract infection in adolescent girls was more or less the same among those whose mothers attained primary

education (2.7%) and secondary education (2.5%). The frequency of allergy rashes among girls whose mothers are illiterate and secondary education was (33.3%) and (25.0%) respectively. The absence of any kind of menstrual problems was reported higher among adolescent girls whose mother attained secondary levels of education (35.0%), followed by illiterate mothers (33.3%) and primary educated mothers (27.7%).

Discussion

Menstruation is the hall mark of every girl. There are various factors which influence age at menarche which includes mother's age at menarche. The mother's menarcheal age is considered a good interpreter of the daughter's menarcheal age in non obese girls.¹⁶ In the present study, the average age at menarche was found to be 12.6 years which is lower than the study conducted among girls in Kalamoli (13.3 years), West Bengal (12.8 years) and Gandhinagar (16.1 years).^{12,17,18} Several factors such as lifestyle, food they intake, physical activities and socio economic conditions could

be explained for lower age at menarche in the study population. Age at menarche also influences menstrual hygienic practices because at the very early age at menstrual onset a girl could not be mentally ready to accept all the menstrual characteristics.

Present study shows that 79.2 percent of adolescent girls took regular bath and discharge their absorbents quite often. Similarly, 76.6 percent of girls has irregular period which is higher than the study conducted among girls 27.3 percent in Hyderabad.¹⁹ Girls do mostly have irregular menstrual cycles during early adolescence.^{20,21} A proper absorbent seems to be healthy hygienic

practices. The present study also reported that 69.8 percent of adolescent girls used sanitary pad as type of absorbent. Whereas, 20.7 percent of girls used cloths and 9.4 percent of girls used both the sanitary pads. A cloth is considered as pocket free and eco-friendly menstrual napkin. A study shows that used of cloths as type of absorbent does not always mean financial restriction; it has some traditional beliefs system such as problems related with disposal of menstrual wasted.²² Mothers are the key informants of their daughter regarding the matter of menstrual characteristics as found in other study at Gandhinagar.¹⁸

Adolescent girls either at school or home do discharge their absorbents quite often. The lesser percentage of adolescent girls do constrain from attending school during menstruation. A study conducted by Guerry found the lack of product is in fact the biggest contributor to absenteeism during menstruation.²³ Another study in Nepal shows that there were no separate toilets for girl in schools. Girls felt embarrassed to go in the same toilet for girls and boys.²⁴ The present study shows that the majority of girls have an average bleeding period of four days. In the study conducted in South India, the menstrual flow lasting more than seven days.⁸ Premenstrual syndrome like breast soreness, leg cramp, mood swing, and back pain are observed in present study. Maximum numbers of participants were nervous on their first menstruation. Restrictions are imposed by their family members of the participants during menstruation.

A socioeconomic condition and mother education plays an important role in problem associate with menstruation of the adolescent girls. Education of mother, awareness and knowledge regarding can contribute the adolescent girls to handle the bodily changes during period in adaptive and participative manner.²⁵ Poor literacy and socio-economic status of mothers have fuelled the inhibitions a mother has to talk her daughter regarding menarche and the significance of menstrual practices.¹ A study in Nigeria found that the majority of girls were using toilet rolls as mode of absorbent to catch menstrual blood.²⁶ The socio-economic variables seemed to influences the chance of having gynaecological problems.³ Higher frequency of menstrual problems such as uterus tract infection and allergy rashes are found in low income group in the

present study.

In conclusion, the present study was conducted to understand the menstrual characteristics among the Nepali adolescent girls of Sikkim. Irregular period and premenstrual syndrome are observed in higher percentage in the study population. Problems associated with menstruation such as urinary tract infection, allergy rashes, excessive bleeding etc. are also reported in the present study. These menstrual health problems are more common among girls from low income family and whose mothers are illiterate. Present study further indicates that mothers are pioneer sources of information to their daughter when it comes to educating their girl on reproductive health issues. Sister and colleagues are the secondary sources of information for the adolescent girls in Sikkim. The adolescent Nepali girls in the present study are more concerned about menstrual health and its consequences.

Clinical Cure and Microbiological Eradication in Respiratory Tract Infections

Eema Chaudhary¹, Shivam Mohan Pandey², Ajay Kumar³, Rishi Yadav⁴,
Vivek Gautam⁴, Shubham Tiwari⁴

¹Associate Professor, ²Final Year Resident, ³Assistant Professor, ⁴Resident, Department of Respiratory Medicine, Subharti Medical College, Meerut, UP, India

Abstract

Aims: To study the concordance between clinical cure and microbial eradication in severe respiratory tract infections.

Methods & Material: A prospective cohort study was done at a tertiary care teaching hospital. Patients above 18 years of age with respiratory tract infections confirmed with positive sputum cultures participated in the study. Microbiological eradication was considered complete when no microorganism was isolated on 2 consecutive sputum cultures.

Results: The number of valid cases was 102. The mean age of patients was 58.6±16.1 (range, 19-82 years). Complete eradication of microorganisms was achieved in 54.5%(n=55) cases. In 33% (n=34) clinically successful cases, strains like Pseudomonas, Acinetobacter and Klebsiella were not eradicated and were isolated at study end point on repeat sputum culture. Relapse was observed in 9.2% (n=9) cases. On multiple logistic regression to ascertain the impact of independent variables on dependent variable (clinical cure/ microbiological cure), it was observed that increasing age, odds ratio=1.66(95% CI, 1.34-2.03), patient's background OR=6.4 (95% CI, 0.68-63.4), ventilatory support OR=2.8 (95% CI, 0.4-22.4) significantly (P<0.05) influenced end stage clinical outcome. Increasing age, odds ratio=2.33 (95% CI, 1.56- 2.84) and ventilatory support OR=3.4 (95% CI, 2.46-4.66) significantly (P<0.05) influenced microbiological eradication.

Conclusion: Clinical endpoint and microbiological eradication correlated in 54.5% cases. Discordance or failed eradication was more frequent in infections with Acinetobacter, Enterobacter and Pseudomonas. Failure to eradicate microorganisms was commonly associated with emergence of resistance to antibiotics.

Keywords: Microbiological eradication; Clinical endpoint; Logistic regression; Antibiotic resistance.

Introduction

The success of an antibiotic treatment has traditionally been considered synonymous with good clinical response.¹ In respiratory tract infections, the appearance, persistence, or recurrence of infection due

to the initial causative organism during treatment clearly indicates an antibiotic treatment failure.

However, in respiratory tract infections, microorganism may still be isolated on culture, even after completion of antibiotic therapy and consequently, a good clinical response. Exacerbations of persistent lung infections are common-place and have been shown to result in significant morbidity and loss of lung function if not treated. Acquisition of a new strain of Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae in the lung is associated with

an increased risk of exacerbation.²

Most physicians however lack consensus whether they should go for microbiological eradication or clinical cure in lower respiratory tract infections. Universally accepted endpoints have not been defined. A study by Denessen et al was done to evaluate concordance between the two issues but failed to establish a significant relationship between microbiological eradication and clinical cure in patients with severe pneumonia.⁵

Active bacterial eradication is now considered as a strategy aimed at optimizing the treatment of infection while minimizing the risk of selection, carriage and spread of resistant strains. However, therapeutic choice becomes more limited as multi-resistant strains become more prevalent. Thus, local susceptibility patterns must be considered when choosing antimicrobial therapy.

There is paucity of literature regarding the association between the two dichotomous end points in severe blood stream infections. The aim of present study was to establish the association between clinical cure and microbiological eradication in patients receiving inhaled antibiotics for severe respiratory tract infections. The study is also aimed to determine the influence of independent variables like age, gender, background, ventilatory support, and follow up duration on microbiological eradication and clinical cure.

Subjects & Method

A cohort study was done at a tertiary care center. Patients with severe respiratory tract infections were invited to participate in the study. The study was performed between October 2017 to January 2019. Prior approval of the institutional review board and Ethics committee was obtained. Written informed consent was obtained from all participating patients.

Patients with severe lower respiratory tract infections, on inhalational antibiotics were evaluated for microbiological eradication and clinical endpoints at completion of treatment and follow-up period (for 2 weeks after antibiotic treatment). Demographic, microbiological and clinical factors affecting clinical cure and microbiological eradication were evaluated.

Inclusion criteria: Patients with sputum culture positive respiratory tract infections were included. The

minimum age for inclusion was 18 years.

Exclusion criteria: Patients with renal failure, and history of ototoxicity were excluded.

Primary outcome Measure: The correlation between microbiological eradication and clinical cure was the primary outcome measure.

Secondary outcome measure: Demographic, microbiological and clinical factors affecting microbiological eradication and clinical cure were secondary outcome measures.

Criteria proposed by the 'Infectious disease society of America' was used to evaluate microbiological outcomes. The society has suggested that microbiological eradication was considered synonymous with elimination of the organism determined by 2 consecutive negative sputum cultures; microbiologic persistence was failure to eradicate the causative organism; microbiologic relapse was the recurrence of the same organism within 5 days after discontinuation of treatment or during treatment after 2 consecutive negative cultures; superinfection was the development of new infection with signs and symptoms due to a new or resistant pathogen other than the original causative organism.⁶⁻⁷ All assessments were based on actual sputum cultures.

Statistics: Statistical analysis was performed using IBM, SPSS Statistics version 25 (IBM Corp., New York, NY). Descriptive data was expressed as mean \pm standard deviation unless otherwise stated. Patients' baseline underlying disease condition and demographic characteristics were compared with microbiological and clinical outcomes, respectively. Continuous data were compared using t-tests. A P-value <0.05 was considered statistically significant. The effect of demographic data on the clinical and microbiological outcomes was evaluated using Chi-square tests. A binary logistic regression model was constructed to predict factors (independent variables like age, gender, background, ventilatory support, follow up duration, and microbiology) affecting the study end point (dependent variable).

Results

The sample size of participants was 108. The mean age of patients was 56 ± 12.9 (range, 18-80 years). The difference in age between males and females was

statistically significant (independent t-test, $P=0.05$). There were 79 (75.5%) males and 29 (24.5%) females. The mean follow-up duration was 14 ± 2 (range, 14-16 days). The demographic profile of study participants is shown in Table 1.

The microorganisms isolated on sputum culture are depicted in Table 2. *Klebsiella pneumoniae* ($n=30$) was the most common isolate and *Citrobacter* ($n=6$), the least common isolate on culture. The clinical diagnosis of study subjects is depicted in Table 3. Chronic obstructive pulmonary disease ($n=33$) with secondary infection was the most common clinical diagnosis.

Ventilatory support was required in 24(24.5%) patients. Colistin (58, 59.2%) and tobramycin (40, 40.8%) were the systemically administered antibiotics in study participants. Nausea, hoarseness of voice, dryness, cough and sore throat were the commonly reported adverse effects to medication. Dryness of mouth (63.3%) was the most reported adverse effect to therapy.

At about 2 weeks follow up after completion of drug therapy, complete microbiological eradication was achieved in 55.5% ($n=60$) cases. In 36.1% ($n=39$) clinically successful cases, strains like *Pseudomonas*, *Acinetobacter* and *Klebsiella* were not eradicated and isolated at the end of antibiotic treatment. Relapse was observed in 10.1% ($n=11$) cases. Table 4 compares microbiological outcome and clinical outcome at study end point by microbiology.

The end-point clinical outcome was cure in 84 (85.7%) cases and death in 14(14.3%) cases. The end point outcome did not differ significantly (Chi-square tests, $P=0.133$) between males and females. The end point outcome did not differ significantly (Chi-square tests, $P=0.133$) in patients on Colistin as compared to Tobramycin.

The outcome (clinical cure and microbiological eradication) was significantly bad (Chi-square tests, $P<0.001$) in patients requiring ventilatory support than those without.

Patients with rural background had a significantly (Chi-square-tests, $P=0.019$) worse clinical outcome than urban patients.

The clinical diagnosis significantly influenced the end stage clinical outcome (Chi-square tests, $P=0.002$). The microbiological outcome at 2 weeks follow up differed significantly (Chi-square tests, $P<0.001$) from clinical outcome. Patience with persistence and relapse had a poorer outcome. There was a significant difference ($P<0.001$) between microbiological end stage eradication between different sputum isolates.

The binomial logistic regression model was statistically significant, $\chi^2(3) = 29.6602$, $p < .0001$. The model explained 71.1% (Nagelkerke R^2) of the variance in clinical outcome and correctly classified 90.4% of cases. The area under the ROC curve (Figure 31) was .820 (95% CI, .718 to .891), which is an excellent level of discrimination according to Hosmer et al. (2013). Sensitivity was 82%, specificity was 93%, positive predictive value was 74.2% and negative predictive value was 93.4%.

Increasing age, odds ratio=1.74(95% CI, 1.34-2.03), patient's background OR=7.2 (95% CI, 0.68-63.4), ventilatory support OR=3.1 (95% CI, 0.4-22.4) significantly ($P<0.05$) influenced clinical cure.

Increasing age, odds ratio=2.54 (95% CI, 1.56-2.96) and ventilatory support OR=3.6 (95% CI, 2.46-4.74) significantly ($P<0.05$) influenced microbiological eradication (Table 4).

Table 1. Sputum Culture Isolates

Isolate	Frequency	Percentage
Kleibsiella pneumonie	30	27.7
E. coli	20	18.5
Acinetobacter calcoacitecus	8	7.4
Citrobacter	6	5.5
Kleibsiella oxytoca	13	12
Pseudomonas aeruginosa	22	20.4
Acinetobacter baumani	9	8.3
Total	108	100

TABLE 2. Clinical Diagnosis

Diagnosis	Frequency	Percent
COPD with Secondary infection	68	62.96
Bilateral pneumonitis	24	22.2
Bronchial Asthma with secondary infection	10	9.25
CA Lung with Pneumonia	2	1.85
CA Larynx with pneumonia	2	1.85
Pulmonary Tuberculosis with Pneumonitis	2	1.85
TOTAL	108	100

Discussion

The results of this study suggest that there occurs gross variation between microbiological eradication and end stage clinical outcome in respiratory tract infections. Complete microbiological eradication was achieved in only 55.5% patients after successful completion of antibiotic course. However, in 36.1% of clinically successful cases, strains of Pseudomonas, Acinetobacter and Kleibsiella could still be isolated at the end of antibiotic treatment. In 10.1% cases, there was relapse indication development of resistance and failure of antibiotic treatment.

The exact reason for the discordance between clinical response and bacterial eradication in respiratory tract infections is not known. It is known fact that persistence of organisms in patients with satisfactory clinical response often exhibit resistance to antibiotics used to treat the initial infection; is it that we rely too much on clinical cure rather than bacterial eradication?

Kousalya et al conducted a study in rural South Indian population. Throat swab samples of 250 patients with upper respiratory tract infections were cultured. The authors found that out of 34 (14.91%) strains of Kleibsiella pneumonie, 19 (8.33%) Pseudomonas aeruginosa and

remaining haemolytic streptococci, *Escherichia coli* and *Haemophilus influenzae*, all *Staphylococcus* spp, were resistant to penicillin., ampicillin and co-trimoxazole. All the isolates were resistant to at least one antibiotic. The authors were of the opinion that surveillance of bacterial infections and monitoring their antimicrobial susceptibility pattern must be carried out not only in tertiary hospitals, but also in small hospital settings. Changing the antibiotic of main prescription periodically (every 6months/ 1 year) akin to crop rotation to increase soil fertility, could keep resistant organisms at bay in the wards. ^{8- 10}

Kiem et al collected data from three clinical trials involving 76 patients with severe pneumonia. Clinical success was considered as total or partial eradication of isolated organisms. They found that complete microbiological was achieved in 44% patients after completion of antibiotic regimen. In 56% clinically successful cases, strains of *Acinetobacter*, *Enterobacter*,

Pseudomonas, *Stenotrophomonas maltophilia* could still be isolated on repeat culture. Resistance to antibiotics was observed in 71% persistent strains and relapse in 7.6% cases. Out of these, non-eradicated organisms accounted for 70% relapsed cases. In comparison, we achieved complete microbiological eradication in 55.5% cases, but the relapse rate was significantly ($P<0.05$) higher (10.1% versus 7.6%) in the present study. This could be explained by a relatively higher sample size in our study and presence of patients with varied etiologies.

Ikemoto et al studied susceptibilities of bacteria isolated from patients with lower respiratory infectious diseases to antibiotics across Japan. The authors found that administration of antibiotics has changed the results of the frequency of isolation of bacterial species. Bacterial isolations before administration of antibiotics were as follows: *S. pneumoniae* 24.5%, *H. influenzae* 21.4%, *S. aureus* 18.4% and *P. aeruginosa* 12.2%. The frequencies of *S. aureus* decreased after antibiotics administration over 15 days, but the frequencies of *P. aeruginosa* was not affected. The frequencies of *P. aeruginosa* was 47.8% after administration over 15 days. ¹²

On binomial logistic regression, the present study found that increasing age, urban background and presence/absence of ventilatory support significantly

influenced end stage clinical outcome whereas increasing age and presence/absence of ventilatory support significantly influenced microbiological eradication, respectively.

In a prospective cohort study in Brazil, 773 adult patients in an intensive care unit on ventilatory support were evaluated. Multivariate analysis was done to identify factors influencing end stage clinical outcome and mortality. Ventilatory support was required for respiratory tract infections (27%), neurologic disorders (19%) and non-lung sepsis (12%). The authors found that increasing age, OR=1.03 (95% CI, 1.01-1.03), significantly ($P<0.05$) influenced end stage clinical outcome in patients with lung sepsis. This observation is similar with the present study.

In the present study, increased mechanical ventilation time significantly influenced both clinical outcome as well as microbiological eradication. In patients on ventilation, strains of *Pseudomonas* and *Acinetobacter* could still be isolated after satisfactory clinical response. ¹⁴

The present study had some limitations. The colony counts of pathogenic bacteria were not compared in patients with clinical and microbiological eradication. Secondly, the sample size though adequate was not representative of all respiratory tract infections. Antibiotic treatment regimens, and quality of supportive care could differ from developed countries standards.

In conclusion, there has been a sharp increase in the interest for antibiotic persistence in the past years in the background of growing concerns about antimicrobial resistance. Discordance or failed eradication was more frequent in infections with *Acinetobacter*, *Enterobacter* and *Pseudomonas*. Even in the absence of any antibiotic resistance, lung bacterial infections are hard to treat and tend to relapse. In this scenario, we should aim for both clinical cure and microbiological eradication

Ethical Clearance : Taken from Ethical committee of the Swami Vivekanand Subharti University.

Abstract

Background: Forward head posture (FHP) means that the head is in an anterior position in relation to the postural line and it is considered to coexist with hyperextension of upper cervical spine, flattening of lower cervical spine, rounding of the upper back and elevation and protraction of the shoulders. Because of associated problems, assessment of head posture has become increasingly important in clinical practices in evaluating and designing treatment regimens.

For clinical diagnosis, angle measurements have been utilized as information for evaluating physical characteristics, determining the effects of rehabilitation and preventing injury induced by physical activity. There are various software's available for measuring angles, one of them being Surgimap. In recent years, angle measurements using Electronic head posture instrument (EHPI) have been clinically researched as new angle measurement methods for the forward head posture apart from photographic measurement methods. Thus, this study evaluated the validity and reliability of the EHPI in measuring Head posture angles with Surgimap photograhic method in young healthy subjects.

Methodology: Ethical approval for the study was granted and cross sectional observational study was conducted for validity and reliability at outpatient department. After written consent the subjects were made to understand the purpose of the study. Craniovertebral angle, Cranio-horizontal angle and Sagittal shoulder angle was measured using Electronic Head Posture Instrument and Photographic Method through Surgimap software. The research constituted of three researchers and intra rater reliability, inter rater reliability and validity was analyzed.

Results: Data analysis was done using SPSS 20.0 version and the statistical significance level was set at $p < 0.05$. Intra rater reliability was found to be $CHA = 0.95$, $CVA = 0.92$ and $SSA = 0.96$, Inter rater reliability was found to be $CHA = 0.98$, $CVA = 0.90$ and $SSA = 0.78$. Correlation between different angles was found as $CHA = 0.95$, $CVA = 0.79$ and $SSA = 0.62$.

Conclusion: EHPI is a valid and reliable tool in clinically assessing and evaluating CHA, CVA and SSA

Introduction:

Posture is the way a person moves, sits, and walks and is individually unique. It is also defined as the spine

being in a neutral position, with good posture being imperative for improved health.⁽¹⁾ Maintenance of posture involves muscles to contract, which enables the body to remain in both seated and standing positions. However, prolonged sitting or standing can have a detrimental effect on an individual's posture and lead to many postural abnormalities.⁽²⁾

Forward head posture (FHP) means that the head is in an anterior position in relation to the postural line.⁽³⁾ FHP is considered to coexist with hyperextension of upper cervical spine, flattening of lower cervical spine, rounding of the upper back and elevation and protraction of the shoulders.⁽⁴⁾ Forward head posture (FHP) is one of the most common cervical abnormalities that predispose individuals toward pathological conditions, such as headache, neck pain, temporomandibular disorders, vertebral bodies disorder, soft-tissue length and strength alteration and shoulder dyskinesia.⁽⁵⁾ Because of these associated problems, assessment of head posture has become increasingly important in clinical practices in evaluating and designing treatment regimens.

In physiotherapy practices, angle measurements have been used for assessing physical alignment and articular range of motion. In particular, for clinical diagnosis, angle measurements have been utilized as information for evaluating physical characteristics, determining the effects of rehabilitation, and preventing injury induced by physical activity. For a number of clinical practices, a goniometer is commonly used to measure the joint angles. However, clinical angle measurements using the goniometer have lower reliability and validity.⁽⁶⁾ Radiograph measurements (RMs) are strongly recommended for reliable measurements of several joint angles to improve the accuracy.⁽⁷⁾ However, radiographic measurement also has disadvantages such as radiation exposure, higher medical costs, and a specialized medical implementation site. Therefore, a non-invasive, simple, and low cost measurement method that has high correlation to RM would be beneficial for various clinical practices.

There are various software's available for measuring angles.⁽⁸⁾ Another software used for measuring angles is Surgimap. The present software has turned out to be a boon and is now being utilized in the medical field as well for measuring joint angles. The software is

also used for research purposes wherein digital -photo analysis is being done. A previous study has found that Surgimap software is a reliable method for measuring spinal postural angles in adolescents from different views in standing position from digital photographs.⁽⁹⁾

Lau and chiu (2009) have developed an Electronic Head Posture Instrument (EHPI) to measure craniovertebral (CV) angle. Its measuring scale is accurate to one decimal place, and the electronic sensor reads the angle automatically. Measuring craniovertebral (CV) angle is one of the common objective methods in assessing head posture.⁽¹⁰⁾

A previous study by Lau and chiu (2010) evaluated the criterion-related validity of the Electronic Head Posture Instrument (EHPI) in measuring the craniovertebral (CV) angle by correlating the measurements of CV angle with anterior head translation (AHT) by lateral cervical radiographs in patients with diagnosis of mechanical neck pain and was found to be a valid and reliable tool for measuring the head posture.⁽¹¹⁾

In recent years, angle measurements using Electronic head posture instrument have been clinically researched as new angle measurement methods for the forward head posture apart from photographic measurement methods. Head posture can be evaluated by measuring the craniovertebral angle (CVA), Craniovertebral angle (CHA) and Saggital shoulder angle (SSA).

Thus, this study evaluated the validity and reliability of the EHPI in measuring Head Postural Angles with Surgimap photograhic method in young healthy subjects.

Therefore, the present study aimed to demonstrate the following two research aspects using the measurement of head postural angles provided from the Electronic Head Posture Instrument:

(1) Criterion validity of EHPI and (2) inter-rater reliability and inter-rater reliability of EHPI.

Methodology

A cross sectional observational validity and reliability study was conducted at outpatient department of Shree Swaminarayan Physiotherapy College. Inclusions criteria are Age group between 18 to 22 both gender are included in this study. Participants were

excluded if they had musculoskeletal or neurological pathologies. Based on this criteria, a total number of 50 young healthy individuals participated in this study by simple random sampling. A written consent was taken from each subject. Following recruitment, the subjects were made to understand the purpose of the study concisely and clearly. Materials used in this study were measuring tape, weighing machine, Digital Camera, EHPI, Surgimap software and reflective adhesive markers. Craniovertebral angle, Cranial horizontal angle and Sagittal shoulder angle was measured using Electronic Head Posture Instrument and Photographic Method through Surgimap software.

Procedure:

The subjects were informed to stand erect with feet width apart. Clothing was rearranged so that neck (C7 spine) and shoulders are exposed; adhesive markers were placed on anatomical point **1**. First point from external canthus of the right eye, **2**. Tragus of the ear **3**. Spinous process of C7 **4**. A midpoint between greater tuberosity of humerus and posterior aspect of acromion process of shoulder. The angles were measured as:

1. Cranio-horizontal angle (CHA)- the angle formed at the intersection of horizontal line through the tragus of ear and external canthus of the eye was measured.

2. Craniovertebral angle (CVA)- the angle formed at the intersection of horizontal line through the spinous process of C7 and tragus of ear was measured.

3. Sagittal shoulder posture (SSA)- the angle formed at the intersection of horizontal line through C7 spinous process and the midpoint of greater tuberosity of humerus and posterior aspect of acromion was measured.

The research constituted of four researchers- who measured angles with Electronic head posture instrument and took lateral view photographs of the upper body for analysis in Surgimap software. For intra-rater validity the angles were measured by the same researcher twice on different sessions. For inter-rater reliability, the angles were measured on the same subject twice by the two researchers. One researcher analyzed the angles in lateral view photograph through surgimap software.

The angles measured by the EHPI which was composed of an electronic angle finder, a transparent plastic base, and a camera stand. The electronic angle finder 'SmartTool,' made by M-D Building Products, was fixed on a transparent plastic base. The combined SmartTool Angle Finder and the plastic base were mounted on a tripod camera. The participant was then asked to stand with his/her left shoulder in front of the EHPI. The participant was instructed to stand comfortably with his/her weight distribution evenly on both feet and to keep the eyes looking straight forward. He/she was then instructed to flex and extend the head three times and then rest it in a comfortable position. The therapist adjusted the EHPI until the two indicator lines were aligned with the markers. Three readings were taken by the researchers and an average was taken.

For photographic method, same angles were measured by placing the markers on respective sites as mentioned above. Images were captured by Digital camera which was mounted on adjustable tripod stand at a distance of 3 m from the subject's shoulder. The same image was inserted in the Surgimap software and angles were measured.

Validity and Reliability of EHPI was analyzed from the data collected.

Fig: CHA, CVA and SSA using EPHI Smart Tool

Results

Data analysis was done using SPSS 20.0 version and the statistical significance level was set at $p < 0.05$. The study recruited 50 participants, out of which 26 males and 24 females were taken by simple random sampling. The scale from Bland and Altman was used in the classification of the reliability values (≤ 0.20 poor, 0.21–0.40 fair, 0.41–0.60 moderate, 0.61–0.80 good, and 0.81–1.00 excellent).⁽¹²⁾ Table shows inter-rater reliability of different angles and Table 2 shows the intra-rater reliability of different angles.

TABLE 1:- Inter-rater reliability of EHPI for CHA, CVA and SSA angles

Angle	Icc	Upper Limit	Lower Limit	Significance
CHA	0.98	0.99	0.95	0.001
CVA	0.90	0.97	0.60	0.001
SSA	0.78	0.94	0.13	0.016

At 95% confidence interval ICC for different angles is found as CHA=0.98 (Excellent), CVA=0.90 (Excellent), and SSA=0.78 (Good) for inter-rater reliability.

TABLE 2:- Intra- rater reliability of EHPI for CHA, CVA and SSA angles

Angle	Icc	Upper Limit	Lower Limit	Significance
CHA	0.95	0.98	0.82	0.00
CVA	0.92	0.98	0.71	0.00
SSA	0.96	0.99	0.85	0.00

At 95% confidence interval ICC for different angles is found as CHA=0.95 (Excellent), CVA=0.92(Excellent) and SSA=0.96 (Excellent) for intra-rater reliability.

The association between different angles measured by Surgimap method and EHPI was explored with Spearman's correlation coefficient. Table 3 shows correlation between different angles measured by Surgimap method and EHPI.

TABLE 3:- Correlation between different angles measured by Surgimap and EHPI

Angle	Spearman's Correlation Value
CHA	0.95
CVA	0.79
SSA	0.62

A Very High Positive correlation was found of CHA, a High Positive correlation was found of CVA and a Moderate Positive correlation was found of SSA. This result suggests that EHPI is a valid tool for measuring head posture angles.

Discussion

This study evaluated the Validity, Inter-rater and Intra-rater reliability for Electronic head posture instrument.

EHPI was found to be a valid tool for assessing head posture. This findings are similar to a previous study by Lau and chiu (2010) who evaluated the criterion-related validity of the Electronic Head Posture Instrument (EHPI) in measuring the craniovertebral (CV) angle by correlating the measurements of CV angle with anterior head translation (AHT) by lateral cervical radiographs in patients with diagnosis of mechanical neck pain and was found to be a valid and reliable tool for measuring the head posture. ⁽¹³⁾

The present study showed the high intra rater and high interrater reliability of EHPI. These results are similar to the previous study which showed a high intrarater (0.91–0.93) and interrater reliability (0.92–0.93) for both nondisabled subjects and those with neck pain. ⁽¹⁴⁾

Various disorders of cervical region like-upper cross syndrome, cervical spondylosis, kyphotic posture, PIVD, scoliosis can affect the surrounding musculature leading to postural changes in the cervical region. Amongst these changes, forward head posture is most commonly seen which not only leads to muscle imbalance but also reduces the cervical ROM. Electronic head posture instrument measures the angles similar to the photographic method but the major difference is EHPI is portable whereas the software requires either computer or laptop. The results showed that both the methods; EHPI and Surgimap photographic method has higher agreements on both the angles. These findings indicate the high validity of EHPI for evaluation of head postural angles.

In one of the previous study, the Head Posture Spinal Curvature Instrument (HPSCI), a noninvasive and simple instrument, was designed by Wilmarth and Hilliard. ⁽¹⁵⁾ The HPSCI is an inexpensive method to measure CV angle. Willford et al. demonstrated that it produced consistent and stable intrarater results (intraclass correlation coefficient [ICC] =0.9) across days and trials in 27 nondisabled subjects. ⁽¹⁶⁾ However, the accuracy of the instrument is limited to whole digits

only without decimal places because no marking exists between digits. In contrast, EHPI measuring scale is accurate to one decimal place, and the electronic sensor reads the angle automatically.

Electronic head posture instrument was found to have high validity, inter-rater reliability, and intra-reliability in the present study. Therefore, angle measurements using images taken in a certain distance from the subject were accurate for the definite angle. The results showed what angle measurements using images could use as criterion for validity, and it supported the legitimacy of high-quality previous studies that used photographic method as a criterion for validity.

One of the limitations of lateral photographic imaging to measure head posture is cumbersome and inconvenient to use in clinical practices. On the other hand, EHPI has high clinical benefits, such as being a simple, non-invasive technique and it is cost effective. Thus, EHPI can provide high-quality data in clinical studies and can be used as a criterion of validity for postural angles (CVA, CHA & SSA).

Age can be a major factor that can affect the results. This study included healthy adults aged between 18-24 years. Hence a study including higher and lower age group might be considered for future studies.

Also, in this study female to male ratio, i.e. gender effects as a confounding factor, on the reliability of measurements was not considered. According to the results and limitations mentioned above, it is suggested that studies can be conducted on different age group and gender group to eliminate confounding factors.

Conclusion

There is a strong association of head postural angles measured by EHPI and Surgimap Photographic Method which supports that EHPI can be recommended and is a valid and reliable tool in clinically assessing and evaluating head posture in terms of CHA, CVA and SSA.

Abstract

Introduction: Pain neck is a very common symptom and associated with cervical spondylosis prevails in all individuals. Though this is an era of advanced MRI, the old technology of plain X-ray cervical spine still gives useful information in patients with pain neck. **Objective:** To study the plain X-ray findings in pain neck cases of neural causes.

Materials and Method: This was the cross sectional study conducted at Sri Manakula Vinayagar Medical College and Hospital over three years(January 2017-December 2019). Informed consent was obtained from all the patients included in the study. Institutional ethical committee clearance was obtained. All patients visiting the Out Patient Department (OPD) with the complaint of neck pain and back were advised to have plain X-ray cervical spine AP and Lateral views. The findings were recorded.

Results Of the 148 patients, 91 patients that are 61% of the patients with the neck pain, the plain X-rays were normal, except for mild Spondylotic changes. 25.6% (38 patients) had single level interbody space narrowing and in those patients common complaint was typical root pain. 4% (6 patients) had 2 or more level narrowing. 6% (8 patients) had cervical ribs of whom it was bilateral in 40% (3 patients). There were 2 cases of Klippel Feil interbody fusion (1.4%) and 3 cases had Spina Bifida (2%). Severe spondylosis with more than 3 level interspace narrowing was seen in 12 cases (8.1%) and all of them was over the age of 55.

Conclusion: Not all cases with neck pain need an MRI study. Plain X-ray cervical spine that is freely available even at the periphery can give valuable findings like interbody fusion, Spondylosis, cervical rib, congenital anomalies and those cases can be managed easily without unnecessary referrals in the initial stage.

Key Words: Spondylosis, Radiculopathy, interbody narrowing; lordosis; thoracic outlet syndrome.

Introduction

Cervical radiculopathy is a pain and/or sensorimotor deficit syndrome that is defined as being caused by compression of a cervical nerve root.¹ The clinical manifestations of cervical radiculopathy are broad and may include pain, sensory deficits, motor deficits, diminished reflexes, or any combination of the above. Similarly, there are a variety of different pathophysiologic

processes that may result in dysfunction of the cervical nerve roots. An accurate history is a critical first step in the diagnosis of radiculopathy. Unlike patients with axial neck pain, patients with radiculopathy usually present with unilateral pain.²

When diagnosing a patient with radiculopathy, it is important to test for cervical myelopathy. Patients with myelopathy will present with upper motor neuron signs including hyperreflexia, changes in gait, and also have difficulty with fine motor tasks (changes in handwriting, buttoning shirts, etc.). Other pathologies that might be confused with cervical radiculopathy include peripheral nerve compression syndromes (e.g., median or ulnar nerve entrapment).

The clinical diagnosis of cervical radiculopathy may be confirmed by the presentation of root compression using MRI, which is the standard approach for identifying disk protrusions, while thin slices of spiral CT may be preferable to foraminal stenosis with bony compression.³

Imaging evidence should also be viewed in the clinical sense, as MRI in particular often generates false-positive findings that indicate abnormalities in asymptomatic patients.⁴ This also refers to simple X-ray results showing degenerative changes that arise with age contrary to clinical signs and symptoms and can thus be found redundant in a patient with cervical radiculopathy's routine diagnostic workup.⁵

Imaging (X-ray, computed tomography, magnetic resonance imaging, and myelography) as a convenient, quick, and practical method, has been widely applied in the clinical diagnosis of cervical spondylosis. Even though this is the era of MRI, many primary care physicians rely on plain X-rays. Plain X-ray film radiography remains the primary imaging modality of choice. The present study aimed to exploit the causes of

neck pain using plain X-ray as a diagnostic tool.

Materials and Methods: This was the cross sectional study conducted at Sri Manakula Vinayagar Medical College and Hospital over three years(January 2017-December 2019). Informed consent was obtained from all the patients included in the study. Institutional ethical committee clearance was obtained. All patients visiting the Out Patient Department (OPD) with the complaint of neck pain and back were advised to have plain X-ray cervical spine AP and Lateral views. The following patients were excluded from the study, Patients below the age of 20 as they are less likely to have degeneration, the trauma of any kind with fracture, tumors of both cervical spine and cord, fracture spine due to Trauma or tumor or tuberculosis, patients with any neurological deficit.

Results: A total of 148 patients were included in the study. Out of 148, 84 were females and 64 were males. The chief complaints that brought them for medical advice are as follows: Pain back of the neck, Pain radiating to one or both Upper limbs, Dull or diffused pain from neck to hand paresthesia and numbness, pain all over the body and joints. Stress and strain that precipitated or aggravate the pain. No definite cause or mode of precipitation.

There was complexity and overlapping of all these symptoms in more than 90% of these patients. Only 12 (8.2%) of them gave a typical history of root pain that is pain precipitated by unusual stress, radiating along a particular root from neck to hand, aggravated by stress and strain like Valsalva maneuver. Among them, 5 patients (42%) gave a typical history of lifting a heavyweight. One patient gave an unusual rare precipitating factor of severe cough after which he developed root pain. The findings noted in the plain X-ray are given in Table.1

Fig 1: C5-6 interbody narrowing and osteophytes with loss of lordosis.

TABLE 1: Plain X-ray findings of patients with neck pain

Findings	No of Patients	Percentage %
Normal with mild spondylotic changes	91	61.49
Single space narrowing 2 and > 2 space narrowing	38	25.68
Cervical rib (40%) bilateral cervical rib)	8	5.40
2 and > 2 space narrowing severe spondylosis 8%,	6	4.05
Spina bifida	3	2.03
Klippel Feil interbody fusion	2	1.35
Total	148	100

All the cervical rib cases were females except 2 males. All of them had a diffused pain on one side with mild paraesthesia. Even the bilateral cervical rib patients had pain only on one side. Normal X-ray cases were that of those patients who had mild to moderate and vague pain in the back of the neck. The pain was not radiating to hand or back. In many of these patients there was no

spontaneous or precipitating factor for a radiating pain even though mild to moderate spondylotic degenerative changes like anterior or posterior osteophytes were noted in the X-rays.

The oblique view was taken in 6 cases with complaints of radiculopathy and whose AP and lateral views were

normal. In those cases the oblique view showed mild narrowing on the involved side at C4-5; C5-6; C6-7 on the symptomatic side. Similarly Flexion and Extension views were taken in whom they complained that the pain aggravated on flexing or extending the neck. In all those cases there was no evidence of instability and the X-rays looked normal with no antero or retro lysis MRI was done in 24 cases on whom surgery was planned and all those cases had disc prolapse with root compression as suspected with plain X-ray.

Discussion

In the present study, 61 % of the patients in our study had a normal X-ray with minor spondylotic changes. Patients with common radiculopathy had either one or more of the following: interbody space narrowing either in one or more levels; anterior or posterior osteophytes; beaking or lipping of the antero superior or inferior vertebrae, loss or obliteration of lordosis. It is best to search for related findings to rule out stenosis characteristics which can precipitate myelopathy later but not necessarily.

An annual occurrence of cervical radiculopathy was recorded at 107.3 per 100,000 males and 63.5 per 100,000 females at a rate of 50 to 54 years. Whilst most cases are self-limited, others are conservative treatment refractory. When patients have failed to control the cervical radiculopathy, several treatments can be used based on patient and surgeon factors.⁶

In our study, C5 and C6 were the most commonly affected levels. This is consistent with the findings of several previous studies showing that the C5-6 and C6-7 disc levels are the most susceptible to degenerative disease and resulting in nerve root impingement.⁷

There are over eight cases in the present sample that had cervical rib and in three of them, it was bilateral. It may be pain with radiculopathy due to the disk bulge that may occur during the spondylosis degenerative process. We should emphasize that in these cases quick X-ray of the cervical spine is easily helpful.

Markus Engquist et al., advises conservative treatment in the form of exercise therapy, therapy for neck stabilization, relaxation training, general exercise, and education.⁸ Muthukumar N suggested laminectomy;

laminectomy with lateral mass fusion and laminoplasty are the common surgical procedures for CSM (Cervical Spondylotic Myelopathy) with Cervical canal Stenosis.⁹ As per the study conducted by Rajshekhar V advises surgical management of a myelopathic patient should be based on clinical and radiological finding rather than surgeon's choice.¹⁰

Certain common things are observed during the study period such as, when a patient comes with the back of neck pain the differential diagnosis (DD) to be thought of are given below: DD in Radiculopathy: Cervical Spondylosis – Disc Prolapse, Fascitis of the neck, Myositis, nonspecific Myalgia, Periarthritis shoulder, Spinal tumors, Syringomyelia, Carries Spine, Thoracic outlet syndrome, Thoracic inlet syndrome, Fracture spine due to Trauma and Tumour, Myocardial infarction, Brachial neuritis, Median Nerve Neuropathy, Multiple sclerosis, Syphilis, Carpel Tunnel Syndrome, Shoulder depression syndrome, Polyneuropathy including Diabetic Neuropathy, Polyarthritis.

Cervical myelopathy caused by multilevel cervical spondylosis (CSM) and/or posterior longitudinal ligament ossification (OPLL) is a common clinical condition.¹¹ In people over 50 years old, CSM is the most frequent cause of acquired neurological illness. The disease's normal, untreated trajectory is usually bad. With adequate surgical care, however, the neurological defects can be corrected or at least stabilized and steps should be taken to ensure that the surgical procedure is cost-effective.¹²

Despite the prevalent incidence of cervical myelopathy, it is still a matter of controversy to select the correct surgical solution. It is disappointing that, given the multitude of specialist societies committed to the treatment of the spine, the specialists of spine surgeons have not been presented with definitive guidance on the option of approach to multilevel cervical myelopathy. To date, the choice of treatment depends in large measure on the experiences of the surgeon. It is clear that this approach is manifestly incorrect and more rational is a patient-specific and pathoanatomy-based approach.¹³

Cervical radiculopathy patient management is best done with an interprofessional team that includes a neurologist, neuro-orthopedic surgeon, physical therapist, nurse practitioner, and primary care provider.

Cervical radiculopathy therapy should be treated in a step by step way. There is still no evidence that surgery provides a definite benefit over non-surgical care in an emergency, while surgery may provide substantial relief. Within 8-12 weeks, more than 85% of acute cervical radiculopathy recovers without any different therapies.¹⁴

There is a growing movement in healthcare to reduce low-value care, including unnecessary and wasteful tests and procedures^{15,16} spearheaded by the Choosing Wisely™ movement¹⁷. Choosing Wisely™ works with healthcare organizations and patient groups to develop campaigns to address the overuse of tests that do not add value for patients and may cause harm.

Conclusion

A simple less expensive study of plain X-ray cervical spine gives an extensive and satisfactory finding that can be easily done in a peripheral set up without much sophisticated MRI or referral to a higher center. Other differential diagnoses can be also ruled out when one suspects radiculopathy due to spondylosis. Interspace narrowing, osteophytes, and cervical rib all can be easily made out.

Acknowledgment: The authors sincerely thank Professor & Head Dr.Kulasekaran, Radiology, Sri Manakula Vinayagar Medical College and hospital for their extensive moral and material (XRyas) support and encouragement.

Salivary Omega6/ Omega 3 Fatty Acid Ratio And Dental Caries-Less is More

Geethu Jose¹, Srikala Bhandary², Amitha M Hegde³, Suchetha Kumari⁴, Shilpa Shetty⁵, Roopa⁶

¹Postgraduate Student (MDS 3rd Year), Department of Pediatric and Preventive Dentistry, A B Shetty Memorial Institute of Dental Sciences, Nitte- Deemed to be University, Deralakatte, Mangalore, Karnataka, India, ²Reader, Department of Pediatric and Preventive dentistry, ³Head of the Departmen, A B Shetty Memorial Institute of Dental Sciences, Nitte- Deemed to be University, Deralakatte, Mangalore, Karnataka, India, ⁴Professor, Department of Biochemistry, K.S Hegde Medical Academy, Nitte- Deemed to be University, Deralakatte, Mangalore, Karnataka, India, ⁵Research Associate, Central Research Lab, ⁶Research Associate Central Research Lab, K.S Hegde Medical Academy Nitte- Deemed to be University Deralakatte, Mangalore, Karnataka, India

Abstract

Background: Omega 3 and omega 6 are essential polyunsaturated fatty acids (PUFA) which cannot be synthesized in the body and needs to be obtained from dietary sources. The omega 6-omega 3 fatty acids ratio is important for human health, hence appropriate amounts of both these fatty acids should be considered for dietary recommendations. A ratio ranging between 2:1 to 4: 1 (Omega 6: Omega 3) has been stated to be the proper ratio by a summary of several nutritional estimation studies. However the relation to dental caries which is an infectious disease with multi-factorial etiology and is attributed to be the major reason for loss of tooth in children & adolescents, has not yet been explored. **Aim:** To assess and compare the salivary omega 6/omega 3 fatty acid ratio in children with varying levels of dental caries. **Methodology:** A total of 205 children aged 7-14 years were selected for the study. The children were grouped based on ICDAS-II classification system into Group I (Study group- 102 children) and Group II (Control = 103 children). Saliva samples were collected and subjected to Gas Chromatography to quantify all the fatty acids. The mean omega 6/omega 3 ratio was compared among the two groups. The statistical analysis was done by one-way ANOVA. **Results:** On comparing the mean fatty acids ratio among the study and control groups, no statistically significant differences ($p=0.313$) was noted. **Conclusion:** No statistically significant difference was observed on comparing the ratio of omega 6 to omega 3 fatty acids in the 2 groups.

Keywords: Omega 3, Omega 6, Saliva, Dental caries

Introduction

Nutrition, being a part of systemic health of an individual, plays an important role in maintaining

equilibrium between health and disease status. ¹These dietary nutrients have an impact on oral health status and can contribute as a major factor in improving oral inflammation and diseased conditions, thus enhancing the overall well-being of an individual. ^{2,3}Omega 6 and omega 3 are essential polyunsaturated fatty acids (PUFA) which cannot be synthesized in the body and needs to be obtained from dietary sources. ⁴ Omega 3 is a combination of alpha-linoleic acid (ALA), eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). The main sources of omega 3 fatty acids are fish (seafood - salmon, mackerel, tuna) and fish oil

beside the plant sources including soybean oil, canola oil, walnut and the seeds of flax, chia.^{5,6} Omega 6 is a combination of linolenic acid (LA), dihomo-gamma linoleic acid (DGLA), docosapentaenoic acid (DPA), gamma linoleic acid (GLA) and Arachidonic acid (AA). The major sources of omega 6 fatty acids are meat, egg yolk and vegetable oils.⁷

Both these polyunsaturated fatty acids are needed for growth and repair, and they play multiple roles in cell membrane structure, lipid metabolism, blood clotting, blood pressure, and in controlling inflammation.⁸ Literature states that these fatty acids also have an anti-inflammatory, anti-oxidant and antimicrobial activity.^{9,10} When compared to normal quantities in which omega 6 fatty acids are biologically active, larger quantities are toxic to health.¹¹

The omega 6-omega 3 fatty acids ratio is important for human health, hence appropriate amounts of both these fatty acids should be considered for dietary recommendations.¹² A ratio ranging between 2:1 to 4: 1 (Omega 6: Omega 3) has been stated to be the proper ratio by a summary of several nutritional estimation studies.⁸ When compared to the olden times of Paleolithic period, where a normal balance was seen in between omega 3 and 6 fatty acids, the present day human life has resulted in a drastic change in the diets of individuals which has consequently resulted in a paradigm shift in the amount and type of several antioxidants including omega 3 and 6 fatty acids and the same has been reported in several studies.¹³⁻¹⁷

Present day diet is rich in prepared and fast foods, which results in excessive amounts of omega 6 PUFA while lacking beneficial amounts of omega 3, thus resulting in a very high omega 6/omega 3 ratio (15:1), which can predispose to cardiovascular diseases, cancer, diabetes, neurodegenerative diseases.¹⁸

However the relation to dental caries which is an infectious disease with multi-factorial etiology and is attributed to be the major reason for loss of tooth in children & adolescents, has not yet been explored.^{19,20}

The amount of fatty acid of a person can be studied by analyzing various biological components namely, saliva, serum and adipose tissue.¹⁸ However the potential of saliva to estimate the levels of PUFA

remains unexplored. The use of saliva is considered to be more effective owing to the fact that the collection of saliva is a non-invasive procedure when compared to others which require invasive methods to acquire the specimens. The other added advantages being less cumbersome equipment required and ease of storage.

This study is done with the hypothesis that if the ratio of omega 6/omega 3 fatty acids are in the normal range there will be a decrease in dental caries levels and other inflammatory diseases.

Since there are no studies that correlate the ratio of omega 6/omega 3 in saliva and its relationship with dental caries, there is a need for this study.

Method

Source of Data: An observational (case control) study was conducted. A total of 205 children, both male and female (102 study and 103 control) aged between 7-14 years were selected after conducting a screening camp at Aided Holy Angels' Higher primary school, Thokkottu, Mangalore. Informed consent was obtained from the parents and school authority and assent was obtained from the children. Ethical clearance was obtained from the institutional ethical committee.

Inclusion Criteria: Children within the age group of 7-14 years with 3 or more carious teeth (ICDAS-II Code 3-6) and children who are willing to participate in the study with parental consent were included in the study group and children within the same age groups as controls. (ICDAS-II Code 0,1,2)

Exclusion Criteria: Children who have systemic diseases, children under any medications and children who are not willing to participate in the study and without parental consent.

Methodology

The children were grouped based on ICDAS-II system for measuring dental caries.

Group 1: Caries Group - 102 children with 3 or more carious teeth classified as Codes 3,4,5,6 under ICDAS – II

Group 2: Control group – 103 children with carious teeth classified as Codes 0,1,2 under ICDAS – II

Method of collection of saliva - 5 ml of unstimulated saliva was collected within a 10 minute period between 9 am and 11 am to minimize any possible effects of diurnal variation. Saliva samples were collected by passive drooling, in which subjects were asked to sit in a quiet environment in the “coachman position” and expectorate for 5 minutes in to sterile containers.

Saliva samples were transported to Central research laboratory, KSHEMA within 30 minutes and centrifuged at 4000 rpm for 15 min at 4 degree Celsius. The supernatants were stored at -80°C. Gas Chromatography was done to quantify all the fatty acids.

Statistical Analysis: Descriptive and analytical statistics were done. The data is represented in mean and standard deviation. The normality of continuous data was analysed by Shapiro-Wilk test. As the data followed normal distribution, parametric tests were used to analyse the data. The independent sample t-test and one

way ANOVA tests were used to check mean differences wherever appropriate. The level of significance was kept at $p < 0.05$.

SPSS (Statistical Package for Social Sciences) Version 24.0 (IBM Corporation, Chicago, USA) was used for carrying out statistical analysis.

Results

Out of the 205 salivary samples collected, omega 3 and omega 6 fatty acid levels could be estimated from only 60 (30%) and 72 (36%) samples respectively. Salivary omega 6/omega 3 fatty acid ratio was calculated only for those children where both these fatty acids were obtained. It was 12(11.76%) for Group 1 and 24 (23.3%) for Group 2. Due to this reason the remaining samples were not considered and the calculations are solely based on these samples.

Table 1: Comparison of mean omega fatty acids ratio between the two groups

Groups	N	Mean	S.D.	S.E.	M.D.	95% C.I.	t-value	P-value#
Group 1(Study)	12	0.75	0.37	0.10	-1.18	-2.72-0.34	-1.573	0.125
Group 2 (Control)	24	1.94	2.58	0.52				

#P-value derived from independent sample t-test

The mean fatty acids ratio (omega 6/omega 3) between the two groups was compared. It was found that there was NO statistical significant difference in mean fatty acids ratio ($p=0.840$) between the caries and control groups. [Table 1]

Discussion

Omega 3 and omega 6 PUFA have been widely studied for their beneficial effects on human health, mainly the brain, eye, cardiovascular system, and general human growth. Recent reports have noted that PUFA could improve oral health since they possess antioxidant,

anti-inflammatory and antibacterial activities. However, their utilization as antimicrobial agents has not been widely appreciated.²¹

Several studies evaluating the level of PUFA in serum are available in literature proving that fatty acid estimation is possible in serum.²² However, a standardization regarding the normal values has not been made. Serum estimation of fatty acid is a relatively invasive procedure that requires blood sample collection from the patient. If a suitable alternative procedure that is non-invasive is available, it would lead to ease in estimation of levels of PUFA. Since many of the

serum biomarkers are also present in saliva, it could be a suitable alternative for PUFA estimation as well.

To the best of our knowledge, this is the first clinical study using saliva for estimation of omega 6/omega 3 ratio and its correlation with dental caries. So, the present study was conducted to find whether such a correlation existed, and if present, to observe its relationship to dental caries. We expect it to open a new avenue for caries control.

Out of the 205 salivary samples collected, omega 3 and omega 6 fatty acid levels could be estimated from only 60 (30%) and 72 (36%) samples respectively. Based on these results, it is evident that not all children in our study showed the presence of omega 3 or omega 6 fatty acids in saliva. Still lesser number of children showed the presence of both omega 3 and omega 6 fatty acids in saliva. Salivary omega 3 and omega 6 fatty acids were both present in 12 children (11.76%) belonging to Group 1 and 24 children (23.3%) from Group 2. This shows that the presence of both these fatty acids could relate to the severity of caries in the children included in our study.

Studies have shown that omega 3 and omega 6 polyunsaturated fatty acids have anti-bacterial activity which could be attributed to the resemblance with the bipolar membrane of the bacterial cell wall due to having both a hydrophilic head and a hydrophobic tail. This similarity suggests that the target of these fatty acids could be the cellular membrane because fatty acids could possibly penetrate into the cell membrane of the bacteria disrupting normal cell²³

A direct comparison could not be made since no studies have been performed on dental caries and omega fatty acids.

The normal ratio of serum omega fatty acids (omega 6/omega 3) is reported to be between 2:1 to 4:1.¹⁹ Although several studies have evaluated fatty acid profiles in saliva, studies on omega fatty acids levels have not been carried out. So a comparison with standard normal ratio could not be done in our study. However when the mean salivary fatty acids ratio (omega 6: omega 3) between the study and control groups were compared, it was found that there was no statistical significant difference. This could be due to the

insufficient number of children exhibiting both omega 3 and omega 6 salivary fatty acids, for calculation of ratio in the different groups. These values cannot be relied upon to form any definite conclusions.

Conclusion and Future Recommendations:

1) With the available estimation methods, the omega 6 and omega 3 fatty acids could not be detected in the saliva of all the subjects in our study probably due to their insignificant levels in saliva. Tools with better precision are required for accurate estimation of omega 3 and omega 6 fatty acids.

2) Similar studies with larger sample size are required to establish the role of omega 3 and omega 6 fatty acids in dental caries definitively.

3) Once standardisation of estimation method and normative values are established, longitudinal studies and clinical trials using salivary omega 3 and omega 6 fatty acids may be undertaken.

Clinical Profile of 46 Non AMD CNVM and Management with Anti-Vegf

Girish A. Gadre¹, Prashant Bulchandani², Vijay H. Karambelkar³

¹Associate Professor, ²Resident, ³Head of Departments, Department of Ophthalmology, Krishna Institute of Medical Sciences, Karad, Krishna Institute of Medical Sciences "Deemed To Be University", Karad, Maharashtra, India

Abstract

Aim: To know clinical profile of non AMD CNVM in context to (Type, location, FFA, OCT characteristics Demography, incidence, causes)

To know clinical response to Anti-VEGF, conventional or PRN

Result:- Type: -14(30.4%) Myopic cnvm, 11(23.9%) Idiopathic cnvm, 9(19.5%) PFT, 4(8.7%) Inflammatory, 3(6.5%), choroidal osteoma with cnvm, 2(4.3%) Angiod streak, 2(4.3%) CSR with cnvm, 1(2.2%) Traumatic cnvm.

Location: - Extrafoveal (2), juxta foveal (14), Sub foveal (27), Peripapillary (1) (Angiod streak), Unifocal (42), multifocal (3) (PFT)

FFA:- 39(84.7%) classic, 4(8.7%) Occult cnvm, 3(6.5%) were undifferentiated. **CT:-**21(45.6%) type-2 membrane, 9(19.5%) undifferentiated, 2(4.4%) type -1 membrane **Demography:-**Average age 49.6 yrs, range (20 – 64 yrs); Male preponderance, M:F ratio is 1.3:1, Almost all had unilateral presentation except PFT (parafoveal telangiectasias) and myopic CNVM which bilateral.

Interpretation: - 6 cases responded to single dose. 10 responded to second dose of anti VEGF and 21 responded to 3rd dose. 9 were not responders to 3 dosages, given option of PDT with anti-VEGF. 2 cases responded to PDT. 1 case responded to high dose steroids with anti-Koch's in inflammatory CNVM. 4 cases remain non responded to treatment. 31(67%) had improvement in vision, 8(18%) had stable vision, while 7(15%) had deteriorated.

Conclusion: - Myopic CNVM cases showed 100% response after 1 to 3 dosages of anti-VEGF. Non-AMD cnvm cases respond well to anti VEGF alone, few more respond to added PDT. Inflammatory CNVM require high dose steroid

Keywords:- Optical coherence tomography (OCT), Fundus Fluorescein Angiography (FFA).

Introduction

Choroidal neovascularization (CNV) may arise in association with several conditions other than AMD¹. These include pathologic myopia, uveitis, central serous chorioretinopathy, angiod streaks, choroidal osteoma, hereditary chorioretinal diseases, and iatrogenic disorders². The initial stimulus leading to the development of CNV is complex and varies according

to the underlying disease aetiology³. The occurrence of CNV associated with non-AMD conditions often affects patients at a younger age; therefore, some patients may develop work limitations leading to considerable financial losses and emotional distress⁴. Regardless of the inciting stimulus involved in the development of CNV, it is now well established that VEGF plays a major role in its pathogenesis⁵.

Inclusion Criteria:

Patient of age 20 – 64 years were taken

Exclusion Criteria:

- CNVM > 55 yrs. with drusen other eye AMD related cnvm or dry AMD
- Any CNVM received previous treatment.
- Media opacities where FFA is inconclusive.
- Follow up minimum 6 months.
- Cases clinically diagnosed as PCV; RAP were excluded.

Material and Methods

A hospital based clinical trial was done with 46 eyes of 41 patients was done.

Source of Data:

This study was conducted on patients attending outpatient department of ophthalmology in a tertiary care centre. It was conducted from NOV 2017 to MARCH 2019. This study was approved from institutional ethics committee.

Sample size: 46 eyes from 41 patients.

Results

TABLE 1 :

This table shows types of non- AMD CNVM from our study of 46 eyes, the different types are and with their percentages- 14 cases are of Myopic cnvm that is 30.4% following which Idiopathic cnvm cases are 11 that is 23.9% then PFT cases are 09 that is 19.5% following which Inflammatory cases are 04 that is 8.7%, then Choroidal osteoma with cnvm are 03 that is 6.5%

and Angiod streak cases are 02 that is 4.3% and CSR with cnvm are also 02 that is 4.3% and the least are Traumatic cnvm cases are 01 that is 2.2% .

Table 2:

This table contains information regarding the location of different types of non-AMD CNVM seen above and its percentage that is most common location is Sub foveal which is seen in 27 cases out of 46 that is 58.69% followed by Juxta foveal which is seen in 14 cases that is 30.4% then Extrafoveal location which is seen in 2cases that is 4.3% and the most uncommon location is Peripapillary which is seen in single case of Angiod streak.

Non -AMD CNVM cases are mostly Unifocal – 42 that is 91.3% and Multifocal are only 3 seen in parafoveal telangiectasia.

Table 3:

This table gives information about the patterns on Fundus Fluorescein Angiography seen in cases of non -AMD CNVM and the 39 cases that is 84.7% had predominantly classic pattern followed by 04 that is 8.7% cases had Occult cnvm and only 03 cases that is 6.5% were undifferentiated on angiography.

Table 4:

This table gives information of the patterns seen in Optical coherence tomography (OCT) in non – AMD CNVM.

But we could retrieve OCT of only 32 eyes so cases are accordingly that is 21 cases out of 32 that is 45.6% showed type-2 membrane followed by 9 cases that is 19.5% were undifferentiated on OCT , and only 2 cases out of 32 that is 4.4% had type -1 membrane.

TABLE 5:

This table deals with the treatment modalities and the number of cases actually responded to the which treatment and its percentages so all patients were exclusively given anti-VEGF(either Lucentis or Avastin) 29 patients primarily received Avastin, 17 received Lucentis and the patients those who had not responded to anti VEGF were given option of PDT or combination out of which 6 cases responded to single dose of anti-

VEGF which predominantly include myopic CNVM cases but 10 more responded to second dose which include Myopic, Idiopathic and PFT related cnvm but then 21 cases responded to 3rd dose of anti VEGF than 9 cases were not responded to 3 dosages, those were given option of PDT with anti-VEGF and also two responded after 5 dosages of anti VEGF and two cases responded to PDT which include Osteoma and idiopathic CNVM moreover one case responded to high dose steroids with anti-Koch's in inflammatory CNVM but out of 46 ,four patients remain non responded to treatment.

Table 6:

This table gives the idea of the visual outcome after the different treatment modalities given and the results are 9 cases had three line (Snellen) visual improvement till last follow up and 7 cases had two line improvement but 15 cases had only one line improvement and 8 had stable vision, but symptomatically better but lastly7 had drop in vision. So, the actual result is 31 cases that is 67% had improvement in vision and 8 cases that is 18% had stable vision while 7 cases that is 15% had deteriorated.

Improvement	31	67
Stable vision	8	18
deteriorated	7	15

Discussion

This study is a hospital based clinical trial was done with 46 eyes of 41 patients conducted on patients attending outpatient department of ophthalmology in a tertiary care centre. It was conducted from NOV 2017 to MARCH 2019. This study was approved from

institutional ethics committee. This study is performed to find out the different types of non-AMD CNVM and their location with respect to their location and patterns seen on Fundus Fluorescein Angiography (FFA) and OCT images. This study was done with principal aim to know the clinical profile of non AMD CNVM in

context to (Type, location, FFA , OCT characteristics Demography, incidence and causes and to know the clinical response to Anti-VEGF or conventional or PRN.

In our study the patient of age 20 – 64 with average age of 49.6 years were taken. In our study the cases of CNVM > 55 yrs with drusen other eye AMD related cnvm or dry AMD were excluded and any CNVM received previous treatment was also excluded to get better result regarding treatment. Cases with media opacities where FFA is inconclusive and Cases clinically diagnosed as PCV, RAP were also excluded.

In our study both the sex were taken into consideration out of the result which came out is Male preponderance of M:F ratio is 1.3:1. This study also gives the result that almost all had unilateral presentation except PFT (parafoveal telangiectasia) and myopic CNVM which showed the bilateral presentation.

In our study the number of cases taken are 46 and out of which the different types are and with their percentages- 14 cases are of Myopic CNVM that is 30.4% following which Idiopathic CNVM cases are 11 that is 23.9% then PFT cases are 09 that is 19.5% following which Inflammatory cases are 04 that is 8.7%, then Choroidal osteoma with CNVM are 03 that is 6.5% and Angiod streak cases are 02 that is 4.3% and CSR with CNVM are also 02 that is 4.3% and the least are Traumatic CNVM cases are 01 that is 2.2% .

The main aim of the study was also to get information regarding the location of different types of non-AMD CNVM seen above and its percentage that is most common location is Sub foveal which is seen in 27 cases out of 46 that is 58.69% followed by Juxta foveal which is seen in 14 cases that is 30.4% then Extrafoveal location which is seen in 2 cases that is 4.3% and the most uncommon location is Peripapillary which is seen in single case of Angiod streak.

The study also gives result regarding the Non -AMD CNVM cases that are mostly Unifocal – 42 out of 46 that is 91.3% and Multifocal are only 3 that are seen in parafoveal telangiectasia cases specifically. In our study of 46 cases information about the patterns on Fundus Fluorescein Angiography seen in cases of non -AMD CNVM is also correlated which comes out to that 39 cases that is 84.7% had predominantly classic

pattern shown in FFA followed by 04 cases that is 8.7% had Occult cnvm and only 03 cases that is 6.5% were undifferentiated on angiography which gives important part in discussion as FFA can be considered as an important diagnostic tool.

In our study the principal is also to note the pattern of non-AMD CNVM on OCT and to get the result according to information of the patterns seen in Optical coherence tomography (OCT) in non – AMD CNVM .

But we could retrieve OCT of only 32 eyes so cases are accordingly that is 21 cases out of 32 that is 45.6% showed type-2 membrane followed by 9 cases that is 19.5% were undifferentiated on OCT , and only 2 cases out of 32 that is 4.4% had type -1 membrane which gives an important result that type-2 membrane on OCT is most commonly seen in non-AMD CNVM.

In our study the role of anti -VEGF is also noted along with some different modality of treatment and the number of cases actually responded to which treatment and its percentages so all patients were primarily exclusively given anti-VEGF (either Lucentis or Avastin) 29 patients primarily received Avastin, 17 received Lucentis and the patients those who had not responded to anti VEGF were given option of PDT or combination out of which 6 cases responded to single dose of anti-VEGF which predominantly include myopic CNVM cases but 10 more responded to second dose which include Myopic, Idiopathic and PFT related cnvm but then 21 cases responded to 3rd dose of anti VEGF .

From the above treatment option 9 cases were not responded to 3 dosages of anti -VEGF so were given option of PDT with anti-VEGF and also two responded after 5 dosages of anti VEGF and two cases responded to PDT which include Osteoma and idiopathic CNVM moreover one case responded to high dose steroids with anti Koch's in inflammatory CNVM

After all treatment modalities it was noted that out of 46, four patients remain non responder to treatment. One of the very important result which comes out in our study is those who are Non-responder out of four patients, one had angiod streak, two had CSR with cnvm, & one had parafoveal telangiectasia and the common factor among three non-responders is presence of large serous PED with mottled RPE alteration.

In our study the last result comes out from the visual outcome after the different treatment modalities given and the results are 9 cases had three line (Snellen) visual improvement till last follow up and 7 cases had two line improvement but 15 cases had only one line improvement and 8 had stable vision, but symptomatically better but lastly 7 had drop in vision. So the actual result is 31 cases that is 67% had improvement in vision and 8 cases that is 18% had stable vision while 7 cases that is 15% had deteriorated.

Thus the cases of non-AMD CNVM was studied well on the basis of type, location , demography and findings on the basis of FFA and OCT and the role of anti -VEGF and visual outcome so most of the cases benefitted from the 3rd dose of Avastin and only 4 were non responders.

Conclusion

PFT related telangiectesia is not uncommon in our area which has female preponderance, multifocal location and bilaterally as classical presentation and respond well to anti VEGF. Myopic CNVM cases showed 100% response after 1 to 3 dosages of anti-VEGF. 85% had predominantly classic CNVM, 65% had type -2 CNVM on OCT. Non AMD cnvm cases respond well to anti VEGF alone, few more respond to added PDT ,67% cases shows visual benefit .Inflammatory CNVM require high dose steroid and more investigations . Non responders have shown common factor of large PED with RPE stippling, all are Occult CNVM on FFA and such cases needs ICG, which may turn out to be RAP, PCV.

Ethical approval: All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

Abstract

Objectives: Metabolic syndrome (MetS) is a cluster of several metabolic disorders including hyperglycemia, reduced high density lipoprotein cholesterol, raised triglyceride level in serum, hypertension and abdominal obesity.

Methods: The present study was conducted at the MM Institute of Medical Sciences and Research. The study includes 300 patients with MetS as a case and 300 healthy volunteers as a control. MetS was diagnosed according to international diabetes federation.

Results: In our study 103 MetS patients of 300 have shown the complications like DM (Diabetes Mellitus), HTN (Hypertension) and obesity which are predisposing factors for atherosclerosis and other cardiovascular diseases which lead to morbidity and mortality.

Conclusions: Our study found that diabetes Mellitus, hypertension, dyslipidemia and obesity are the predisposing factors for metabolic syndrome.

Key Words: Diabetes Mellitus, Hypertension, Obesity, Metabolic Syndrome, Dyslipidemia.

Introduction

MetS is a group of signs and symptoms which include abdominal obesity, insulin resistance, and elevated blood pressure (BP). It is related to cause risk of chronic kidney disease, Type 2 Diabetes Mellitus, cardiovascular disease (CVD) and these diseases are important cause of mortality¹. Early identification of MetS is important because it raises the risk of CVD between 1.5 to 1.8 times more and raise relative risk of coronary artery disease and 4.2 fold a death². In persons with MetS, the prevalence of CVD increases 2-3 folds³.

International Diabetes Federation (IDF) defines MetS, as central obesity defined as waist circumference

(WC) ≥ 90 cm for men and ≥ 80 cm for women) along with presence of any two of the following⁴.

- Systolic blood pressure (SBP) ≥ 130 mm Hg or diastolic blood pressure (DBP) ≥ 85 mm Hg.
- Increased fasting blood Sugar (FBS) ≥ 100 mg/dl.
- Increased triglyceride (TG): ≥ 150 mg/dl.
- Decreased high density lipoprotein cholesterol (HDL-C): < 40 mg/dl in men, < 50 mg/dl in women.

Fast economic development with accelerating change in lifestyle, urbanization, nutrition, reduced physical activity and socio-economic status play key roles in the dramatic acceleration of MetS⁵.

MetS is very common among patients with type 2 diabetes mellitus. Participants who subsequently developed MetS had greater obesity, higher triglyceride.

Corresponding author:

Dr. Suvarna Prasad, Professor, Department of Biochemistry, MMIMSR, Mullana, Ambala, Haryana, India

A study documented the pivotal role of obesity in the pathogenesis of MetS in different population⁶. A subject with abnormal glucose tolerance were analyzed, they displayed a higher BMI, blood pressure, triglyceride level, central obesity and lower HDL levels than normal glucose tolerance groups, all were the recognized features of metabolic syndrome⁷.

Aims and Objectives

1. Selection of the MetS patients and control subjects.
2. Measurement of SBP, DBP and WC in MetS patients and control subjects.
3. Assay of fasting blood sugar, triglyceride, and high density lipoprotein cholesterol in MetS and control subjects.

Materials and Method

The study has been conducted between February 2017 to August 2018

Study Area:

The present study was conducted in the Department of Biochemistry in collaboration with Department of Medicine, Maharishi Markandeshwar Institute of Medical Sciences and Researches, Mullana, Ambala, Haryana, India.

Study Population:

Group 1: 300 subjects with metabolic syndrome.

Group 2: 300 healthy Volunteers controls (age and sex matched) without metabolic syndrome.

Informed consent has been taken from the participants included in the study.

Inclusion Criteria:

- Patients with Metabolic syndrome above 18 years of age.

Exclusion Criteria:

- Familial hyperlipidemia
- Pregnancy

- Thyroid disease
- Any history of liver disease
- Lactation
- Oral contraceptives
- Recovery from non thyroidal illness
- Cushing disease
- Renal disease
- Patients with history of chronic drug use (steroid treatment, antidepressant and anti psychotic drug user)

Waist Circumference Measurement: WC was measured with a tape in a horizontal plane, mid way between the inferior margin of the ribs and the superior border of the iliac crest.

Sample Collection:

5 ml of blood sample was aseptically collected as per the standard guidelines and protocol. Serum was allowed to separate and subsequently analyzed for various parameters. FBS was assayed by glucose oxidase and peroxidase method, triglyceride by glycerol-oxidase peroxidase method and HDL-C by enzymatic assay method.

Statistical Analysis

Data obtained was analysed by using SPSS 21 version software and results was compared in cases and controls. P value < 0.05 was taken as significant at 95% confidence intervals. Student's t-test was used to find the association between thyroid profile and various components of MetS.

Result

The total number of patients in our study were 600 (100%) out of which 300 (50%) were healthy controls subjects and 300 (50%) were MetS patients. Among 300 patients with MetS in the study, 102 (34.0 %) were male and 198 (66.0 %) were female. Similarly there were 300 control subjects, out of which 102 (34.0 %) were male and 198 (66.0 %) were female.

Table 1: Anthropometric and laboratory finding amongst metabolic syndrome patients and control subjects.

Parameters	Control	Case	P Value
WC (cm)	80.49 ± 4.70	102.26 ± 7.92	<0.000
SBP (mm Hg)	115.31 ± 6.62	148.26 ± 21.24	<0.000
DBP (mm Hg)	76.31 ± 5.42	91.77 ± 10.96	<0.000
FBS (mg/dl)	79.35 ± 6.05	141.08 ± 56.02	<0.000
TG (mg/dl)	126.26 ± 14.76	167.0 ± 50.92	<0.000
HDL-C (mg/dl)	52.16 ± 6.33	37.79 ± 14.52	<0.000

The table 1 shows that the mean and standard deviation (SD) of WC for control subjects is **80.49 ± 4.70** cm and for MetS patients is **102.26 ± 7.92** cm. A statistically highly significant difference was observed among two groups (**p < 0.000**). The mean and SD of SBP for control subjects is **115.31 ± 6.62** mm Hg and for MetS patients is **148.26 ± 21.24** mm Hg. A statistically highly significant difference was observed among two groups (**p < 0.000**). The mean and SD of DBP for control subjects is **76.31 ± 5.42** mm Hg and for MetS patients is **91.77 ± 10.96** mm Hg. A statistically highly significant difference was observed among two groups (**p < 0.000**).

The mean and SD of FBS for control subjects is **79.35 ± 6.05** mg/dl and for MetS patients is **141.08 ± 56.02** mg/dl. A statistically highly significant difference was observed among two groups (**p < 0.000**). The mean and SD of triglyceride for control subjects is **126.26 ± 14.76** mg/dl and for MetS patients is **167.0 ± 50.92** mg/dl. A statistically highly significant difference was observed among two groups (**p < 0.000**). The mean and SD of high density lipoprotein for control subjects is **52.16 ± 6.33** mg/dl and for MetS patients is **37.79 ± 14.52** mg/dl. A statistically highly significant difference was observed among two groups (**p < 0.000**).

Table 2:- Complication present amongst metabolic syndrome patients and control subjects

Group		Frequency	Percent
Control	No Complication	300	100.0
Case	Dyslipidemia, HTN, Obesity	71	23.7
	Dyslipidemia, Obesity	21	7.0
	DM, HTN, Dyslipidemia, Obesity	78	26.0
	DM, HTN, Obesity	103	34.3
	DM, Dyslipidemia, Obesity	27	9.0
	Total	300	100.0

The above table shows that in control subjects no complication were present. In case 71 (23.7 %) patients had dyslipidemia, HTN, obesity, as a complication. 21 (7%) patients had dyslipidemia, obesity present as a complications, 78 (26%) patients had DM, HTN,

dyslipidemia, obesity as a complication, 103 (34.3%) patients had DM, HTN, obesity present as a complication and 27 (9%) patients had DM, dyslipidemia, obesity as a complications.

Figure 1:- Showing complication present amongst metabolic syndrome patients.

Figure 1 shows that complication present in metabolic syndrome patients. 71 (23.7 %) patients have dyslipidemia, HTN, obesity present as a complication. 21 (7%) patients have dyslipidemia, obesity present as a complications, 78 (26%) patients have DM, HTN, dyslipidemia, obesity present as a complication, 103 (34.3%) patients have DM, HTN, obesity present as a complication and 27 (9%) patients have DM, dyslipidemia, obesity present as a complications.

Discussion

In our study the mean WC (102.26 ± 7.92) was significantly higher in MetS patients than in control groups (80.49 ± 4.70) p (<0.000). The mean SBP (148.26 ± 21.24) was significantly higher in MetS patients than in control group (115.31 ± 6.62) p (<0.000). The mean DBP (91.77 ± 10.96) was significantly higher in MetS patients then in control group (76.31 ± 5.42) p (<0.000). The mean FBS (141.08 ± 56.02) was significantly higher in MetS patients when compared to control group (79.35 ± 6.05) p (<0.000). The mean triglyceride (167.0 ± 50.92) was significantly higher in MetS patients when

compared to control group (126.26 ± 14.76) p (<0.000). The mean HDL-C (37.79 ± 14.52) was significantly lower in MetS patients when compared to control group (52.16 ± 6.33) p (<0.000).

We have conducted a study to evaluate the major complications of metabolic syndrome. In our study, control patients had no complications. In metabolic syndrome patients, most commonly complications present were DM, HTN, obesity and the complications were present in 103 (34.3%) MetS patients, 78 (26.0%) MetS patients had DM, HTN, Dyslipidemia, obesity as complications, 71 (23.7%) MetS patients had Dyslipidemia, HTN, Obesity as complication, 27 (9.0%) MetS patients had DM, Dyslipidemia, Obesity as complication and 21 (7.0%) MetS patients had Dyslipidemia, Obesity as complications.

Conclusion

Our study advocate that diabetes Mellitus, hypertension, obesity, dyslipidemia are the predisposing factors for metabolic syndrome. To prevent from metabolic syndrome we have to control blood sugar,

blood pressure, waist circumferences and lipid profile, which are predisposing factors for atherosclerosis and other cardiovascular diseases which lead to morbidity and mortality.

Ethical Clearance: Taken from Institutional Ethics Committee vide letter no. 904 date 17.12.2016.

Hypoglycaemic Effect of Alcoholic Extracts of the Leaves of *Abroma Augusta* & *Gymnema Sylvestre* Plants in Type II Diabetes Mellitus Patients

H. Venkatesan¹, S. A. Karthi²

¹ Research Coordinator and Associate Professor, ² Intern, Dept of Practice of Medicine, Vinayaka Mission's Homoeopathic Medical College & Hospital, A Constituent College of Vinayaka Mission's Research Foundation (Deemed to be University), NH 47, Sankari Main Road, Seeragapadi, Salem, Tamil Nadu, India

Abstract

Diabetes mellitus is the most common disease of the world causing much Morbidity. It is very evident that the incidence of this disease is rapidly increasing in both developed and developing countries. Also the mean age of acquiring the disease is lowering day by day. The Diabetes mellitus is classified into many types like, Type I / Juvenile, Type II / Non-insulin dependent, Gestational Diabetes, etc., But irrespective of the type affected, the patients suffer equally. India is having the largest Diabetic population of the world. So at this context the Natural Herbal Medicines which can have a Good Diabetic Control should be tested on the patients and reported effectively.

Leaves of *Abroma augusta* belonging to Malvaceae family is traditionally being used to treat Diabetes mellitus in India and Southern Asia. Thin-layer chromatography studies revealed the presence of Abromine (betaine), Triterpenoids, Flavonoids and Phenolic compounds in *Abroma augusta* L which are found to be Anti-diabetic. *Gymnema sylvestri* belonging to Asclepiadaceae family found in central and peninsular India is a potent Anti-diabetic plant used in folk, Ayurvedic and Homeopathic systems of medicine. *Gymnema sylvestri* leaves contain Gymnemic acids that have Anti-diabetic, Anti-sweetener and Anti-inflammatory activities.

These details intended us to carry out an Experimental Study on Type II Diabetes mellitus patients. The alcoholic extracts of *Abroma augusta* and *Gymnema sylvestri* were compared for their Hypoglycaemic effects by means of a Randomized Control Trial on Type II Diabetes mellitus patients which was executed with a Placebo control group for higher significance. Pre & Post Treatment Fasting Blood Glucose Levels were analyzed statistically. By the end of the study both the extracts showed Statistically good Hypoglycaemic effect with a P Value < 0.00001. *Gymnema sylvestri* (Mean lowering modulation – 29.03 mg/dL) has proved to be slightly more effective than *Abroma augusta* (Mean lowering modulation – 26.00 mg/dL).

Key Words: *Abroma.augusta*, Abromine, Betaine, Gymnemic acids, *Gymnema sylvestri*, Type II Diabetes Mellitus, Hypoglycaemic.

Introduction

Diabetes mellitus is the World's leading Non-Communicable disease and India is having the largest

Diabetic population of the world.^{1,2} Diabetes mellitus is a group of metabolic disorder involving carbohydrate, lipid and protein metabolism characterized by chronic hyperglycaemia, as a result of defects in insulin secretion from β – cells of pancreas or peripheral action of insulin or both.³ The Diabetes mellitus is classified into many types like, Type I / Juvenile, Type II / Non-insulin dependent, Gestational Diabetes, etc., But irrespective

Corresponding Author:

Email: venkathompath@gmail.com

Mobile: +91 98651 34561; +91 86678 53212

of the type affected, the patients suffer equally.⁴ This is often associated with other disorders like central obesity, hypertension and dyslipidaemia.⁵

The economic burden of diabetes mellitus and its complications are very high and increasingly affecting the lives of urban poor.^{6,7} Number of people with diabetes across the world has risen from 108 million in 1980 to 422 million in 2014. WHO projects that diabetes will be 3rd leading cause of death in 2030.⁸ It was estimated that India had 65.1 million adults with diabetes in 2013, and had the 2nd position among the top 10 countries with the largest number of diabetes. This number is predicted to increase to 109 million by 2035 unless steps are taken to prevent new cases of diabetes.⁹ Prevalence of impaired glucose tolerance is also high in the urban population. Subjects under 40 years of age have a higher prevalence of impaired glucose tolerance than diabetes. The important risk factors for high prevalence of diabetes include: High familial aggregation, obesity specially central one, insulin resistance and lifestyle changes due to rapid urbanization.¹⁰

Young-onset Type II Diabetes mellitus seems to be an aggressive disease owing to the rapid deterioration of metabolic function. This deterioration coincides with high levels of other risk factors for CVD and disease progression frequently leads to the development of microvascular and macrovascular complications at an early age, with associated premature mortality. These adverse outcomes occur at higher rates than in Type I Diabetes mellitus and late-onset Type II Diabetes mellitus.¹¹

Recent researches explore the effectiveness of many traditional herbs in treatment of Lifestyle disorders. 'Abroma agusta - Devil's cotton' and 'Gymnema sylvestre - Australian cowplant' are such herbs which are traditionally used in treating Diabetes mellitus.¹²⁻¹⁵ But only few researches have been carried out with these herbs in justifying their judicious use. These details intended us to do a comparative study of the effectiveness of the Alcoholic extracts of these plants in controlling serum glucose levels of Type II Diabetes mellitus patients with a placebo control arm.

Materials & Method

Methodology used was Single Blind Comparative

Experimental Study design of two parallel groups with a placebo control group. Patient Selection (Sampling) was made according to the following inclusion, exclusion criteria 30 patients were selected by Random Sampling Method. Both male & female Type II Diabetes Mellitus Patients belonging to the age group of 35 - 65 yrs³ with Fasting Blood Glucose levels more than or equal to 126 mg/dL³ were included in this study. Type II Diabetes Mellitus Patients with systemic complications & other systemic diseases were excluded. 'Systematic Random Sampling' method was adopted to assign patients in 3 Treatment Groups. Data collection was made by Case taking, Investigatory findings, Past history, Medical Reports & Diabetic Risk Screening Questionnaire.

Operational Design:¹⁶

As per the study protocol 30 Type II Diabetes Mellitus patients were selected randomly from Medical Unit IV of Vinayaka Mission's Homoeopathic Medical College Hospital, Salem, Tamilnadu in the period between 01.11.2016 to 31.12.2016. The Institutional Ethics Committee approval for this study was ordered on 26.10.2016. This Study was registered under Clinical Trial Registry of India with Reg. No: CTRI/2017/11/010528. The selection of cases was made on careful consideration of the Inclusion and Exclusion Criteria. The 'Case History' of each patient was recorded in a Standardized Case Format to evaluate and to rule out any co-morbid diseases or complications. 'Informed Patient Consent' in their local language was obtained from each patient. Then these selected patients were allotted equally in the 3 Treatment Groups by 'Systematic Random Sampling Procedure' such that each group carried 10 patients. Considered Treatment Groups were, **Group-A:** Alcoholic extract of *Abroma agusta*; **Group-B:** Alcoholic extract of *Gymnema sylvestre* & **Group-C:** Dispensing alcohol as Placebo. The Pre treatment Fasting Blood Glucose Levels of each patient were tested and recorded. Few patients were found already under other Medications for Diabetes mellitus; they were prescribed with placebo for a month and then included in the study.

Each patient was given their respective Treatment for at least 2 months i.e, 60 days. They were prescribed with 10 drops of their respective alcoholic plant extracts / Dispensing alcohol mixed with 10 ml of water orally

in morning and night every day after food. The Patients were blinded to know the name of the medicines they were prescribed with, by coding the medicines as A / B / C. Also the placebo was prescribed in the form of "Dispensing Alcohol" so as to make it similar to other extracts. All the patients were explained about 'Diabetic Diet' and advised to follow, which was closely monitored. The Fasting Blood Glucose Levels of each patient were tested at 3rd, 6th and 9th Weeks of Treatment. Some Sample Characters like Age Distribution, Gender Distribution, etc., were analyzed. This study was carried out during November 2016 to March 2017 at Medical Unit IV of Vinayaka Mission's Homoeopathic Medical College Hospital, NH 47, Sakari Main Road, Seeragapadi, Salem, Tamilnadu, Pincode - 636308.

Statistical Analysis of Outcome:

The Pre Treatment and Post Treatment (Average of 3rd, 6th and 9th Week Values) Fasting Blood Glucose Levels were considered for Statistical Analysis using "Analysis of Variance - ANOVA".¹⁷ The Statistical Analysis was prepared both manually and with the 'Statistical Package for Social Sciences.22 – SPSS' software.

Laboratory Investigatory Method / Procedure:

Fasting Blood Glucose Measurements were made by 'Glucose Oxidase - Peroxidase (GOD / POD) Method'. The Diagnostic Kit of 'Beacon Diagnostics Pvt. Ltd' was used for this. The Standard Normal Fasting Blood Glucose Value for this kit / method is ranging between 70 to 110 mg / dl.

Properties of the Plants:

Abroma augusta belonging to Malvaceae family, an evergreen shrub, is found throughout the hot and humid parts of India. Leaves and seeds of *Abroma augusta* are considered to be edible in India, South Asia and New Guinea. Its Leaves are used as a remedy for diabetes, inflammation, rheumatic pain of joints, uterine disorders, and headache. Thin-layer chromatography

studies revealed the presence of Abromine (betaine), Triterpenoids, alkaloids, steroids, triterpenes, flavonoids, megastigmanes, and phenylethanoid glycosides which are found to be Anti-diabetic.¹⁸⁻²⁰

Gymnema sylvestre belonging to Asclepiadaceae family found in central and peninsular India is a potent Anti-diabetic plant used in folk, Ayurvedic and Homeopathic systems of medicine. *Gymnema sylvestre* leaves contain Gymnemic acids that have Anti-diabetic, Anti-sweetener and Anti-inflammatory activities. It renders glucose lowering activity due to the presence of phytochemicals, such as gurmamin, gymnemic acid as well as gymnemasaponins. Its leaves are known to have anti-oxidant, antibiotic, anti-inflammatory, antiviral, gastro & hepato-protective, anticancer & lipid-lowering activities.²¹⁻²³

Alcoholic Extracts of the Plants:

The preparation of the alcoholic extract of leaves of *Abroma augusta* is to be done by macerating 1 part of freshly collected moist magma of its leaves with 10 parts of 95 v/v % alcohol for 14 to 28 days. The alcoholic extract of *Gymnema sylvestre* should be prepared by macerating 1 part of coarse powder of its leaves with 10 parts of 95 v/v % alcohol for 14 to 28 days. It should be shaken occasionally, and filtered. So obtained alcoholic extracts will be having the drug strength of 1/10 and this will be called as Homoeopathic Mother Tincture. Such prepared extracts should be standardized by using various physical, chemical and chromatographic parameters.²⁴ For this study the alcoholic extracts manufactured by Sharda Boiron Laboratories Ltd, SBL House, Commercial Complex, Shrestha Vihar, Delhi-110092, India were used. Sharda Boiron Laboratories Ltd is an ISO 9001:2000 certified company and the products produced by it are GMP certified.²⁵

Results

Observations:

Study showed a Maximum Prevalence of Type II Diabetes mellitus in the Age Group between 46 & 55 Years (56.67%) and in Males (66.67%).

Fasting Blood Glucose Levels of the Patients:

The Fasting glucose levels of the patients & their modulations before, during and after treatment in the 3 groups are shown in the Figure 1.

Figure 1. Fasting Blood Glucose Levels of Patients Before & After treatment

Descriptive Statistics:

Descriptive Statistics of Modulation of Fasting Blood Glucose Levels in mg/dL before and after Treatment is shown in Table 1 and Figure 2.

Table 1. Descriptive Statistics of Modulation of

Fasting Blood Glucose Levels in mg/dL before and after Treatment

	Minimum	Maximum	Median	Mean	Std. Deviation	Confidence Interval @ 95% LOS
Group A Before treatment	136.00	215.00	164.00	170.0000	25.92296	170.0000 ± 16.05
Group A After treatment	99.00	198.33	142.67	144.3000	29.07781	144.3000 ± 17.97
Group B Before treatment	134.00	182.00	158.00	157.1000	15.31484	157.1000 ± 09.48
Group B After treatment	99.67	158.67	126.50	128.0670	18.55604	128.0670 ± 11.46
Group C Before treatment	134.00	192.00	150.50	157.3000	21.38042	157.3000 ± 13.26
Group C After treatment	140.67	214.67	172.00	174.1350	22.25698	174.1350 ± 13.82

Figure 2. Box plot of Fasting Blood Glucose Levels in mg/dL

ANOVA Results:

‘Analysis of Variance’ of before & after treatment modulations in Fasting Blood Glucose levels between the groups is highly statistically significant both at 95% and 99% Confidence Levels with a P Value < 0.00001. Since the p Value calculated is < 0.00001, the modulation is highly significant and this is not due to any chance.

Discussion

Both the alcoholic extracts of leaves of *Abroma agusta* (26 mg/dL) & *Gymnema sylvestre* (29 mg/dL) have marked Hypoglycaemic effect. When compared *Gymnema sylvestre* had shown a slight more lowering effect than the *Abroma agusta*. The effectiveness of the Hypoglycaemic effects are graded as shown in the Figure 3. The Placebo Control Group C does not show any such effects.

Figure 3. Grand Modulation of Fasting Blood Glucose Levels of the Patients

Conclusion

This ‘Single Blind Placebo Controlled Comparative Experimental Study’ proved that both the alcoholic extracts of the leaves of *Abroma agusta* and *Gymnema sylvestre* had a Good Hypoglycaemic effect on Type II Diabetes mellitus patients. Such that both the plant extracts can widely be used in the treatment of Type II Diabetes mellitus patients to maintain their blood glucose levels within normal range.

Explore the Parental Determinants associated with Malnutrition among Children Under Five Years Residing in Rural Areas

Hanamesh H Karkappanavar¹, Deelip S Natekar², Utalbasha Dhandargi³

¹Basic B Sc Nursing 4th year, ²Principal, (Ph.D in Nursing), Shri B.V.V.S, Sajjalashree Institute of Nursing Sciences, Navanagar, Bagalakot, Karnataka, ³Professor, Department of Community Health Nursing, Shri B.V.V.S Sajjalashree Institute of Nursing sciences Navanagar Bagalkot, Karnataka, India

Abstract

Introduction: It has been estimated that each year death of about 2.3 million under five children in developing countries is attributed to malnutrition.¹ Rural Indian children are facing this problem of lethal evil more as compared to Urban children in India.

Objective: To explore the parental determinants associated with malnutrition among under five children in rural area.

Method: Descriptive survey approach was used for the study with cross sectional case control design. 166 underfive rural children between 6 months to 5 years of age, were selected by complete enumeration method from Bhagawati village, Bagalkot. The data regarding determinants was collected by structured interview schedule. WHO anthro Plus software was used to categories the children according to their Nutritional status. The association was explored by Chi square test, Fisher's exact probability test and Linear regression.

Results: Total 166 children were screened for nutritional status, in that 40 (24.10%) were found moderately underweight and 2 (1.20%) were severely underweight. A significant association was found between nutritional status of underfive children and Parental determinants: Mother's education, Mother's occupation, Mother's age at delivery, Presence of illness or health problem during delivery and Post natal illness and Father's educational status.

Conclusion: The findings revealed that better socio-economic status, mother's age, birth order, spacing, recommended exclusive breast feeding, early recommended supplementary foods, complete immunization and timely care seeking had positive effect on children health, which were also statistically significant.

Key words: Malnutrition, Underfive children, Parental determinants, breast feeding, Weaning.

Introduction

According to Assocham-EY report India is home to the largest number of malnourished children in the

world. The prevalence of underweight children was higher (38%) in rural areas compared to urban cities (29%). "Only about 10 per cent children under the age 6-23 months were reported to receive an adequate diet. In India the age bracket of 1-5 years, the prevalence of underweight children ranged from 42% in Jharkhand, followed by Bihar, MP and UP with 37%, 36% and 34.1% respectively, to 14.1% in Manipur. The report found that the prevalence of stunting ranged from 50.4% in UP to 19.4% in Kerala².

Children in Rural India continue to consume non-nutritious, non-balanced food either in the form of under nutrition, over nutrition or micronutrient deficiencies, according to the report¹.

The World Bank estimates that India is one of the highest ranking countries in the world for the number of children suffering from malnutrition. The prevalence of underweight children in India is among the highest in the world, and is nearly double that of Sub Saharan Africa with dire consequences for mobility, mortality, productivity and economic growth.³

The 2017 Global Hunger Index (GHI) Report by IFPRI ranked India 100th out of 118 countries with a serious hunger situation. Amongst South Asian nations, it ranks third behind only Afghanistan and Pakistan with a GHI score of 29. The 2019 Global Hunger Index (GHI) report ranked India 102nd out of 117 countries with a serious issue of child wasting. At least one in five children under the age of five years in India are wasted.⁴

When it comes to child malnutrition, children in low-income families are more malnourished than those in high-income families. It is indeed necessary to explore the parental factors that contribute to malnutrition among under-five children. The nutritional status is ultimately associated with mental development and future life of the child; hence control of such factors in early life of a child can contribute to healthy future of a child preventing morbidities. Parents play the most crucial role in every child's life. Their contribution to child's health is of utmost importance. It is highly necessary to explore the parental factors that contribute to child's nutritional status.

Objective: The aim of the study was to explore the parental determinants associated with malnutrition among under five children in rural area by comparing cases and controls.

Hypotheses:

H₁: There is a significant association between parental determinants and Malnutrition among underfive children.

H₂: There is a significant association between nutritional status and extraneous factors of children under-five years

Method

Study design. It was a cross sectional study with case control research design. The study was conducted among 166 children selected from Bhagawati village, Bagalkot. Among 166 children 42 children with malnutrition were enrolled as cases and the remaining 124 children with normal nutritional status were enrolled as controls. **Cases:** The cases were identified by using WHO Anthro software. Children within the age group 6-60 months with weight for age Z score, less than -2SD, were considered as cases. **Controls** Controls were the children within the age group of 6-60 months, with weight for age Z score between -2SD to + 3D.

Setting of the study: The study was conducted in Bhagawati village of Bagalkot. It is located in the Bagalkot Tehsil of Bagalkot District in Karnataka. It is situated 16 kilometers from Bagalkot city. The total population is around 4,182. The data regarding children between the age group from 6 months to 5 years was obtained from 3 anganawadis in Bhagawati.

Participants: The study participants were underfive children and their parents residing at Bhagawati village of Bagalkot district. Bhagawati village of Bagalkot district was randomly selected as accessible population by lottery method and all the under five children residing in the Bhagawati village were enrolled as study sample.

Criteria for selection of sample.

Cases

Inclusion criteria: 1. under five children and their parents available at the time of data collection. 2. Parents of under-five children willing to participate in the study. 3. Parents of under five children who know to read/write kannada or English.

Exclusion criteria: 1. Children/parents who are hospitalized and cannot provide data. 2. Parents or children who are supposed to be out of the study area, during data collection. 3. Parents who are mentally challenged. 4. Children who are enrolled in any research study intended to improve nutritional status.

Controls

Inclusion criteria: 1 normal under five children and their parents available at the time of data collection.

2. Parents willing to participate in the study. 3. Parents of normal under five children who know to read/write kannada or English.

Exclusion criteria: 1. Children/parents who are hospitalized and can not provide data. 2. Parents and children who are suppose to be out the study area, at the time of data collection.

3. Parents who are mentally challenged. 4. Under five children who's Weight for age Z score is more than +3 SD. 5. Children who are enrolled in any research intended to improve nutritional status.

Selection of cases: As part of the study, children in the age group of 6 months to 60 months were screened by using WHO Anthro 3.2.2 software. The subjects were selected from Bhagawati village. The list of children was obtained by three anaganawadis. Anthropometric measurements like height and weight were done. The collected data was then entered in data sheet. 42 children were found as malnourished. Hence those 42 children and their parents were considered case group.

Selection of controls: Among 166 children screened 124 were found to be normally nourished with WFA Z score more than -2 SD. The children without malnutrition and their parents were considered as control group.

Sample Size estimation: sample size was estimated by using Epi info software based on results (mean and standard deviation) of a previous similar study conducted in India. The level of confidence was 95% ($\alpha=5\%$) and $Z\alpha=1.96$. The power of test was considered 80%. The sample size estimated by the statistician was 124. Considering attritions, all the available 166 children were enrolled in the study.

Description of data collection tool

The data collection instrument is divided into 2 sections.

SECTION A: It is divided into 4 parts: Part 1: Baseline factors: Part 2: Child nutritional status: Body weight and height/length of the child and WAZ- weight for age Z scores. Part 3: Child birth history: Part 4: Child present history: H/O any diarrhea at last fortnight H/O any illness or fever within last fortnight, H/O worm infestation in last 6 months, H/O any dewormification

in last 6 months.

Section B was divided into 3 parts: Part1: Parental General factors: present age, Age at the time of marriage, Educational qualification, Occupation, Nutritional status of mother and father, any present illness, Immunization of the mother during pregnancy. Part 2: Antenatal and postnatal factors: Regular health checkup, mother's age at the time of delivery, Any illness during pregnancy, mother's weight gain during pregnancy, Place of delivery, H/O any post natal illness, Gestational age at the time of delivery, H/O any abnormal event during pregnancy, H/O abortion before pregnancy of this child. Part 3: Breast feeding history: Exclusive breast feeding, Weaning was started at the age, When was breast feeding started after birth, Administration of pre-lactation goods, Breast feeding was administered up to the age.

Data Collection: Data collection was done from 16-01-2020 to 25-01-2020. Data collection was carried out in two phases- First phase: Data collection regarding Nutritional status of children Second phase: Data collection regarding Parental determinants.

Variables of the study: Dependent Variable: Nutritional status of the under-five children.

Independent Variable: parental determinants.

Statistical Analysis: The data was analyzed using SPSS 18 statistical package. Numerical data obtained from the sample, was organized and summarized with the help of descriptive statistics like percentage mean, and standard deviation. Association of parental determinants with malnutrition was assessed using Fisher exact probability test, Linear regression test and Chi square test were used to analyze association of malnutrition with socio demographic variables.

Ethical Consideration: Ethical clearance certificate was obtained from B.V.V.S Sajjalashree Institute of Nursing Sciences, institutional ethical committee. Written consent was obtained from each participant.

Results: The study was begun with selection of 166 children from 3 anaganawadis of Bhagawati village. All the children were screened for their nutritional status. Among 166 children 42 children were found as malnourished who were considered as cases and

remaining 124 normal children were considered as controls. The analysis was carried out according to objectives of the study.

Table No. 1 Classification of cases/controls based on level of malnutrition

Nutritional status	Weight for age score		Height for age score		Weight for height score	
	F	%	F	%	F	%
Normal Z=> -2SD	124	74.70	98	59.04	130	78.32
Mild/Moderate Z=< -2SD to -3SD	40	24.10	54	32.53	34	20.48
Severe Z= < -3SD	02	01.20	14	08.43	02	01.20
Total	166	100	166	100	166	100

Results related to association between baseline factors and nutritional status of children: A significant association was found between Nutritional status of under-five children and birth order ($P < 0.042$), Family monthly income ($P < 0.010$), Father's education ($P < 0.001$) and Number of siblings ($P < 0.041$). A significant association was found between malnutrition among under-five children and history of Diarrhea ($P < 0.001$) and fever/illness ($P < 0.024$) in last fortnight.

Table 2: Association between Parental determinants and Nutritional Status of under-five children.

SL NO	Ante natal and post natal variables	Df	Chi square value	p-value	Table value	Level of significance	Significance of association
1	Mother education	4	22.87	0.000	9.49	0.05	Significant*
2	Mother occupation	3	11.58	0.000	7.89	0.05	Significant*

4	Immunization of mother	1	0.148	0.701	3.84	0.05	NS
5	Regular health check up		2.42	.000	9.49	0.05	NS
6	Mother age at delivery	1	6.450	0.842	3.84	0.05	Significant*

Cont... Table 2: Association between Parental determinants and Nutritional Status of under-five children.

7	Any illness during pregnancy	1	17.145	0.000	3.84	0.05	Significant*
8	Place of delivery	3	4.378	0.039	7.89	0.05	NS
9	Post natal illness	1	8.637	0.000	3.84	0.05	Significant*
10	H/o any abnormal event during pregnancy	1	2.54	0.111	3.84	0.05	NS
11	H/o abortion before this child	1	3.168	0.009	3.84	0.05	NS
12	Father Education	4	13.367	0.001	9.49	0.05	Significant
13	Father occupation	4	3.182	0.186	9.49	0.05	NS

Results related to association between breast feeding practices and nutritional status of children

A significant association was found between Nutritional status of Underfive children and breast feeding practices; exclusive breast feeding upto 6 months ($p < 0.000$), Weaning started at 6 months of age ($p < 0.000$), Time taken to start breast feeding after birth ($P < 0.010$), administration of pre-lactational goods ($P < 0.005$) and administration of Breast feeding upto 24 months ($P < 0.000$).

Discussion

The aim of the study was to explore the parental determinants associated with malnutrition among underfive children. The data was obtained from 166 children in Bhagawati village. A similar study was conducted among 246 children and their parents (143 cases and 143 controls) attending tertiary care center Bikaner, Rajasthan.⁵

Total 166 children were screened for nutritional status, in that 40 (24.10%) were found moderately underweight and 2 (1.20%) were severely underweight.

Similar results were found in a community based descriptive cross sectional study in Pimpri Maharashtra where 263 (40.46%) under five children were stunted, 248 (38.15%) were underweight, 104 (16.00%) were wasted i.e. 34(5.23%) were having Severe acute malnutrition⁵

In case groups, 76.19% mothers in case group and 54.84% mothers from control group were between 22-25 years of age⁶.

A significant association was found between nutritional status of underfive children and Paternal Determinants: Mother's education ($P < 0.000$), Mother's occupation ($P < 0.000$), Mother's age at delivery ($P < 0.042$), Presence of illness ($P < 0.000$) or health problem during delivery and Post natal illness ($P < 0.000$) and Father's educational status (0.001).

Hence the hypothesis H_1 : There is a significant association between parental determinants and level of malnutrition among children under five years was accepted.

Similar results were found in a cross sectional study conducted to find out the factors associated with childhood malnutrition in Kapilvastu district, Nepal. Results showed that Better socio-economic status, mother's age (20-35 years), birth order up to second, gap more than two year between two pregnancies, recommended exclusive breast feeding, early recommended supplementary foods, complete immunization and timely care seeking had positive effect on children health, which were also statistically significant.⁷

A significant association was found between nutritional status of children and baseline factors hence the hypothesis H₂: There is a significant association between nutritional status and extraneous factors of children under-five years was accepted.

Limitations of the study: The study was confined only to exploration of Parental determinants associated with malnutrition among under five children. The study focused only on Under five children and their parents residing in rural area of Bagalkot.

Source of Funding: Grant for short term research 2019-20, from Rajiv Gandhi University of Health sciences, Bengaluru, Karanataka.

Web-Based Application Development of Early Detection of High-Risk Maternal Referral System in the Islands Region (SIDILAN) in South Bangka Regency

Harindra¹, Liana Devi Oktavia²

¹Lecturer at the Health Polytechnic of Pangkalpinang, Ministry of Health, Indonesia

Abstract

Every pregnancy can develop into complications at any time; therefore, pregnant women need to monitor their health during pregnancy. Maternal problems/complications can be reduced or prevented by various improvement efforts in the field of obstetric health services. Failure in handling obstetric emergency cases is generally caused by failure to recognize early risk in pregnancy. Currently, there are many efforts as early detection of pregnancy risk factors, one of them is by using the Scor Poedji Rochyati Card method as a means of detecting pregnancy risk and as a recording and reporting system for midwives. Computerization is very helpful in the process of early detection and recording of reports for midwives in health centers/regions. This research developed a web-based application of early detection of high-risk maternal referral systems in the island regions (SIDILAN) in South Bangka Regency in 2018. This study uses a study *Quasi Experiment Design* with research design of *pre-post only group design*. The results of the study using the Willcoxon test and obtained a value of $P < 0.001$. It is found that SIDILAN has higher benefits compared to manual data recording and detection.

Keywords: *Pregnancy, early detection, application*

Introduction

World Health Organization (WHO) has launched the *Sustainable Development Goals (SDGs)*, replacing the previous *Millennium Development Goals (MDGs) program*, which was completed at the end of 2015. On the target of SDGs 3.1, which is to reduce maternal mortality globally in 2030 to 70 per 100,000 live births, where this target is to continue the program from the MDGs 5a target, which is to reduce 75% of maternal mortality rate from 1990-2015¹. Maternal mortality figures are indicators that reflect maternal health status, especially the risk of death for mothers during pregnancy and childbirth².

South Bangka Regency is part of the Bangka Belitung Islands Province, consisting of eight districts and three

villages. The population of South Bangka Regency according to data from the Central Statistics Agency of the Republic of Indonesia in 2014 was 194,686 people³. The maternal mortality rate in this region was 105.26 per 100,000 live births and decreased compared to the 2013 maternal mortality rate of 107.12 per 100,000 live births. Even though the maternal mortality rate has decreased over the past four years, this figure has still not reached the Millennium Development Indicator target Goals (MGDs) in 2015 which only amounted to 102 per 100,000 live births³.

Maternal death and illness can be reduced or prevented by various efforts to improve obstetric health services. Failure in handling obstetric emergency cases is generally caused by failure to recognize the risk of pregnancy, late referral, lack of means to care for high-risk pregnant women, lack of knowledge of medical personnel, medic and sufferers in recognizing high-risk pregnancies early, problems in obstetric services and economic conditions can cause maternal

Corresponding author:

E-Mail: harindra.babel@gmail.com

death⁴. Therefore, early detection by health workers and the public about the presence of risk factors and complications, as well as adequate treatment as early as possible, is the key to success in reducing maternal and infant mortality rates⁵. Scorecard in a simple format is easier to fill by health workers in order to screen pregnant women and classify mothers according to the problem so that they can determine in the process of decision making and appropriate interventions for pregnant women based on the card⁶. Other factors that influence the high maternal mortality rate are the late referral process and the unpreparedness of health facilities to conduct the comprehensive emergency obstetric services⁴. Poor infrastructure, inadequate transportation services, distances, and travel times that are too far from health facilities and dangerous social practices play a significant role in maternal mortality⁷.

With a good referral system, it is expected that cases with high risk can be handled more quickly, accurately, and sustainably, which in turn can lead to reduced maternal and child mortality as a benchmark for reproductive health services⁸. The scoring system can also be correct, but there are non-medical constraints, such as the term “Three Late”: late in decision making, late in transportation, late in getting. These occurrences are still prevalent and are a significant contributor to perinatal maternal mortality morbidity⁹. The referral process that is following procedural will speed up the handling of obstetric emergency cases. If the situation gets worse and cannot be handled, the health center will follow up by referring the woman to the regional hospital due to limited facilities and is not supported by obstetricians, so often patients with obstetric emergencies are referred again to hospitals that have facilities and infrastructure for obstetric emergencies¹⁰.

Thus, the task of a midwife is the key to success in reducing maternal mortality by making proper early detection and referring patients to the referral health facility quickly and accurately. The only obstacle encountered in the preliminary observations in South Bangka Regency is geography. The distance of the village health post to the health center is far, and some are located on islands that are separated from the mainland, such as Lepar Island and Pongok Island, making it challenging to report early detection and reconciliation manually. Therefore we need accommodative technology to solve

this problem. Under these conditions, the development of the High-Risk Early Detection Application, the web-based Maternal Provisions System (SIDILAN) for midwives in the South Bangka Regency, is an innovation to overcome this gap.

Method

The design of this study is a quasi-experimental study with *pre* and *post-test one-group design* research that the conclusions are obtained by assessing respondents before and after the intervention by learning about the use of pregnancy risk detection tools and the referral system. This research conducted in the South Bangka Regency Health Office, during January-October 2019. Collaboration with IT staff related to the concept and purpose of the model, the content of the model, and the use of the model is established. Included in this step is the preparation of supporting components to prepare guidelines and manuals. Then an initial product trial is carried out. The initial product/model draft will be tested on a limited sample of midwives who provide services at the community health center in the Toboali district. Respondents will be given a high-risk early detection application (SDILAN). At the time of the trial, the researcher made observations and, afterward, interviews with respondents. At revision stage, an evaluation of the results of the field trial will be carried out from assessing any deficiencies. From the evaluation results, improvements were made to improve the existing deficiencies. Testing was conducted on 32 respondents through a questionnaire, and interviews and results were analyzed.

Results

Pregnant Women Screening Data in the South Bangka Region

Based on the screening data of pregnant women in the South Bangka region, data on pregnant women with low risk are 83 pregnant women, 62 are at high risk, and very high risks are 18 pregnant women. Pregnant women with low, high, and very high risks are found in the Simpang Rimba Health Center, each at 46.9%, 82.2%, and 44.4%.

Analysis Usability based on the questionnaire

The pre-test and post-test data were conducted on the same 32 respondents. A pre-test to measure the use of manual recording and reporting used at the health center while the post-test data to measure the use of recording and reporting applications. Data are presented as mean \pm SEM. Furthermore, the data distribution testing was performed with *Shapiro-Wilk* using SPSS 24.0. Both pre-test and post-test data were not normally distributed ($p < 0.05$).

Table 4. Recap of the value of Usability Application-based Reporting Recording (Post-Test)

No	Question	Value percentage	Information
1	Manual recording and reporting (MRR) helps effectively record and reporting activities	78,1 %	S
2	MRR helps midwives become more productive	78,1 %	S
3	MRR is very useful	65,6 %	S
4	MRR can make midwives more in control	71,9 %	S
5	MRR can make the midwife's things to do easier	75%	S
6	MRR can save time in recording and reporting	68,8 %	S
7	MRR according to recording and reporting needs	68,8 %	S
8	MRR is in line with the midwife's expectations	75%	S
9	MRR are easy to use	71,9 %	S

Cont... Table 4. Recap of the value of Usability Application-based Reporting Recording (Post-Test)

10	Simple MRR is used	81,3 %	S
11	User-friendly MRR	71,9 %	S
12	MRR only requires very few steps to complete recording and reporting	71,9%	S
13	MRR are easily adjusted	71,9%	S
14	MRR can be done without difficulty	75%	S
15	MRR can be used without written usage instructions	68,8 %	S
16	MRR, both fixed and occasional, will like this manual recording and reporting	75%	S
17	Midwives can fix errors quickly and easily	78,1%	S
18	Midwife successfully uses the application whenever opening it	75%	S
19	Midwives can quickly learn to use the application	75%	S
20	Midwives can easily remember how to use the application	75 %	S
21	The application is easy to learn how to use	71,9 %	S
22	Midwives are quickly involved in using the recording and reporting application	71,9%	S
23	Midwife satisfied with the application	68,8%	S
24	Midwives will recommend applications to their peers	68,8%	S
25	Interesting application to use	68,8%	S
26	The application works following what the midwife wants as a recording and reporting application	71,9%	S
27	This application is good	71,9%	S
28	Midwives feel the need for this recording and reporting application	71,9%	S
29	Midwives feel the need for this recording and reporting application	71,9%	S
30	Fun application when used	65,6%	S

Bivariate Research Results Application and Manual

The application utilization and manual recording can also be divided based on four criteria, namely usability, ease of use, ease of study and satisfaction. The difference between the four criteria in each of them is manual, and the application can be seen in Fig. 1.

Figure 1. Analysis of the difference criteria for utilization of recording manual reporting compared to application.

Discussion

Data on Pregnant Women in South Bangka Regency

Based on the map of the distribution of high-risk pregnant women screening in the South Bangka Regency and Table 1, it can be seen that all pregnant women in the area in South Bangka Regency have been cleared using the application. Although there are still several of the community health centers that are still not maximally screening pregnant women, this is due to the difficulty of internet signals in several puskesmas in South Bangka. It is in line with research conducted by the *National Research Council (US) Committee*¹³, which states that many health recording and reporting processes are highly dependent on the internet network.

Data on Screening of Pregnant Women in the South Bangka Region

Based on Table 3, it can be seen that all pregnant women have been screened by Puskesmas midwives, which can be seen grouping pregnant women according to the Risk category. For low risk, there are 83 pregnant women, 62 high-risk pregnant women, and a very high risk of 18 pregnant women. It is in line with Poedji Rochyati's theory of a risk approach or Risk Approach Surgery strategy.

Some of these risk factors can be identified and measured so that we can use them in efforts to preventive health services⁹. So, the so-called risk approach strategy starts with the discovery of these indicators, then uses

them as a guide for further action. This understanding means that no one is free from risk. The hypothesis of a risk approach strategy is the more accurate the risk calculation is, the easier it is to understand the needs needed and the better (effective) the results⁹. Using risk factors or "scores" will make it easier for health workers to reduce delays in terms of early detection and referral.

Membership in Health Insurance

Based on data available in the SIDILAN application, 64.2% of pregnant women have not registered in health insurance membership (BPJS). It indicates the need for advocacy to people to have BPJS immediately, since it is very much needed in the referral process. One of the factors that cause mothers do not want to be referred to because it costs.

Types of Referrals

Based on data Table 3, types of referrals to pregnant women divided into two groups, namely ERP and TR. The SIDILAN application can support effective referral activities. While TR is done in GDO cases (obstetric emergency services) and requires a services emergency⁹. Based on univariate results, it is obtained that the data on the residence of pregnant women are more in the mainland. The application SIDILAN has included the distance and travel time required by the patient. It is expected that the mapping of mileage and time of travel will minimize the occurrence of delays in the referral process. The better the geographical conditions, the easier it will be to access referrals. Several studies have

used a distance of 5 km to determine whether pregnant women in rural areas are easier to get to health facilities than if the mother is within a distance of more than five kilometers¹⁴.

Bivariate Research Results of Application and Manual Utilization

The system (SIDILAN) shows an increase in utilization compared to the records carried out manually and considered more comfortable to use and applied in general, and this application can quickly detect pregnant women at risk who need to get immediate referrals to facilitate health workers/midwives, in particular, to prevent maternal and neonatal emergencies in their work area. Test results conducted in general show a significant difference between early detection of high risk, manual reference systems in the islands (103) with $p < 0.001$ ($p < 0.05$). Consecutively, the mean usability of the application is higher than the manual.

Conclusion

The research results conclude that the results of the design of high-risk early detection applications, the application-based archipelago maternal referral system (SIDILAN) has higher benefits compared to the manual-based ones.

Knowledge and Awareness Regarding Bruxism and its Management in Dakshina Kannada Population

Isha Singh¹, Manoj Shetty², Chethan Hegde³, Bharath Raj Shetty⁴

¹Post graduate Student, Department of Prosthodontics, ²Head of Department, Department of Oral Implantology, ³Head of Department, Department of Prosthodontics and Crown & Bridge, A B Shetty Memorial Institute of Dental Sciences, Mangalore, ⁴Reader, Department of Prosthodontics and Crown & Bridge, A B Shetty Memorial Institute of Dental Sciences, Mangalore

Abstract

Bruxism is defined as a ‘repetitive jaw-muscle activity characterized by clenching or grinding of the teeth and/or by bracing or thrusting of the mandible’ with ‘two distinct circadian manifestations; either occurring during sleep (sleep bruxism) or during wakefulness (awake bruxism).’ Bruxism may lead to masticatory muscle hypertrophy, tooth surface loss, fracture of restorations or teeth, hypersensitive or painful teeth and loss of periodontal support. A sample of 100 patients were selected for a questionnaire study to assess the knowledge and awareness regarding bruxism and its management. The results showed that there was an overall lack of awareness in the population. Knowledge and awareness should thus be provided to the population to ascertain early treatment and less discomfort to the patients having signs and symptoms of bruxism.

Keywords: bruxism, knowledge and awareness, bruxism management.

Introduction

Bruxism was adopted from ‘La bruxomanie’, and is used to describe gnashing and grinding of the teeth occurring without a functional purpose.¹ According to Glossary of Prosthodontics, bruxism is an oral habit consisting of involuntary rhythmic or spasmodic non-functional gnashing, grinding, or clenching of teeth, in other than chewing movements of the mandible, which may lead to occlusal trauma. It can occur during wakefulness, known as diurnal bruxism or in sleep; known as nocturnal or sleep bruxism.²

Various research studies have found that prevalence of bruxism ranges from 5-20% in adult population. Most of the subjects are unaware of them being affected by this disorder. It is usually first recognised by the Dentist, as most subjects are unaware regarding its signs and symptoms. Presence of tooth wear, fractured restorations/ teeth, pain in the masticatory muscles or pain in the temporomandibular joint may be signs seen by the dentist. At times, patient may also consult a physician for episodes of atypical jaw pain or headache.

In literature, there are various etiologic factors which have been reported for bruxism. These include peripheral factors such as tooth interference in dental occlusion; psychosocial influences such as stress or anxiety; central causes involving brain neurotransmitters or basal ganglia.³

Materials and Method

Study sample consist of 100 patients selected from the OPD of Department of Prosthodontics. A self-explanatory questionnaire was given to the subjects to collect the data. Prior to data collection informed consent

was taken from all the subjects. Of 100 questionnaires distributed, all 100 were received back, and were considered valid for the study.

Results:

The questionnaires analysed 100 patients. The following conclusions were made from the answers provided.

63% have heard about clenching/bruxism and most of them heard it from their relatives(71.4%) & dentists(22.9%)

11% of the patient clenched their teeth,62% dint clench and 27% weren't aware if they clenched their teeth. Nevertheless, 17% had morning soreness in the jaw . 22% had headache in the morning .

91% of the patients weren't aware if they were clenching during the day.

The following figures show other results concluded from the answers.

7. Do you know the causes/factors responsible for Bruxism?
100 responses

Figure 1: Knowledge about the causes of bruxism.

If yes, then which factors do you think is/are responsible?
17 responses

Figure 2: Factors responsible for bruxism according to responders

If yes, then what are the effects of grinding of teeth?
15 responses

Figure 3: Effects of bruxism according to responders

Even though the patients dint know about the various treatment plans availbale most of them knew that they should seek treatment and should consult a dentist for treatment.

Around 6% sought treatment and had a successful outcome based on their response.

Discussion

Bruxism is characterised by clenching or grinding of the teeth due to contraction of the masseter, temporalis and other jaw muscles. Bruxism may lead to masticatory muscle hypertrophy, tooth surface loss, fracture of restorations or teeth, hypersensitive or painful teeth and loss of periodontal support. Sleep bruxism has previously been viewed as a dysfunctional movement or pathological condition, whereas it is now accepted as a centrally controlled condition with various systemic risk factors.⁴

The excessive forces on the teeth can contribute to alveolar bone resorption, which may be visible radiographically as generalised widening of the periodontal ligament space, and increased mobility which may be transient or permanent

A diagnosis of sleep bruxism may be made via patient report and clinical interview, clinical examination, intraoral appliances or recording of muscle activity. This epidemiological study was conducted on 100 subjects to assess knowledge and awareness regarding bruxism and its management among Dakshina Kannada population.

When asked the subjects if they have heard the terms teeth grinding/ clenching/ bruxism, out of 100 subjects only 37 subjects responded yes which depicts that majority of the population is not even aware of these terms.

Out of the 37% subjects, it was found that the majority, i.e, 71% have heard it from a relative while only 22% have heard it from a dentist.

To assess if the subjects knew the causes and factors or effects of Bruxism, it was found that 83% and 85% subjects were not aware regarding the above, respectively.

Management for bruxism is only indicated where problems arise causing patient various difficulties. Oral appliances primarily aim to protect the dentition from damage caused by clenching/grinding, although they may reduce muscle activity. Irreversible occlusal adjustments have no evidence in the management of bruxism. Behavioural strategies include biofeedback, relaxation and improvement of sleep hygiene. Administration of botulinum toxin (Botox) to the masticatory muscles appears to reduce the frequency of bruxism, but concerns have been raised regarding possible adverse effects.⁵

To assess the awareness among the subjects regarding the need for treatment of bruxism, out of 100 subjects, 66% subjects knew that bruxism requires treatment. While 95% subjects were unaware regarding the various treatment options of bruxism.

It was also observed that if patients suffered from any aforementioned symptoms, 81% preferred consulting a physician in comparison to a dentist.

This causes the delay in identification of signs and symptoms of bruxism and thus further delay in the treatment also.

According to this study it was observed that there was overall lack of knowledge and awareness among the population regarding bruxism and its management in the considered population. It is essential for both, the patients and the dentists to be aware of the potential aetiology, pathophysiology and management strategies

of sleep bruxism. Also, to ascertain the treatment at the earliest it is crucial to make the population aware. This can be done by conducting various local awareness programs which may help people to understand bruxism and its associated problems. With the aid of print and digital media, this knowledge and awareness can also be spread to a larger population.

Conclusion

Based on the results of the above study it was observed that there is lack of knowledge and awareness among the Dakshin Kannada population regarding Bruxism and its management. It should be ensured that the population is made aware of the various causes and factors and management strategies of Bruxism via a suitable aid.

Empowerment of Family Planning (FP) Cadres and Influencing Factors with SEM Analysis

J.J. Kristiarini¹, H.M. Syamsulhadi², Kusnandar³, E.S.Sulaeman²

¹Student of Doctoral Study Program of Counseling Development/ Community Empowerment, Postgraduate Program, University of Sebelas Maret Surakarta, ²Professor in Doctoral Study Program of Development Counseling/Community Empowerment, Postgraduate Program, University of Sebelas Maret Surakarta, ³Assistant Professor in Doctoral Study Program of Counseling Development/Community Empowerment, Postgraduate Program, University of Sebelas Maret Surakarta

Abstract

Objective: This study aims to examine the factors that influence empowerment of family planning cadres.

Method: The study design was observational correlational type, with a survey approach. The number of research samples is 220 people, taken based on proportional cluster random sampling. Data analysis techniques using SEM analysis.

Results:(1) Program policies significantly influence cross-sectoral commitment and support with $p = 0.000 < 0.05$; (2) Cross sectoral commitment and support has a significant effect on satisfaction with $p = 0.004 < 0.05$; (3) Program policies have a significant effect on satisfaction with $p = 0.000 < 0.05$; (4) The satisfaction has a significant effect on the empowerment of FP cadres with $p = 0.000 < 0.05$; (5) Program policies do not significantly influence the empowerment of FP cadres with $p = 0.957 > 0.05$; (6) Commitment and cross-sectoral support does not significantly influence the empowerment of FP cadres with $p = 0.774 > 0.05$.

Conclusion: (1) Policy planning programs direct and significant impact on cross-cutting commitments; (2) FP program policies have a direct and significant effect on FP cadre satisfaction; (3) FP program policies do not directly influence the empowerment of FP cadres; (4) Cross-sectoral commitments and support directly and significantly influence the satisfaction of FP cadres; (5) Cross-sectoral commitments and support do not directly influence the empowerment of FP cadres; (6) Cadre satisfaction directly and significantly influences the empowerment of FP cadres.

Keywords: Program policies; Cross-sectoral commitments and support; Satisfaction cadre; Empowerment of Family Planning cadre.

Introduction

The problems faced by Indonesia are a large population increase and low quality of life. The

total population of Indonesia in 2015 was 255.18 million people with an area of 1,910,931.32 km², a population density of 134 inhabitants / km². In the last five years (2010-2015) Indonesia's population growth rate was 1.43 percent. Indonesia's population continues to increase. In a period of fifteen years (2000 to 2015), the population of Indonesia experienced an increase of around 50.06 million people or an average of 3.33 million annually.² The high rate of population growth has an impact on the provision of food, non-food consumption materials, agricultural land, residential land, employment, education, community health level, and quality of life of the people.²

Indonesia is included in the category of a slow country in achieving the MDGs (Millennium Development Goals) which are now continued by Sustainable Development Goals (SDGs). This achievement is due to the high maternal mortality rate (MMR). MMR in 2012 reached 359 / 100,000 live births, and in 2015 there were 305 / 100,000 live births.²

Specifically, in Klaten Regency, the acceptors of family planning acceptors spread in 34 sub-districts are as follows: Couples of Childbearing Age (CCA) unmet need 10.13%, CCA is not FP participant 21.29% of the total PUS 201,950. There were 158,943 active participants (78.70%) acceptors of active family planning. Active FP participants at the beginning of the year were 142,048 (70.39%) acceptors, additional active FP participants were 16,895 (8.37%) acceptors. New participants were 26,481 (13.11%) acceptors and Drop Out participants were 9,586 (4.75% acceptors), meaning that the number of active family planning acceptors was still low, requiring an inspirational awareness to take part in family planning programs to increase the level of family welfare manifested in Family Norms. Small prosperous (now: quality family).³

The role of family planning cadres spread in each village greatly determines the success of the family planning program. FP cadres are very effective motivators and recruiters of family planning acceptors. FP cadres are members of the community who work voluntarily in the success of the family planning program. The role of family planning cadres includes promoting family planning programs, inviting, motivating, recruiting couples of childbearing age to become active FP participants. In this regard, it is necessary to empower family planning cadres to increase their role in the family planning program.

Some factors that influence the empowerment of FP cadres, namely: (1) External factors include: training, leadership, type of work, work design, reward system, resources (facilities), organizational climate (environment); (2) internal factors include: level of education, knowledge, personality, attitude, perception, background, experience (years of work), age, motivation, job satisfaction, organizational commitment.⁵

Considering that various factors can influence the empowerment of FP cadre, this research only focuses on program policy factors, cross-sectoral commitment and support, and cadre satisfaction. Based on the above can be formulated by the problem 's research, how namely model of the relationship between the policy of family planning programs, commitment and support cross-sectoral, and a cadre of satisfaction with the empowerment of the family planning cadre?

Materials and Method

The study design was a correlational type observational analytic with a survey approach. This research was conducted in the Klaten Regency area in 2019. The population of the research is in the area of family planning cadres in district: Prambanan, Manisrenggo, Karangnongko. South Klaten, North Klaten, Jatinom, Kebonarum, Kemalang, Tulung, Karangnom, Bayat, Delanggu, Juwiring, and Ceper. Total population of 401 cadres. The number of research samples is 220 FP cadres. The sampling technique uses proportional cluster random sampling. Data analysis techniques using SEM analysis.

Instruments research be my questionnaire compiled based on constructs, variables, and indicators that have been set. The questionnaire was also tested for validity and reliability before being used to collect data.

Result

Feasibility Model Intervariable Relations

Relationship model has met the feasibility of this model, because the value AGFI = 0.819 and GFI = 0.876, both included the marginal fit category. Then the value of TLI = 0.91 and RMSEA = 0.079, both included in the good fit category.

The significance of the relationship between variables can be seen from the values of CR and P as shown in table 1 below.

Table1. Significance of Intervariable Relations

Model			Estimate	SE	CR	P.
COMMITMENT	<---	POLICY	0.675	0.066	10.241	***
SATISFACTION	<---	COMMITMENT	0.292	0.101	2.893	0.004
SATISFACTION	<---	POLICY	0.330	0.089	3.716	***
EMPOWERMENT	<---	SATISFACTION	0.692	0.081	8.514	***
EMPOWERMENT	<---	POLICY	-0.004	0.067	-0.054	0.957
EMPOWERMENT	<---	COMMITMENT	-0.022	0.075	-0.288	0.774

Table 1 shows that: (1) Program policies significantly influence cross-sectoral commitment and support with a value of $p = 0.000 < 0.05$; (2) Cross sectoral commitment and support has a significant effect on cadre satisfaction with a value of $p = 0.004 < 0.05$; (3) Program policies have a significant effect on cadre satisfaction with $p = 0.000 < 0.05$; (4) The satisfaction of cadres has a significant effect on the empowerment of FP cadres with a value of $p = 0.000 < 0.05$; (5) Program policies do not significantly influence the empowerment of FP cadres with a value of $p = 0.957 > 0.05$; (6) Commitment and cross-

sectoral support does not significantly influence the empowerment of FP cadres with a value of $p = 0.774 > 0.05$.

Direct Influence, Indirect Influence, and Total Influence

To determine the influence of direct, indirect influence, and influence between variable total research can be seen from the output of Standardized Direct Effects, Standardized Indirect Effects, and Standardized Total Effects, such as in Table 2 to 4 in below.

Table 2. Standardized Direct Effects

Influence	Policy	Commitment	Satisfaction	Empowerment
COMMITMENT	0.713	0.000	0.000	0.000
SATISFACTION	0.382	0.320	0.000	0.000
EMPOWERMENT	-0.005	-0.029	0.857	0.000

Table 3. Standardized Indirect Effects

Influence	Policy	Commitment	Satisfaction	Empowerment
COMMITMENT	0.000	0.000	0.000	0.000
SATISFACTION	0.228	0.000	0.000	0.000
EMPOWERMENT	0.502	0.274	0.000	0.000

Table 4. Standardized Total Effects

INFLUENCE	POLICY	COMMITMENT	SATISFACTION	EMPOWERMENT
COMMITMENT	0.713	0.000	0.000	0.000
SATISFACTION	0.610	0.320	0.000	0.000
EMPOWERMENT	0.497	0.245	0.857	0.000

In tables 2 to 4 above it is known that: (1) FP program policies directly influence cross-sectoral commitment and support with a path coefficient of 0.731; (2) Policy planning programs directly affect the satisfaction of cadres with path coefficient of 0.382, and the indirect effect (through commitment and support cross-sectoral) to the satisfaction of cadres of 0.228. The total effect of family planning program policies on the empowerment of family planning cadres is $0.382 + 0.228 = 0.610$; (3) FP program policies directly influence the empowerment of FP cadres with a path coefficient of -0.005, and the indirect effect (through cadre satisfaction) on FP cadres empowerment of 0.502. The total effect of family planning program policies on FP cadre empowerment is $-0.005 + 0.502 =$

0.497; (4) Cross-sectoral commitment has a direct effect on cadre satisfaction with a path coefficient of 0.320; (5) Cross-sectoral commitment directly influences the empowerment of FP cadres with a path coefficient of -0.029, and the indirect effect (through cadre satisfaction) on the empowerment of FP cadres by 0.274. The influence of total cross-sectoral commitments on the empowerment of FP cadres is $-0.029 + 0.274 = 0.245$; (6) Cadre satisfaction directly affects the empowerment of FP cadres with a path coefficient of 0.857.

Based on the results of the above analysis, then the model of the relationship between variables that can be declared significant can be illustrated as shown in Figure 2 below.

Figure 2: Relationship Model between Program Policies, Cross-Sectoral Commitment and Support, FP Cadre Satisfaction, and FP Cadre Empowerment

Discussion

Relationship of FP Program Policies, Commitment, and Cross-Sectoral Support, and FP Cadre Satisfaction

Family planning program policies have a direct and significant effect on cross-sectoral commitment and support. The results of this study support the results of research by Muslikh and Nugraha¹¹; Asnani, Mattalatta, and Gunawan¹ who concluded that the effectiveness of the Performance of Village Family Planning Assistance (PVFPA) performance was largely determined by indicators of the work environment and the efforts made. The work environment indicators are related to policies made by the government. Research Mailisa, Hendri, and Fauzan¹² concluded that the organizational climate positive and significant effect on performance, a positive value means the conducive organizational climate, it is expected to upgrade also performance.

Cross-sectoral commitment and support have a direct and significant effect on the satisfaction of FP cadres. Existence commitment and support cross-sectoral will increase the satisfaction of cadres FP so that with the commitment and support of cross-sectoral, cadres FP will strive in earnest to complete a given task. The results of this study support the results of research conducted by Suarjana, Putra and Susilawati¹⁵; Wirmayanis¹⁷; Permatasari, Swasto, and Iqbal¹² which concluded that organizational commitment has a positive effect on one's performance. The results of this support the theory Siagian¹⁴ which states that the commitment of the organization is one of the factors that determine the high lows performance of a person.

Relationship of FP Program Policy, FP Cadre Satisfaction, and FP Cadre Empowerment

PF program policies have a direct and significant effect on the satisfaction of FP cadres. This indicates that the relationship between government policies and cadre satisfaction is close because government policies related to family planning programs will affect the satisfaction of health cadres. Research Khamis and Njau⁶ conclude that health care workers' Mentioned extrinsic as well as intrinsic factors, which may influence the quality of health care services. Extrinsic factors included poor physical infrastructure, unavailability of medical equipment and/

or essential drugs and poor staffing levels.

Besides relating to the situation and conditions, government policies can also be related to intensive. Research by Muslikh and Nugraha¹¹; Asnani, Mattalatta, and Gunawan¹ concluded that the effectiveness of PVFPA performance was largely determined by indicators of the work environment and the efforts made. Work environment indicators are related to policies made by the government, one of which is intensive.

Therefore, according to Ife and Tesoriero⁴ government policy must use a community-based humanitarian service approach. The essence of the community-based humanitarian service approach is that the community must be responsible not only for providing services, but also for identifying needs, planning services for those who need them, setting priorities within the scope and among services that are "competing", and monitor and evaluate programs.

While the relationship between cadre satisfaction with cadre empowerment is closed because someone who feels satisfied at work will show high morale and show his ability to work. He will make every effort to carry out his duties as well as possible. Research by Novita, Sunuharjo, and Ruhana⁸ concluded that satisfaction influences performance (empowerment).

An FP cadre can feel satisfaction as an FP cadre if he feels satisfaction in terms of (a) Relationships with colleagues; (b) Relations with leaders; (c) The ability and efficiency of department heads; (d) Working hours; (e) Opportunity for initiative; (f) Promotional opportunities; (g) Salary or income; (h) Job security; (i) Work being handled; (j) Other job satisfaction (Ward and Sloane 2011, in Koesmono).⁷

Relationship of Cross-Sectoral Commitment and Support, FP Cadre Satisfaction and FP Cadre Empowerment

Cross-sectoral commitment and support direct and significant impact on the to cadres PF satisfaction. This indicates that the relationship between commitment and cross-sectoral support and cadre satisfaction is very close because, with the commitment and support from cross-sectoral, the cadre will make every effort to complete the

assigned tasks. Research conducted by Suarjana, Putra, and Susilawati¹⁵; Wirmayanis¹⁷; Permatasari, Swasto, and Iqbal¹² show that organizational commitment has a positive effect on one's performance. The results of this supports the theory Siagian²³ which states that the commitment of the organization is one of the factors that determinethe high lows performance of a person.

While the relationship of cadre satisfaction with cadre empowerment is also very close as explained above. Robbins¹³ mentions job satisfaction is a general attitude towards one's work as the difference between the number of rewards a person receives and the amount of rewards believed to be received. Luthans⁹ states that job satisfaction has three dimensions. First, job satisfaction cannot be seen, but can only be suspected. Second, job satisfaction is often determined by the extent to which work results meet or exceed someone's expectations. Third, job satisfaction reflects the relationship with various other attitudes of individuals. Koesmono⁷ job satisfaction is a positive or pleasant emotional statement as a result of an assessment of one's work or work experience. The statement implies that job satisfaction is a positive or pleasant emotional state that results from an assessment of one's work or work experiences.

Conclusion

Based on the results of research can be concluded: (1) Policy of family planning programs direct effect and significant to the cross-sectoral commitments and support; (2) FP program policies have a direct effect and significant on FP cadre satisfaction; (3) FP program policies do not directly influence the empowerment of FP cadres; (4) Cross-sectoral commitments and support directly and significantly influence the satisfaction of FP cadres; (5) Cross-sectoral commitments and support do not directly influence the empowerment of FP cadres; (6) Cadre satisfaction directly and significantly influences the empowerment of FP cadres.

A Study on Prevalence of Metabolic Syndrome in Young Medicos of South Karnataka

Jai Prakash¹, Venkatesh P², Rajesh S.S³, Krishna Iyengar⁴

¹Professor, ²Associate Professor, ³Assistant Professor, ⁴Professor & HOD, Community Medicine Dept., Sri Siddhartha Medical College, Tumkur

Abstract

Background: It has been calculated that Non Communicable Diseases cause 68% mortality across the world, but mostly in low and middle income countries. Southeast Asia has seen growing NCD deaths since 2000. 60% of total deaths in India in 2012 were attributed to NCDs. International Diabetic Federation (IDF) consisting of experts from various countries and organizations has adopted a definition of Metabolic Syndrome (MetS) which is an aggregation of fatal heart attack risk factors, diabetes and pre-diabetes, abdominal obesity, high cholesterol and high blood pressure. **Objectives:** To assess the prevalence of Metabolic Syndrome in medical students and determine the behavioral risk factors associated with it. **Material and Method:** A cross sectional study was conducted on sample of 110 randomly selected medical students of second-year MBBS. Sample size calculated keeping the prevalence of metabolic syndrome 21% with precision of 10% and confidence level of 99%. Data was processed using latest SPSS version. Descriptive statistics, chi square, odds ratio and logistic regression were used for statistical analysis. **Results:** Out of 110 medical students 54 (49.09%) were males and 56 (50.91%) were females. Based on IDF criteria, only 10 (9.09%) had Metabolic Syndrome. The prevalence of individual parameters for Metabolic Syndrome were abdominal obesity (100%), low HDL (60%), High TG 80%, High FBS 50% and raised Blood Pressure 20%. Low intake of fruits was found in 90% and high sugar intake was found among 70% and low level of physical activity was reported in 80% students. Overall risk factors were found in 66% cases. **Conclusions:** This study concludes that prevalence of metabolic syndrome was 9.09% among young medicos. The prevalence of individual components for metabolic syndrome highest was TG 80%, followed by low HDL then high FBS 50% and raised Blood Pressure 20%. About 66% of young medico showed at least one risk factor for developing Metabolic Syndrome.

Keywords: Metabolic syndrome, prevalence, medicos.

Introduction

It has been calculated that Non Communicable Diseases cause 68% mortality across the world, but mostly in low and middle income countries¹. Southeast Asia has seen growing NCD deaths since 2000. 60% of total deaths in India in 2012 were attributed to NCDs². It has been estimated that 47% of the total out-of-

pocket expenditure is spent for managing NCDs³. In macroeconomic terms NCDs in India will cost 5%-10% of the GDP⁴. World Economic Forum and Harvard School of Public Health have estimated that over the next 20 years NCDs will cost more than US \$ 30 trillion i.e. 48% of global GDP in 2010 and force millions of people below poverty line⁵. A high level committee recently has set the goal of “25x25” - reducing the premature death due to major NCDs by 25% by year 2025⁶. The prediction models suggest that the reduction of six NCDs risk factors namely, tobacco use, alcohol use, high salt intake, obesity, high BP and glucose, can lead to achieving this target⁷. Metabolic Syndrome, a precursor of NCDs, is a global public-health challenge

Corresponding author:

Dr.Venkatesh.P,

Associate Professor, Community Medicine Dept., Sri Siddhartha Medical College, Tumkur

Email ID: vepa77@gmail.com

because of increasing sedentary lifestyle and excessive calorie-intake.

International Diabetic Federation (IDF) consisting of experts from various countries and organizations has adopted a definition of Metabolic Syndrome which is an aggregation of fatal heart attack risk factors, diabetes and pre-diabetes, abdominal obesity, high cholesterol and high blood pressure⁸. The people with Metabolic Syndrome have 2-3 times higher risk of CVDs and 3-5 times higher risk of Diabetes Mellitus compared to healthier individuals⁹. This syndrome is a rising threat to the young adult Indian population with prevalence from 11% to 41%. It is thought to be the primary driver behind the epidemic of Diabetes Mellitus and CVDs. The lowest prevalence in first-year medical students of North Karnataka was found 10.83%¹⁰ whereas highest prevalence, 40.9% was reported in Northern India¹¹. It was found that 30% of obesity starts with childhood¹² and roughly 50-80% of these obese children become obese adults¹³. Recently scientists have seen evidence that Vitamin D deficiency not only affects the skeletal system but also makes one prone to CVDs, Diabetes Mellitus, autoimmune diseases and cancer¹⁴.

A Comprehensive National Nutritional Survey conducted by Ministry of Health and Family Welfare found that almost one in 10 school children and adolescents were pre-diabetic and 1 percent were diabetic. 5% school-aged children and adolescents had hypertension. Report also mentioned growing incomes leading to increased spending on fried foods, junk foods, sweets and aerated drinks. Only 25% of the adolescents were found to have consumed green leafy vegetables once a week¹⁵.

World Health Assembly endorsed the global plan for prevention and control of NCDs 2013-2020. A holistic approach by the governments with public and private sector participation is the key to meet the main objectives of a 25% reduction in NCD-mortality, 30% reduction in the mean population intake of salt & tobacco in people over 15 years, reduction of 10% in the prevalence of physical-inactivity and alcohol-consumption¹⁶.

The IDF has defined Metabolic Syndrome as the presence of central obesity (waist circumference > 90 cm for men and >80 cm for women) along with any two of the four criteria below:

1. Fasting blood sugar ≥ 100 mg/dl
2. Triglycerides ≥ 150 mg/dl
3. High Density Lipoprotein < 40 mg/dl in males and < 50 mg/dl in females
4. Systolic Blood Pressure ≥ 130 mm Hg and diastolic BP ≥ 85 mm of Hg

The detection of Metabolic Syndrome at early age and follow-up intervention is the only way to prevent and minimize its progression. Hardly any study has been conducted in young population in this area. The present study has two main research questions: First to update on changing patterns of Metabolic Syndrome in this region; second to quantify factors significantly contributing to it.

Objectives

1. To assess the prevalence of metabolic syndrome in medical students.
2. To determine the behavioral risk factors associated with Metabolic Syndrome.
3. To assess the dietary habits and physical activities of the study subjects.

Material and Method

A cross sectional study was conducted from Sep to Dec 2019 on sample of 110 randomly selected medical students with age ranging from 18 to 22 of second-year MBBS. The study has been approved by Institutional Ethical Committee, SSMC. Sample size calculated keeping the prevalence of metabolic syndrome 21% with precision of 10% and confidence level of 99%.

So, $n = Z^2PQ/d^2$ where $P=21\%$, $Q=79\%$ ($100-21$), $d = 10$, $Z=2.58$ (99% CL)

$$n = 2.58^2 \times 21 \times 79 / 10 \times 10 = 110$$

A written informed consent from all the students involved in study was taken. Pre-tested proforma was filled by each student with details of demography, behavioral and dietary details history and physical activities. Waist circumference was measured using an inch tape immediately above the iliac crest, Blood Pressure was measured in right arm sitting position by electronic calibrated BP apparatus after 10 minutes rest

and repeated 3 times keeping 1 minute interval and average of all three readings was recorded. Blood investigation such as fasting blood sugar, triglyceride and high density lipoprotein were carried out as per instruction manual provided by the kit (ERBA-Diagnostic Germany) and FBG was estimated by glucose oxidase-peroxidase end point colorimetric method in hospital lab on the next day. Descriptive statistics, chi square, odds ratio and logistic regression were used for statistical analysis using latest SPSS 16th version.

Results

Out of 110 medical students 54 (49.09 %) were males and 56 (50.91%) were females. The mean age was 20 years. Based on IDF criteria only 10 (9.09%) had Metabolic Syndrome (MetS) and male were 6 (5.45%) and female were 4 (3.64%) but difference is not statistically significant. [Table-1]

Table 1 – Gender-wise Prevalence Rate

Gender-wise Prevalence Rate						
	Male		Female		Overall	
	Number	Percentage	Number	Percentage	Number	Percentage
Total	54	49.09%	56	50.91%	110	100.00%
With MetS	6	5.45%	4	3.64%	10	9.09%

Chi-square with Yates correction-0.1537 and p value- 0.695036

The prevalence of individual parameters for Metabolic Syndrome were abdominal obesity 100%, low HDL 60%, High TG 80%, High FBS 50% and raised Blood Pressure 20%. Low intake of fruits was found in 90% and high sugar intake was found among 70% and low physical activity for 80% students. Overall risk factors were found to be at 66%. [Table-2].

Table 2- Clinical Profile of Metabolic Syndrome

Clinical Profile of Metabolic Syndrome							
	MetS	% MetS	No MetS	% No MetS	Total	X ²	p-Value
Waist Obesity	10	100%	20	20%	30	29.33	0.0000
High FBS	5	50%	8	8%	13	15.39	0.0001
High TG	8	80%	16	16%	24	21.83	0.0000
Low HDL	6	60%	28	28%	34	4.36	0.0368
High BP	2	20%	9	9%	11	1.22	0.2689
Low Fruit Intake	9	90%	71	71%	80	1.65	0.1983
Unhealthy Food	5	50%	9	9%	14	13.76	0.0002
High Sugar Intake	7	70%	21	21%	28	11.50	0.0007
Low Phy Activity	8	80%	47	47%	55	3.96	0.0466

Correlates of Metabolic Syndrome in univariate analysis are shown in [Table-3]. Students having high Triglycerides were 21 times more likely to have Metabolic Syndrome (MetS) and those having high Fasting Blood Sugar were 11 times likely to have Metabolic Syndrome. Similarly individuals with low HDL and high Blood Pressure were likely to have MetS about three times. Likewise there was more risk of Metabolic Syndrome among those who had low Fruits Intake and low Physical Activity as well as unhealthy food.

Table 3 - Correlates of Metabolic Syndrome

Correlates of Metabolic Syndrome					
	Risk Factor Present		Risk Factor Absent		Odds Ratio
	MetS	No MetS	MetS	No MetS	
Waist Obesity	10	20	0	80	NA
High FBS	5	8	5	92	11.50
High TG	8	16	2	84	21.00
Low HDL	6	28	4	72	3.86
High BP	2	9	8	91	2.53
Low Fruit Intake	9	71	1	29	3.68
Unhealthy Food	5	9	5	91	10.11
High Sugar Intake	7	21	3	79	8.78
Low Phy Activity	8	47	2	53	4.51

Discussion

This cross sectional study was conducted for the first time among young medico of South Karnataka and lowest metabolic syndrome prevalence rate of 9.09% was found. The prevalence of Mets for male and female was 5.45% and 3.64% respectively but difference was not statistically significant. While in the first-year medical students of North Karnataka, the prevalence of MetS was found at 10.83%¹⁰. The prevalence of Metabolic Syndrome was 22%, abdominal obesity was the commonest risk factor for the development of MetS in the studied group of medical students¹⁷. Forty percent of faculty members were overweight (BMI > 23) and another 40% were obese (BMI > 25)¹⁸. 21.7% prevalence of MetS was detected among apparently healthy workforce of Pakistan¹⁹. The prevalence of MetS has been seen highest in Mexican adults as 54.8%, reaching 73.8% in obese subjects²⁰ followed by USA at 30% and Japan 27.2%.

The prevalence of components of metabolic syndrome in our study in decreasing order was high TG-80%, low HDL-60%, high FBS-50%, high BP-20%. Low HDL was the first common component of MetS with mean prevalence of 62.9% seen in systemic review²¹, which is same as in our study but hypertriglyceridemia was third most prevalent (30.8%) component. Nine in ten Bengalureans lack HDL in the age group of 30-40 years.

Men in Chennai, Mumbai, Delhi and Pune reported to be 8 out of 10²². In this study 90% of students had low consumption of fruits; while in another study conducted by the author, 27.9 % of interns had consumed 400 gm of fruits and vegetables as recommended by WHO²³. The consumption of one serving of fruits was observed among 48.8% of participants while 10.5% consumed two serving in a day²⁴.

Latest study conducted by Selvaj K, Sekhar S et al in adults over 18 years living in urban field practice area of JIPMER Puducherry had shown clustering of NCDs risk-factors as high as 73%. Low intake of fruits and vegetables, high salt intake and large waist circumference were reported as major risk factors across all groups²⁵. We found that 70% of students consumed high amount of sugar. High intake of sugar is main culprit in development of diabetes and cardiovascular diseases followed by low intake of fruits and vegetables. India is the largest consumer of sugar 25.01 kg per person per year which is five times the WHO recommended threshold for sugar intake²⁶. Consumption of sugar per capita has increased from 22 gm/day in 2000 to 55.3 gm/day in a span of 10 years and total fat consumption increased from 22gm/day in 2000 to 54 gm/day over the same period while total salt consumption went up from 9 to 12 gm/day per-capita. A single can of sugar sweetened beverage contains up to 40 gm of sugar²⁷. Sievenpiper conducted 20 controlled feeding trials and

found that high doses of fructose, rather than glucose, may increase cholesterol, uric acid and postprandial triglyceride²⁸. Sugar intake associated with a healthy life should be at 5% of total energy intake. A message that free sugar consumption is causative for NCDs should be comprehensively conveyed through health warnings across media²⁹. We also observed that 80% of students had low level of physical activity and sedentary lifestyle was reported by nine studies to increase prevalence of MetS¹⁸. MetS is affected by genetic/epigenetic make up of individuals, predominant lack of physical activity and other factors like quality and composition of food and composition of the gut microbes³⁰.

Conclusion

Our study concludes that prevalence of metabolic syndrome was 9.09% among young medico with no statistical difference in genders. In prevalence of individual components for Metabolic Syndrome, TG was found to be highest (80%), followed by low HDL (60%), high FBS (50%) and the least by raised Blood Pressure (20%). About 66% of young medicos showed at least one risk factor for developing Metabolic Syndrome. Early detection and early prevention by eating healthy diet, regular physical activities and other lifestyle modifications may be very helpful for the young medicos to decrease risk of having Metabolic Syndrome and its various components. There is an urgent need to address these issues regarding NCDs with inclusion of nutritionist at clinics and at community-level.

Limitation: Small sample size, the results of which cannot be generalized.

Source of Funding: The study was conducted with financial support for laboratory and stationary expenses from Sri Siddhartha Academy of Higher Education.

A Study to Find Out the Effect of Dynamic Soft Tissue Mobilization (DSTM) with Retro - Walking on Hamstring Flexibility and Dynamic Balance in Young Collegiate Students – An Interventional Study

Jaydev Pandya¹, Krupa D. Tank²

¹MPT Musculoskeletal and Sport Science, Sports Physiotherapist at Saurashtra Cricket Association Rajkot,

²MPT Musculoskeletal (Ortho) Assistant Professor, School of Physiotherapy RK University, Rajkot

Abstract

Background: Prevalence of hamstring muscle tightness among undergraduate students shows 40.17%. Hamstring muscle tightness is “inability to extend the knee completely when the hip is flexed accompanied by discomfort or pain along the posterior thigh and/or knee is usually attributed to. Dynamic soft tissue mobilization developed with the aim of increase muscle length. It utilizes combine technique classic massage followed by dynamic component with the limb is moved through its range. Retro – walking is a dynamic activity which can improve be used to treat the flexibility as well as dynamic balance. **Aim:** To find out the effect of dynamic soft tissue mobilization with retro - walking on hamstring flexibility and dynamic balance in young collegiate students. **Methodology:** 25 subjects were selected Based on the selection criterion, the whole procedure of the study was explained to all the subjects. Prior and after to treatment both the outcome measures, Active Knee Extension Test and Y - Balance Test were measured. Intervention in the form of Dynamic Soft Tissue Mobilization Technique with Retro – walking were given alternate 3 sessions per week for 4 weeks. **Results and Discussion:** The data were analysed by Paired t test. P value for both the outcome measures were <0.05 which shows significant improvement by improving flexibility and dynamic balance. **Conclusion:** Intervention of the study was effective, very simple and easy to apply in Hamstring tightness subjects. So it can be implemented clinically as well.

Key Words: *Dynamic Soft Tissue Mobilization (DSTM), Retro- Walking, Y - Test, Active Knee Extension Test, Manual therapy, Hamstring Flexibility*

Introduction

Prevalence of hamstring muscle tightness among undergraduate students shows 40.17% in which tightness has found more in male than female participants.¹ The hamstring muscles are commonly linked with movement dysfunction at the lower lumbar spine, pelvis and lower limbs, and have been coupled with low back pain and gait abnormality.²

The back of thigh Muscles are called as a hamstring muscle. This includes semitendinosus, semi-membranous, Long head biceps femoris and the ischial head of the adductor magnus.³

The biomechanically hamstring muscle is proved as a knee flexors. However, it is important to recognize that because these muscles attach on both the medial and lateral aspect of knee joint, pure knee flexion requires activity of both the medial and lateral muscle mass. Medial hamstring Contraction produce medial rotation with knee flexion and also lateral hamstring Contraction produce Lateral rotation with knee flexion.⁴

In addition to flexion and rotation of knee, hamstrings reportedly contribute to stability of knee. The hamstring provide resistance to anterior glide on tibia on femur. Thus, they are described as important adjunct to the anterior cruciate ligament and perhaps a

critical substitute in the ACL deficient knee. The most prominent period of activity is at the transition of swing and stance period of gait cycle.⁴

The Weakness of hamstring muscles causes loss of knee flexion. Weakness in knee flexion in the erect posture produces little disability. However, weakness of hamstring muscle also leads to affect functional impairments at hip, where hamstring muscle provides substantial part of extension strength. The flexion moment is resisted by an extension moment generated at least in part by the hamstring muscle. Weakness of hamstring may result in difficulty in lifting and bending.⁴

Hamstring muscle tightness is “inability to extend the knee completely when the hip is flexed accompanied by discomfort or pain along the posterior thigh and/or knee”.¹ Hamstring tightness commonly found in both symptomatic and asymptomatic subjects. The hamstring is a group of muscle that have tendency to shorten. Decrease hamstring flexibility leads to increase chances of hamstring injuries in athletes. Tightness of hamstring muscle result in limitation in knee extension ROM when hip is flexed. Tight hamstring causes increased patello femoral compressive force. This may lead to patello femoral syndrome. And also causes low back pain in young adult.⁴

Flexibility is considered as an essential element for normal biomechanical function. Tightness of hamstring lead to post- exercise soreness and decreases coordination among athletes.⁵ the literature reports few associated benefits of flexibility including improved athletic performance, reduced injury risk, prevention or reduction of post-exercise soreness, and improved coordination. Some studies have shown that decreased hamstring flexibility is a risk factor for the development of patellar tendinopathy and patellofemoral pain, hamstring strain injury and symptoms of muscle damage following eccentric exercise.⁶⁻⁹

Body balance consists of maintaining the centre of gravity within the base of support defined by the feet, and it may be static or dynamic.¹⁰ In static balance, the base of support remains fixed while the centre of gravity moves. In this case, the sense of balance maintains the centre of gravity within the base of support defined by the feet. Whereas, in dynamic balance, both the center of gravity and the base of support are in constant motion,

and the center of gravity never aligns itself to the base of support during the stance phase of the movement.¹

DSTM technique is developed with the aim of increase muscle length. It utilizes combine technique classic massage followed by dynamic component. Determine specific area of tightness, where the treatment is concentrated. And Retro – walking is a dynamic activity which can improve be used to treat the flexibility as well as dynamic balance.

Many literature shows many benefits of hamstring flexibility including reduce injury risk and that’s why improved performance. Various techniques are available for soft tissue mobilization. Among them DSTM is also effectively improving flexibility individually. DSTM combine with Retro – walking may effective in improvement of flexibility and dynamic balance but lack of evidences are available. So, the Hypothesis of the study was that there was significant effect of DSTM with Retro – walking on hamstring flexibility and dynamic balance on young collegiate students.

Method

After approval from Institutional Ethical committee and CTRI registration process 25 subjects were selected Based on the inclusion and exclusion criteria. The whole procedure of the study was explained to all the subjects and written informed consent was taken. Prior and after to treatment both the outcome measures, Active Knee Extension Test and Y - Balance Test were measured. Intervention in the form of Dynamic Soft Tissue Mobilization Technique with Retro – walking were given alternate 3 sessions per week for 4 weeks.

- Consent Form
- Data Collection Form / Assessment Form
- Pen
- Paper
- Goniometer
- Active Knee Extension Frame
- Stabilizer belt
- Couch

- Treadmill
- White tape for Y-TEST
- Measure tap
- Weight machine
- Stadiometer

Materials used in study

Study Design: An Interventional Study.

Study Setting: RK University.

Sampling Technique: Purposive Sampling

Study Population: Young Collegiate Students

Study Sample: 25

Study Duration: 6 Months

Inclusion Criteria:

- Males and females of age between group 17 - 25 years
- Inability to achieve active knee extension above 160 degrees in active knee extension test.²⁴

Exclusion Criteria:

- Hamstring injury at least for the past 1-year.
- Any past traumatic and non-traumatic lower extremities of history
- Individual engaged with Sports activity
- Hyper mobility of the lower extremity joints²⁴

Intervention:

DSTM:

The Subject was positioned in prone and researcher

stand on same side of hamstring tightness and following the steps explained here.

Deep longitudinal strokes were applied to the entire hamstring muscle group to locate the specific area of hamstring muscle tightness. Once the specific area of was located, the remaining treatment was limited to this target area. After that the subject was positioned supine with the hip and knee flexed to 90 degrees. Deep longitudinal strokes were applied in a distal to proximal direction to the area of hamstring tightness when the leg was passively extended. Then the next progressive, dynamic technique was applied.

During this technique, the subject was required to actively extend their leg, to achieve reciprocal inhibition of the hamstrings. In this final procedure, the subject was instructed to contract the hamstring muscle group eccentrically against the resistance offered by the investigator's hand as the muscle is elongated up to the end range of motion.

During this movement, five deeps distal to proximal longitudinal strokes over the reduced hamstring area of muscle tightness are performed.¹²

Retro Walking:

In starting of retro walking on treadmill first subject opportunity to acclimate with backward walking on a treadmill by one supervise 10 min practice section at 0-degree inclination.

During intervention period the treadmill will adjust to produce a speed of 4 km/h and 0-degree inclination for 6-minute period of retro walking 3 times a week.²⁴

Result & Statistics

The present study was carried out to find out the effectiveness of Dynamic Soft Tissue Mobilization with Retro - walking On Hamstring Flexibility and Dynamic Balance in Young Collegiate Students. Data was analysed using SPSS software version 20 and Microsoft Excel 2016. Before applying statistical tests, data was screened for normal distribution. All the outcome measures were analysed before and after intervention.

Table: 1 INTRA GROUP ANALYSES FOR AKE TEST.

	Pre treatment		Post treatment		p value
	Mean	± SD	Mean	± SD	
RIGHT SIDE	113.60	5.50	134.2	6.72	0.000
LEFT SIDE	116.0	6.61	134.2	8.25	0.000

Here the intra group analysis for AKE test was done by using Paired T test. Where the p-value is <0.05. It is statistically significant and it shows improvement in hamstring flexibility after intervention.

Table 2: INTRA GROUP ANALYSES FOR Y TEST

	Pre treatment		Post treatment		p value
	Mean	± SD	Mean	± SD	
RIGHT SIDE	81.106	10.71	90.90	11.71	0.000
LEFT SIDE	80.24	11.43	89.33	11.68	0.000

Here the intra group analysis for Y- test was done by using Paired T test. Where the P- value is <0.05. It is statistically significant and it shows improvement in dynamic balance after intervention.

Discussion

The result of the present study demonstrated that hamstring flexibility and dynamic balance improved after intervention.

Dynamic soft tissue mobilization technique releases the scar tissue adhesions to allow full lengthening of the muscle and to regain flexibility for functional use. In the DSTM component, the hamstring muscle group receives progressive dynamic techniques that work in synchrony as the muscle moves to the end ROM. In last stage of technique the muscle works eccentrically at its functional length and hamstring flexibility is optimised. For DSTM, it is hypothesized that incorporating active contraction into a massage protocol may increase muscle perfusion and decrease muscle stiffness.¹⁵

During Retro - walking, the stance begins with toe contact and ends with heel being lifted off the ground the normal eccentric contractions of the rectus femoris is replaced by propulsive concentric contraction, during the

activity at 0 degrees of inclination the knee was flexed approximately 31 degrees during initial contact. By mid-stance, the knee had extended position of approximately 14 degrees of knee flexion. period, the rectus femoris is also contracting, presumably Concentrically to assist with knee extension during backward walking, at the ankle, backward walking produced greater demands on dorsiflexion range of motion.

Active knee extension test was found as the gold standard test for the measurement of hamstring flexibility with intra-tester reliability (ICC) of 0.94 in a study done by **D. Scott Davis** on concurrent validity of four clinical tests.^{16, 17} The Y Balance Test is a dynamic stability test, it considered efficient and clinically applicable to provide an accurate assessment of the lower limb neuromuscular control.²¹

Sachin maghade et al (2018)¹⁵ compared immediate effect of DSTM and Active release technique on hamstring tightness in young adults. Hamstring tightness was assessed by sit and reach test.

After the treatment session again assessed hamstring flexibility and it shows improvement in flexibility of hamstring muscle. Both the technique shows equal effect on hamstring flexibility. **Suraj bhusal (2013)**¹⁶ when compared the DSTM and Active release technique for hamstring muscle flexibility and measured the Flexibility by AKE test, concluded that DSTM was effective as compared to Active knee release in improving knee extension test. **D Hopper et al (2005)**⁵ conducted study to compare DSTM and Classical massage technique on hamstring muscle flexibility in hockey players. By Passive straight leg raises (PSLR) and Passive knee extension (PKE) were used to measure indirect hamstring length before, following and 24-hour post intervention. It was concluded that both classic massage and DSTM had an immediate, significant effect on hamstring length in competitive female field hockey players. This all literature supports the present study.

Adilah Logde (2018)¹² studied the effect of retro - walking on hamstring flexibility in normal healthy individual. And concluded that Training protocol for 4 weeks, showed significant improvement in the hamstring flexibility. **Sami S. Alabdulwaha et al (2018)**¹⁹ studied an analysis of physical performance between backward and forward walking training in young healthy individuals and it shows the Backward walking training has been proved to be effective in improving the lower limb functional strength, aerobic and anaerobic capacities of the normal healthy individuals.

According to **whitely et.al (2009)**, an increase in length of muscle could be the possible reason for increase in the dynamic balance. As well as **costa 2009** had reported that stretching duration of 15 seconds hold may improve balance performance by decreasing postural instability. Here, intervention was effective in improving the flexibility which is reflected in AKE score and Retro – walking. Hence these shows strong correlation between improvement in flexibility and dynamic balance.

Further Recommendation

- Study can be done in other population
- Study can be done to
- Compare male and female.

Conclusion

The result of the present study showed that subjects were improved after the study intervention by improving flexibility and dynamic balance. Hence, concluded that the DSTM with Retro – walking was very effective, simple and easy to apply in Hamstring tightness subjects. So it can be implemented clinically as well.

Relationship between Perceived Stress and Coping among Caregivers of Patient with Schizophrenia

G.J. Sara Sapharina¹, G. Neelakshi²

¹Lecturer, ²Professor, Faculty of Nursing, Sri Ramachandra Institute of Higher Education & Research (DU)

Abstract

Background: Caring for a family member with a mental illness can be a strenuous and are responsible for day to day needs of the patient which is done meticulously with adequate supervision. The principal investigator intended to investigate the relationship between stress and coping among caregivers of patient with schizophrenia.

Materials and Method: A total of 75 caregivers were included in the study. The tools used for this study are Perceived Stress Scale (PSS) 14 items was developed by Cohen, S., Kamarck, T., & Mermelstein, R. (1983). and the coping checklist has 70 items developed by Rao, Subbhakrishna and Prabhu (1989). which cover a wide range of behavioral, cognitive and emotional responses that may used to handle stress.

Results: The study findings shows that there was a significant association between age and perceived stress and coping. Perceived stress had significant association with educational qualification, type of family and monthly family income. Coping had significant association with occupation, social support and relationship with the patient. This association is statistically highly significant at $p < 0.000$ level. The Study reveals a significant positive correlation between perceived stress and coping ($r = 0.529$).

Conclusion: The mental health care professionals to be actively involved in prevention of mental illness and promotion of mental health through the assessment of stress perceived by the caregivers of mentally ill in order to help them to be resilient and use more constructive coping strategies in stressful situations.

Keywords : *Perceived Stress, Coping, Caregivers, Schizophrenia*

Introduction

Mental illness is currently a major health issue worldwide, as it is increasingly found in the day-to-day life of the population and caregivers are generally vulnerable and unprepared to cope with the entire process of the illness and treatment². Schizophrenia is perhaps the most dramatic and tragic manifestation of mental illness known to mankind. The consequences of the

illness for the individual affected, his or her family, and society in general are distressing. In India, where about 1.1 billion people reside, the prevalence of schizophrenia is about 3/1000 individuals⁴. This illness places a huge burden not only on the individuals afflicted, but also the people closest to them, termed caregivers, who live with the individuals, interact with them regularly and lend a helping hand in their day to day activities. The impact of schizophrenia on families is often distressing and disruptive. The first signs in a family member appear as confusing changes in behavior. As a result of de-institutionalization and the increasing shift of psychiatric care to the community, the role of family caregivers has gained in importance. Today, after their relatively short stay at inpatient care, most schizophrenia patients are discharged to their homes in most cases this means back to their families¹⁰. Coping with stress is one of the

biggest health concerns and its effect can be different from one person to another. Stress is primarily a process of motivation since it requires some sort of adaptation (coping) to the demand or set of demands. The effect of stress is directly linked to coping. Caregivers are using a wide variety of coping strategies in both aspects. It was problem-focused coping strategies and emotion-focused strategies. While taking care of mentally ill-patient, caregivers are facing overburden, stress, anxiety and depression⁴. So, they are trying to adopt the situation, even though trying also, they don't have that much adequate coping abilities.

On the one hand, this development represents an immense progress for the patient because natural social integration into the family and partnership cannot be replaced by any psychiatric care service—regardless of how good it may be. On the other hand, living with a schizophrenia patient can put considerable burdens and restrictions on the rest of the family⁵.

Caregivers may experience considerable amount of distress themselves and may have a poor quality of life (QOL) if they are unable to cope with the stress associated with the process of caregiving. Accordingly, it is important to evaluate and understand the coping strategies used by the caregivers of schizophrenia⁴. Caring a mentally ill at home is a burden upon the family in terms of time, energy and finance, caring for a schizophrenic relative can increase the likelihood that the caregiver is at risk to develop symptoms of physical and mental illness³. Stressors are coped with based on how significant they are for those involved. Coping means trying to overcome that which is causing stress, and may refocus the significance associated with the difficulties, guide the individual's life and keep him/her physically, psychologically and socially healthy⁶.

Based on the past studies at various places done a research on distress, coping and stigma these outcome variables found to be affected during the caregiving process there by the caregivers tend use different coping strategies to overcome the stress and other problems related to caregiving. Hence, this study aims to examine the correlation between stress and coping among caregivers of patients with schizophrenia.

Objectives

1. Assess the level of stress and coping among caregivers of patients with schizophrenia
2. Correlate stress and coping among caregivers of patients with schizophrenia
3. Associate the stress and coping with selected background variables of caregivers of patients with schizophrenia

Method and Material

A descriptive research design was adopted for this study conducted at psychiatric ward and Psychiatric Outpatient department of Sri Ramachandra Hospital, Porur. The good infra structure facilities available in the psychiatric ward and Psychiatric Outpatient department which enabled the investigator to meet the participants easily. 75 caregivers of patient with schizophrenia were recruited to participate in this study. The research was conducted using self-rated questionnaires. The study included were between the age group of 21-50 years, available during data collection, able to read and write in English and Tamil, willing to participate in this study, both male and female caregivers, not on special treatments like diabetes mellitus, hypertension and other disease and must have been with the patient for more than 6 months. Purposive sampling technique was used to select the samples for this study. Researcher began the recruitment process by obtaining the names and identification numbers of the caregiver who is staying in inpatient and caregiver who is visiting outpatient department. Written informed consent was obtained before the distribution of questionnaires. The participation was completely voluntary. Subjects were given the freedom to withdraw from the study at anytime. Confidentiality of the collected data was maintained. Subjects were also informed that they can withdraw from the study at any point of time. Each questionnaire consisted of three sections namely sociodemographic profiles, perceived stress scale and coping checklist. This research was approved by Institutional ethical committee of Sri Ramachandra institute of Higher Education and Research (DU) and permission was obtained from the principal college of nursing, the Head of the Department of Psychiatry of Sri Ramachandra Hospital to carry out the study.

Background variables :

This section included information about the caregivers: age, sex, religion, marital status, place of residence, educational qualification, occupation , duration of caregiving, and relationship with the patient, social support, medical expenses.

Perceived Stress Scale

Perceived Stress Scale (PSS) was developed by Cohen, S., Kamarck, T., & Mermelstein, R. (1983). The tool consists of 14 items (0 = Never; 1 = Almost Never; 2 = Sometimes; 3 = Fairly often; 4 = Very often) Scores 0–18 show that there is low stress, 19–37 moderate stress, 38–56 high perceived stress. The reliability of the scale is $r = .78$.

Coping Checklist (CCL)

The coping checklist developed by Rao, Subbhakrishna and Prabhu (1989). The tool comprises of 70 items, which cover a wide range of behavioral, cognitive and emotional responses that may used to handle stress. The items are scored dichotomously in a yes/ no format. One point is given to every ‘yes’ responses. It consists of seven subscales; one of problem focused coping (problem solving), five of emotion focused coping (positive distraction, negative distraction, acceptance/ redefinition, religion/ faith and denial/ blame) and one of problem and emotion focused coping (social support seeking).

- A) Problem focused coping: 1-10
- B) Emotion focused coping:
 - Ø Positive distraction: 11-20
 - Ø Negative distraction: 21-28
 - Ø Acceptance and redefinition: 29-37

- Ø Religion/ faith: 38-45
- Ø Denial/ blame: 46-55
- C) Problem and emotion focused coping: 56-70

Scoring

SCORE	Category
0-23	Inadequate
24-39	Moderately adequate
40-60	Satisfied

The reliability of the scale is 0.74

Data Analysis

The collected data were analysed using descriptive and inferential statistics based on the objectives. Descriptive methods used were frequency, percentage, mean and standard deviation. Inferential statistics like Chi square and correlation coefficient etc. were used to assess the stress and coping among caregivers of patient with schizophrenia. The value of statistical significance was determined as $P < 0.05$.

Results

The study results showed that most of the caregivers 24(32%) were above 50 years and majority 66(88%) were female caregivers. In connection with place of residence 36(48%) of them from urban and having secondary education 34(45.3%). With regard to occupation 47(62.7%) of were home makers and 52(69%) were from nuclear family. The medical expenses for the patient was taken care by only caregivers 76%. Most of the patients were male 53.3%.

Table 1. Distribution of level of stress and coping among Caregivers of patient with schizophrenia

Level of Stress	Frequency	Percentage
Moderate Stress (19-37)	64	85.3
High Perceived Stress (38-56)	11	14.7
Overall Stress (Mean \pm S.D.)31.13 \pm 8.35		
Level of Overall Coping	Frequency	Percentage
Inadequate (0-23)	3	4.0
Moderately adequate (24-47)	61	81.3
Satisfied (48-70)	11	14.7
Overall Stress (Mean \pm S.D.)34.56 \pm 7.76		

Majority of the caregivers of patient with schizophrenia has moderate perceived stress 85.3% and the Overall Stress Mean \pm Standard deviation(SD) score is 31.13 \pm 8.35. Most of the caregivers of patient with schizophrenia has Moderately adequate 81.3 % coping and Overall Stress Mean \pm SD score is 34.56 \pm 7.76. Table 1

Table 2. Mean score of the Coping in various domain among Caregivers of patient with schizophrenia

Coping Domain	Descriptive statistics for coping score		
	Mean	Standard Deviation	Range (Min. – Max.)
Problem focused	52.13	16.94	30.0 – 90.0
Emotion focused:			
Ø Positive distraction	46.26	18.87	20.0 – 90.0
Ø Negative distraction	52.83	10.79	37.5 – 75.0
Ø Acceptance and redefinition	47.85	14.26	11.1 – 77.8
Ø Religion/faith	62.00	16.36	25.0 – 100.0
Ø Denial/blame	54.80	13.49	30.0 – 80.0
Problem and emotion focused	38.31	13.20	13.3 – 60.0

The coping strategy most often used by Caregivers of patient with schizophrenia was religion / faith and the least coping method used was Positive distraction. Table 2.

Table 3 Association between Overall Stress and Demographic variables among Caregiver(N=75)

Demographic variables	Number	Overall Stress Score		Overall coping Score	
		Mean (SD)	F- p value	Mean (SD)	F- p value
Age (years)					
a. 21 – 30	20	34.05 (9.57)	F = 4.545 P = 0.006 **	32.65 (6.39)	F = 12.354 P = 0.000 ***
b. 31 – 40	18	27.28 (8.30)		31.89 (4.21)	
c. 41 – 50	13	35.85 (6.39)		44.38 (9.50)

c. Husband	24	31.67 (7.40)		31.21 (6.94)	
e. None	16	27.31 (8.83)		33.38 (3.36)	
Family monthly income					
b. 2501 – 5000	10	39.40 (13.58)	F = 6.592 P = 0.002 **	34.20 (13.49)	F = 0.935 P = 0.397
c. 5001 – 7500	25	29.36 (8.28)		32.96 (3.03)	
d. > 7501	40	30.18 (5.20)		35.65 (7.98)	
Relationship with the patient					
a. Parents	38	29.71 (9.35)	F = 1.228 P = 0.306	32.63 (6.41)	F = 3.126 P = 0.031 *
b. Spouse	21	33.81 (7.67)		38.29 (10.20)	
c. Siblings	12	30.25 (3.79)		32.92 (3.09)	
d. Grandparents	4	33.25 (10.59)		38.25 (8.69)	

Note: * - P<0.05, ** - P<0.01, *** - P<0.001 level of significant

Perceived stress and coping were found to be significantly associated with a number of variables. The study shows that there was a significant association between age and perceived stress and coping.

Perceived stress had significant association with educational qualification, type of family and monthly family income. Coping had significant association with occupation, social support and relationship with the patient. This association is statistically highly significant at $p < 0.000$ level. Table.3

Table 4 Correlation between Overall Stress and Overall Coping (n=75)

Variable	r	p
Stress Coping	0.529	0.01 **

Note: *- $P < 0.05$, ** - $P < 0.01$, *** - $P < 0.001$ level of significant

Table 4 Show that there is a significant positive correlation ($r = 0.529$, $P = 0.01$) between stress and coping adopted by caregivers of patient with schizophrenia.

Recommendation for Future Study

1. Interventional based studies can be done to strengthen the physical health
2. A comparative study can be done to caregivers of patient with acute and chronic schizophrenia
3. A qualitative study can be conducted to explore psychosocial aspect of caregivers of patient with schizophrenia

Conclusion and Implication

The present study shows that moderate stress and moderately adequate coping strategies are adopted by the caregivers of patient schizophrenia. Perceived stress and coping were found to be significantly associated with a number of variables. The study shows that there was a significant association between age and perceived stress and coping. Perceived stress had significant association with educational qualification, type of family and monthly family income. Coping had significant association with occupation, social support and relationship with the patient. This association is statistically highly significant at $p < 0.000$ level. The Study reveals a significant positive correlation between perceived stress ($r = 1.0$) and coping ($r = 0.529$).

The findings of this study urge the mental health care professionals to be actively involved in prevention of mental illness and promotion of mental health through the assessment of stress perceived by the caregivers of mentally ill in order to help them to be resilient and use more constructive coping strategies in stressful situations. Caregiver Empowerment strategies can be highlighted in the nursing curriculum and can be thought at basic level and separate speciality or clinic which will be taken care by mental health Nurse for handling caregivers can reduce the further burden and stigma.

Ethical Clearance: Institutional ethics committee (IEC) of SRIHER (DU) approved the study

Conflict of Interest: Authors do not have anything to disclose and declare not conflict of interest.

Informed Consent: Informed consent was obtained from the participants with the option to withdraw them from the study at any time.

Source of Funding: None

Role of Diagnostic Laparoscopy in Chronic Pelvic Pain

Imreen Jamal¹, Devika Mor², Sukla Debberma²

¹Post Graduate, ²Assistant Professor, Department of Obstetrics and Gynaecology,
Saraswathi Institute of Medical Sciences Hapur (U.P)

Abstract

Introduction: Chronic pelvic pain is non cyclic pain of six or more months duration that localizes to the anatomical pelvis, anterior abdominal pain at or below umbilicus, the lumbosacral back, or the buttocks, and is of sufficient severity to cause functional disability or lead to medical care¹Chronic pelvic pain is one of the most common gynecological symptoms and one of the most important in terms of social costs

Objective: To study the role of diagnostic laparoscopy in chronic pelvic pain. To compare the findings of laparoscopy in patients of chronic pelvic pain and patients undergoing routine laparoscopic tubal ligation.

Materials and Method: This study was conducted at Saraswathi institute of medical sciences(HAPUR,U.P) during the period between January 2018 to December 2019. Total 110 cases were enrolled.55 cases who had been suffering from chronic pelvic pain for 6 months (or more) were taken as study group-(A).55cases without any symptoms who underwent laparoscopic sterilization were taken as control group-(B).

Results: 10.60% cases with chronic pelvic pain had normal findings whereas 25.25% cases were normal on laparoscopy. Endometriosis was suspected in 7.27% cases on ultrasonography, where as it was confirmed on laparoscopy in 18.1%.Similarly PID was suspected in 12.72% cases whereas it was confirmed on laparoscopy in 14.54% cases.

Conclusion: In our study we could conclude that the treatment of cases of chronic pelvic pain post diagnostic laparoscopy are adhesiolysis, endometriotic cyst removal, Ovarian Cystectomy and Hydrosalpinx.

Keywords: endometriosis, cystectomy, laproscopy

Introduction

Chronic pelvic pain is non cyclic pain of six or more months duration that localizes to the anatomical pelvis,anterior abdominal pain at or below umbilicus,the lumbosacral back, or the buttocks,and is of sufficient severity to cause functional disability or lead to medical care¹Chronic pelvic pain in one of the most common gynecological symptoms and one of the most important

in terms of social costs.Chronic pelvic pain (CPP) is a common symptom and a difficult condition to manage specially during adolescence.Too often the physical signs are not specific².Chronic pelvic pain is more common than its cause being diagnosed. There is no correlation between pain and amount of tissue damage. It affects many women and leads to significant impairment in their quality of life. Howard conducted a study and found that 61% of the patients with chronic pelvic pain were found to have endometriosis, pelvic adhesions, pelvic inflammatory disease and ovarian cysts. women with primary infertility who were asymptomatic went for laparoscopy found the similar results in 28% of this study group. Therefore, the researcher stated that laparoscopy should be the last method used in etiology research and concluded that laparoscopy is still controversial. Our study aimed to investigate the causes for chronic

pelvic pain using laparoscopy and compare the results with asymptomatic patients undergoing laparoscopic sterilization.

Material and Method

The prospective study was conducted at Saraswathi institute of medical sciences, Hapur the period of 2018-2019.

Total 110 cases were enrolled. 55 cases who had been suffering from chronic pelvic pain for 6 months (or more) were taken as study group-(A). 55 cases without any symptoms who underwent laparoscopic sterilization were taken as control group-(B).

Selection Criteria :

cases from age 20-40 years

Exclusion Criteria

(1) Women with morbid obesity, severe hypertension, coronary artery disease, acute bronchiolitis, chronic obstructive lung disease.

(2) Women having systemic illness, cardiac illness, bleeding disorders and coagulopathies

(3) Women having local abdominal infection and PID

Method of Analysis

McNemar Chi square test.

The test is applied to a 2×2 contingency table, which tabulates the outcomes of two tests on a sample of n subjects, as follows.

Results

A Prospective study was conducted in Saraswathi institute of medical sciences, Hapur from 2018-2019. Total 110 cases were enrolled. 55 cases who had been suffering from chronic pelvic pain for 6 months (or more) were taken as Study Group (Group A). 55 cases without any symptoms who underwent laparoscopic sterilization were taken as Control Group (Group B).

Following results were obtained.

In present study, the mean age for the study group

(Group A) was found to be 28.6 years with a range of 20- 40 years while for the control group (Group B) mean age was found to be 30.3 years with a range of 18-40 years. Both Groups were comparable as far as age is considered.

The incidence of chronic pelvic pain was found to be highest in Gravida 2 (41.81%) and lowest in infertility (1.87%). In control Group (B), maximum number of cases were Gravida 2 (45.45%). In current study also in Group A maximum number of patients were Educated till primary level (47.27%) followed by education till secondary level (41.81%). Similarly in group B also maximum number of patients were educated till primary level (45.45%) followed by education till secondary level (41.81%).

Incidence of history of previous Surgery was found to be 27.27% in Group A as compared to 38.18% in Group B. Maximum number of cases reported with Chronic pelvic pain lasting from 6-9 months (63.64%). Only one patient (1.22%) reported with Pain lasting from 22 months. Mean duration of chronic pelvic pain before laparoscopy was found to be 10.49 ± 7.46 months.

In current study Maximum number of cases (56.36%) had no other symptoms associated with Chronic pelvic pain. Associated vaginal discharge was present in 20.00% cases 14.54% cases had dysmenorrhea and 7.27% patients presented with dyspareunia. One patient (1.81%) had associated infertility. 36.36% cases with chronic pelvic pain had normal per vaginal findings. 14.54% cases each had fornix tenderness and retroverted uterus. In 12.72% cases endometriosis was suspected.

In Present study 60% Cases with chronic pelvic pain had normal USG findings. 12.72% women had free fluid in POD. Adnexal cyst was present in 7.27%, Hydrosalpinx was present in 5.45% cases. TO mass and fibroid could be visualized in 3.63% cases and cases of chronic pelvic pain endometriosis 18.18% was the most common pathological finding found on laparoscopy and 7.27% cases had Endometriosis in Group B. chronic pelvic inflammation found in 14.54% in Group A and 9.09% in Group B Adhesions were found in 9.09% cases in Group A and 7.27% cases in Group B. These patients Underwent adhesiolysis.

In our study we found that normal per vaginal findings were found in 72.72% cases of chronic pelvic pain whereas on laparoscopy normal finding were seen only in 25.45%. PID could be diagnosed in 14.54% cases which was confirmed by laparoscopy. Endometriosis could be diagnosed clinically only in 3.63% cases as compared to 18.18% cases diagnosed by laparoscopy.

Extraperitoneal gas insufflation occurred in 3.63% cases of Group A and 5.45% cases of Group B. Shoulder pain and wound infection occurred in one case each (1.81%) in Group A. No other complications occurred in both the groups.

In cases of chronic pelvic pain adhesiolysis was done in 9.09%, Endometriotic cyst removal was done in 9.09%. Ovarian Cystectomy was done in 7.27% and Hydrosalpinx removal was done in 5.45% cases.

Discussion

The present study was a prospective randomized controlled study conducted at department of Obstetrics and Gynecology, Saraswathi institute of medical sciences, hapur. The purpose of the study was to analyse the role of diagnostic laparoscopy in chronic pelvic pain. The study was carried out from 2018- 2019. Total 110 cases were enrolled. 55 cases who had been suffering from chronic pelvic pain for 6months (or more) were taken as study group (A). 55 cases without any symptoms who underwent laparoscopic sterilization were taken as control group (B). Different authors have different definitions of chronic Pelvic pain. Howard redefined the definition of chronic pelvic pain in 2001 as pain lasting for 6months or more.

Demographic Characteristics

Age

In present study, the mean age for the study group (Group A) was found to be 28.6 years with a range of 20- 40 years while for the control group (Group B) mean age was found to be 30.3 years with a range of 18- 40 years. Both Groups were comparable as far as age is considered. Demir et al (2011) conducted a study on 44 patients with chronic pelvic pain as Study Group and 31 patient who had laparoscopic tubal ligation as control Group.

Gravity

In present study the incidence of chronic pelvic pain was found to be highest in Gravida 2 (41.81%) and lowest in infertility (1.87%). In control Group (B), maximum number of cases were Gravida 2 (45.45%). In a study by Hebbler and Chawla (2005) in cases of chronic pelvic pain, Parity ranged between 0 to 8 and nine women were Nulliparous²². 86 patients of chronic pelvic pain was studied by Zubor (2000) in which mean parity was 1.6, ranging from 0 to 5.¹²

Education

In current study also in Group A maximum number of patients were Educated till primary level (47.27%) followed by education till secondary level (41.81%). Similarly in group B also maximum number of patients were educated till primary level (45.45%) followed by education till secondary level (41.81%).

Socioeconomic Status

In current study, the incidence of chronic pelvic pain in Group A was found to be highest in Middle class (58.18%) and lowest in lower class (12.72%). Similarly in Group B maximum number of cases were found to be in middle class (74.54%) and lowest in lower class (3.63%). There was no statistically significance difference between the two Groups as far as socioeconomic status was concerned.

History of Previous Surgery

In present study Incidence of history of previous Surgery was found to be 27.27% in Group A as compared to 38.18% in Group B. Hebbler et al (2005) studied 86 patients of chronic pelvic pain and found that nineteen patients had history of previous surgery and nine women had history of first trimester MTP. Eight had undergone D and E.²⁰

Duration of Pain

In Present study maximum number of cases reported with Chronic pelvic pain lasting from 6-9 months (63.64%). Only one patient (1.22%) reported with Pain lasting from 22 months. Mean duration of chronic pelvic pain before laparoscopy was found to be 10.49±7.46 months. In a study by Zupor (2000), 86 Patients with chronic pelvic pain were studied and average pain

duration was found to be 11.5 months.¹⁹

OTHER SYMPTOMS ASSOCIATED WITH CPP

The long duration pelvic pain symptomatology when subjected to proper clinical assessment, investigations and procedural interventions commonly concluded and correlated in the past with the clinical conditions like dysmenorrhea, dyspareunia, abnormal uterine bleeding, infertility, vaginal discharge, etc. In Study by Hebbert et al (2005) in cases of chronic pelvic pain, most patients presented with acyclic abdominal pain (79.1%) followed by congestive dysmenorrhea (26.7%).¹⁰

PER VAGINAL FINDINGS

In present study 36.36% cases with chronic pelvic pain had normal per vaginal findings. 14.54% cases each had fornix tenderness and retroverted uterus. In 12.72% cases endometriosis was suspected. In a Study by Hebbert (2005) 86 patient of chronic pelvic pain was studied. Pelvic tenderness was found to be most common (27.9%), followed by fornix fullness (15.1%). 61.6% women did not reveal any significant pathology.²¹

USG

Compared to laparoscopy ultrasound has a little or no value in diagnosing endometriosis but it can help in making or excluding the diagnosis of an ovarian endometrioma. The typical ultrasound features of an endometriotic ovarian cyst in premenopausal women were described as "ground glass echogenicity of cyst fluid, one to four locules and no solid parts". In Present study 60% Cases with chronic pelvic pain had normal USG findings. 12.72% women had free fluid in POD. Adnexal cyst was present in 7.27%, Hydrosalpinx was present in 5.45% cases. TO mass and fibroid could be visualized in 3.63% cases.

COMPARISON OF LAPAROSCOPY FINDING IN BOTH GROUP

In present study cases of chronic pelvic pain endometriosis 18.18% was the most common pathological finding found on laparoscopy and 7.27% cases had Endometriosis in Group B. chronic pelvic inflammation found in 14.54% in Group A and 9.09% in Group B Adhesions were found in 9.09% cases in Group A and 7.27% cases in Group B. These patients

Underwent adhesiolysis. Ovarian cyst was more common in Group B 14.54% as compared to Group A 7.27% in these cases cystectomy was done. Fibroid and TO mass found in 3.63% in Group A whereas in Group B. 63% cases had small fibroid and no TO mass found in Group B. Fibroid was medically managed whereas in TO mass antibiotic was given.

COMPARISON OF PER VAGINAL FINDINGS WITH LAPAROSCOPY

In our study we found that normal per vaginal findings were found in 72.72% cases of chronic pelvic pain whereas on laparoscopy normal finding were seen only in 25.45%. PID could be diagnosed in 14.54% cases which was confirmed by laparoscopy. Endometriosis could be diagnosed clinically only in 3.63% cases as compared to 18.18% cases diagnosed by laparoscopy. Hebbert & Chawla (2005) showed there was better correlation between abnormal preoperative pelvic examination and abnormal laparoscopic findings¹⁴.

COMPARISON OF USG FINDINGS WITH LAPAROSCOPY.

In our study Normal findings were seen in 60% cases of chronic pelvic pain on USG as compared to 25.14% cases on laparoscopy. Endometriosis could be diagnosed only in 7.27% cases on USG as compared to 18.18% cases on laparoscopy. Study by Zubor et al (2000) revealed pelvic organ pathology in 88.4% of patients and the most frequent finding was endometriosis (31.4%). Preoperative Ultrasonic examination with pelvic pathology findings performed in 36 patients and laparoscopy correlated with ultrasonographic findings in 31 (81.6%)¹⁵.

COMPLICATIONS OF LAPAROSCOPY

In present study Extraperitoneal gas insufflation occurred in 3.63% cases of Group A and 5.45% cases of Group B. Shoulder pain and wound infection occurred in one case each (1.81%) in Group A. No other complications occurred in both the groups. Kang et al (2007) studied 3068 cases of chronic pelvic pain. In their study 85 complications associated with diagnostic laparoscopy including 3 cases of major complications.

Mortality

Vilos GA et al (2007) in their study concluded that bowel and visceral injuries from Veress needle insertion or trocar placement may occur. They may or may not be seen at the time of the injury. The delayed presentation contributes to the morbidity and mortality of bowel injuries. The incidence of bowel injury is between 0.04% and 0.5%.

Operative Procedures

In cases of chronic pelvic pain adhesiolysis was done in 9.09%, Endometriotic cyst removal was done in 9.09%. Ovarian Cystectomy was done in 7.27% and Hydrosalpinx removal was done in 5.45% cases. Demir F et al (2012) conducted a study of 44 patients with chronic pelvic pain out of which they performed adhesiolysis and ovarian cyst removal in 8 patients, endometrioma excision was done in nine cases and lastly salpingectomy and endometrioma cauterization was done in one patient each¹⁸

Conclusion

In this study we can conclude that laparoscopy is an excellent tool in evaluation of patients with pelvic pain, because diagnosis and often treatment can be accomplished in one sitting, without subjecting the patients to exploratory laparotomy. In the study population per vaginal finding found to be normal in majority of cases and endometriosis found to be the most common laparoscopic finding and almost undetectable on per vaginal examination.

Determination of Occlusal Splint Thickness for TMJ Derangement based on MRI- A Review

Jennifer Suhasini S¹, Kathiravan Selvarasu²

¹Undergraduate Student, Saveetha Dental College, Saveetha University, Chennai, India,

²Department of Oral Surgery, Saveetha Dental College, Saveetha University, Chennai, India

Abstract

Aim: To review the accuracy of thickness of occlusal splints, used for particular temporomandibular joint derangement based on MRI findings.

Objective: To understand the various aspects of managing Temporomandibular joint derangement and the accuracy of MRI scans in determining the thickness of occlusal splints.

Background: Occlusal splints are a standard method to treat the pain associated with temporomandibular joint derangement. They can be further classified into three groups on the basis of function: stabilization splints, distraction splints and anterior repositioning splint. MRI findings help clinicians in complete assessment and determining the strategy of management of TMJ dysfunction. Its main advantages include: higher accuracy of the anatomical structures, detection of changes in soft tissue, necrosis, edema, is a noninvasive procedure and does not offer exposure to ionizing radiation.

Reason: To gain knowledge and understanding about the occlusal splint thickness for particular temporomandibular joint derangement based on MRI findings.

Keywords : *Anatomy, Occlusal splint ,temporomandibular joint , Magnetic resonance imaging , TMJ dysfunction, TMJ derangement*

Introduction

Temporomandibular joint is one of the most complex joints which mainly helps in mastication, phonetics and opening and closing of the mouth. Temporomandibular joint is located at the front of the middle ear with a disc which has the capacity to bear pressure separating the mandible from the skull (temporal bone). To diagnose temporomandibular joint disorders it is important to understand the anatomy of the joint. It is a complex compound diarthroidal synovial joint. It can be structurally and functionally be divided into a lower and upper compartment. The lower compartment comprises of tissues that surround the condyle and articular disc. The disc is bound to the condyle by lateral and medial ligaments of the disc and is responsible for the rotational movement of the TMJ. This is the hinge movement of a joint similar to an elbow joint . The upper compartment comprises of the condyle-disc complex functioning against the surface

of the mandibular fossa. The disc is not attached to the fossa so translation movement can occur. This is the sliding component of the joint. Temporomandibular joint dysfunction is a term which encompasses a range of clinical disorders the masticatory musculature and/or the temporomandibular joint [1]. Proper recording of the clinical findings and diagnostic data is important for diagnosing for the temporomandibular joint disorder. Many surgical or non-surgical treatments have been reported to restore the correct disc-condylar relationship. Some researchers have advocated the use of an adjunctive pumping and hydraulic pressure technique and reported great improvement in clinical symptoms and a higher incidence of disc reduction [2,3]. Previously, many surgical or nonsurgical methods of treatment have been reported to restore a correct disk-condylar relationship. Mandibular protrusive repositioning splint therapy (often called a disk repositioning splint) is one type of treatment and to gain a “normal” disk-condyle relationship [4,5]. Only about 3%-7% of the patients with

pain related to TMJ seek medical attention [6,7]. Many surgical or non-surgical treatments have been reported to restore the correct disc-condylar relationship. The disorders of temporomandibular joint can be mainly categorised into myofascial pain, intracapsular problems and Arthritis or degenerative joint disease.

Myofascial pain is the most commonly encountered type of temporomandibular joint disorder. It involves the muscles of the facial complex as opposed to the joint. The condition usually manifests as frequent headaches and sore muscles, as well as pain when chewing. It can affect people of all ages, most commonly seen in children. It is sometimes accompanied by frequent headaches. Degenerative joint disease usually manifest in individuals with Osteoarthritis, Rheumatoid arthritis and Psoriatic arthritis.

The Temporomandibular joint is one of the last diarthrodial joints to develop in utero and does not emerge in the facial region until the 8th week of intra uterine life. The maxilla and mandible, muscles of mastication, and biconcave disc develop from the first branchial arch through the 14th week of intra uterine life. The TMJ is considerably underdeveloped at birth in comparison to other diarthrodial joints making it susceptible to perinatal and postnatal insults. The joint continues to develop in the early childhood years as the jaw is utilized for sucking motions and eventually masticatory function.

A diagnostic accuracy of 95% has been established comparing postmortem cryosections to previous TMJ-MRI (Westesson et al. 1985; Tasaki and Westesson 1993), whereas arthrography shows merely 83% accuracy combined with videofluoroscopy (Westesson and Bronstein 1987) and is associated with radiation exposure, invasive and may be complicated by allergy, infection and pain. Magnetic resonance imaging (MRI) is the most widely used and is diagnostic technique of choice. MRI has a promising approach in dentistry. MRI has become one of the best methods in recent decades as it is non-invasive, and uses non-ionizing radiation and its ability to differentiate between the soft and hard tissues. In the recent past the MRI has found widespread usage in dentistry despite the high cost, differential and limited accessibility of the MRI equipment. MRI being a non-invasive technique with the use of non-ionizing radiation

has been used in diagnosis of TMJ disorders, soft tissue pathologies and bone topography for the placement of the dental implants [8]. MRI demonstrates the internal structure of TMJ with great precision and contrast resolution. The MRI findings in terms of functional aspect of disc position, degree of disc displacement, disc deformity, joint effusion, and osteoarthritis has been used for the prediction of Temporomandibular Dysfunction (TMD) symptoms in patients with and without TMJ disorders. The anterior disc displacement as seen in the MRI correlates well with the presence and absence of the symptoms of TMJ disorders. The findings are in agreement with study conducted by Kumar et al., [9].

The main purpose of this review is to gain knowledge and understanding about the occlusal splint thickness for particular TMJ derangement based on MRI findings and to determine its efficiency when compared to the other imaging modalities that are available.

Magnetic resonance imaging(MRI) :

MRI is an advance imaging modality which uses mainly non-ionising radiation. It was initially called as Nuclear Magnetic Resonance Imaging after its early use for chemical analysis. The word 'Nuclear' was the omitted as it instigated a fear among the public that there might be something radioactive involved in the procedure. Historically, Block and Purcell discovered the nuclear magnetic resonance (NMR) phenomenon. However, it was only in 1970s that Damadian applied the techniques of NMR to imaging. MRI has been applied successfully in imaging and diagnostic measures of the hearts, brain, spine, peritoneal and retroperitoneal structures, as well as in musculoskeletal anatomy and pathology. Previous studies also state that MRI has been of high diagnostic importance and an effective imaging modality for meniscal, ligamentous, osseous, and articular structures of various joints of the body [10,11].

Applications of MRI in dentistry:

MRI plays a significant role in diagnosis and management of diseases. It has many advantages when compared to the other modalities. In dentistry, MRI has been found to be extremely useful in eliciting the exact anatomical location and extent of the disease. Moreover, ultrasonography cannot show the associations between

a tumor and adjacent structures, and thus, it is indicated to use MRI whenever tumors are big or judged to have higher possibility for malignancy or intruded to adjacent structures^[10]. The other advantage of MRI is the lack of ionizing radiation and excellent soft-tissue contrast. Involvement of condyle of mandible is not that apparent on radiographs or computed tomography images. MRI has an important role in examining the true extent of the lesions as there may be slight changes in areas which looks normal on radiographs or CT. Magnetic resonance imaging (MRI) is considered the “reference standard” for imaging of the temporomandibular joint (TMJ)^[11,12] MRI along with gadolinium (GAD) enhancement has been proven to detect inflammation in the temporomandibular joints of adults^[13] and early inflammatory changes in other joints, such as the knees and wrists^[14,15] before the onset of morphologic changes detected by other forms of conventional radiography.

Occlusal splint therapy

Occlusal splints are usually designed to cover the occlusal surfaces of the teeth resulting change in occlusion to be responsible in part or in total for the therapeutic effect. There are various types of occlusal splints (bite plates or intra-oral appliances of variable designs used in the management of TMD) and described in the literature. There is one type of occlusal splint called as the stabilization splint. It is also called as the Tanner appliance, the Fox appliance, the Michigan splint, or the centric relation appliance. The stabilization splint is made up of acrylic and helps in providing a temporary and removable ideal occlusion (ideal contact between the teeth for the muscles and the temporomandibular joints)^[16,17]. After few visits, the muscles of mastication tends to relax and thereby reducing stress on the temporomandibular joint. This usually takes about 2-3 months^[17]. Other than the stabilization splint, there are other types of splint namely: Non occluding splints, soft splints and bite plates. Hard splints along with counselling have proven to show the best results.^[18] Previous studies about the comparison of the efficiency of the various types of splints have shown different results. Dao et al. conducted random controlled studies which showed that there was no significant clinical difference between the types of splints^[19]. Whereas Rubinoff et al.^[20] found a minor difference between their efficiencies and Ekberg et al^[21] reported that the stabilizing splint

had significantly better than the other types.

Effectiveness of MRI in occlusal splint therapy

The temporomandibular joint can be demonstrated using both sagittal and coronal imaging planes. The sagittal plane helps in the recognition of the relative position of the disc and condyle in a antero-posterior direction. The coronal sections of the MRI demonstrates the medial and the lateral

position of the disc relative to the condyle.^[22] In the sagittal section, a normal disc has a biconcave lens-like configuration with the posterior band at a 12 o'clock position in relation to the condyle. An anteriorly displaced disc has its posterior band forward of the 12 o'clock position and usually has an alteration in disc configuration. The moderately low signal intensity of the disc is usually well demarcated from the relatively higher signal structures such as the lateral pterygoid fat pad and bilaminar zone posteriorly^[23]. In the coronal plane, the disc has an arc-shaped configuration with its medial and lateral margins attaching to the medial and lateral poles of the condyle respectively^[23]. It has also been found that with MR images internal disc displacement appears to be present in asymptomatic individuals while in other patients who are symptomatic, there is often a lack of evidence of internal disc displacement. This suggests that TMJ dysfunction may be caused by factors which are independent of internal disc displacement or may act in combination with it^[24]. The introduction of MRI as a diagnostic tool for Temporomandibular joint dysfunction enables the clear visualization of the static position of the disc relative to the condyle^[25].

Conclusion

The temporomandibular joint is one of the most complex joints which has been very difficult to understand and treat is the past. MRI is an advance imaging modality which uses mainly non-ionising radiation. Occlusal splints are usually designed to cover the occlusal surfaces of the teeth resulting change in occlusion to be responsible in part or in total for the therapeutic effect. Thus Magnetic resonance imaging can be used as a efficient diagnostic tool for dysfunction involving the temporomandibular joint. However, further studies have to done for further

Ethical Clearance: The study was carried after ethical approval from The Department of Research, Saveetha Dental College and Hospitals, Saveetha University.

Clinical Profile of Amblyopia in Young Adults

Girish A. Gadre¹, Surabhi Khandelwal²

¹Associate Professor, ² Resident, Department of Ophthalmology, Krishna Institute of Medical Sciences, Karad, Krishna Institute of Medical Sciences “Deemed To Be University”, Karad, Maharashtra, India

Abstract

Aim: To study clinical profile of amblyopic patients in relation to refractive status, socio economic status, use of glasses and social impact on society.

Results: Hypermetropies improving to 6/9 is 13% and myopes improving with spectacles are 45% and mixed astigmatism 69%. Most common age group for detection of amblyopia in young adults is 21-30 years(47.1%) with predominance of female(55.7%) belonging from middle class families (81.4%) having studied mostly from Government Marathi medium school(45.7%) with previously not using given glasses(57.1%) and with taken amblyopia of only (7.1%) and with spectacles maximum correction with mixed astigmatism (54.2%) between 6/36-6/9 in right eye (43%) and in left eye (30%) .

Interpretation: Lack of school screening programs and awareness for health check-up delays the diagnosis of amblyopia leading to non-improvement of vision and due to lack of knowledge and social stigma girls especially avoid wearing glasses even after prescribing leading to amblyopia.

Conclusion: School health camps, proper health education, timely examination, and proper use of spectacles is must.

Keyword: Myopics: M ,Hypermetropics: H

Introduction

Amblyopia is a “developmental defect of spatial visual processing that occurs in the central visual pathways of the brain.” It presents most dramatically as loss of visual acuity in one or, rarely, both eyes, but amblyopia is more than this; certain forms of amblyopia also present with diminished contrast sensitivity, Vernier acuity, grating acuity, and spatial localization of objects. These defects may be explained by the mechanism of lack of use of an eye because of media opacity or extreme refractive errors that cause a chronically blurred image to form on the fovea of that eye; however, the cause of amblyopia in an eye that has strabismus is not as straightforward and is the result of abnormal binocular interaction¹.

Types of amblyopia²: -

- 1.Strabismic
- 2.Stimulus deprived

3.Anisometric

4.Bilateral ametropic

5.Meridonal

- In the absence of an organic lesion, a difference in best corrected VA of two Snellen lines or more (or >1 log unit) is indicative of amblyopia³.
- Visual acuity in amblyopia is usually better when reading single letters than letters in a row. This ‘crowding’ phenomenon⁴ occurs to a certain extent in normal individuals but is more marked in amblyopes and must be taken into account when testing preverbal children⁵.

Aim: -

To study clinical profile of amblyopic patients in relation to refractive status, socio economic status, use of glasses and social impact on society.

Inclusion Criteria: -

- Patients of age <30 years
- Visual acuity less than log mar 0.2 in one eye or both eyes without any organic cause

Exclusion Criteria: -

Vision affected due to any cause anterior segment or posterior segment cause

Study Design: -

- Hospital based longitudinal non-randomized study.

Materials and Method

- All the young adults up to the age of 30 years coming to Department of ophthalmology, KIMS DU Hospital, Karad were screened out by taking visual acuity and correction with refraction for amblyopia over a period of 1 year from August 2018 to July 2019.

SAMPLE SIZE: -

- 70 patients were enrolled

Observations and Results**Observation:**

TABLE 1 This table shows that sample size of 70 cases when given the vision correction with refraction the result comes out to be 43 patients that is 50.2% of patients had spherical correction and amongst them 26 patients that is 37.1% are myopic correction and 17 patients that is 24.2% are hypermetropia correction.

This table also shows about the cylindrical correction which is minimum only in 8 patients that is 11.4% and remaining 19 patients that is 27.14% patients have mixed correction.

- **TABLE 2** : Taking results from above table now further extending our discussion regarding correction and its visual acuity relation, this table will discuss about relation of hypermetropies with its visual acuity correction.

Amongst the hypermetropies that is total 17 patients so here n=17, out of them 10 patients power for refraction

comes out to be between (+2.5- +5) and amongst the 10 patients only 3 patients that is 30% have full correction but 60% that is 6 patients have correction till log mar 0.4-1 and only 1 patient could have correction till log mar 1.

Rest of 23.07% patients have correction till +2 in which 75% patients have good visual correction ranging from log mar 0-0.3 .

- **TABLE 3:** This table gives you the Relation of myopia with visual acuity correction. The total patients which comes out to be myopic are 26 that is 37.1% and amongst them 76.8% Patients who had myopic correction had spectacles of more than -2 power

- Precisely, 38.4% patients' spectacles range from 2-5sph and amongst them 70% patients their visual acuity correction is up to logmar0-logmar 0.3 which is almost full correction and rest 38.4% patients have spectacles no. more than 5sph for which spectacles correction for 50% patients is > logmar1.

- Rest 23% patient having spectacles correction <-2 visual correction ranges from log Mar 0-logmar0.3

- **Conclusion—low myopic number have good spectacles correction but very high myopic number do not have full correction even if higher refraction is given.**

- MOST OF AMBLYOPIC MALE (42.3%) AND FEMALE (53. %) ARE MYOPIC.

TABLE 4: RELATION OF AMBLYOPICS WITH THE TYPE OF SCHOOL STUDIED FROM:

This table shows that out of 70 students, 56 students have studied from Marathi medium government school and 10 from semi -government and only 4 from private school.

TABLE 5:

This table shows the relation between the type of school to its regular school health check-up , and the socio economic status regarding glasses advised and still not using.

The results shows that out of 56 marathi medium students only 23 had school health check up , and

amongst them only 20 were advised glasses previously and only 10 students were using it .

Semi-govt schools are better in position as out of 10 , 9 had school check up and 5 were advised previously to wear glasses but only 4 are wearing.

Private schools are conducting school check ups regularly as all 4 had previously school health check up done and all 4 are wearing spectacles though not regularly.

Table 1: With N=70, Patients with Different Spectacles Number are as Follows:-

SPHERICAL -MYOPIA	26(37.1%)
SPHERICAL -HYPERMETROPIA	17(24.2%)
CYLINDRICAL	08(11.42%)
MIXED	19(27.14%)

TABLE 2:

SPECTACLES	+2	+2.25 - +5	> +5	Total
NO. OF PATIENTS	4(23.5%) Log0-0.3 0.4-1 >log1 3(75%) 0(0%) 1(25%)	10(58.8%) Log0-0.3 0.4-1 >log1 3(30%) 6(60%) 1(10%)	3(17.6%) Log0-0.3 0.4-1 >log1 2(66.6%) 1(33.3%) 0(0%)	17

Relation of HYPERMETROPIA with visual acuity (N=17)

TABLE 3: Relation of MYOPIA with visual acuity (N=26)

SPECTACLES	-2	-2.25 -- -5	>-5	Total
NO. OF PATIENTS	6(23.07%) Log0-0.3 0.4-1 >log1 5(83.3%) 1(16.6) 0	10(38.4%) Log0-0.3 0.4-1 >log1 7(70%) 2(20%) 1	10(38.4%) Log0-0.3 0.4-1 >log1 2(20%) 3(30%) 5(50%)	26

TABLE 4: REALTION OF AMBLYOPIC STUDENTS WITH THEIR TYPE OF SCHOOL

	MARATHI MEDIUM	SEMI- GOVT	PRIVATE SCHOOLS
N=70	56	10	4

	SCHOOL CHECK UP	ADVICED GLASSES (FROM SCHOOL / OUTSIDE)	WEARING GLASS
MARATHI (56)	23	20	10
SEMI GOVT (10)	9	5	4
PRIVATE (4)	4	4	4

Discussion

- This study is conducted on all the young adults up to the age of 30 years coming to Department of ophthalmology, KIMSDU Hospital, Karad by taking visual acuity and correction with refraction for amblyopia over a period of 1 year from August 2018 to July 2019. This study was approved from institutional ethics committee. This study is done with the primary aim to see clinical profile of amblyopic patients in relation to refractive status, socio economic status, use of glasses and social impact on society.

- In this study the sample size of 70 cases when given the vision correction with refraction the result comes out to be 43 patients that is 50.2% of patients had spherical correction and amongst them 26 patients that is 37.1% are myopic correction and 17 patients that is 24.2% are hypermetropia correction.

- And this study also shows about the cylindrical correction which is minimum only in 8 patients that is 11.4% and remaining 19 patients that is 27.14% patients have mixed correction.

In our study , we now further extending our discussion regarding correction and its visual acuity relation, our further discussion is about relation of hypermetropies with its visual acuity correction.

Amongst the hypermetropies that is total 17 patients so here n=17 , out of them 10 patients power for refraction comes out to be between (+2.5- +5) and amongst the 10 patients only 3 patients that is 30% have full correction but 60% that is 6 patients have correction till log mar 0.4-1 and only 1 patient could have correction till log mar 1.

- Rest of 23.07% patients have correction till +2 in which 75% patients have good visual correction ranging from log mar 0-0.3 .

- In our study we also get the relation of myopia with visual acuity correction.

- The total patients which comes out to be myopic are 26 that is 37.1% and amongst them 76.8% Patients who had myopic correction had spectacles of more than -2 power

- Precisely, 38.4% patients' spectacles range from 2-5sph and amongst them 70% patients their visual acuity correction is up to logmar0-logmar 0.3 which is almost full correction and rest 38.4% patients have spectacles no. more than 5sph for which spectacles correction for 50% patients is > logmar1.

- Rest 23% patient having spectacles correction <-2 visual correction ranges from log Mar 0-logmar0.3

- In our study we also correlate with the type of school which is in direct proportion to its socio-economic status like Marathi medium and semi-govt school students are considered from lower status and private school students are higher socio-economic students.

- This study shows that out of 70 students, 56 students have studied from Marathi medium government school and 10 from semi-government and only 4 from private school.

- In this study shows the relation between the type of school to its regular school health check-up, and the socio-economic status regarding glasses advised and still not using.

- The results show that out of 56 Marathi medium students only 23 had school health check-up, and amongst them only 20 were advised glasses previously and only 10 students were using it.

- Semi-govt schools are better in position as out of 10, 9 had school check-up and 5 were advised previously to wear glasses but only 4 are wearing.

- Private schools are conducting school check-ups regularly as all 4 had previously school health check-up done and all 4 are wearing spectacles though not regularly.

Conclusion

- This study gives us following points to note down:

- 1) Spherical number is more common than mixed or astigmatism

- 2) Myopia is more common than hypermetropia (37.73%)

- 3) Amongst demographic distribution male and female both have more percentage of myopic number.

- 4) 58.8% of hypermetropies have spectacles number between 2-5sph with visual acuity improving up to logmar0.4-1

- 5) Low myopic number have good spectacles correction but very high myopic number do not have full correction even if higher refraction is given.

- MOST OF THE AMBLYOPIA DETECTED PATIENTS (70%) ARE FROM MARATHI MEDIUM SCHOOL AND FROM MIDDLE CLASS FAMILIES WHERE ROUTINE SCHOOL HEALTH CHECK UPS ARE NOT CONDUCTED PROPERLY SO NOT DIAGNOSED ON TIME, ONLY 30% OF STUDENTS WHO STUDIES IN ENGLISH MEDIUM PRIVATE SCHOOLS HAVE PROPER SCHOOL HEALTH CHECK UP SO WERE DETECTED FOR AMBLYOPIA.

- OUT OF THOSE ONLY 10% STUDENTS WERE WEARING SPECTACLES SO HAD FULL CORRECTION, BUT STUDENTS BELONGING TO MIDDLE CLASS OR LOW SOCIO-ECONOMIC STATUS WHO HAD LESSER AWARENESS ABOUT THE DISEASE HAD NOT WORE GLASSES DUE TO WHICH THEY DONOT HAD FULL CORRECTION.

- OUR STUDY FOCUSES ON THE FACT:

Early detection of amblyopia by proper school health check-up and then treatment of amblyopia and also to avoid those factors causing amblyopia since childhood like proper use of glasses.

Why treats amblyopia? ⁶ Direct benefits include potentially improved stereoptic appreciation and the occasional realignment of strabismic eyes with attainment of improved visual acuity. For most patients, the creation of a better-sighted⁷ “spare tire” should trauma or disease claim the sound eye is all that can be promised logically. Of interest is a study that showed a threefold greater risk of loss of the sound eye if the other is amblyopic.

Ethical approval: All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

- **Source of Funding:** Self

- **Conflict of Interest:** None.

Estimation of Salivary Heat Shock Protein 70 (HSP70) in Children With Early Childhood Caries

Jithin George¹, Manju R², Amitha M Hegde³, Priyal Sheth⁴, Lekshmi R Suresh⁵

¹Post Graduate, ²Professor, ³Head of the Department, ⁴Post graduate, ⁵PhD Scholar, Department of Pediatric and Preventive dentistry, A B Shetty Dental College, Mangalore

Abstract

Aim: To assess the heat shock protein levels in children with early childhood caries (ECC) and to compare its levels before and after caries control procedure.

Method: 36 children who visited the department of Pediatric and Preventive dentistry and the school dental clinic associated with the department who fit in the inclusion criteria were divided into three group of 12 each. Group 1 was caries free children, group 2 and group 3 were mild to moderate and severe ECC group respectively. Saliva samples were collected pre and post caries control and were analysed for heat shock protein 70 levels. The results were statistically analysed.

Results: The mean value of the salivary Hsp70 levels estimated in the control group of children was 5988.88 pg/ml (± 358.613 pg/ml). Similarly, mean values for the pre-treatment salivary Hsp70 levels estimated in the mild to moderate ECC and S-ECC study groups were 5419.97 pg/ml (± 159.472 pg/ml) and 5982.99 pg/ml (± 610.675 pg/ml), respectively. The post-treatment salivary Hsp70 levels estimated in the mild to moderate ECC and S-ECC study groups were 5148.34 pg/ml (± 365.063 pg/ml) and 5240.55 pg/ml (± 257.023 pg/ml) respectively. Intra-group comparison between the pre-treatment and post-treatment salivary Hsp70 values in the mild to moderate ECC study group showed a statistically significant reduction. The intra-group comparison between the pre-treatment and post-treatment salivary Hsp70 values in the S-ECC study group also showed a statistically significant reduction. Comparisons showed statistically significant difference between control and mild to moderate ECC groups, and between mild to moderate ECC and S-ECC groups, but not between control and S-ECC groups.

Conclusion: With the available evidence and the results obtained in our study, it is safe to assume that levels of salivary Hsp70 can be used as an indicator for dental treatment prognosis and evaluation of efficacy of newer treatment protocols in children.

Keywords: Heat shock proteins, HSP 70, Early Childhood Caries

Introduction

Heat shock proteins (Hsp) are said to be omnipresent in the cells of all the organisms¹. It is now known that an array of stresses, which may be metabolic or environmental in nature such as free radicals, microbial infections, ischemia, surgical stress, hormones induce the production of these proteins.

Of all the heat shock proteins, Hsp70 is said to be stress inducible.² Hsp70 present in saliva can

be considered as a stress marker in poor oral health conditions.³ Hsp70 has been demonstrated as an efficient stress marker within cells in conditions of poor oral health. It has also been shown to increase in the saliva of patients with high caries activity which can be credited to the increased bacterial load resulting from high DMFT score of the individual. The bacterial load is a stressful event which leads to the production of Hsp70 for immune response.⁴

A significant relationship has been established

between caries activity and salivary levels of Hsp70 in adults. However, the correlation between the salivary Hsp70 levels and early childhood caries (ECC) and the effects of treatment of these carious lesions on salivary levels of Hsp70 has also not been studied extensively. Hence, the present study was undertaken to analyse the salivary Hsp70 levels in children with varying severity of ECC and the response to caries control.

Methodology

A total of 36 children in the age group of 36-72 months of age who reported to the Department of Pediatric and Preventive dentistry and school dental clinics associated with the department were selected for the study. The inclusion criteria were a group of 12 caries free children (group 1), children with mild to moderate ECC (group 2) and children with severe ECC (group 3).

Children on any medications, those with systemic and metabolic disorders, those with special health care needs, uncooperative and those without consent from parents were excluded from the study.

Convenience sampling was used for selecting the study subjects and informed consent was obtained from the parents of these children. A thorough dental examination was done to record the oral findings of each patient and profile maintained with the details. Baseline salivary samples were collected from all the three groups.

12 children with no clinical signs of dental caries and who were of good oral hygiene were recruited as controls. Expecting a dropout rate in group 2 and group 3, pre-treatment salivary samples of 16 children in group 2 and 48 children in group 3 were collected prior to caries control procedures. Upon completion of the study, a total of 3 patients from group 2 and 34 patients from group 3 who failed to appear and follow through with study protocol were excluded.

The children from group 2 and group 3 were treated according to the requirement for caries control, which included advice on oral health education, diet counselling, oral prophylaxis, restorative procedures, topical fluoride application and pulp therapy. The patients in group 2 and group 3 were recalled after a period of 21 days and post caries control saliva sample was collected. The collected saliva samples in all the

groups was analysed for heat shock protein 70 (Hsp70) levels by using salivary ELISA kit.

The saliva samples from each child was collected by spitting method. Each child was given sterile 10ml containers and asked to spit into it till a sufficient amount of saliva (minimum 3 ml) was collected. These samples were then labelled and transported to the lab, where they were processed and stored in vials under -80°C temperature, until the ELISA was performed.

Statistical Analysis

Descriptive statistics were tabulated in the form of mean and standard deviation. Inferential statistical analyses were performed for comparison between the data obtained from children in all the groups using paired t-test for intra-group comparison and ANOVA test for inter-group comparison, following the test for normality (Shapiro-Wilk test). The level of significance was fixed at $\alpha=5\%$.

Results

The mean value of the salivary Hsp70 levels estimated in the control group of children were 5988.88 pg/ml (± 358.613 pg/ml). Similarly, mean values for the pre-treatment salivary Hsp70 levels estimated in the mild to moderate ECC and S-ECC study groups were 5419.97 pg/ml (± 159.472 pg/ml) and 5982.99 pg/ml (± 610.675 pg/ml), respectively. The post-treatment salivary Hsp70 levels estimated in the mild to moderate ECC and S-ECC study groups were 5148.34 pg/ml (± 365.063 pg/ml) and 5240.55 pg/ml (± 257.023 pg/ml), respectively.

The pre-treatment inter-group comparison of the mean salivary Hsp70 levels between the control group and the two study groups showed statistically significant differences. [Figure 1]. Post-hoc Tukey test for pairwise comparisons showed statistically significant differences between control and mild to moderate ECC groups, and between mild to moderate ECC and S-ECC groups. There were no statistically significant differences between control and S-ECC groups [Table 1].

The post-treatment inter-group comparison of the mean salivary Hsp70 levels between the control group and the two study groups showed statistically significant differences. [Figure 2]. Post-hoc Tukey test for pairwise comparisons showed statistically significant differences

between the control and ECC groups, and between the control and S-ECC groups, but not between the ECC and S-ECC groups [Table 2].

Intra-group comparison between the pre-treatment and post-treatment salivary Hsp70 values in the mild to

moderate ECC study group was done using paired t-test, which showed a statistically significant reduction [Table 3]. Similarly, the intra-group comparison between the pre-treatment and post-treatment salivary Hsp70 values in the S-ECC study group also showed a statistically significant reduction [Table 4].

Table 1: Pairwise comparisons of control and pre-treatment salivary Hsp70 levels(pg/ml) using post-hoc Tukey test:

Group pairing	Mean	SD	M. Diff	95% CI	p-value (adj)
Control (No ECC) vs Mild to Moderate ECC (ECC)	5988.88	358.613	568.916	150.969, 986.864	0.005
	5419.97	159.472

p-value > 0.05 not significant; p-value < 0.05 significant								

Discussion

Heat shock proteins (Hsp), also called “stress proteins” are produced by a family of highly conserved genes.¹ There are two forms of heat shock proteins—one which is constitutively expressed, and the other that is induced in stressful conditions.⁵ Hsp70 kDa family (HSPAs) present in the saliva⁶ are known to perform defence functions by binding to several cariogenic bacteria. These chaperones also tend to attach themselves onto the hydroxyapatite crystals of the tooth surface. They have also been shown to perform a role in the acquired pellicle formation, and subsequent drop in critical pH which inhibits bacterial colonisation.^{7,8} Considering its role in the oral defence mechanism, in the present study we analysed the levels of HSP in early childhood caries patients before and after caries control. The study groups selected for our study were mild to moderate ECC and severe ECC or (S-ECC). This grouping provided an insight into not only the variation

of expression of Hsp70 levels in relation to severity of carious lesions (intergroup comparisons), but also the effect of caries control protocol on Hsp70 on intra group comparison.

Considering the caries control protocol, time required for stabilization of oral biofilm following restorative procedures⁹ and duration of time for setting in of new routines in oral hygiene practices, a post treatment follow-up time period of 21 days was adopted. This is in accordance with observations made by Marsh PD,¹⁰ Van Der Hoeven JS et al.,¹¹ and Winnier JJ et al.¹²

Saliva was collected only once for the control group samples with good oral hygiene, since our aim was to establish a reference range for comparison of Hsp70 levels in this age group. The pre-treatment saliva samples of the drop-outs were discarded. Data was tabulated with the estimated salivary Hsp70 levels in those patients who complied and completed the caries control protocol

set out for the study. The dropout rates in the study were 18.7% in the mild to moderate ECC group and 70.8% in severe ECC group. This observation is in line with previous literature where it has been documented that parental avoidance behavior¹³ and lack of understanding the seriousness of dental caries implications on general health and well-being on the child¹⁴ plays a major in continued severity of ECC.

The mean salivary Hsp70 levels in the control group was 5988.88 pg/ml. This value is comparable to the serum Hsp70 levels obtained in adults in a study by (Hegde MN et al). However, the baseline pre-treatment values in both our study groups with dental caries significantly were lower than those of the control group ($p=0.001$) [Table 1]. This is in contrast to the observations made by (Hegde MN et al), where the Hsp70 levels in saliva were significantly greater in adults with poor oral hygiene. However, the measured salivary Hsp70 values were comparable between the control and S- ECC in the pre-treatment saliva samples ($p=0.999$). The possible rationale behind the observations remain unclear due to lack of substantial evidence in literature.

Similar observations were also made between the control and post-treatment salivary Hsp70 levels in the study groups ($p<0.001$). Pairwise post-hoc comparison using Tukey test showed statistically significant decrease in the salivary Hsp70 levels from control to ECC ($p<0.001$) and from control to S-ECC ($p=0.001$) as well. However, there was an increase in the mean post-treatment salivary Hsp70 estimations from ECC to S-ECC study samples, which was not statistically significant. These observations are contrary to the expected trend and as in the inter-group comparisons using the pre-treatment salivary samples, the possible rationale behind them remain elusive. We hypothesize based on the conclusions made by Fabian T.K. et al¹⁵ that the role of these molecular chaperones under pathological conditions are “Janus-faced”. This further adds to the evidentiary base that ECC by itself should be viewed as a pathologic condition that is predisposed by dietary, nutritional, environmental and microbiologic mechanisms already established in literature.^{16,18}

The estimation of Hsp70 molecular chaperones was also expected to throw light on the efficacy of the caries control protocol adopted in our study. Intra-group

comparison using salivary Hsp70 yielded statistically significant reduction from pre- treatment to post-treatment intervals in ECC study groups ($p=0.007$) (Table 3) This reduction was more statistically significant in the S-ECC study group ($p<0.001$) as compared to mild to moderate ECC group. These trends are in line with the prognostic role of HSPAs suggested by Tavassol F. et al¹⁷, considering the increased severity of dental disease in the S-ECC group.

Our study involved the children with early childhood caries whose caries activity was the only variable considered to create a change in Hsp70 expression, while other stresses can also induce the same. it would have been beneficial to re-assess the Hsp70 levels in saliva of control subjects after the 21-day follow up period set for this study. This would have provided better reference for the variability that should be accounted for in healthy controls with no apparent dental disease as Hsp70 levels are prone to changes due to any stress that the body encounters

With the available evidence and the results obtained in our study, it is safe to assume that the levels of salivary Hsp70 can be used as an indicator for dental treatment prognosis and evaluation of efficacy of newer treatment protocols in children. However, its role in disease etiopathogenesis remains unclear.

Pre-Processing and Image Segmentation Techniques

Jyothisri.V

Assistant Professor, Hindu College of Engineering & Technology, Guntur, Andhra Pradesh

Abstract

Image are known as image analysis. First step in image analysis is to segment an image. Image segmentation is a key step for partitioning an image into several segments to find objects, borders & meaningful objects for an image. In image processing for any application when the work is done on an image, the initial step is to divide the image in order to solve the difficulty. Divided images are widely used in a multitude of different applications like density of tissue volumes, pathology, Satellite imaging, Extracting features & recognizing objects, treatment planning & few computer integrated surgeries etc.

This paper gives an overview of different image pre-processing techniques & image segmentation techniques. Before we do segmentation of an image, we need to pre-process an image to **remove noise**.

Index Terms— *Image segmentation, Pre-processing technique, image analysis,*

Introduction

Digital image processing is common subject in today's period. Digital image processing basically refers to processing of 2-D picture by digital computer. Sujatasaini et.al.^[8] Proposed, several image segmentation Techniques, significantly on edge-based and region- based segmentation. Segmentation action means segmenting image into parts that relate different parts of object. Each pixel in an image is given a number from the below categories.

Well quality segmentation has, Pixels in the same classification are of same grayscale of different values & shape a related area. Adjacent pixels in complicated groups have dissimilar values^[14].

If the segmentation component procedure had done well, then all other stages in the analysis of the image becomes simple.

Image Segmentation is separated into two forms, specifically considering the properties of an image^[8].

Discontinuity method: Approach of this method is, image is separated focused on few sudden variations depending on the intensity level of images. The key highlighting in the approach is to distinguish isolated points, lines and edges in image.

Similarity based method: In this approach, Principle is focused on partitioning an image into related regions based on set of prewritten rule (on similarity). Types of methods are

Thresholding

Region growing

Region splitting & merging

Clustering

Procedure in this method is, image is divided into set of groups having similar features based on some predefined rule^[6].

Method

Pre-processing methods

Pre-processing an image spots at selectively removing the redundancy present in the captured images without affecting the overall process^[7].

Steps in Pre-Processing

Image Resizing

This is done by performing the process of interpolation. It is a process which re-samples the image

to determine values between defined pixels. Thus, resized image consists more (or) less pixels contrast to original image. The intensity values of added pixels are obtained through interpolation if resolution of image is increased.

Filtering

Due to the movement of camera some disturbances are created in the image such as random image noise, intensity non-uniformity traces.

Low pass Filtering

LPF resists the edge and sharp details in an image. They are achieved by placing the rate of each pixel in an image with neighborhood mean of gray levels identified by filter mask.

By employing linear low pass filter, the edges are not maintained, but noise reduction is achieved by blurring an image, which results in loss of fine details. Filter mask used for LPF is

1/9

1	1	1
1	1	1
1	1	1

LPF Mask

High Pass Filter

Purpose of HPF is to restrict the slowly varying characteristics like background and sharp details. This filter mask includes negative coefficients at the center and positive coefficients in the outer part. Sum of entire coefficients in HPF mask is '0'. Mask for HPF is

1	1	1
1	-8	1
1	1	1

HPF Mask

When the above mask passes over a constant (or) slowly varying region, output is '0' (or) very small. Result of this is an edge enhanced image over a dark background.

Detection of discontinuities in a digital image

Point Detection

Finding of isolated points in image due to noise is done by the following mask.

-1	-1	-1
-1	8	-1
-1	-1	-1

Mask for point detection

When the above mask is placed on an image it covers 9 pixels in an image. Average response of the mask is calculated as

$$R = \frac{1}{9} [W_1Z_1 + W_2Z_2 + \dots + W_9Z_9]$$

$$= \frac{1}{9} \sum_{i=1}^9 W_i Z_i$$

Where W_i = coefficient in the mask

Z_i = gray level value of pixel in the image under

-1	2	-1
-1	2	-1
-1	2	-1

Vertical Mask

-1	-1	-1
2	2	2
-1	-1	-1

Horizontal Mask

-1	-1	2
-1	2	-1
2	-1	-1

+45° Slanting line

2	-1	-1
-1	2	-1
-1	-1	2

-45° Slanting line

If the horizontal mask is shifted around an image, the response value is larger to lines that are oriented horizontally. If all the masks are applied to an image and the responses calculated are denoted as R_1, R_2, R_3 and R_4 For all $j \neq i$, at some point, the particular point is additional accurately connected with the line in the path of mask.

Edge Detection

Edges located as considerable local distortions in the intensity of an image. They occur on the borderline in the middle of two different portions in image. The result of edge detection is to know main types like corners, lines and curves in image. Intensity changes in an image are due to assorted material events.

Dark Background having Light Stripe **Light Background having Dark Stripe**

Fig: 1. Detection of edges using derivatives.

Gray level sketch is negative at the foremost edge of the change, positive at the trailing edge and zero in the area of constant gray area in first derivative.

For the part of the change associated with the light side of the edge, the second derivative is negative, positive for the portion of the transition in cooperated along the dark side of the edge and zero for pixels lying exactly at the bottom.

On observation the first derivative calculation is used to detect the presence of edge in the image and second derivative shows whether the edge pixel are positioned along dark side (or) light side of the edge .

Edge detection with Gradient Operator

Gradient is a vector that has certain magnitude and direction. It is measurement of change in image function

$f(x,y)$ in X(across/columns) and Y (down/rows). This is the first derivative for enhancement of an image. Gradient operator is represented as

$$\nabla f = \begin{pmatrix} G_x \\ G_y \end{pmatrix} = \begin{pmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \end{pmatrix}$$

$$\text{Mag} (\nabla f) = [G_x^2 + G_y^2]^{1/2}$$

$$\text{Dir} (\nabla f) = \tan^{-1} (G_y/G_x)$$

Angle relative to x-axis is measured

The direction of an edge at (x, y) is at right angles to the gradient vector direction at the particular point.

Robert Cross-Gradient operator

In [1] it is proposed that Robert is 2-D mask which can be used when there is a need of diagonal edge direction.

$$G_x = \frac{\partial f(x,y)}{\partial x} = W_9 - W_5$$

$$G_y = \frac{\partial f(x,y)}{\partial y} = W_8 - W_6$$

W_1	W_2	W_3
W_4	W_5	W_6
W_7	W_8	W_9

3X3 Image Region

-1	0	0	1
0	1	-1	0

Roberts Cross Masks [1]

Roberts Cross Masks [1]

Edge detection using Prewitt operator

For edge detection Prewitt is used which can be also called as discrete differentiation operator. It finds two types of edges.

- a) Horizontal edges
- b) Vertical edges

Masks for edge detection are well-known as derivative masks. Derivatives masks should have the following properties.

- 1) Inside the mask will be opposite symbol
- 2) Size of mask is zero
- 3) Higher value means better edge detection

-1	0	1
-1	0	1
-1	0	1

Vertical Direction Mask

The above mask finds the edges in vertical direction and it is because of the zero columns in the vertical direction, when we convolve mask on an image, it will give vertical edges in an image.

Working Procedure

By adding to an image this mask highlights the vertical edges. It just functions like the first derivative and measures the pixel intensity difference in an edge field. As the middle column is zero it will not be the original value of the image, but the difference between the right and left pixel values around the edge is calculated.

Horizontal Direction Mask

The mask shown above will find edges in horizontal direction. Due to the presence of these zero columns in horizontal direction, when convolving the above horizontal mask onto image given, it tells us horizontal edges in image.

-1	-1	-1
-1	8	-1
-1	-1	-1

Sobel operator

This is same as prewitt operator, can be called as derivative mask and the purpose is for edge detection. For prewitt’s operator the response to diagonal elements is weak but it is not so weak for sobel operator since it gives better weights to the points nearer to the point (x,y) which we had considered^[12]. A Sobel operator provides both differencing and smoothing effect

1	2	1
0	0	0
-1	-2	-1

Mask for computing G_x

Component using sobel operator

-1	0	1
-2	0	2
-1	0	1

Mask for computing G_y

Component using sobel operator

$$G_x = (W_7+2W_8+W_9) - (W_1+2W_2+W_3)$$

$$G_y = (W_3+2W_6+W_9) - (W_1+2W_4+W_7)$$

Where W’s are the gray pixels rates of covered by the masks at any position in image.

Laplacian operator

The former operators are named the first difference operator. Laplacian then again, is a second differential operator ^[12]. Laplacian operator is given by

$$\nabla^2 f = \frac{\partial^2 f}{\partial^2 x} + \frac{\partial^2 f}{\partial^2 y}$$

$$\nabla^2 f = 4W_5 - (W_2 + W_4 + W_6 + W_8)$$

For a 3X3 mask, regularly used practice is

0	-1	0
-1	4	-1
0	-1	0

Laplacian Operator

The vital necessity in identifying the Laplacian

is, it knows about coefficient presence .Presence of coefficient related with the center pixel is positive and the coefficient related with the external pixel is negative. Kernel that are regularly utilized are

-1	-1	-1
-1	8	-1
-1	-1	-1

Laplacian Operator

With diagonal components

Region-based segmentation

Edges based method searches the object borders and then locate the object itself by packing them in. This region based technique is a reverse approach it starts in the image and starts expanding outward until it go off to the object boundaries. Two strategies are explained under this Region-based segmentation.

- 1) Region Growing
- 2) Region splitting and merging

Region Growing

This method gives explanation about pixels which are close together which have comparative gray level values.

Procedure: This approach develops the information that pixels which are close together have similar gray values [6][9].

Procedure begins with a single (seed) & adds new pixels slowly

- 1. Select pixels for seed.
- 2. Find neighboring pixels which are very similar to the seed and add them
- 3. Continue with the step 2 for every recently new pixels and conclude the method if no further pixels are

added.

Region splitting & Merging

The Procedure for this method is to partition the image initially into random collection; unconnected areas until the region become small enough for segmentation. Region splitting & merging visually is executed using the theory based on quad-tree data.

Following diagram shows division based on quad tree.

Fig: 2 Division of region w.r.to quad tree

Steps for region splitting and merging are.

Let A signify complete region of image & pick a predicate P.

- 1. Each region is divided into four disjoint quadrant which satisfy the condition $P(A_i) = \text{false}$.
- 2. Join any adjacent regions A_j & A_k which follows

$$P(A_j \& A_k) = \text{true}.$$

- 3. Stop the method if no more merging or splitting is likely to happen.

Conclusion

Various segmentation methods are mentioned in this paper. These techniques can be used in different fields like restorative picture applications, for object recognition & detection. Depending on the application, distinctive segmentation strategy can be selected.

Cryotherapy in Knee Osteoarthritis

Jyoti¹, Shabnam Joshi², Meenakshi Bagri²

¹Ph.D Scholar, ²Assistant Professor, Department of Physiotherapy, Guru Jambheshwar University of Science & Technology, Hisar

Abstract

Knee osteoarthritis (OA) is the most common chronic musculoskeletal disorder characterized by pain and disability. It is the most common form of degenerative joint condition that affects synovial joints and does not cause any systemic involvement. It is an inflammatory and degenerative disorder which leads to joint cartilage destruction and ultimately joint deformity. The treatment aims to decrease the presenting symptoms of the disease leading to slow down the progress of the disease. Various treatment options are available for the treatment of OA that includes superficial heat or cold, obesity control, physical exercises and medications. Cryotherapy which is a non-invasive treatment option is widely used in various musculoskeletal disorders to control pain, inflammation and oedema. It is a safe and inexpensive treatment option that can be used alone or in conjunction with available treatment options. This article intends to focus on the role of cryotherapy in Knee Osteoarthritis.

Keywords- Cryotherapy, osteoarthritis, heat therapy

Introduction

Osteoarthritis is the most prevalent musculoskeletal degenerative disease that affects synovial joints¹ without causing any systemic involvement and associated mortality². OA knee is an inflammatory disorder that causes degeneration and destruction of joint cartilage ultimately leading to deformity of joint³. Approximately, 6% of adult population suffers from knee osteoarthritis and their prevalence increases with each and every decade of life.⁴ Lawrence et al⁴ demonstrated that the estimates of knee OA (symptomatic and radiographically) in 45 years and older is 16.7%³ having more women's ratio than men's ratio⁴. Pain is the first presenting symptom, subsequently leading to joint changes and progressive decreased function¹. With the progression of OA, pain becomes continuous in nature, with severe impairment of the affected joint⁵. Patients often complain of tenderness, joint stiffness, muscle weakness, limited joint range of motion, crepitus, osteophytes, deformity, impaired proprioception and disability. Because of the joint instability & weakness of thigh muscles, patients may experience serious effect on ADL's^{6, 7}. The mechanism of OA and its progression in the joint is not completely unknown because of which, it is not a curable disorder. Various options of treatment are available for

OA including superficial heat or cold, obesity control, physical exercises, medications, corticosteroids and joint replacement⁹. Among different physical agents, this study focuses on the cryotherapy. Cryotherapy is a non invasive treatment commonly used in different musculoskeletal disorders to control pain, inflammation and oedema^{10, 11, 12}. It is an inexpensive, easy to use and relatively safe method both for the patients and medical professionals. It can be used alone or in association with other available treatment options^{11, 13, 14}. Various international guidelines also recommend that cryotherapy is a treatment option for Knee OA^{15, 16}. There are certain risks/ADRs associated with drug therapy & surgical treatment but there are no side effects associated with superficial heat or cold therapy^{17, 18}. In spite of limited knowledge about the heat therapy, cryotherapy or contrast therapy for the treatment of knee OA, superficial heat or cold is most commonly used as "first-line" treatment option for the treatment of knee pain^{5, 19}. Porcheret et al¹⁹ investigated approx 201 patients with older knee pain. Out of which, about 84% of patients were reported to take superficial heat therapy or cryotherapy, as a self-started treatment option. Cetin et al⁴ found that the cryotherapy or superficial heat can be used with TENS, diathermy or ultrasound that leads

to symptomatic relief and functional improvement in patients of OA knee. It is found to be very helpful in improving patient's physical activity level, decreasing fatigue in patients.

Objective

The current study focuses on the role of cryotherapy in knee osteoarthritis.

Methodology

A comprehensive computerized search performed on google scholar, pubmed etc.

(Publication from 2007-2019) is used.

Search strategy

Knee osteoarthritis

Cryotherapy

Mechanism of action of cryotherapy

Cryotherapy acts by lowering the tissue temperature to achieve an analgesic effect by withdrawing heat from the body (Knight, 1995). Cryotherapy is used to reduce swelling and inflammation and to relieve spasm in clinical practices (Bleakley, 2004). Cold therapy influences the proprioceptive receptors located in the soft tissues and It is recommended that if cryotherapy influences the proprioception of body, then use of cold can also influence the receptors of both muscle spindles and Golgi tendon organs (GTO) that affects the muscle length and muscle tension respectively (Proske, 2005; Proske and Gandevia, 2012).

Different modes/methods of cryotherapy

Cold therapy includes whole body therapy (dry air with temperature ranges between -80°C to -110°C for about 1–3 min), ice packs or cold gel packs application, cold-water immersion (CWI), other local or general cold application or ice massage used for therapeutic purposes²⁰. From the different modes of cryotherapy, CWI is the most popular method used in clinical practices²¹. Various studies have investigated²²⁻²⁸ and reviewed²⁹⁻³³ the effects of cold water immersion technique for decreasing the muscle soreness and for speeding up the recovery of skeletal muscles. However, the evidence regarding the cold water immersion

and the cold therapy in general, for speeding up the recovery of skeletal muscles remains equivocal. In metabolically stressful activities, cold therapy helps to decrease hypoxic stress, reduce the reactive oxygen species (ROS) generation and subsequent damages³⁵⁻³⁶. It also decreases oedema and soreness by inducing vasoconstriction^{34, 37, 38}, decreases exercise induced metabolic stress locally in skeletal muscles leading to high rate aerobic energy transformation and heat generation^{39,40} by decreasing intramuscular temperature and metabolism³⁴. All these factors lead to an increase in generation of reactive oxygen species (ROS), that are highly reactive in nature and that denatures the nucleic acid structure, lipids and proteins, leading to alteration in the muscle cell structures including both sarcolemma⁴¹ and the excitation–contraction coupling system⁴². Due to the damage, this coupling system impairs the kinetics of contraction, while alteration in sarcolemma makes the muscle fibres more permeable and more prone to injuries⁴³. Cold therapy can act as a temporary analgesic^{20,33,44-46}. Because of anti-inflammatory effect, cryotherapy can reduce the stimulus that initiates the pathways that causes secondary muscle damage^{36,46}.

Summary of included study's characteristics

Adriana Lucia Pastore Silva, Daniela Mayumi Imoto, Alberto Tesconi Croci (2007) studied Comparison of cryotherapy, exercise and short waves in treatment of OA knee. The aim of this study was to compare the physical exercise, cold therapy and short waves in patients. And found that **the ice and kinesiotherapy was the most appropriate intervention options for the relief of pain.**⁴⁷

Carolina Carreira Breda, Lucas Ogura Dantas et al (2019) studied that Short-term cryotherapy did not substantially reduce pain and had unclear effects on physical function and quality of life in people with knee osteoarthritis: a randomised trial. The study included various RCTs with enshrouded allotment and blinded assessment of outcome variables. Cryotherapy was used as crushed ice packs with slight compression to the knee for experimental group. The control group received sham packs that were filled with sand. The result suggested that cryotherapy was not better intervention than sham for relieving the pain or for improving function and QOL in patients with knee. Although, in clinical practice

cryotherapy is considered as a commonly used treatment option.⁴⁸

Craig R Denegar, Devon R Dougherty et.al (2010) studied, Preferences for heat, cold or contrast in patients with knee osteoarthritis affect treatment response. The study checked the effectiveness for superficial heat, cold, or contrast therapy in knee osteoarthritic patients. The study found that superficial heat or cold provides greatest relief and after that contrast is also treatment option⁴⁹.

Tomasz Chruściak (2016) studied, Subjective evaluation of the effectiveness of whole-body cryotherapy in patients with osteoarthritis. The study was done to investigate the effect of whole-body cryotherapy in osteoarthritis. The result of the study suggested that the Whole-body cryotherapy plays important role in relieving both degree and frequency of pain in patients.⁵⁰

Manal E. Fareed and Amal E. Shehata (2013) studied, Effect of Cold, Warm or Contrast Therapy on Controlling Knee Osteoarthritis Associated Problems. This study investigated the Comparative effect of cryotherapy, heat therapy and contrast therapy in decreasing problems with knee OA and the result of study suggested that all the methods of therapy for knee pain results in improvement of pain and symptoms but the most acceptable method of therapy for symptomatic relief is contrast therapy⁵¹.

Mariusz P. Furmanek, Andrzej Sobiesiak, Kajetan J. Słomka1, et al (2018) studied, The Effects of Cryotherapy on Knee Joint Position Sense and Force Production Sense in Healthy Individuals. The study aimed to check the effectiveness of local cryotherapy on the force production sense (FPS) and knee joint position sense (JPS). The results of the study recommend that local cold therapy does not affect proprioception of healthy knee joint⁵².

Discussion

The objective of the study was to reveal the role of cryotherapy in OA knee. The timely application of both superficial heat therapy and cryotherapy is quite safe treatment option. There are only few studies that demonstrate whether superficial cold, heat or contrast therapy are better options to control osteoarthritis¹¹.

In spite of limited knowledge about the effect of heat, cold or contrast modalities in the treatment of knee OA, superficial cold or heat is frequently used, and is assumed as “first-line” treatment option for the treatment of knee pain.^{8,9} Additionally, Cetin et al⁸ found that the application of cold or superficial heat in combination with SWD, TENS or ultrasound results in both symptomatic relief and functional improvements in individuals with osteoarthritis.

Conclusion

Cryotherapy (cold therapy) is a non-invasive intervention which is commonly used in several musculoskeletal disorders for decreasing pain, inflammation and oedema¹⁰⁻¹². It is assumed as inexpensive, safe and easy to use method for both medical professionals and for patients. Cryotherapy can be used alone or in conjunction with various therapies^{11,13,14}. Warren et al. (2004) suggested that after 30 min of cryotherapy application (crushed ice) intra-articular temperature of patient is reduced by 3.3°C, whereas surface temperature of patient's body is decreased upto 21.4°C. Myrer et al. (1998) suggested that after 20-min of treatment with cryo (crushed ice) there is reduction in the intramuscular temperature by 7.1 ± 4.1°C. The above investigations resulted that cryotherapy was effective to provide coolness to both the muscles and the knee joint.

Assessment of the Prevalence of Kidney Stone Disease: A Structural Equation Model

K. Lokesh¹, K. Alagirisamy², P. Manigandan¹, D. Pachiyappan¹

¹Research Scholar, ²Assistant Professor, Department of Statistics, Periyar University, Salem-11, Tamilnadu, India

Abstract

Background : This study entitled “Assessment of the Prevalence of Kidney Stone Disease: A Structural Equation Model” deals with the Kidney stones are of many types and have many causes, treatment depends on the size, nature and cause of the stone. Calcium and Oxalate stones are the most common varieties. Changes in the daily intake of Sodium, Protein, Calcium, Oxalate and fluid will slow stone formation. Dietary restrictions slow but do not cure kidney stones.

Materials and Method : A retrospective cross-sectional study design was conducted. In this study, we have discussed the detection of kidney stones using structural equation modeling (SEM).

Results : In general, structural equation models with scores for these measures of 0.9 or above are considered to have acceptable model fit and RMSEA is also a very popular measures this value is 0.19. This value indicates a not good model fit.

Conclusion : There is strong evidence that there is no association between stone size, age, sex, height, BMI, and hydronephrosis.

Keywords : *Structural equation modeling (SEM), Confirmatory factor analysis (CFA), Patients with Kidney stone disease, Stone size and Demographic variables.*

Introduction

Kidney stones are one of the everyday problems people face. Increasing the prevalence of Chronic Kidney Disease (CKD) is an important public health problem, especially for the elderly. The burden of CKD is severe in terms of medical costs and shortened health care, and people with CKD are at increased risk of end-stage kidney disease, cardiovascular disease, and premature death^{1,2}. Kidney stone disease is a devastating disease, with recurring pain episodes, surgical intervention, drug use and risk of side effects, all of which affect the quality of life of patients³. Early detection of decreased renal function can help prevent kidney disease from progressing to kidney failure, cardiovascular events, and early death^{4,5}. Although CKD risk factors such as poorly controlled diabetes mellitus and hypertension are well established, efforts to reduce these risk factors alone have not yet led to a reduction in the prevalence of CKD⁶.

Nearly 12 percent of our country suffers from kidney stone damage. There are two reasons why stones come in the kidneys. One comes from outside. This includes factors such as food, drinking water, and lifestyle. Another is the damage to the body. Children are often affected in this manner. That is, the heredity of the genus is kidney stones. The lack of adequate water is the main reason for the formation of kidney stones. Excess calcium, uric acid, oxalate, phosphate nutrients excretion in urine. It is necessary to dissolve them in liquid form and drink enough water to get rid of the urine. Otherwise, excreting calcium, uric acid, oxalate salts in the urine will be completely dissolved in liquid water and stay on the urine track. Then it will grow into a kidney stone.

A kidney can also be affected either at the same time or at both kidneys. These can come in many different sizes and different forms. There are 5 types of kidney stones. First type of calcium phosphate Oxalate type

stones. This type of stones is mostly formed by people over the age of 30. More than 60 percent of kidney stones are affected by this type of stone. The main reason is the excess of calcium nutrients in the urine. This means that more calcium supplements, high Vitamin D pills, stoic drugs, more nutritious food consumers, lactic drinkers and calcium-rich water are not affected by this type of stones. Once these stones come once again in 2 or 3 years, there is a chance to be back again. About 60 per cent of these people have a problem. By the end of the year they are also broken by the stones on the kidney path, and there is a risk of permanent kidney failure due to infection. Citric acid has the power to prevent such stones. Lemon and orange juice help prevent kidney stones. The following can be said of uric acid stones in the order of impact. This impact cannot be detected by an image. Ultra-scan or CT scan can only be found. This impact will be easier for mobile lovers. Uric acid stones are at risk for damaging the urine, especially the liver and the brain. Some medications, pillars and uric acid gems come. Even some people have inherited this disease. 3rd Type Oxalate Stones. Adding some of the ingredients like tomatoes, spinach leaves, chocolate, drinking tea, cashews, almonds, and pistachios can also cause this effect. 4th type Sistine stones. This is often the impact of children. Or maybe descending. Adults rarely occur. 5th Stones Invention Stone, which comes from urinary tract infection. This is a very hazardous. Because of this damage there is a risk of permanent kidney failure. These stones can also come back to the urinary tract infected. Therefore, urine should not be ignored.

It is important to investigate the long-term follow-up of disease rather than kidney disease and cross-sectional studies as a potential risk factor for kidney disease. Such insights will lead to new strategies to prevent the development of kidney disease. Therefore, the purpose of this longitudinal study was to investigate whether stone size, age, sex, height, BMI and hydronephrosis are a risk factor for decreased renal function ⁴.

Materials and Method

Subject and methods

A retrospective cross-sectional study design was conducted. This study population includes all patients who have been diagnosed with kidney stones in the medical

records of the tertiary care center of Vedanayagam Hospital, RS Puram, Coimbatore. In order to quantify the prevalence of kidney stones among patients admitted to Vedanayagam Hospital, steps were taken to collect a random sample from them and to differentiate between patients with kidney stones and those without kidney stones. The present study uses a 95% confidence level with an acceptable error of 1% ³.

Study population

A hospital-based observational study was conducted during August 2017–August 2018 in Coimbatore district of Tamil Nadu state, India. Coimbatore is the largest district of Tamil Nadu with an approximate population of 15.1 lakhs. The city is famous for medical tourism because of its wide network of cost-effective tertiary-care hospitals catering to the need of population of not only from Tamil Nadu but also from neighboring states and even from abroad.

Sample size

A sample-size of 150 was decided on the basis of review of data of the Department of Urologist which revealed that at least 23 subjects (newly diagnosed) were presented every month.

Study limitation

The limitation of the study was due to relatively small sample size. Although the minimum sample size of the proposed model is satisfied, the structural equation requires at least 150 samples to make the sample size reliable in the model. With a sufficient sample size, the mediation effect may be apparent by the structural equation model of relationships between the variables ⁷.

Data Analysis

The quantitative data analysis process includes an analysis of the descriptive statistics using the SPSS AMOS statistical program (Statistical Package for the social Sciences for Windows (student version)) to describe the general information. Furthermore, the SEM models of general public services in Coimbatore district were assessed using a continuity measurement index and empirical data. Therefore, we used structural equation modeling to test our

hypothesis model, using data from patients with kidney stone disease Vedanayagam Hospital in Coimbatore district ⁸.

Statistical Analysis

Frequency analysis

A frequency is used for looking at detailed information on nominal (category) data and describing the results. Frequencies options include a table 1 showing counts and percentages.

Structural Equation Modeling (SEM)

Structural Equation Modeling (SEM) is a multivariate analysis technique. It is used to estimate

simultaneous multiple hypothesis relationships between latent variables (or underlying constructs) and observable variables ⁹. This study used a cross-sectional design and structural equation modeling (SEM) to analyze the relationships between the variables ¹⁰ related to the patients with kidney stone disease. The model was evaluated using several criteria: χ^2/χ^2 value indicating the probability was <0.05 significance, Goodness-of-Fit Index (GFI) greater than 0.90, Comparative-Fit Index (CFI) greater than 0.90, Normed-Fit Index (NFI) greater than 0.90, and Root Mean Square Error of Approximation (RMSEA) less than 0.08 ¹¹⁻²⁵. The conceptual model specifying the relationships between the concepts that are employed in this study (numbered) can be seen in Fig.1. As a precursor, we predicted 4 pathways that directly and / or indirectly affect the kidney, emerging from stone size variable ⁸.

Fig. 1 Association between Stone size and demographic variables: Best-fitting model with pathways and standardized estimates

Results and Discussion

Table 1 Frequency analysis for Demographic variables

Gender	Frequency	Percent
Male	114	76.0
Female	36	24.0
Total	150	100.0
Weight	Frequency	Percent

Cont... Table 1 Frequency analysis for Demographic variables

10-20	2	1.3
21-40	2	1.3
41-60	33	22.0
above 60	113	75.3
Total	150	100.0
Height	Frequency	Percent
80-100	2	1.3
121-140	1	.7
141-160	48	32.0
161-180	98	65.3
above 180	1	.7
Total	150	100.0

Information on socio-demographics including gender, weight, and height should be concise³. Table 1, shows that it can be seen that 76% of the respondents are male and 24% of the respondents are female, it can be seen that 1.3% of the respondents are 10-20, 1.3% of the respondents are 21-40, 22% of the respondents are 41-60 and 75.3% of the respondents are above 60, and 1.3% of the respondents are 80-100, 0.7% of the respondents are 121-140, 32% of the respondents are 141-160, 65.3% of the respondents are 161-180 and 0.7% of the respondents are above 180.

Table 2, shows that more popular measures of model fit include the not significance level of our chi-square value, the ratio of chi-square divided by its degrees of freedom (CMIN/DF), NFI (Normed Fit Index) and CFI (comparative fit index), RMSEA (Root Mean Square Error of Approximation) and Hoelter's critical N. So, it would not be considered to have good model fit using this measure. Next, NFI and CFI are popular measures of model fit. Both of these measures range on scale from 0 to 1. Both NFI and CFI were 0.21 and 0.19 respectively. In general models with scores for these measures of 0.9 or above are considered to have acceptable model fit and RMSEA is also a very popular measures this value is 0.19. This value indicates a not good model fit.

Conclusion

Fig.1 shows that, it infers that there is strong evidence that there is no association between stone size, demographic variables.

Kidney stones can be formed by precipitation or crystallization of minerals and urine components. This is a common problem worldwide, manifested by a series of intermittent pain episodes, surgical interventions, and medication

consumption affecting patients' quality of life³. The present evidence strongly concludes that the variables taken in this study had no association between age, sex, height, BMI, hydronephrosis and the size of the stones. The study also considers that kidney stones may come in some other way.

Acknowledgement: We are grateful to the study participants for their cooperation and participation. We thank P. Manigandan, D. Pachiyappan, K. Prema, P. Yalni and S. Vijayan for their help in data collection. We also thank Dr. K. Alagirisamy for the contributions for the preparation of the study.

Contributorship statement K. Lokesh designed the study, carried out the study, analyzed the results, and contributed to the discussion of results and drafting of the manuscript. Dr. K. Alagirisamy contributed to designing the study and discussion of results, and the final manuscript. All authors have read and approved the final manuscript.

Funding This work received no specific grant from any funding agency in the public, commercial or non-profit sectors.

Compliance with ethical standards

Ethical approval This article does not contain any studies with human participants or animals performed by any of the authors.

Informed consent Before any study-related activity, eligible patients were provided with oral and written study information, and their informed consent was obtained.

Competing interests The authors declare that they have no competing interests.

Comparison of Application of Bio-Statistics in National and International Medical Journals

K.S.Sridhara

Assistant Professor cum Statistician, Department of Community Medicine, Vijayanagara Institute of Medical Science Ballari, Karnataka

Abstract

Bio-statistical methods are increasingly used in the medical research for designing, presentation and analysis of current medical research. The objectives of present study are to compare application of Bio-statistical methods used in medical research in National and International Journals. Study method is by reviewing the current medical journals both National and International, which are received at the Medical college Library of Vijayanagara Institute of Medical science. The more common methods of Bio-statistics used in designing, presentation, and analysis is compared among different specialties of Medical research both in National as well as International journals. The study is helpful for the Bio-Statisticians in selection of proper Bio-Statistical methods for medical research and is also helpful for the medical researchers to know the current methods of Bio-Statistics for data presentation, analysis and interpretation.

Keywords: *Medical research, National medical journal, International medical journal, Study design, Study presentation, Study analysis, Biostatistics.*

Introduction

Lifelong learning as a physician demands facility in the assessment and application of clinical evidence from medical literature. Appraised of an articles methodological rigor depends on an understanding of the study design and analysis used by the author^[1].

The accreditation council for Graduate medical education and American Board of Pediatrics mandate that to attain competency in practice based learning and improvement, residents are expected to apply knowledge of study design and statistical methods to the appraisal of clinical studies and to appraise and assimilate evidence from scientific studies related to their patient health problem^[2].

It is also not clear which statistical concepts are most necessary and useful for readers to become familiar with. There has been a well documented trend towards the use of new and increasingly complex statistical techniques in published article^[3].

An earlier study demonstrated that reader of Pediatrics who understood descriptive statistics (for

example Means and SD) and three inferential statistical procedure (student t-test, chi-square test, Pearson's r) could understand the statistical analysis in 97% of research article published in 1952 but only in 49% of article in 1982^[4].

The present study is relating to the Bio-Statistical methods used In Medical research both in National as well as International Medical journals.

Objectives:

1. Comparing the National Medical journals and International Medical journals for their use of Bio-statistical methods in the Medical research.
2. To study the Bio-statistical methods that are currently at use in Medical research both in National and International Medical journals.

METHODS:

This study is based on the review of articles published in the National and International journals which are received at the medical college library. Minimum of one article is selected which used Bio-statistical method in

their study. All the journals were published in the year 2007 except few which are published in the year 2006.

All together there were 85 article from Indian Medical journals and 84 articles from International journals selected. The total number of article reviewed is 169.

In each article Bio-statistical design used, presentation of diagram graph or table, and Bio-statistical methods used for data analysis is recorded. Percentages are calculated and compared.

Results

The number of National Journals taken for study is 22 and number of International journal taken for study is 20. All together 42 journals are used for the study. Also journals represent all the distinct specialty of Medical field and 26 journal articles from National and International medical journals reviewed for the study is listed in the reference section^[5-30].

Table 1 below lists the Sampling Designs that are used by the study.

Table 1: Sampling Design that are used in the study.

Sampling Design	No. in the National Journal (with %)	No in the International Journal (with %)	Total (with %)
Observational study	23 (27%)	20 (24%)	43 (25%)
Clinical Trials	16 (19%)	06 (07 %)	22 (13%)
Animal Experiment	08 (10%)	05 (06%)	13 (8%)
By reviewing the published articles	00 (00%)	04 (5%)	04 (2%)
Using sampling method study taken	02 (2%)	25 (30%)	27 (16%)
Demographic and Health survey	00 (0%)	03 (4%)	03 (2%)
Using Questionnaire	01 (1 %)	01 (1 %)	02 (1 %)
Disability Adjusted life (DALY) Years	00	01 (1 %)	01 (1 %)
Not specified	35 (41%)	19 (22%)	54 (32%)
Total	85	84	169

Sampling designs that are used in the National Medical journals shows 27% are observational studies and 19% are clinical trials. Animal experiments consists 10%. Sampling design not specified in 41 % of the articles.

Sampling designs that are used in International Medical journals shows 30% of the articles specified sampling method used in the study. 24% of them are observational study. Not specified in 22% of the article.

Of the total article 32% not specified any sampling design while 25% are observational study. Sampling methods specified in 16% of the study.

Table 2: Average no of Graphs and Table used per article.

Type	In the National Journals	In the International Journals	Total
Graph	0.94	1.52	1.23
Table	0.40	0.51	0.47

According to this table average no. of graph used per article is 0.94 in the National journals and 1.52 in the International over all 1.23 graph used in both the journals.

The average no of Table is 0.40 per article in the National journals and 0.51 in the International journals. And 0.47 tables per article when combined together.

Both average no of graph and tables are more in International journals than in National journals.

Table 3: Types of Graphs used.

Types of Graph	National journals	International journals	Total
Bar diagrams	18 (21%)	18 (21 %)	36 (21%)
Frequency Polygon	06 (7%)	02 (2%)	08 (5%)
Trend line	05 (6%)	11 (13%)	16 (9%)
Error bar	00	04 (5%)	04 (2%)
Scatter diagram	04 (5%)	07 (8%)	11 (7%)
Log LD50 Graph	00	01 (1%)	01 (0.6%)
Pie diagram	03 (4%)	00	03 (2%)
Kaplor meir survival curve	01 (1 %)	00	01 (0.6%)
Total	37 (44%)	43 (51 %)	80 (47%)

Most commonly used graphs are Bar diagram and Trend line in both National and International journals. Other types of graphs such as Scatter diagram used more in International journals than in National journals.

Table 4: Bio-statistical methods used in National Journals.

Bio- statistical methods	No. of articles (%)
Pearson chi-square test, fisher exact test, student t test, z test	57 (67.05%)
Mean + SD	39 (45.88%)
95% C.I	02 (02.35%)
ANOVA	13(15.29%)
Percentage or proportion	11 (12.94%)
Pearson correlation coefficient, Spearman rank correlation coeff	09 (10.58%)
Multiple regression analysis Multiple logistic regression analysis	08 (09.40%)
Life Table method	01 (01.17%)
Scheffe 's multiple comparison Test	07 (08.23%)
Median quartiles Geometric mean	04 (04.70%)
Mean + SEM	01 (01.17%)

By comparing the National and International journals, Pearson chi-square Test, Fisher exact test or student t test are used maximum number of times for the analysis. In the International journals 25% of tests are new methods of test of significance.

Similarly multiple regression analysis, multiple logistic regression analysis is used in 20.23% of articles in International journals but it is only 9.4% in National journals.

Use of correlation coefficient is 10.58% in National journals but it is 15.47% in International journals.

In the National journals 95% confidence interval is used in 2.35% of the articles and 19% in International journals.

Discussion

The study design is important for the reliable and valid results in the Medical research. Sampling design mentioned in 59% of National journals while in International journals it is mentioned in 78% of the

articles. In National journals 27% are of observational study followed by 19% clinical trials but in International journals sampling study is highest with 30% and next is observational study. (Refer Table-1).

Both average number of table and graph per article used by International journals is more than National journals i.e. 0.51 and 1.52 respectively. (Refer Table-2), National and International journals used Bar diagrams for presentations (21%). This is followed by Frequency polygon (7%) in National journals, and Trend line (6%) in International journals. One or the other type of graphs is used by 44% of National journals and 51% in International journals. (Refer Table-3).

Pearson chi-square test, Fisher exact test, student t-test and Z-test is used maximum number of times 67.05% in National journals and it is 32.14% in International journals.

Mean + Standard deviation are calculated for analysis in National journals by 45.88% of the articles, but it is 11.9% in International journals. ANOVA is used

in 15.29% of articles in National journals and is used in 25% of International journals.

Newer method of statistical significant test such as Bonferoni's post hoc test is used in 14.28% of International journals. Tests such as Kaplan Meir Log rank test, Kappa statistics, Students-Newmen-Keels test are used in International journals but none of these methods are used in National journals (Refer Table-4).

Regression analysis technique is used in 20.23% of research articles in International journal but it is not used in National journals. (Refer Table-4).

Conclusion

Bio-statistical methods used in International journals are more when compared to National journals. The use of these newest methods needs to be further studied for adoption in our research methods.

Familiarities of these methods are needed for both Bio-statisticians and Medical researchers. The necessity of learning biostatistics for research in Medical field is increasing. It is further required to train Bio-statisticians to use present methods which are introduced in International journals. Training has to be given to the medical persons on the usage of newer methods in Bio-Statistics.

Conflict of Interest: None Exist

The Role of Ayurveda in Public Health

Kamath M

Associate Professor, Division of Ayurveda, Centre for Integrative Medicine and Research, Manipal Academy of Higher Education, Manipal

Abstract

Ayurveda is India's traditional system of medicine. around 80% population, especially using this system of medicine for their health care management. There are many issues and concerns over the usage of Ayurveda, They are simplified and try to deal in this paper. The methodology used to complete this review was through empirical research. This is a cross-sectional study where the use of Ayurveda utilized in this current period is examined. The sources are mostly from a doctor of Ayurvedic medicine and credible online sources.

Key words: *Ayurveda, Public, health*

Introduction

Ayurveda is an alternative form of medicine that originated in India. This traditional practice is personalized to each patient and primarily uses a holistic approach.¹ Ayurveda is known for its promotive, curative, and therapeutic concepts. The main objective of Ayurvedic treatments is to promote a healthy lifestyle through proper nutrition, prevention of disease, and specialized treatments based on the diagnosis.¹ It is part of AYUSH, which stands for Ayurveda, Yoga, Unani, Siddha, and Homeopathy.² AYUSH is widely used in public health sectors within India.

From the 2013 census, India was clocked at less than one doctor working in public health for every 1,000 people, for a total population of 1.375 billion.³ The health care system is pluralistic, meaning there are options of alternative medicine and modern biomedicine.⁴ Each state in India is responsible for providing its population with health care.⁵ Indian citizens do not need to pay for health visits or medicine when visiting a public health

centre in India. Health care is distributed in a vertical system; district hospitals, urban and rural primary health centres that reach over 50,000 people each, and sub-centres with some specialists.⁶ These centres often have provisions for AYUSH care with 15 AYUSH workers per 2,000 people.⁴ It is widely understood that traditional medicine can be utilized in resource-poor settings and has the potential to make a difference in rising nations.⁴

Material and Method

Empirical, Cross-sectional study.

Discussion

Health care can be more than just one note. India is such a diversified country and consisting of a myriad of different cultures, religions, and beliefs that influence the needs of each person. The National Rural Health Mission (NRHM) is attempting to make up for the shortage of medical professionals in India by mainstreaming AYUSH.⁷

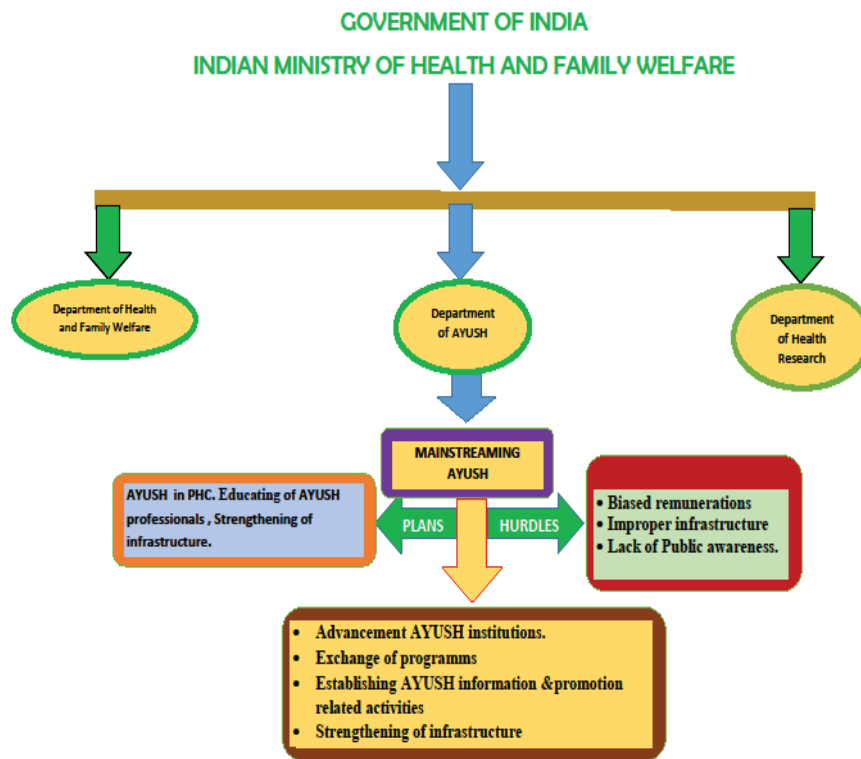

Figure 1. the strategies and barriers of integrating AYUSH in the public health system

In Figure 1. the strategies and barriers of integrating AYUSH in the public health system are revealed. By incorporating AYUSH, more opportunities for health care will rise and more people will want to study alternative forms of Indian medicine. Ayurveda is advantageous in resource-poor areas in India because it is curated to the climate and seasons in this region. In India, poverty accumulates in rural villages and urban slums, both of which are heavily populated and low in resources. Ayurveda can be beneficial in both rural and urban areas due to the use of plants from the ecosystem and everyday spices in an Indian diet that aid in healthy living.⁸

Traditional medicine is presently utilized in developing countries in Asia, Africa, and Latin America, and have begun to pop up in North America and Europe.⁴ There is an emerging demand for body-based methods and alternative Indian medicine has already spread to Ayurveda centres and spas in the western hemisphere.⁹ The ability to choose between therapies is gaining

popularity worldwide.⁹ Ayurveda is becoming popular across the world because of its natural remedies and hands-on techniques, which appeal to people who want an alternative to the chemical route.

Currently, the public health scene in India is researching a methodology for combining Ayurvedic practices with modern biomedicine, or Ayurvedic Biology.⁸ If more research is conducted, this new health care service could be used worldwide and new treatments and drug developments can be created.⁸ In 2013, it was found that out of 700,000 AYUSH doctors in India, seventy per cent practised Ayurvedic Biology for distributing pharmaceuticals, diagnostics and Ayurvedic treatments.¹⁰ Twenty per cent of AYUSH doctors work in district hospitals and primary health centres where they sub in for biomedical doctors.¹⁰ If there is a rise in AYUSH workers, more Ayurvedic treatments could be performed and relieve doctors looking after hundreds of people. A problem India faces in public health is the shortage of doctors and a shortage of fully trained

licensed doctors. It shows that only 100,000 of the one million biomedical doctors work in public health.

The World Health Organization found that only twenty per cent of doctors practising in rural areas are licensed and these types of ‘doctors’ take on seventy per cent of primary health centre visits.³

Figure 2 shows that only 100,000 of the one million biomedical doctors work in public health.

If AYUSH workers all had proper training this could make a difference in gaining better health care in India. conveys the absence of AYUSH doctors in hospitals. Since there are so few AYUSH workers in hospitals, a plan to create a department for AYUSH in hospitals would bring job openings for more workers.

Figure 3. Allocation of AYUSH doctors in India's public health sector

A weakness of popularizing Ayurveda is the move toward commercialization. An important value within Ayurveda is using natural plants, herbs, minerals, and oils from the local ecosystem and market. This process is necessary for the freshness of all ingredients and to be as chemical-free as possible since AYUSH doctors

are to make the medicine directly before treatment. Since Ayurveda is affordable and can accommodate any patient, commercialization is unnecessary.² However, to promote AYUSH internationally, manufacturing of Ayurvedic pharmaceuticals and medicines is becoming common to supply industries, not on the local level.¹⁰ To

be affordable, Ayurveda uses plants from right outside, and by manufacturing products, costs go up and the effectiveness of the treatment goes down.

Ayurveda has a concept of microbial water purification that is the world's least expensive method.⁸ The method includes storing drinking water in copper vessels, which eradicates pathogens and viruses.⁹ This concept put to a global scale could greatly decrease water contamination in water-stricken areas around the globe. Especially in developing countries that struggle to find a plentiful source of water, let alone a clean drinking supply. Marketing this technique of purification or spreading awareness could aid many in need.

Conclusion

Ayurveda has the potential to reach many people from all walks of life. Ayurveda's versatility may be used to address global health issues. In lower-income households in rural India, Ayurvedic treatments are often self-administered for minor ailments. If these treatments are globalized, more people would be able to go to a professional for treatment, or on the other hand, the lower risk treatments could be taught in sessions to lower-income areas around the world. If the quacks working as AYUSH health care workers could be properly trained, this could give AYUSH a better reputation. People deserve to have proper health care and with quacks and a shortage of doctors, India's public health sector is falling short. The easily taught concepts in Ayurveda could be taught in schools as life skills. If Ayurveda was more globally known, India could attract more tourism with their authentic Ayurvedic dispensaries. More opportunities for professional education in Ayurveda should be available. Ayurveda may not have the biggest role in public health currently, but the opportunities for expansion are limitless.

A Review on Medication Adherence in Asthma

Kavitha P¹, Umamaheswari D²

¹PhD Research Scholar, Department of Pharmacy Practice, Vinayaka Mission's College of Pharmacy, ²Associate Professor, Department of Pharmaceutical Chemistry, Vinayaka Mission's College of Pharmacy, Salem, Tamil Nadu, India

Abstract

Asthma is a constant fiery aviation route ailment with a high commonness, around 10% in youngsters and 5% in grown-ups in Western nations ^{1,2}. Asthma is a noteworthy reason for inability and wellbeing asset use, and diminishes personal satisfaction ³. To limit asthma intensifications, treatment ought to be balanced stepwise, determined by the patient's asthma control level⁴. Breathed in corticosteroids (ICS) are the foundation of support treatment for asthma.¹⁵ Numerous examinations have demonstrated ICS to improve manifestations and lessen asthma-related bleakness and mortality,¹⁶⁻¹⁸ however regardless of this, a high number of patients being treated by rules stay hard to control with successive intensifications and continuing symptoms.¹⁹

Keywords: Asthma, Medication Adherence, Corticosteroids, Side Effects

Introduction

Asthma treatment incorporates day by day utilization of a controller medication and utilization of short-acting bronchodilators when required for fast side effect alleviation⁵. Adherence to treatment is basic to improve the advantages of treatment. Poor adherence has been related with results like mortality⁶, asthma side effects⁷, direct and roundabout expenses of consideration and nature of life⁸. In asthma, adherence to treatment will in general be poor, with rates of <50% in kids ⁹and 30–70% in grown-ups ^{10,11} relying upon nation, age, sex and ethnicity ¹². These low adherence rates have been credited to security worries about breathed in corticosteroids (ICS) (“steroid fear”) by both the patients and the parental figures ¹³. For sure, utilization of ICS has been related with development impedance in kids and other foundational antagonistic

impacts, for example, an expanded danger of pneumonia ¹⁴. In expansion, most ICS should be regulated twice day by day, which builds the danger of poor adherence contrasted and once-day by day organization. It has been proposed that poor adherence to ICS expands the danger of intensifications. With this orderly audit, we expect to give a basic evaluation of the writing, looking at the relationship between adherence to asthma controller treatment and the danger of serious asthma intensifications in kids and grown-ups.

Breathed in corticosteroids (ICS) are the foundation of support treatment for asthma.¹⁵ Numerous examinations have demonstrated ICS to improve manifestations and lessen asthma-related bleakness and mortality,¹⁶⁻¹⁸ however regardless of this, a high number of patients being treated by rules stay hard to control with successive intensifications and continuing symptoms.¹⁹ One of the conceivable explanations behind inadequately controlled asthma might be that patients with asthma will in general display poor adherence.²⁰ Poor adherence to controller prescription may prompt a decrease in lung function,²¹ poor side effect control,²² and expanded danger of asthma-related hospitalizations.²³

Techniques

The audit was led for a half year and an aggregate

of 100 articles were chosen. Out of that 20 articles were prohibited after analysis as it doesn't meet enough figures. Aggregate of 80 articles were taken for information extraction. The articles were gathered from information bases like pubmed, medline, elsevier.

Medicine Adherence Review

Williams et al²⁴ conducted an investigation dependent on 1,064 subjects with a specialist's conclusion of asthma and at any rate one electronic remedy for ICS over a 18-month period. Adherence was determined as the complete number of long stretches of provided drug partitioned by the quantity of long stretches of perception by connecting the electronic solutions with the medicine fill data. The quantity of days a canister would last was determined by partitioning the quantity of puffs by the recommended number of puffs/d. To represent prior drug excess, the past 3 months' ICS solution fills were inspected, and the record date was moved back as needs be the point at which a conceivable surplus was found. All things considered, adherence in the whole populace was 46%. In light of the degree of adherence, the rest of the subjects were delegated either poor-to-direct follower (adherence of < 80%) or disciple (adherence of > 80%). In any case, these subjects likewise had lower comorbidity scores and less utilization of short-acting β_2 agonists and oral corticosteroids in the earlier year, recommending that these subjects may have milder asthma contrasted and the more follower subjects. Shockingly, be that as it may, they found no contrast between these gatherings as to number of visits to out-persistent centers or, all the more strangely, number of crisis room visits or hospitalizations.

In 2 extra examinations, Williams et al²⁵⁻²⁶ also detailed a normal adherence to ICS at or underneath half. In the first of these investigations, they determined CMA preceding and following the file medicinal services contact to evaluate changes in adherence when a worsening. In the second of these examinations, they determined CMA for 176 asthma subjects joined up with huge wellbeing support associations for in any event 2 y after the record year. The CMA was observed to be $50 \pm 37\%$ (mean \pm SD). Besides, the creators likewise evaluated the ceaseless numerous interim proportion of drug holes (CMG) as the absolute number of long stretches of treatment holes partitioned by the all-out

number of days between refills during the perception time frame to $54 \pm 27\%$. CMA and CMG were determined dependent on the first and last ICS medicine fills during the examination time frame, with a necessity of a 2-fill least in that period.

Murphy et al²⁷ studied the degree of adherence to ICS in 115 subjects normally going to a particular troublesome asthma facility. Adherence was determined as CMA dependent on medicine information from their general experts and the clinic's apportioning framework. Imperfect adherence (< 80% of the medicine taken) was found in 65.2% of the all-out populace. Of the subjects recommended fixed-mix treatment with ICS and long-acting β_2 agonists, 62.4% had poor adherence, while 85.7% of the subjects endorsed ICS and long-acting β_2 -agonists in independent inhalers had adherence of < 80%. In the last gathering, adherence to long-acting β_2 agonists was vastly improved (half) than to ICS (14.3%). In this manner, these discoveries emphatically propose that patients with asthma requiring treatment with a mix of ICS and long-acting β_2 agonists ought to be endorsed fixed-mix treatment.

Bet et al²⁸ explored adherence to ICS in 182 subjects likewise alluded to a particular facility for troublesome asthma. Thirty-five percent of the subjects filled \leq half of their ICS medicines. Ladies were essentially bound to be non-follower than men. At the point when subjects were gone up against with the proof for non-adherence, 88% conceded not utilizing their ICS as endorsed, while the staying 12% kept on asserting great adherence in spite of the medicine records.

Drinking spree et al²⁹ concentrated filled ICS medicines for 1 y in 5,504 subjects with asthma and revealed a normal adherence to fixed-blend treatment with salmeterol/fluticasone of 22.2%. Besides, the greater part of the subjects (58.9%) filled their medicines just once in the year examine period. Men were somewhat more follower than ladies (23% versus 21%), though more youthful subjects had less fortunate adherence than more established subjects (< 20% adherence in the 12–35-y-old gathering and > 20% adherence in the > 35-y-old group). The most noteworthy adherence was seen in subjects > 70 y of age, despite the fact that it was just 26%. Different variables related with poor adherence were low-portion ICS and lower drug costs.

The previous finding is most likely on the grounds that subjects endorsed higher portions of ICS experienced more manifestations and along these lines were bound to fill their remedies. Moreover, Drinking spree et al³⁰ likewise examined steadiness with ICS, characterized as the level of subjects who kept filling their medicines consistently. They found that solitary 8.8% of the subjects continued with their controller treatment, and low tirelessness was related with sexual orientation (ladies had a 9.2% higher danger of cessation contrasted and men, $P = .002$) and age (subjects < 55 y of age were bound to suspend treatment than those > 70 y of age, $P < .001$).

Hwang et al³¹ considered 108 subjects > 60 y of age with a finding of asthma. The selected subjects were assembled by their asthma control, as characterized by the Asthma Control Test, into gathering I with a score of < 19 (poor control) and gathering II with a score of > 19 (great control). Adherence of > 75% was seen in 29% of subjects in gathering I and 20% in gathering II. Normal adherence for every single included subject was 23%.

Breathed In Corticosteroids And Adherence

In the examination referenced above by Murphy et al²⁷ subjects with adherence of > 80% had an altogether higher percent-anticipated FEV1 and lower level of sputum eosinophil's contrasted and subjects with a lower level of adherence). No distinction was found with respect to side effects (evaluated by the Asthma Control Poll [ACQ] 32), hyperventilation (surveyed by the Nijmegen questionnaire³³), or uneasiness and wretchedness (surveyed by the Medical clinic Tension and Gloom Scale³⁴). Moreover, when taking a gander at the earlier year, they found no noteworthy contrasts in the quantity of salvage courses of oral corticosteroids or emergency clinic or ICU affirmations because of extreme asthma intensification. In any case, they saw that poor adherence was an autonomous indicator of a past scene of mechanical ventilation because of serious asthma.

Williams et al²⁵ found changes in ICS adherence and how adherence identifies with asthma intensifications, characterized as asthma-related hospitalizations, salvage course of oral corticosteroids. The enlisted subjects were a piece of the SAPPHERE examination, as depicted by Jin et al.²⁹ All subjects had a conclusion

of asthma, therapeutic and drug store inclusion, and at least one ICS remedy filled during the investigation time frame. An aggregate of 298 subjects were joined up with the investigation, and mean adherence at pattern was 26%. In spite of the fact this could be translated as positive relationship between great adherence and intensifications, further examinations, subsequent to modifying for asthma seriousness and earlier intensifications. Actually, every 25% expansion in adherence gave 11% less danger of having one of the negative asthma-related results. Be that as it may, in the wake of isolating the subjects into gatherings dependent on asthma control at standard and level of adherence. They observed the impacts to be measurably critical just in the gathering with poor beginning asthma control and in subjects with > 75% adherence to ICS. By and large, the creators found that 24% of all asthma intensifications in the investigation could have been stayed away from with ideal ICS adherence.

Medication And Asthma

An examination from Denmark, Rasmussen et al³¹ explored the impact of a web put together administration device with respect to asthma results. An aggregate of 300 subjects with asthma, as characterized by the American College of Allergy, Asthma and Immunology asthma questionnaire,³² were selected. The subjects were randomized to standard asthma care by their general professional, treatment by authorities in aspiratory prescription in an out-tolerant center, or expert treatment through a web based administration device. At the season of enlistment and toward the finish of the half year time for testing, all subjects had planned arrangements at the out-tolerant center for clinical meeting, surveys, bronchial test testing (methacholine), and spirometry. Subjects randomized to the general professional gathering were approached to give their general specialist the test outcomes got before randomization, and for the rest of the piece of the examination time frame, these subjects were overseen exclusively by their general expert, and no extra data or treatment counsel was given by auxiliary consideration. In the master gathering, subjects were treated by the seriousness of their asthma. All gatherings demonstrated an expansion in ICS use at development, however fundamentally more subjects in the pro and web gatherings utilized ICS at development. The web, authority, and general specialist gatherings gave self-

detailed great adherence (taking the ICS consistently/ quite often) rates of 87, 79, and 54%, individually.

Conclusion

In this review most of the papers showed that more elevated amounts of adherence were related with decreased danger of extreme asthma intensifications. Further, there is a requirement for new, all around planned genuine forthcoming investigations, utilizing steady institutionalized measures for both treatment adherence and asthma intensifications.

Nutritional Assessment of Japanese Encephalitis and Acute Encephalitis Syndrome confirmed patients of Gorakhpur Uttar Pradesh

Khushnoor Ansari

Research Scholar, Department of Home Science, NKBMG PG College Chandausi Sambhal, UP

Abstract

Malnutrition and infectious diseases are closely interlinked, Japanese Encephalitis and Acute Encephalitis Syndrome has also been associated with malnourishment and or poor immune system of children. The present study investigates the nutritional and growth status of children of Gorakhpur, Uttar Pradesh, infected with JE/AES. For this study 100 patients were selected (58 boys and 42 girls) purposively. The subjects were divided into 3 age groups viz, 1-3, 4-7 and 8-10. Their anthropometric characters viz, height and weight were measured. The results were compared with WHO standard. From the study, it is clear that a large number of JE/AES patients from Gorakhpur UP suffer are severely malnourished. The nutritional status of both boys and girls is lower than the WHO standard both in terms of overall bodily development and BMI.

Key Words: *Malnutrition, JE/AES, Gorakhpur, Anthropometry, WHO*

Introduction

The relationship between malnutrition and infection is the leading cause of morbidity and mortality in many poor regions of the developing countries¹. Every year about 10 million children are killed by infectious diseases worldwide before they reach age 5 and 50% of these deaths occur due to malnutrition^{2,3}. Immune system of an individual is intimately linked to the quantity and quality of food taken, and it is immune system that fights against pathogenic organisms such as bacteria, fungi, viruses, toxins, and allergic compounds⁴ and these pathogenic organisms are associated with high death rate⁵ but on the other hand malnutrition impairs immune system and thus leads to many infectious diseases. Malnutrition has been defined as a “pathological state resulting from a relative or absolute deficiency or excess of one or more essential nutrients”⁶ or it may be a consequence of energy deficit or micronutrient deficiency⁷.

There are many factors associated with malnutrition or under-nutrition but poverty has been recognized as one which is both cause and consequence of malnutrition⁸. The impact of poverty upon health is largely mediated by nutrition and is expressed throughout the whole life course⁹. Generally poverty and malnutrition effects children of a country and impairs their growth and development and this effect has been well documented and reviewed in both developed and developing countries^{10,11}. Whilst more than 30 countries are home to 90% malnourished children, India stands distinct in having the largest number of malnourished children in the world^{12,13} ranks 100 out of 119 countries¹⁴. On the other hand India has been counted in the list of counties having the weakest commitment to ending child malnutrition¹⁵. Having the number double than Sub Saharan Africa, malnourishment in India has negative impact on productivity and economic growth, along with mortality rate being very high¹⁶.

As has been said earlier in this section, malnutrition and infectious diseases are closely interlinked, Japanese Encephalitis and Acute Encephalitis Syndrome has also been associated with malnourishment and or poor immune system of children. Research shows that

Corresponding author:

Mob.No: +916006061575

children with JE/AES admitted in various hospitals of India were either malnourished or from poor socio-economic backgrounds, despite this very few researchers have focused on nutritional aspect of this deadly virus. The main objective of the present study was therefore to assess the nutritional status of confirmed JE/AES cases of Gorakhpur region of Uttar Pradesh, India.

Materials and Method

Anthropometric measurements (height and Weight) were taken of 100 JE/AES confirmed children of Gorakhpur region of Uttar Pradesh. A list of patients was obtained from District Hospital Gorakhpur. Phone number of the parents of Patients written against the respective names of patients was extracted from the list and phone calls were made to know the exact dwelling address, since the dwelling units were scattered across the region. Anthropometric measurements were taken by directly visiting the patient's home as they were discharged from hospitals. The heights of above 2 children were measured using a metal anthropometer of two meters length. In case of those children who were below two years of age, were measured using an auto-recoiling tape made up of hard steel which was identical to anthropometer in calibration. To measure weight of the children, a portable weighing scale (capacity 100 kg) was used. Children were asked to wear minimum clothes during weight and were asked to take off shoes during measuring height.

Table 1: Distribution of study subjects according to age and gender

Age Group	Boys	Girls	Total
1-3	21	14	35
4-7	31	17	48
8-10	6	11	17
Total	58	42	100

Data Analysis

Data of the children were grouped according to their gender and age. BMI of every child was calculated from his/her height and weight. BMI was calculated using online calculator of *Centre for Disease Control and Prevention*. The calculator also gives exact percentile along with BMI. Further to calculate Frequencies, Percentages, Mean and Standard Deviation, and Z-Scores, data was analyzed by using SPSS 16.0 and Microsoft Excel 7.

Results

The study included 100 JE/AES patients (58 Boys and 42 Girls) aged 1-10 years (Table 1). Table 2 shows age and sex wise mean and SD of height, weight and BMI of JE/AES confirmed children.

Table 2: Mean±SD of Anthropometric measurements of JE/AES Patients

Age Group	Boys				Girls			
	Mean Height (cm)	Mean Weight (kg)	BMI (kg/m ²)	Mean Z-Score	Mean Height (cm)	Mean Weight (kg)	BMI (kg/m ²)	Mean Z-Score
1-3	87.02±5.96	10.93±2.14	14.39±2.29	0.08	83.78±6.33	9.45±1.13	13.54±1.49	-0.06
4-7	103.59±7.39	14.54±2.23	13.55±1.65	0.16	107.31±6.87	15.88±2.94	13.68±1.42	-0.27
8-10	128.93±4.55	22.65±3.32	13.59±1.55	-0.44	126.95±2.26	21.6±2.26	13.38±0.77	0.17

The mean and SD of anthropometric measurements (height and weight) of each age group is shown in table 2. The mean height of boys ranged from 128 ± 4.55 to 87.02 ± 5.96 and among girls the mean height range was found to be 126.95 ± 2.26 to $83.78.8 \pm 6.33$. In the age groups of 1-3 and 8-10 boys weighed (10.93 ± 2.14 and 22.65 ± 3.32) more than girls except in the age group of 4-7 where girls both mean height and weight (107.31 ± 6.87 and 15.88 ± 2.94) were slightly more and better than boys. The mean BMI ranged from 14.39 ± 2.29 to 13.59 ± 1.55 in case of boys and girls had a mean BMI of 13.54 ± 1.49 to 13.38 ± 0.77 . The mean BMI Z-Score for boys ranged from 0.08 to -0.44 and girl patients had mean BMI Z-Scores ranging from -0.06 to 0.17.

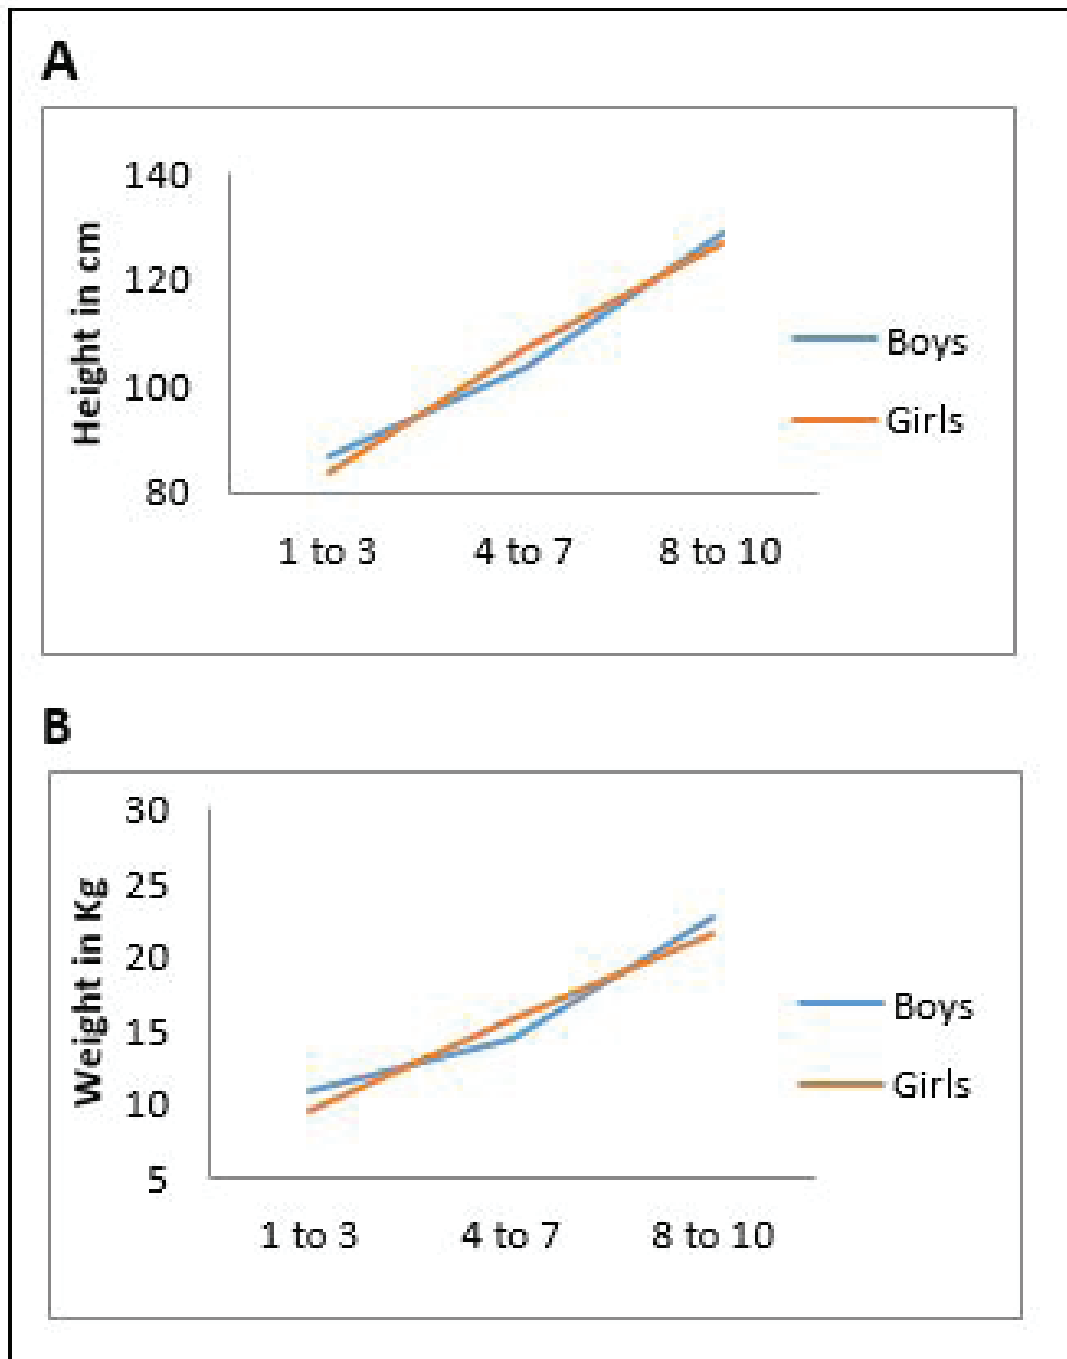

Fig 1. Showing Comparison of mean height and weight of Boys and Girls

The mean height of the patients was compared with WHO (World Health Organization) reference range, a significant difference was found in both sexes and in all age groups. Fig. 2 (C, D, E and F) shows variation between mean height and weight of boys and girls with WHO standard. It was observed that in all age groups both genders showed lesser average weight and height than the respective standard of WHO and the difference was significant. The difference is assumed to be a result of their poor economic background and food habits.

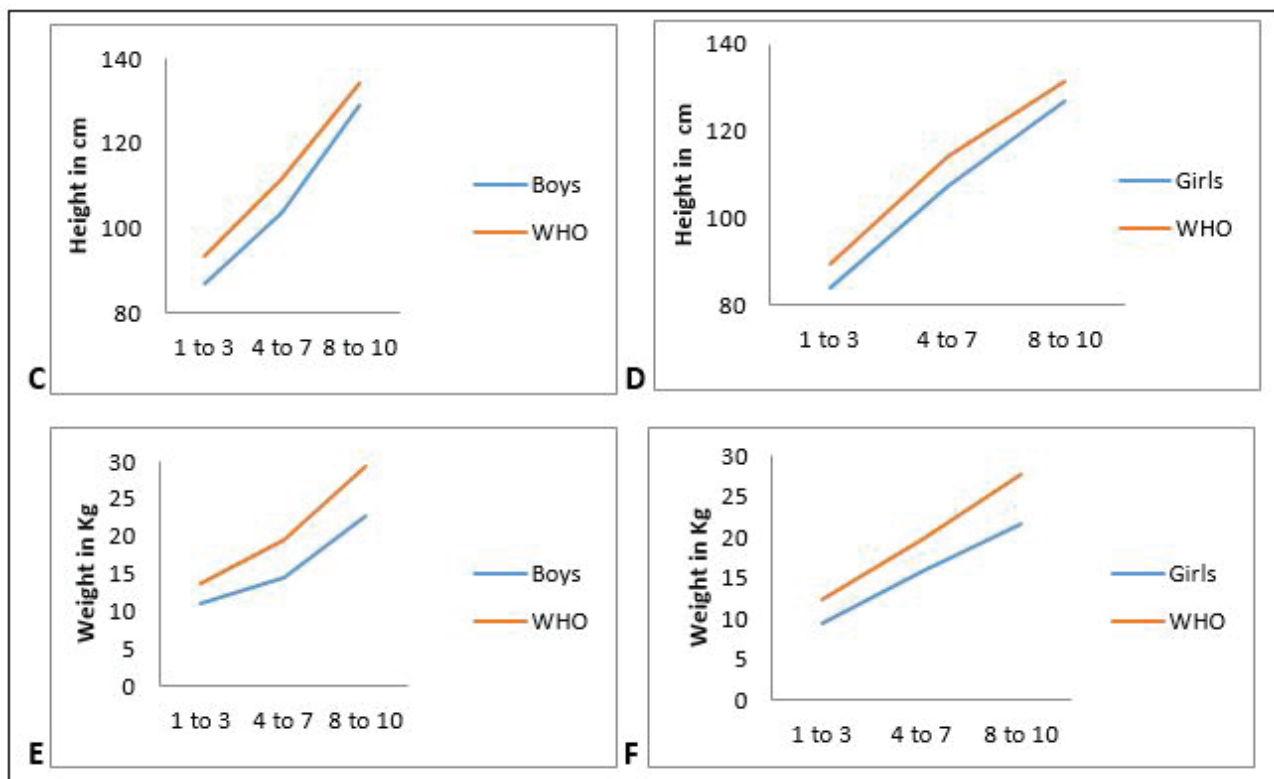

Fig. 2. Showing comparison of mean Height and weight of Boys with WHO reference.

Table 3. Shows prevalence of malnutrition based on SD

Gender	Severe Malnutrition <-2SD BMI	Moderate Malnutrition <-1SD BMI	Overweight/Obesity >+1SD/>+2SD	Normal	Total
Boys	31 (53.44)	15 (25.86)	7 (12.06)	5 (8.62)	58
Girls	27 (64.28)	10 (23.80)	2 (4.76)	3(7.14)	42
Total	58 (58)	25 (25)	9 (9)	8(8)	100

The above data of boys and girls when compared with WHO cut-off for BMI, it was found that 53.44 % boys were severely malnourished (in terms of both height and weight), 25.86% were moderately malnourished and small percentage (12.06%) were overweight or obese. A similar trend of malnourishment was recorded in case of girl subjects. 27 out of 42 girls (64.28%) were

found severely malnourished, 23.80% moderately malnourished and 7.14% were either overweight or obese when compared with WHO standard. Out of total 100 patients, only 5 boys and 3 girls were found having normal anthropometric measurements.

Discussion

Overall nutritional status of the host affect immune function and a result has profound effect on the virus itself¹⁷. Malnourished children suffer more from viral infections, viral diarrhoea, measles and malaria, with a prolonged course and intensified disease. Similarly, poor nutrition represents a significant risk factor for JE / AES, records National Programme for Prevention and Control of Japanese Encephalitis/ Acute Encephalitis Syndrome, Government of India^{18,19}. *India Today* on June 2019 reported that about 48% of children under the age of 5 in Muzaffarpur, Bihar are stunted (short for their height), 17.5% are wasted (too thin for their height), and 42% are underweight-a conspicuous sign of chronic under-nutrition, which is worse than most African countries. This trend of under and malnourishment seems to be directly linked with encephalitis and child deaths. Another record showed the association of under-nutrition and poor outcomes in the patients with viral encephalitis²⁰. As a neurotropic virus, JEV attacks the central nervous system and the clinical picture vary with the degree of central nervous system's involvement, age and nutritional status of the person affected²¹. Mosquitoes that proliferate in close association with pigs & other animal reservoirs are found to spread virus of Japanese encephalitis in malnourished children of poor families²². So, while the cause of AES is still being studied, hypoglycaemic AES can be caused by malnutrition. Malnutrition is high in Bihar and UP and children who are malnourished are prone to infection.

Conclusion

From the study, it is clear that a large number of JE/AES patients from Gorakhpur UP suffer are severely malnourished. The nutritional status of both boys and girls is lower than the WHO standard both in terms of overall bodily development and BMI. This is assumed to be a direct outcome of their low socio-economic status and poor food that they eat. Therefore need of the hour seems to implement intervention programme more effectively to improve overall nutritional status of children to keep them away from getting infected or falling prey to JE/AES or any such deadly virus.

Conflict of Interest: Nil

Ethical Approval: Before conducting research on

the selected subjects, approval was sought from District Hospitals and University Research Cell and later the consent of both parents and adult subjects was taken.

Funding Agency: Self

Abstrac

The primary function of the respiratory system is to oxygenate blood and eliminate carbon dioxide, which requires that blood come into virtual contact with fresh air to facilitate diffusion of respiratory gases between blood and gas. It refers to any number of infectious diseases involving the respiratory tract. **Materials and Methods: Place of Study:** The study is carried out in patient “Department of Pulmonology” IP at Narayana Hospitals, Nellore, collaborated with a 1440 bedded multidisciplinary hospital.

Results: Demographic details of the patient was collected and presented as results in the data.

Discussion: In our study total of 405 patients 360 are willing to provide the information of age group 20-60 and which the maximum people suffered with respiratory tract infections were above 60 is 174(48.3%) and minimum were 20-30 Of 12(3%).

Conclusion: Our study concluded that most of the suffered with respiratory tract infections was mainly due to the different types of lifestyle. It is treated with different types of drugs and the patients feel better after treatment. As a clinical pharmacist we should educate the patients regarding the health issues and their problem. It is most effective to educate the unemployed patient regarding the disease.

Key words: *pulmonology, clinical pharmacist, Estimation, Evaluation*

Introduction

Respiratory system: The primary function of the respiratory system is to oxygenate blood and eliminate carbon dioxide, which requires that blood come into virtual contact with fresh air to facilitate diffusion of respiratory gases between blood and gas [1, 6].

Respiratory tract infection: It refers to any number of infectious diseases involving the respiratory tract [2, 8]. Infections includes group of conditions which causes inflammation from nose to alveoli [1].

Estimation:

Ø An approximate calculation of value, number, quantity of something or judgment of worth of character of someone.

Evaluation:

Ø Analysis of completed or ongoing activities that determine or support management accountability, effectiveness & efficacy using criteria governed by a set of standards.

Outcomes:

Ø These are the final results or consequences that follow from an action or situation.

Corresponding author:

Kanamala Arun Chand Roby
arunchandroby@gmail.com

Tertiary care hospital:

Ø It is a hospital that provides tertiary care from specialists in a large hospital after referral from primary care and secondary care.

Materials and Method

Ø PLACE OF STUDY:

The study “**Clinical pharmacist role in estimation and evaluation of treatment outcomes in patient suffering with respiratory tract infections in Tertiary care Teaching Hospital**” which was carried out in patient “Department of Pulmonology” IP at Narayana Hospitals, Nellore, collaborated with a 1440 bedded multidisciplinary hospital

Study Design:

The study was prospective observational study conducted in the Department of pulmonology inpatient ward of tertiary care teaching hospitals

Ø Study Population:

This study was conducted in 400 patients who are suffering with Respiratory Tract Infections.

Ø Study Duration:

This study was conducted for a period of 6 months.

Ø Study Criteria:

Patients are considered for the study based on inclusion and exclusion criteria.

Ø Inclusion Criteria:

•All the patients suffering with different types of Respiratory Tract Infections.

- Patient age group in between 20 to above 60yrs.
- Patients with co-morbid conditions.

- Who are willing to provide the information.
- Complaints of any respiratory tract infections.
- Patient with alcohol and smoking habits.
- People suffering with seasonal Respiratory Tract Infections.
- Patient dependent upon medication.

Ø Exclusion Criteria:

- Pregnancy women.
- Lactating women
- Lack of interest to provide information.
- Pediatrics.
- Whose verbal communication was poor.
- Unconscious patients.
- Mentally retarded patients.

Ø Study Material:

- Patient informed consent form.
- A specially designed respiratory tract infection questionnaire.

Ø Study Method:

The study will be initiated after obtaining the permission from Head of the institution and Head of Department of Pulmonology. The patients considered in the study after taking informed consent from the patients or patient attendants. The patients are considered for the study based on the inclusion and exclusion criteria.

Results

Demographic details of the patient was collected and presented as results in the data:

Table-1 Shows the assessment of life in four weeks

Assessment of life	Very poor	Neither poor nor good	Good	Very good
Quality of life	24	256	62	18
Satisfaction of health	12	282	56	10
Feel of daily life	18	237	99	6
Healthy environment	34	177	136	13
Access of health services	19	113	196	32

Table-2 Shows the condition and follow up of the patient

Condition and follow ups	Never	Seldom	Very often	Always
Negative feeling	297	55	6	0
Visit of doctor	0	8	290	62
Proper medication	14	27	301	18
Medication adherence	0	36	171	153

Table-3 Shows reasons for admission in the department

Conditions	No.of patients	Frequency
Shortness of breath	324	90%
Cough	198	55%
Cough with expectorant	216	60%
Chest pain	252	70%
Fever	171	47.5%
Fluid accumulation in chest cavity	153	42.5%
Weakness/fatigue	258	71.6%
Loss of weight	174	48.3%
Loss of Appetite	226	62.7%
Decrease sleep	162	45%
Exacerbation	135	37.5%
Difficulty in swallowing	117	32.5%
Pedal edema	99	27.5%

Table-4 Shows different types of upper respiratory tract infections and lower respiratory tract infections

Types of respiratory tract infections	No.of patients	Frequency
Upper respiratory tract infections		
Allergic rhinitis	5	1.38%
Sinusitis	2	0.5%
Pharyngitis	6	1.66%
Laryngitis	8	2.22%
Lower respiratory tract infections	131	36.3%
Bronchial asthma	157	43.6%
Chronic obstructive pulmonary disease	27	6.66%
Pulmonary tuberculosis	18	5%
Pleural effusion	6	1.66%
Hydro Pneumothorax		

Discussion

In our study total of 405 patients 360 are willing to provide the information of age group 20-60 and which the maximum people suffered with respiratory tract infections were above 60 is 174(48.3%) and minimum were 20-30 Of 12(3%). The sex differentiation in which males were more prone to respiratory tract infections of 282(78.3%) and females of 78(21.66%) with educational status of uneducated members are maximum were 282(78.3%) and the minimum were graduated of 6(1.6%) and occupation was labor is more in our study i.e, 282(78.3%) and last was employed 18(5%). Nutritional status of the patients is average 234 (65%) and the minimum were good 54(15%) and food intake is also analyzed in the patients with standards and it was found that maximum were average of 270(75%) and minimum was poor 42(11.6%).

The reason for admission in the hospital is due to the shortness of breath is more after observed in maximum number of patients weakness or fatigue cough with sputum, chest pain and last was pedal edema. Based on the questionnaire the assessment of life for 4 weeks was calculated and analyzed in the patients based on this the maximum patients was satisfactory with the life, and their felt a sad feeling daily life and having a satisfactory quality of life and good healthy environment was found from the assessment of questionnaire.

The different classes of drugs used in the treatment of respiratory tract infections are mainly antibiotics 360 (100%), bronchodilators 293(81.3%) and vitamin supplements 280(77.7%) were maximum and minimum were corticosteroids 45(12.5%), antihistamines 96(26.6%) and antipyretics.

Conclusion

Our study concluded that most of the suffered with respiratory tract infections was mainly due to the different types of lifestyle. It is treated with different types of drugs and the patients feel better after treatment. As a clinical pharmacist we should educate the patients regarding the health issues and their problem. It is most effective to educate the unemployed patient regarding the disease. The government should take measures for avoiding smoking so that the health of the patient becomes good and effective. We are providing leaflets to

the patients for this conditions and measures to be taken in future to overcome Respiratory tract infections.

Acknowledgement: All thanks and praises to God Almighty for his countless, abundant and never ending blessings in completing this work. It is a proud privileged honor for us to express our hatful thanks and gratefulness to all the persons who backed us directly or indirectly through out of this research work as magnitude. Most importantly authors are thankful to patients and health care professionals.

Effect of PNF in Improving Lower Extremity Function in Adolescent with Spastic Diplegic Cerebral Palsy-A Case Report

Kovela Rakesh Krishna¹, Ajay Thakur², Pamidigantam Raghava Priya³, Sunjyoth HS⁴, Subhash Srivastav⁴, Sridevi Prabhu⁵

¹Associate Professor, ²Professor and Principal, ³Lecturer, ⁴Assistant Professor, ⁵Tutor, Vikas College of Physiotherapy, Mary Hill, Airport Road, Mangalore

Abstract

Cerebral palsy is a common non-Progressive neuromotor disorder which leads to various impairments and disabilities. There are various treatment approaches in the management of children, adolescents and adults with cerebral palsy. Proprioceptive Neuromuscular Facilitation (PNF) is used to stimulate the neuromuscular system in an effort to excite proprioceptors in order to produce a desired movement. Patient was 19 years old boy with spastic diplegia. He was under physiotherapy treatment elsewhere for the past 10 years here they were focussing more on passive movements and mat activities. Patient's main concerns on approaching us were difficulty to stand independently and walk. The important clinical findings were Grade 1+ Muscle tone according to Modified Ashworth scale in bilateral adductors of hip, hamstring muscles and Bilateral Calf muscles. Highest functional status was he can able to sit independently. Patient was initially treated with tone inhibitory techniques and movement facilitatory techniques. Once the tone is normalized PNF techniques mainly rhythmic stabilization and dynamic reversals were given for 12 weeks. Berg balance scale and Gait parameters(Stride length, Cadence and Gait velocity) were taken before beginning of study and after completion of 8 weeks. There were significant changes in Berg balance scale and Gait parameters. This case report confirms that a goal oriented problem specific treatment approach can yield better outcomes even in adolescents with cerebral palsy.

Key Words: *Cerebral Palsy, Spastic diplegia, Proprioceptive Neuromuscular Facilitation, balance impairments, Gait impairments.*

Introduction

Cerebral Palsy (CP) defines a group of permanent disorders of the development of movement and posture, causing activity limitation, that are attributed to non-progressive disturbances that occurred in the developing fetal or infant brain. The motor disturbances of cerebral palsy are often accompanied by disturbances of sensation, perception, cognition, communication and behaviour, by epilepsy and by secondary musculoskeletal problems¹.

Developed countries have a prevalence of cerebral palsy, 2 per 1000 live births. Males are found to have a higher prevalence of cerebral palsy than females, with sex ratios ranging from 1.1:1 to 1.5: 1².

Topographically CP is classified into monoplegia, diplegia, hemiplegia and quadriplegia. Based on abnormal muscle tone into spastic, hypotonic, athetoid, ataxic and mixed³.

Spasticity is defined as a velocity dependant increased resistance to passive muscle stretch, or alternatively as inappropriate involuntary muscle activity associated with upper motor neuron paralysis⁴.

Spastic diplegia is the predominant type of CP in preterm children, especially in the most immature preterm children (64% to 75% of children with cerebral

Corresponding Author:

Associate Professor, Vikas College of Physiotherapy, Mary hill, Airport Road, Mangalore.

palsy born before weeks of gestation or with birth weights below 1000gm)⁵. Many children with spastic diplegia have normal tone, or even hypotonia, during the first 4 months. The onset of spasticity in the legs is insidious and slowly progressive during the first year⁶.

Common impairments in spastic diplegia include Connective tissue and muscle contractures, Cognitive and perceptual deficits, Visual and visuomotor abnormalities, Speech and learning problems, Impaired trunk control, Pelvic asymmetry, Balance and gait asymmetry^{7,8,9}.

Various interventions are proved to be effective in spastic diplegia such as Strength training programs, Constraint Induced Movement Therapy, Sensorimotor training program, balance training, Neuro Developmental Therapy and Proprioceptive Neuromuscular Facilitation to improve gait, balance and lower extremity function¹⁰

Most of the literature was focussed on young children with CP. This case report is unique as it is showing the changes in movement control in late adolescent patient with spastic diplegic CP.

Patient information: Patient was 19 year old Spastic diplegic adolescent who was under physiotherapy treatment since past 10 years. Physiotherapy treatment which he had taken previously included Passive movements and Mat exercises. He was having good communication skills, He was not going to any school, his highest functional ability was independent sitting and supported standing and walking. His primary concern was his difficulty of independent standing and walking. He stays with his father and mother who does not have any economic issues. He was the second child and elder one was fine. He was not under any medication and there were no psychological illness found.

Clinical Findings: The important clinical findings were Grade 1+ Muscle tone according to Modified Ashworth scale in bilateral adductors of hip, hamstring muscles and Bilateral Calf muscles. Bilateral Knee and Ankle Reflexes were exaggerated. Extensor lag was noticed in bilateral knee joints. Bilateral flat foot was seen, Dorsiflexion was not seen in bilateral feet. Slight exaggerated Kyphosis was noticed in spine. There was no pelvic mobility. Upper limbs were fine and able to perform bilateral asymmetrical activities.

Diagnostic Assessment: Berg balance scale was used to assess balance and various gait parameters (Stride length(cm), Cadence(steps/min) and Gait velocity(m/min)) were used to understand gait characteristics. Initial Pediatrician diagnosis of Spastic cerebral palsy was taken into consideration but to diagnose as spastic diplegia, functional movement analysis was done and based on the activities performed diagnosis was confirmed. Pre and Post scores of BBS and Gait parameters are given in table 1 and graph 1.

Therapeutic Intervention: Initially to normalise tone facilitatory and inhibitory techniques were given. It took 3 months to normalise tone. Once the tone was normalized we concentrated on strengthening with PNF techniques. To gain distal mobility proximal stability is must. We gave Rhythmic Stabilisation exercises to gain proximal joint stability in lower limbs. We started with Dynamic reversals, Repeated contractions in various patterns for pelvis and lower limbs. Intervention was given one hour a day, five days a week for 12 weeks post normalizing tone. Outcome measures were taken on the first day of PNF treatment and after completing 12 weeks. We have not changed the treatment protocol for 12 weeks and dosage was same. There was not a single day where treatment is missed. Follow up was done after 3 months of study completion and it was found that treatment was effective and maintained. Vigorous home program was given to the patient to perform at home which includes, sit to stand activities, Task oriented lower limb movements and active lengthening exercises to maintain muscle tone.

Table 1: Showing Pre post scores of outcome measures

	Pre Scores	Post Scores
Berg Balance Scale	15	28
Stride length(cm)	65	78
Cadence(steps/min)	41	68
Gait Velocity(m/min)	33	44

Discussion

This Study was aimed to evaluate the effectiveness of PNF Techniques on balance and Gait parameters in an adolescent patient with Spastic diplegic Cerebral

palsy. The previous studies of PNF in stroke populations were proved to be highly beneficial. Sang Wang et al in their study applied PNF in chronic stroke patients they concluded that PNF decreases the abnormally increased muscle tone and reduces muscle stiffness¹¹. Our study has similarities where Abnormal tone which was normalized was not reversible with three months of PNF training. One more study by Chandan et al where PNF was compared with task oriented therapy on lower extremity function in children with CP concluded that both are beneficial in improving lower extremity function¹². Our study which mainly focuses on PNF only in adolescent population showed similar results as task oriented program was given at home. There was not a significant improvement in Berg balance score because of the amount of motor learning and control which happens in adolescents is quite slow than children. Eventhough change of scores is less it is significant considering age of the child. Gait parameters were significantly improved as child started walking with cane. Child perceived that the treatment is effective and helping him to progress day by day. Though we may have not achieved complete independent walking, the achievements what we got in the patients motivated us to follow the similar protocol in other patients too.

CARE Guidelines¹³ were followed while preparing the manuscript.

Acknowledgement: We would like to thank the parents of the patient and also the patient himself who stood with us for almost 8 months. We also would like to thank Management of Vikas College of Physiotherapy for providing necessary infrastructure.

Informed consent was obtained from patient and ethical clearance was obtained from Institutional ethical committee

Class Imbalance Applied to Medical Neuroimaging for Classification of Alzheimer's Disease

KR Kruthika¹, Rajeswari²

¹Research Scholar, ²Professor, Department of Electronics and Communication Engineering, Acharya Institute of Technology, Bangalore, India

Abstract

Class imbalance is an issue that naturally occurs when a database is sparse or incomplete. This can occur in medical diagnostics when a large percentage of tests ran to return negative results rather than a positive. Classification models are sensitive to an imbalanced training set, and training on one can cause undesirable biases. This work presents an overview of the effects of class imbalance on classification models in Alzheimer's detection utilizing voxel based-morphometry (VBM). MRI scans are processed by FreeSurfer where cerebral volumetric and thickness are taken as feature vectors. The effects of class imbalances on multiple machine learning models were compared to one another. Furthermore, different biomarkers were studied for their effect on different metrics of trained models. The classification models were trained to detect the following categories: Alzheimer's disease (AD), mild cognitive impairment (MCI), and normal controls (NC). SVM, KNN, MLP, Random Forest, etc. algorithms were evaluated for the prediction analysis. It was observed that class imbalance did not produce any significant effects on the disease classification process.

Keywords: *Classifiers, Alzheimer's disease, Mild cognitive Impairment, Voxel-Based Morphometry*

Introduction

Alzheimer's disease (AD) is a neurodegenerative disorder that presents with symptoms including memory impairment, executive dysfunction, and other deficits in other cognitive domains. Normal neuron activity creates amyloid precursor protein, but in AD, a dysfunctional enzyme creates a shorter protein. A build-up of these form of beta-amyloid plaques, which are toxic to and inhibits neuron function by injuring synapses and neurites.¹ Beta-amyloid plaques also promote the formation of neurofibrillary tangles that stops neuron function.² Both result in neurons disconnecting from others, they stop communicating and die, resulting in memory loss.³ As this continues, those brain regions shrink and function is impaired.

Neuroimaging technology such as magnetic resonance imaging (MRI) has significantly contributed to further understanding of brain regions, and associated diseases such as AD. Despite the limits to detail in images, (units called voxels make up an image, and a single voxel can represent a million brain cells)⁴ predictions can be made from observations of activity among groups of voxels correlating to specific brain regions. MRI is also able to accurately measure the size of brain structures, in three-dimensional volume.³

Classifiers

Recently, machine learning has been applied to the medical field.⁵ A decrease in the cerebral volumetric and thickness are physiological symptoms of Alzheimer's disease.⁶ These biomarkers can be utilized as indicators for machine learning algorithms to detect AD.^{6,7} Although several classification methods have been utilized, Support Vector Machines (SVM) is the most common approach in practice, along with both the MRI images^{8,9,10} and PET images.^{11,12} For instance, Davatzikos et al.¹³ implemented SVM in MRI imaging

and cerebrospinal fluid (CSF) biomarkers and applied it for MRI, FDG-PET, and CSF as in.¹⁴

However, only the binary classifier has been discussed in many of the earlier referred researches. As an example,¹³ regarded the only AD vs NC classifications, while Cui et al.¹⁵ considered investigating both MCI vs NC and AD vs NC. In¹⁶ the author has dealt with the transition of MCI to AD, whereas, Vounou et al.¹⁷ reported the differences in progressive p-MCI and stable s-MCI patients that were discussed as a binary issue. As noted by Amir et al. in their study on the use of convolutional neural networks (CNN) for classification of spinal MRIs, and as discussed in recent papers on utilizing SVM^(18,19,20) valuated diffusional MRI images using multilayer perceptron (MLP) and Kohonen self-organizing map (SOM) classifiers to improve the standard analysis of apparent diffusion coefficient (ADC) maps. MLPs are a staple artificial neural network (ANN) architecture that utilizes a feed-forward system with multiple layers of nodes that have a linear or nonlinear activation function. These nodes are typically trained with some variation of back propagation. Kohonen SOM is a different ANN architecture that utilizes unsupervised learning to create a map, which is a form of dimensionality reduction.

The research group utilized 3 different images with varying exponent diffusions to calculate an ADC map. What they found was a Kohonen organization map of 99.9% accuracy and MLP with an accuracy of 88.5%²⁰. Similar studies by Hamou, et al.,²¹ in 2010 utilized clustering techniques and decision trees to determine whether or not participants with AD or MCI states from MRI images. Their study revealed that that standard K-means clustering was not accurate enough and they were able to obtain a better representation by further refining the results with decision trees.²¹ Even though the binary classification is easier and far less complex, AD treatment is a multi-class problem, and multi-class methods should, therefore, be studied.

Class Imbalance

The class imbalance is often a case wherein the category allocation is complicated. This case is frequently observed within the data of Alzheimer's disease, that differentiates conventional models from various greater categories.²² In order to evaluate the pair of results from

each class, training of the binary classifiers has been suggested^(22,23,24), and therefore, both groups also add to the selection criteria. In a multi-class analysis that was outlined in²⁵, deliberately included class allocation for AD prediction. The analysis primarily depended on multi-class segregation of the problem into binary problems. The findings, thus, acquired were promising. Though, their strategy did not significantly addressed the class imbalance, that motivates the current study.

Materials and Method

Table 1: Stages of cognition and size of samples used with a train/test split of 80:20.

Stages	Number of Samples	Train/Test
Alzheimer's Disease (AD)	65	52/13
Mild Cognitive Impairment (MCI)	116	93/23
Normal Cognition (MC)	96	84/12

Datasets

Data used in the preparation of this article were obtained from the Alzheimer's disease Neuroimaging Initiative (ADNI) database (adni.loni.usc.edu).²⁶ The ADNI sample comprising pooled ADNI1, ADNIGO, and ADNI2 subjects was used to perform primary analysis comprising modeling and prediction tasks.²⁷ ADNI has 3 phases: ADNI-1, ADNI-GO, ADNI-2 that varied in their goals and cognitive stages. The stages given in the dataset are normal control (NC), significant memory concern (SMC), early mild cognitive impairment (EMCI), mild cognitive impairment (MCI), late mild cognitive impairment (LMCI), and Alzheimer's disease (AD). In this research, MCI, NC, and AD data sets from ADNI were studied with their quantities highlighted in Table 1.

Validation of Data for the Study

Many researchers have identified specific neuropathic behaviors linked to the cognitive and functional decline in Alzheimer's disease and its prodromes²⁸ in search of the detection of accurate biomarkers. The absence of manifestations of localized canonical atrophy may be related to behavioural, biological and environmental

factors.²⁹ Therefore, models with an ensemble of imaging characteristics, genotypic and diagnostic information were delivered.³⁰ The improvements in performance delivered by the image details however are ambiguous in some of these multimodal systems.

MRI Processing

After the data was received from ADNI, the data was processed further using FreeSurfer. A set of software tools released by FreeSurfer has allowed researchers to study cortical and subcortical brain anatomy in a streamlined method. Here, the three types of probabilities are computed at each point (voxel): the probability that a point belongs to each of the label class, probability of the spatial configuration, and the probability of the intensity/curvature.

Feature Vectors

For our work, the trained prediction models use three distinct sets of features. In the first feature set, aseg.stats files were utilized containing 45-dimensional vectors. The volumes of the anatomical structures were then normalized with the subject's intracranial volume to account for variance in head-size. The left and right cerebral white matter, cerebral cortex, 3rd and 4th ventricle, lateral ventricle, inferior lateral ventricle, cerebellum white matter, cerebellum cortex, thalamus proper, caudate, putamen, pallidum, hippocampus, and the amygdala were a part of this set. For the second feature set, aparc.stats files were used containing 68-dimensional vectors. This second feature set contained the average thickness for the various structures like superior frontal, rostral middle frontal, caudal middle frontal etc. And finally, the last feature set contained a combination of the two aforementioned feature sets

In the case of MRI images, FreeSurfer was utilized to extract important features and then utilized principal component analysis (PCA) where a trained classification model can be used to query new images.

Results and Discussion

One is more inclined to believe that a stronger model is easier to create with a larger dataset. That is, however, not necessarily the case. As seen in Table 1, the largest data provided were for MCI and NC patients; it is observed that MCI vs NC was the most difficult

to model. Moreover, drastic changes in biological structures as seen in AD vs NC patients are more readily classified. Alzheimer's disease classification versus patients who show mild cognitive impairments are also moderately detectable. What this alludes to is that the progression from MCI to Alzheimer's disease is severe. EE and BC are shown to have moderate performance in all three binary classification problems in comparison to other classifiers. Although EE and BC were incorporated specifically to mitigate class imbalances, it was found that the model either performed moderately or generally under performed.

In contrast, SVM drastically decreases in overall metrics when classifying NC vs. MCI while it excels at classifying AD vs. NC and AD vs. MCI. In the case of MCI vs. NC, MLP architecture has shown to be slightly more favorable. This slight advantage could be attributed to MLPs' advantage of extracting complicated trends from data. What is surprising is that the imbalanced dataset has no drastic effects seen in AD vs. NC and AD vs. MCI, as their F-1 and MCC scores show adequate values. From the cross-validation results for AD vs. NC classification, there is a clear distinction that can be made for the binary classification and that it generalizes well. Moreover, SVM seems to continually indicate strong cross-validation results. Furthermore, there is a decrease in the ability of classification when both biomarkers are used to train the models as seen by low MCC numbers. EE and BC are shown to have moderate performance in all three binary classification problems in comparison to other classifiers.

Although, EE and BC were incorporated specifically to mitigate class imbalances, it was found that the model either performed moderately or generally underperformed. In contrast, SVM shows a drastic decrease in metrics when classifying NC vs. MCI while excels at AD vs. NC and AD vs. MCI. In the case of MCI vs. NC, MLP architecture has shown to be slightly more favorable.

Moreover, the ROC analysis coincides with the confusion matrix analysis. In general, the ROC curves for MCI vs. NC lies either below linear or oscillate around a slope of 1. This indicates that the methods either under-performed or were no better than random search.

Conclusion

SVM demonstrated a drastic decrease in metrics when classifying NC vs. MCI while excelled during the classification of AD vs. NC and AD vs. MCI. In the case of MCI vs. NC, MLP architecture was slightly more favorable. Consecutively, it was surprising that the imbalanced dataset had no significant effects in AD vs. NC and AD vs. MCI, as their F-1 and MCC scores. However, the differences in an MRI image between patients that shows MCI versus one that is not impaired is subtle. Therefore, more advanced neural network architecture may prove to be advanced classifiers. Advanced classifiers will allow us to create significant CBIR systems that are more robust, where a robust CBIR system is one of many requirements to deploy a query image for classification.

Acknowledgment: Data collection and sharing for this project was funded by the Alzheimer's Disease Neuroimaging Initiative (ADNI) (National Institutes of Health Grant U01 AG024904) and DOD ADNI (Department of Defense award number W81XWH-12-2-0012). The grantee organization is the Northern California Institute for Research and Education, and the study was coordinated by the Alzheimer's Therapeutic Research Institute at the University of Southern California. ADNI data are disseminated by the Laboratory for Neuro Imaging at the University of Southern California.

The Dearth of Dengue Awareness in Rural Population – *Time to Act!!!*

Kumar. Vikas¹, Mayur S. Sherkhane², Shruti. Kardalkar³

¹Postgraduate Student, ²Professor, Department of Community Medicine, SDM College of Medical Sciences and Hospital, Dharwad, Karnataka, ³Senior Resident, Department of Community Medicine, Gulbarga Institute of Medical Sciences and Hospital, Gulbarga, Karnataka

Abstract

Background: Dengue, accounts to a notable economic and disease burden universally, is surging rapidly into the countryside. This research was undertaken to study awareness of dengue and factors affecting it among adults in a rural area.

Methods: Cross sectional study was conducted and data was collected by house to house survey after taking consent, using predesigned and pre-tested proforma.

Results: Majority of 53.92% belonged to 30-39 years. 52.94% were males, 54.41% were literates and 33.33% constituted to lower class. The common information source was hospital/health care personnel. 58.33% considered dengue as fatal, 55.88% opined that dengue could not be prevented. The mode of transmission was quoted as mosquito bite by 65.20%, 57.35% considered day and night as the biting habits of mosquito. Most common symptom was quoted as fever, joint, bone or muscle pains and headache. 89.71% considered insect repellents/creams as most common preventive measures. Comprehensively, 38% had sufficient awareness about dengue. Significant associations were age ($p=0.000016$) and literacy ($p<0.00001$).

Conclusion: Despite various efforts in pursue of dengue, awareness in rural region is underneath in diverse aspects. The disease prevention and treatment can be alleviated through variety of endeavours and thus abate morbidity and mortality.

Keywords: Adults, Awareness, Dengue, Literacy, Morbidity, Mortality, Rural.

Introduction

Dengue is an important public health concern globally.^{1,2} It is a mosquito-borne arboviral infection.^{3,4} The virus accountable for causing dengue, is named as dengue virus (DENV). There are four types of DENV serotypes (DENV1, DENV2, DENV3 and DENV4).¹ Dengue virus is transmitted by female mosquitoes

mainly of the species *Aedes aegypti* and, to a lesser extent, *Aedes albopictus*.^{1,5} The *Aedes aegypti* mosquito is contemplated as primary vector of DENV. It dwells in urban habitats and breeds in man-made containers. *Aedes aegypti* is a day-time feeder and peak biting periods are early in the morning and in evening hours before sunset.⁶

Dengue viruses cause symptomatic infections or asymptomatic seroconversion. Symptomatic dengue infection is systemic and dynamic disease which has wide spread clinical spectrum.⁷

Dengue is a severe, flu-like illness affects infants, young children and adults, but seldom causes death. Symptoms last for 2–7 days, after an incubation period of 4–10 days after bite from an infected mosquito. The

World Health Organization (WHO) classifies dengue into dengue (with / without warning signs) and severe dengue.^{1,8}

The global incidence has raised to such an extent that half of world's population is at risk.⁹ In last 50 years, incidence has extended to 30-fold with enlarging geographic expansion to new countries, from urban to rural zones.^{10,11,12}

In defiance of risk of infection existing in 128 countries, 70% of actual burden is shouldered by Asia.^{1,13,14}

In India, epidemiology of dengue was first proclaimed in Chennai 1780 and first outbreak occurred in Kolkata in 1963. India has seen subsequent outbreaks of dengue.^{15,16,17} Earlier dengue was restricted to urban region but now advanced into countryside rural areas.¹⁵

During 2017, about 157,996 cases were reported with 253 deaths. The case fatality rate was 0.16 per cent. The highest numbers of cases were reported from Tamil Nadu, Kerala, Karnataka, Punjab and West Bengal. Karnataka registered 17265 cases with five deaths during 2017.³

With above overview, this study was undertaken with an objective to assess awareness about dengue.

Methodology

Study design:

A community-based cross-sectional study was done in Yadwad village, field practice of Rural Health Training Centre attached to a tertiary care hospital in Dharwad district of Karnataka, India. The study was conducted for a period of three months. All individuals 18 years and above were included.

Sampling method:

The sample size was calculated by using the formula $n = 4pq/L^2$, anticipated proportion of inadequate knowledge regarding dengue as 50%, absolute precision as 7% and 95% confidence interval. Final sample size was estimated to be 204.

The total population of Yadwad village is 3600. A total of 720 houses were estimated in study area with

an average of five members in each family. To achieve required sample size, every 3rd house was selected and only one person from each family was included in study and was considered to be representative of selected family and to avoid duplication, covering entire population.

Sampling procedure:

House to house survey was carried out by the investigators; by doing systematic random sampling (every 3rd house was considered). Anganwadi workers and medico social workers helped in developing rapport with participants. One person was selected from each house and was considered as representative of family, to avoid duplication of data and recall bias.

Inclusion and exclusion criteria:

People who were residing in study area for more than one year and who gave consent on a voluntary basis to participate were included. People who denied to consent for participating in the study, history of having contacted dengue infection among themselves or any of the family members in the recent one year and those who could not be contacted after three visits were excluded.

Data collection:

Data were collected by interviewing all 204 study participants by conducting house-to-house survey using a pre-designed and pre-tested semi structured proforma, in which, part I included socio-demographic profile like age, gender, religion and socioeconomic status. Part II comprised of questions relating to general awareness about dengue as well as questions pertaining to dengue vector, disease signs and symptoms.

The score relating to awareness of dengue was assessed on three essential questions:¹⁹

- 1) Mode of spread of dengue
- 2) Common symptoms of dengue
- 3) Preventive measures both personal and environmental.

To categorize dengue awareness as "Sufficient", participant needed to have correct responses to all three questions. All other combinations were captioned as

“Insufficient”.

The questionnaire used in study was translated to vernacular language and validated by investigators. Data was collected after signing a written informed consent form on voluntary basis and assuring the confidentiality face to face interview was conducted. Data analysis was done using SPSS software version 22.0. Descriptive statistics and Chi-square test was applied to find an association between two attributes and $P < 0.05$ was considered as statistically significant.

Results

A total of 204 people participated in the study. The socio-demographic characteristics were as follows: majority of 53.92% were in the age group of 30-39 years. 52.94% males, 59.31% were Hindus. 54.41% were literates. 33.33% and 29.41% of belonged to lower class and lower middle class respectively [(SES), Modified B. G. Prasad's Classification 2019 - India].²⁰

Table 1 shows the general awareness about dengue. Most common source of information was found to be hospital/health care personnel followed by mass media. (58.33%) considered dengue as a fatal illness.

Awareness about dengue vector and disease is described in table 2. The mode of transmission of dengue was quoted as mosquito bite by 133 (65.20%), 117 (57.35%) considered day and night as biting habits of the mosquito. The participants told most common symptom as high fever 189 (92.65%), 183 (89.71%) insect repellents/creams as common preventive measure.

Table 3 illustrates data pertaining to association of sociodemographic profile with awareness of dengue. 77 (38%) had sufficient awareness about dengue. Significant associations were age ($p=0.000016$) literacy ($p<0.00001$) and nuclear families ($p=0.002015$).

Discussion

The present study was aimed at assessing awareness of dengue. Sufficient awareness regarding dengue was seen in 77 (38%) of rural population. Regardless of dengue being a major public health problem, there is dearth in awareness.

In our study, 53.92% were of 30-39 years whereas in a study conducted by Naik R P et al.,²¹ in Nalgonda, Andhrapradesh, 53.4% belonged to 15-30 years of age.

In a study conducted by Chinnakali P et al.,²² AIIMS, New Delhi 14.8% were illiterates in contrast to the present study where in 45.59% had no formal education.

In a study done in Puducherry, by Krishnamoorthy Y et al.,²⁴ it was found that majority of 34% belonged to class IV socio-economic status which was in similarity to present study where a maximum of 33.33% belonged to lower middle class as per Modified B G Prasad Classification 2019.²⁰

Also, in our study, 55.88% told that dengue could not be prevented; whereas in study done by Arora P et al.,²³ in Delhi it was found that 90% considered dengue as preventable.

In the present study, 65.20% of respondents told that mode of transmission of dengue was mosquito bite which was in similarity to a study done in Puducherry, by Krishnamoorthy Y et al.,²⁴ where in 52.3% respondents knew about mode of transmission.

In a study conducted by Chinnakali P et al.,²² AIIMS, New Delhi. It was found that 73% were aware of one of breeding sites of *Aedes aegypti* which was in contrast to our study where in only 20.10% knew about the correct breeding site of the mosquito.

25.98% of respondents in present study knew about day time biting habits of mosquito where as in a study done in Chennai by V Ashok Kumar et al.,²⁵ 40% knew that dengue transmitting mosquitoes bite at day-time.

In a study conducted by Naik R P et al.,²¹ in Nalgonda, 57.53% respondents could enumerate fever as the presenting symptom whereas in the present study 189 (92.65%) knew that fever was most common.

In a study done by Arora P et al.,²³ in Delhi it was found that 96.4% respondents considered dengue as serious illness which was in contrast to present study where 32.84% told dengue as fatal.

As a result of various climatic changes, rise in novel serotypes of dengue vectors and epidemiological transition there is rapid rise of dengue cases. It is need of hour to extend efforts to create awareness and thereby reduce morbidity and mortality of disease.

Conclusion

The present study revealed that 38% population in rural area had sufficient awareness of dengue. There is definitely a dearth in knowledge of dengue. On that account, wide spread information, and communication through health education and campaigns must be intensified actively involving the individuals, families and community as a whole to bring about sufficient and authentic awareness about dengue and thus prevent the consequences related with disease and hence promoting positive health and thereby preventing illness. With adequate knowledge, positive attitudes and right practices spread of dengue can be limited and rise in cases can be impeded effectively.

Acknowledgement: We express our sincere heartfelt gratitude to all study participants for contributing in research.

Current Scenario of Health Insurance in India: A Study Comprising Various Challenges and Measures For It

Kunuma Das

Ph.D scholar, Gauhati University Department of Economics

Abstract

Ensuring healthy lives and promoting the wellbeing at all stages is necessary for making the process of sustainable development into reality. However, Poor accessibility to healthcare services especially in developing countries acts as a barrier towards this. Every year, Insufficient Government expenditure on healthcare services resulting heavy out of pocket healthcare expenses push people into vulnerable situation. In such a situation, the role of health insurance becomes very significant. Considering all these factors, in country like India, a well organised health insurance market has been gradually evolved over the years. But it is not sufficient because many people are still left untreated and even approximately 25% people are pushed below poverty line by catastrophic impact of out of pocket healthcare expenditure every year. Factors like lack of awareness, policy loopholes, poor infrastructure etc. are mainly responsible for the poor performance of the health insurance market in India. Through this paper, it is tried throw light on all these phenomena comprehensively along with some measures to correct the lacunas.

Keywords: *Health insurance, Challenges, Measures, India*

Introduction

Choices about financing healthcare services have become primary concern to health policy makers so as to achieve health policy goals. Dominance of out of pocket healthcare expenditure in most low income countries indicates that access to healthcare services is primarily a function of individual's ability to pay which cannot be of equal in any case. Only 30% of total health expenditure is spent by Government of India is not at all sufficient to cover almost 1.21 billion populations.¹ Healthcare expenditure in India in 2014 constitutes almost 4.7% of GDP, but contribution of Government is only 1.4% of GDP.² Majority (62.4%) of total healthcare expenditure constitutes out-of-pocket payment at the time of service utilization.³ Based on 2015 estimates, only 288 million approximately, less than one-fifth of India's population, were covered by health insurance in India.⁴ In treating the in-patients, private institutions dominated both the rural (58%) and urban areas (68%) respectively.³ High value diagnostics and drugs make healthcare cost rapidly rising and in most of the cases it forces people to opt for borrowings, sale of physical assets in order to support their expenses on healthcare. Especially

24.9% of rural and 18.2% of urban households depend primarily on borrowings for meeting their healthcare expenditures.⁵ The 52nd report of NSS shows that 24% and 21% of untreated ailments in both rural and urban areas respectively was mainly due to lack of monetary resources.⁵ Again, among those who get hospitalized, approximately 25% are pushed below poverty line by catastrophic impact of out-of-pocket healthcare expenditure.⁶ Dual disease burden of communicable and Non-communicable diseases and coupled with spiraling health costs and poor healthcare delivery due to inadequate public spending on health along with lack of insurance coverage results in excessive financial burden on the poor and erosion in their incomes. In such a situation, health insurance can really work as a protective shield against any health related emergency. Purchase of health insurance not only brings peace of mind but also one can avail tax benefits under section 80D of the Income Tax Act, 1961.⁷

In response to growing demand for health insurance, this paper tries to make an overview of Health Insurance business in India along with various challenges faced by it.

Theoretical Framework:**Health Insurance**

Health insurance is a kind of insurance coverage against uncertain health risks to an individual. It is a type of contract in between an insurer and an individual or group in which insurer agrees to provide specified health insurance cover at a particular "Premium".⁸

The rationale for Health Insurance is based on "Laws of large numbers" which explains that the average behavior of a group of individuals is more predictable than that of a single individual.⁹

Demands for Health Insurance:

The conventional models of demand for health insurance assumes that under conditions of rationality and risk averseness, decisions to purchase insurance is based on the expected utility gain.^(10,11)

Again according to contingent theory, demand for health insurance is derived from the demand for an uncertain payoff in the ill state rather than demand for certainty or risk averseness.^(12,13,14)

Feldstein (1973), states that the price of healthcare or healthcare expenditure also has a relation with demand for insurance.¹⁵

Increased income and education also have link to the demand for insurance. Higher income decreases the opportunity cost associated with the purchase of health insurance.^{16, 17}

Adverse Selection

It is a situation where people having different health risks are not charged premium equal to their expected marginal cost of their insurance. Thus, the customer base of the insurer consists mainly of high risk people.¹⁸

Moral Hazard

This is the incentive to increase risky behavior because the adverse outcomes of that behavior are covered by insurance. Informational asymmetry is mentioned as the source of moral hazard. It is a tendency of the insured people to increase their consumption of healthcare.¹⁹

Forms of Health Insurance:

Health Insurance is mainly categorized into four forms- Mandatory/social, voluntary, Employer provided and community based and further classified as public and private. Two mandatory Government run health insurance schemes are- Employee State Insurance Scheme (ESIS) and Central Government Health Scheme (CGHS). Government of India launched some voluntary social health insurance schemes like Rastriya Swasthya Bima Yojna . Again, in 2018 Central Government launched Ayushman Bharat- Pradhan Mantri Jan Arogya Yojna, largest health insurance scheme in the world.²⁰ Medilaim, voluntary health insurance policy is offered by both Public and Private sector General Insurance companies. Again, Community health insurance schemes are there to serve the needs of the poor and are mainly offered by NGO's, Trusts and hospitals etc.

Objectives

To provide an overview of health insurance in terms of its current performance, challenges faced by it and also to provide suggestions towards the development of health insurance sector in India.

XV.**Methodology:**

This study is mainly based on secondary sources comprising of Annual reports and Handbook of Insurance Regulatory Development Authority (IRDA), reports of National Sample Survey, various articles and research papers etc.

Overview of Health Insurance in India:

Performance of Health Insurance in India:

Initially, Government was enjoying the monopoly over health insurance market but, with the liberalization of Indian economy and enactment of Insurance Regulatory Development Act in 1999; private and foreign players were allowed to enter into the health insurance business.²¹ Health Insurance business has been growing in India. During 2015-16, the gross health insurance premium collected by general & health insurance companies was Rupees 24,448 crore and achieved a growth rate of 21.7 percent in gross premium which was the highest reported in the past five years.²²

Table 1: Health Insurance Premium over the last Five years (Rs.Crore)

Sectors	2011-12	2012-13	2013-14	2014-15	2015-16	2016-17
Public Sector General Insurers	8015 (61%)	9580 (62%)	10841 (62%)	12882 (64%)	15591 (64%)	19227 (63%)
Private Sector General Insurers	3445 (27%)	4205 (27%)	4482 (26%)	4386 (22%)	4911 (20%)	5632 (19%)
Stand Alone Health Insurers	1609 (12%)	1668 (11%)	2172 (12%)	2828 (14%)	3946 (16%)	5532 (18%)
Industry Total	13,069	15,453	17,495	20,096	24,448	30392

Source: Annual Report of IRDAI 2015-16 and 2016-17.^(10,21) Note: Figures in the bracket of the table indicate the market-share in total HI premium.

From, the above Table 1, it is seen that the four public sector general insurance companies continued to contribute a major share at 63 percent of total health insurance premium in 2016-17. Standalone health insurers have also contributed 18 percent of total health insurance premium in 2016-17, registering an increase of 2 percent over the previous year 2015-16. But, there is a drop in the share of private general insurers, whose share has come down from 20% in 2015-16 to 19% in 2016-17. The increasing share of both the Public sector

General Insurers and Standalone health insurers over the past six years might be because of offering the health insurance product at a subsidized price. The health insurance industry in terms of total premium growth has been on a rapid progress and the reasons behind this can be termed as Medical inflation. The private sector insurance companies have also raised the premium per insured to compensate for the high medical bills and also it is the effect of asymmetric information on the part of the insurer where the companies raise the price of the policies.¹

Table 2: Categorization of Health Insurance Premium (Rs. Crore)

Class of Business	2011-12	2012-13	2013-14	2014-15	2015-16	2016-17
Government Sponsored Schemes including RSBY	2225 (17%)	2348 (15%)	2082 (12%)	2474 (12%)	2425 (10%)	3090 (10%)
Group Business (other than Government business)	6948 (46%)	7186 (47%)	8058 (46%)	8899 (44%)	11621 (48%)	14718 (48%)

Cont... Table 2: Categorization of Health Insurance Premium (Rs. Crore)

Individual Business	4896 (37%)	5919 (38%)	7355 (42%)	8772 (44%)	10353 (42%)	12584 (42%)
Grand Total	13,069	15,453	17,495	20,096	24,448	30392

Source: Annual Report of IRDAI 2015-16, 2016-17.^(10,21) Note: Figures in bracket indicate the share of each class of business in total health insurance premium

The above table 2 shows that the Government sponsored health insurance business remains the lowest with 10% share in insurance premium. Most of the Government schemes do not require premium payment and again those which require is of very negligible. But, there has been a massive declining trend in Government health insurance premium which may be due to fierce competition between the insurance companies. Again, problems like information asymmetry and lack of awareness aggravates the matter.²

Table3: Percentage distribution of person by coverage of health expenditure support

	Not covered	Government funded insurance schemes	empl. (not Govt.) supported health protection	Arranged By household with insurance company	Others	All
Rural	85.9	13.1	0.6	0.3	0.1	100
Urban	82.0	12.0	2.4	3.5	0.2	100

Source: NSSO 71stroundreport

It is seen that, around 86% of rural households and 82% of urban households of India were still not covered under any scheme public or private, to support health expenditure. Lack of awareness, refusal of treatment by empanelled hospitals to BPL in many cases etc. are the main reasons behind poor coverage. Mostly in rural areas, the problem tends to be more prominent.

Table 4: Coverage of Persons under Health Insurance (Rs. Lakh)

Class of Business	2011-12	2012-13	2013-14	2014-15	2015-16	2016-17
Government Sponsored Schemes including RSBY	1612 (76%)	1494 (72%)	1553 (72%)	2143 (74%)	2733 (76%)	3350 (77%)
Group (other than GOVT. Business)	300 (14%)	343 (17%)	337 (15%)	483 (17%)	570 (16%)	705 (16%)
Individual Business	206 (10%)	236 (11%)	272 (13%)	254 (9%)	287 (8%)	320 (7%)
Grand Total	2118	2073	2162	2880	3590	4375

Source: Annual Report of IRDAI 2015-16, 2016-17.^(10,21) Note: Figures in bracket of the table indicate the share of each class of business in total number of persons covered

The Table 4 shows that, the percentage of coverage of person under Government sponsored health insurance

schemes is more than that of private insurance schemes. Adverse selection, moral hazard and lack of awareness are the major reasons for the private individual business still in the grim of poor scenario.⁶

Table 5: Net Incurred Claims Ratio of Health Insurers (in percent)

Class of business	2011-12	2012-13	2013-14	2014-15	2015-16	2016-17
Government sponsored schemes including RSBY	90%	87%	93%	108%	109%	122%
Groups (other than Govt. Business)	100%	104%	110%	116%	120%	125%
Individual Business	85%	83%	83%	81%	77%	76%
Grand total	94%	94%	97%	101%	102%	106%

Source: Annual Report of IRDAI 2015-16 and 2016-17.^(10,21)

From the above table, it is observed that there has been an increase in the net ICR from 94% in 2011-12 to 106% in 2016-17. The main factor responsible for this is adverse selection or poor risk identification. It is also seen that, in most of the cases members converting outpatient procedures as inpatient, resulting in Healthcare spending of population with insurance is thrice that of the population without insurance.¹¹

Challenges:

During 2015-16, the General and other health insurance companies have issued around 1.18 crore health insurance policies covering 35.90 crore persons, which is less than one-fifth of India's population and the underlying reason behind this poor coverage is due to lack of awareness or poor insurance literacy.² Moreover, Lack of proper health infrastructure, sufficient regulation on providers and inefficient TPAs, poverty, importance, lack of product variety etc are mainly responsible for the backwardness of this sector.

Suggestions

Rising premium resulting from High medical costs can be dealt with some measures like Hospital bills to be controlled through Health Management Organisation (HMO) and transparency to be initiated with the help of developed IT infrastructure which will help in increasing efficiency to reduce operating cost. Government must develop efficiency with respect to various publicly sponsored schemes so as to face the competition from the various new and innovative private individual and group insurance schemes. Rural population face greater risk of being in unhealthy condition due to lower access to sanitation and pure drinking water and inside house pollution arising out of the smoke from coal or wood used as fuel. Moreover, they also face the financial hardship to cure any illness etc. Facilitating and enhancing Micro Insurance for the disadvantaged people in rural and backward areas is really important. Creating more awareness regarding health insurance and making all insurance providers proper responsible in delivering their services should be the prime focus of both the insurers and Government of the country. Again, to increase the

health insurance penetration, Agents and private players must target new markets in rural and semi-urban areas. Moreover, Introduction of new product portfolios is also the need of the hour. TPAs in Insurance have to be more effective, so that the whole system of insurance can be made clear and efficient while dealing with the problem like information asymmetry.

Since, Insurance acts as a protection to high unexpected healthcare costs so initiatives must be taken so as to facilitate Public-Private Partnership in a competitive environment.

Conclusion

In the backdrop of escalating population, the Health Insurance as a tool of advanced healthcare financing play an indispensable role. Although, India has the highest potential for Health Insurance, the penetration still remains lowest when compared to western economies. Challenges remains are like the prevalence of high informal sector, adverse selection, moral hazard, lack of awareness and so on. The health insurance premium is in the increasing growth path which is mainly the result of high cost healthcare services. Poor coverage in health insurance mainly in rural areas shows the problem of lack of awareness regarding health insurance advantages. Again, high incurred claim ratios mainly in case of group business really hint to the matter of rising adverse selection and fraudulent cases in this industry. In such a situation Regulations and managed insurance market can play an effective role in moving health financing towards greater equity. Enhancement of Health Insurance industry with the help of Mass Marketing strategies like- Micro health insurance for the poor people, promotion of group insurance will be greatly helpful. All the stakeholders" like- healthcare providers, TPAs, Insurance agents, Insurance companies, Government and consumers must play a cohesive role towards increasing the health insurance penetration and density in India.

Impact of Automobile Emission on Pulmonary Function Parameters of Non-Smoking Road Side Vendors and Shopkeepers

Lata Mullur¹, Livingston Sharon², C Mahesh²

¹Professor, Dept of Physiology ²MBBS students, BLDE (Deemed to be University) Shri B.M. Patil Medical College, Hospital and Research Centre, Vijayapura-586103, Karnataka, India

Abstract

Background: Airborne dust plays a major part in the overall atmospheric pollution and motor vehicle emissions constitute the most significant source of ultra particle in urban environment. Traffic related air pollution is an occupational health hazard to individuals who work close to traffic.

Objectives: To assess the impact of dust and traffic related air pollution on pulmonary functions of the exposed, non-smoking road side shopkeepers at busy traffic congested areas and to compare with age and sex matched non-smoking shop keepers from residential localities.

Materials & Method: Cross-sectional study was conducted on 60 healthy adults aged 20-40 years. 30 shopkeepers exposed to dust and traffic pollution residing nearer to busy road-crossings of Vijayapura city. Control group is 30 age and sex matched non-smoking, non-exposed healthy subjects who are working in shops away from the road traffic pollution. Anthropometric parameters, Physiological Parameters, Pulmonary function test were recorded in both control and subjects using standard techniques. Statistical analysis is done using SPSS.

Results: We observed a significant reduction of FVC [subjects-2.63±0.40, control- 2.63±0.40, (p=0.03)] and FEV1 [subjects-2.47±0.59, control- 1.75±0.42, (p=0.000)] and an insignificant reduction of PEF [subjects-506.00±34.07, control-488.66±27.89, (p=0.610)] among the road side shopkeepers.

Conclusion: The results of the study indicate the possibility of impaired lung function or obstructive lung disorders among the shopkeepers exposed to higher traffic pollution.

Keywords: Automobile emission, FEV1, FVC, PEF, shopkeepers, traffic air pollution

Introduction

It is well documented that air pollution is associated with a number of respiratory and cardiovascular adverse health effects.⁽¹⁾ Air pollution generated by motor

vehicle exhaust has become a major cause of scientific and public concern world-wide. The rapid and marked increase in motor vehicular traffic and its associated gaseous pollutants in the urban areas have caused a sharp increase in prevalence of respiratory allergies.⁽²⁾ Road traffic produce volatile organic compounds, suspended particulate matter, oxides of sulphur, oxides of nitrogen and carbon monoxide which makes adverse health effects on exposed population.⁽³⁾ Airborne dust plays a major part in the overall atmospheric pollution and motor vehicle emissions constitute the most significant source of ultra particle in urban environment. Traffic related air

pollution is an occupational health hazard to individuals who work close to traffic. Shopkeepers nearer to various traffic junctions through which maximum numbers of vehicles pass and they are more prone to develop health hazards of automobile exhaust on respiratory system.⁽⁴⁾

In a study by Kunzli et al. (2000)⁽⁵⁾ estimated that in European countries France, Switzerland and Austria, with a total population of 74 million inhabitants, 3% of total mortality per year (i.e. 20,000 deaths) are due to traffic emissions alone; hypothetically total omission of traffic emissions would lead to prolonged life expectancy of 0.35 years.

Areas with increased Ozone and automobile exhaust had a higher prevalence of asthma in all regions. The results of the study by Schmitz Berger *et al.*, (1993)⁽⁶⁾ provide evidence that outdoor pollution is a risk factor for childhood respiratory health.

Many studies suggest that there is an adverse effect on health following exposure to traffic pollution. No such studies have been carried out in this part of the country particularly on busy road side shopkeepers.

Vijayapura is one of historic and fast growing city of Northern Karnataka (India). The growth is associated with an enormous increase in vehicular traffic emitting exhaust and polluting the atmosphere. City pollution is entirely due to automobile exhausts as main city has no industries which can be blamed for air pollution of city.

Many studies have been carried out to examine the relationship between lung functions and exposure to traffic pollution in traffic policemen. But in India least studies done to know the effects of air pollution on residents, shopkeepers or school children who are residing in close proximity with busy road crossings and exposed to dust and traffic pollution. In view of this, our study is aimed to assess the effects of dust or possible traffic pollutants on pulmonary functions of road side shopkeepers.

Materials & Method

Cross-sectional study was conducted on 60 healthy, non-smoking male individuals in age group of 20-40 years who are residents of Vijayapura city since 15 years or more.

In order to study the impact of vehicular pollution on pulmonary functions, 30 individuals who are shopkeepers (book stall, provisional stores, juice centres, ice-cream parlours, vegetable stalls, chat centres, fruit stalls etc) and exposed to dust and traffic pollution for about 8-10 hours daily have been selected. These subjects were residing along busy road (2-3 kms long) passing besides BLDE (Deemed to be University) campus and connecting to NH-13, a connecting road between Vijayapura (Karnataka) and Solapur (Maharashtra) where approximately 1200-1500 vehicle pass per hour.

Control group included 30 healthy, non-smoking male shopkeepers from residential area which is away from the busy roads (where about 10-20 vehicles pass per hour) and they were from same socio-economic group and have similar life style as that of subject group.

With 5% level of significance and power of test 90%, the anticipated mean difference of FEV1 as 1.34% between comparison groups and anticipated distendable deviation as 1.4, the minimum sample size per group is 28, hence we have incorporated the sample size as 30 per group.

Institutional Ethical Committee clearance and consent from the participants were obtained.

Following thorough history taking and general physical examination, the individuals with history of smoking, heart/pulmonary disorders, musculoskeletal abnormalities, obese and malnourished individuals, drivers and shop keepers of drug stores, vehicle repair shops, were excluded from the study.

The Anthropometric parameters like Height (cms) and Weight (kgs) were measured. Using these parameters Body Surface Area (BSA) and Body Mass Index (BMI) were calculated.

Physiological parameters like Respiratory rate (cycle/min), Heart rate (beats/min) and Blood Pressure (mmHg) were recorded using standard techniques.

Pulmonary function parameters recorded were FVC (L), FEV1(%) & PEF (L/min). FVC & FEV1(%) were recorded using computerized spirometer- 'SPIROEXCEL', PEF was recorded using Mini Wright's Peak flow meter. The testing was performed in the relaxed sitting position after adequate demonstration,

motivation and encouragement.

Statistical analysis was done using SPSS version 16.0. Mean and Standard Deviation (SD) of all parameters was taken. Unpaired t-test was applied to know the statistical significance.

Results

Table I: Anthropometric and Physiological parameters of both control and study groups.

Parameters	Control group (n=30)	Study group (n=30)	P-value
Age (years)	32.43 + 5.59	30.00+4.21	0.062
Height (cms)	165.53+7.52	165.03+7.46	0.797
Weight (Kgs)	66.46+10.74	63.23+9.07	0.213
Body Surface area (Sq m/m ²)	1.72+0.15	1.70+0.18	0.710
Body Mass Index (Kg/m ²)	24.43+3.96	22.98+3.08	0.119
Pulse rate (Beats/min)	84.30+13.29	77.73+11.78	0.048*
Systolic Blood Pressure (mm Hg)	123.93+10.79	123.66+9.29	0.919
Diastolic Blood Pressure (mm Hg)	78.66+9.05	76.40+8.05	0.310

*P<0.05- significant, ***P<0.001-very highly significant

Table I shows the comparison of anthropometric and physiological parameters in residential and traffic exposed shop keepers. It can be seen that there is a statistically significant difference in the pulse rate of control and study groups however, both the values are within normal range. No statistical changes in BMI and BSA of both study and control group of our investigation suggest similar nutritional and socio-economic status.

Table II: Pulmonary function parameters of both control and study groups

Parameters	Control group (n=30)	Study group (n=30)	P-value
FVC (L)	2.90+0.53	2.63+0.40	0.03*
FEV1 (%)	84.97+13.89	67.61+16.85	0.000***
PEFR (L/min)	506.00+34.07	488.66+27.89	0.610

*P<0.05- significant; ***P<0.001-very highly significant.

Table II shows comparison of pulmonary function tests in control and study group. The results show variations in the lung parameters (FVC, FEV1(%), and PEFr) among the traffic exposed shopkeepers and residential shopkeepers. FVC and FEV1(%) of traffic exposed shopkeepers are found to be significantly lesser when compared to residential shopkeepers. These observations indicate possibility of obstructive lung disorders in case of shop keepers exposed to traffic pollution.

Discussion

Our observations of significant reduction of FVC and FEV1(%) and insignificant reduction of PEFr in road side shopkeepers exposed to traffic pollution were very much corroborated with observations of Ingle and Wagh in their study on shopkeepers working near national highway in Jalgaon⁽⁵⁾.

Ingle et. al. (2005)⁽⁷⁾ reported decrease in lung efficiency in the shopkeepers exposed to traffic pollution. Significant reduction in the lung capacity was observed in the higher age group of residential people living along the highway roadside. The forced expiratory volume in one-second (FEV1) and peak expiratory flow rate (PEFR) of exposed residential population was significantly affected as compared to control.

Jeelaniet al. (1992)⁽⁸⁾ reported reduced PEFr in the Kashmiri population than healthy western population due to anthropogenic, environmental, genetic and socioeconomic factors. This study concludes that the traffic policemen are highly vulnerable for respiratory impairment due to vehicular exhaust at workplace environment.

Emissions from road transport are the primary source of health hazardous pollutants, such as nitrogen oxides and carbon monoxide, and a significant source for fine particulate pollution. Exposures to these emissions are typically non voluntary and represent serious risk to human health.⁽⁹⁾

Decrease of FVC and FEV1 (%) in our study group indicates possible lungs and airway inflammation by automobile emissions. Diesel exhaust particles (DEP) emitted from automobiles capable to adsorbed organic hydrocarbons thought to consist of a carbon core

surrounded by trace metals, such as nickel, and its salts. A number of these components have shown inflammatory effects in the lungs of laboratory animals^(10, 11).

Conclusion

The results of the study indicate reduction in the lung function efficiency among the shopkeepers exposed to higher traffic pollution. The forced expiratory volume in one-second (FEV1) and Forced Vital Capacity (FVC) of exposed residential population was significantly affected as compared to control group who are residing away from higher traffic pollution.

Emphasis has to put on preventive aspects rather than on diagnosis and management of respiratory diseases. Hence protective mask wearing and reduction in timing of work shifts will help in reducing the exposure to air pollutants.

Conflicts of Interest: Nil

Limitation: Detailed information on air pollutants of the study area would have helped to understand the issue better.

State of Ethical Issues in Published Literatures: A Non-Systematic Review

Lokesh Kumar S.S¹, Sowmiya KR²

¹Lokesh Kumar.S.S, Post graduate, Department of Community Medicine, Chettinad Hospital and Research Institute (CARE), Rajiv Gandhi salai, Kelambakkam, Kanchipuram District, Tamil Nadu, ²Professor, Department of Community Medicine, Chettinad Hospital and Research Institute (CARE), Rajiv Gandhi salai, Kelambakkam, Kanchipuram District, Tamil Nadu

Abstract

Introduction: Research ethics govern the standards of conduct for scientific researchers. It is important to adhere to ethical principle to protect the dignity, rights and welfare of research participants. According to ICMR National ethical guidelines for biomedical research involving human participants should be conducted in accordance with the basic and general ethical principles. The researcher and the team are responsible for protecting the dignity, rights, safety and well-being of the participants enrolled in the study. They should have the appropriate qualifications and competence in research methodology and should be aware of and comply with the scientific, medical, ethical, legal and social requirements of the research proposal. All research involving human beings should be reviewed by an ethics committee to ensure that the appropriate ethical standards are being upheld. The importance of ethics in clinical research has been well-established for many decades. A growing attention is given to determine the best ethical practices for conducting observational and experimental studies.

Methods: A non-systematic review was performed of existing published articles in three different journals for normative ethics literature which includes Institutional ethical clearance, informed consent, assent and voluntary participation of the study participants.

Results : A total of 315 articles published in 3 different journals between 2014 and 2018 demonstrated that informed consent was obtained in 80% of articles and institutional ethical clearance was obtained in 88% of articles.

Conclusions: Ethical conduct is important for any sphere of life in medical research and publication as they directly affect the humanity. No research activity involving human subjects can be conducted and proceed unless informed consent is completely sought.

Key words: *Ethical issues, Informed ethical consent, Institutional ethical clearance.*

Introduction

Research is the pillar of knowledge, and it constitutes an integral part of progress. In the

fast-expanding field of biomedical research, this has improved the quality and quantity of life. Research that involves human subjects or participants raises unique and complex ethical, legal, social, and political issues. Research ethics specifically deals with the analysis of ethical issues that are raised when people are involved as participants in research.

The Indian Council of Medical Research (ICMR) issued the Policy Statement on Ethical Considerations Involved in Research on Human Subjects in 1980^[1]. Due to rapid advances in biomedical science and technology,

new ethical dimensions emerged which necessitated further updation of these guidelines. Subsequently the Ethical Guidelines for Biomedical Research on Human Subjects was released in 2000,^[2] followed by the revised Ethical Guidelines for Biomedical Research

on Human Participants in 2006^[3]. In the meantime, the Central Drugs Standard Control Organization (CDSCO) also released the Indian Good Clinical Practice Guidelines (2001)^[4] for clinical trials and revised Schedule Y of the Drugs and Cosmetics Act, 1940, in the year 2005^[5] with several amendments in the Rules under Drugs and Cosmetics Act in the year 2013. ICMR and the Department of Biotechnology (DBT) jointly brought out Guidelines for Stem Cell Research and Therapy in 2007 and a further revision in 2013 which is now revised as National Guidelines for Stem Cell Research, 2017^[6].

The code of conduct for physicians was well laid out in traditional Indian systems of medicine and do no harm was the underlying universal principle besides other principles applicable to the prevalent culture and the class systems of the society. Research ethics govern the standards of conduct for scientific researchers. It is important to adhere to ethical principle to protect the dignity, rights and welfare of research participants. According to ICMR National ethical guidelines for biomedical research involving human participants should be conducted in accordance with the basic and general ethical principles. The researcher and the team are responsible for protecting the dignity, rights, safety and well-being of the participants enrolled in the study. They should have the appropriate qualifications and competence in research methodology and should be aware of and comply with the scientific, medical, ethical, legal and social requirements of the research proposal. All research involving human beings should be reviewed by an ethics committee to ensure that the appropriate ethical standards are being upheld. The importance of ethics in clinical research has been well-established for many decades. A growing attention is given to determine the best ethical practices for conducting observational and experimental studies.

Informed consent protects the individual's autonomy to freely choose whether or not to participate in the research. The Nuremberg Code makes it clear that voluntary consent of the human subject is absolutely

essential for research^[7]. The process involves three components—providing relevant information to potential participants, ensuring the information is comprehended by them and assuring voluntariness of participation. Informed consent should be in a language that can be understood by the participants and it also should explain medical terminology in the research in simple terms. The informed consent document (ICD), which includes patient/participant information sheet (PIS) and informed consent form (ICF) should be reviewed and approved by the EC before enrolment of participants.

There are no available studies regarding documentation of these basic ethical practices followed during descriptive epidemiological studies.

Indian Journal of Community Medicine (IJCM), Indian Journal of Public Health (IJPH), Indian Journal of Community Health (IJCH) are three peer-reviewed national journals which are widely read by public health professionals and which publishes novel and interesting descriptive studies. Hence these three journals were chosen and reviewed for the documentation of ethical practices in their articles which is published between period of 2014 and 2018.

Method

A non-systematic review was performed of existing published articles in three different journals viz. Indian Journal of Community Medicine (IJCM), Indian Journal of Public Health (IJPH), Indian Journal of Community Health (IJCH) between 2014 and 2018 for normative ethics literature which includes Institutional ethical clearance, informed consent, assent and voluntary participation of the study participants. Descriptive epidemiological studies were only included for the study.

Statistical Analysis

The number of research articles mentioning about ethical clearance, informed consent, and assent in case of children were expressed in terms of descriptive statistics.

Data is expressed as proportions with 95% confidence interval (CI).

Results

A total of 315 articles published in 3 different

journals between 2014 and 2018 was reviewed for the study.

2014			
JOURNAL	NO. OF ARTICLES	IC	IEC
IJCH	81	54 (66.7%)	41(50.6%)
IJCM	03	03(100%)	02(66.7%)

2015			
IJCH	52	38(73.1%)	33(63.5%)
IJCM	15	13(86.7%)	10(66.7%)
IJPH	10	10(100.0%)	09(90.0%)
2016			
IJCH	18	11(61.1%)	14(77.8%)

Cont.... Table

IJCM	17	12(70.6%)	13(76.5%)
IJPH	10	08(80.0%)	09(90.0%)
2017			
IJCH	20	14 (70.0%)	16(80.0%)
IJCM	11	08(72.7%)	11(100.0%)
IJPH	18	15(83.3%)	17(94.4%)
2018			
IJCH	14	08(57.1%)	08(57.1%)
IJCM	21	18(85.7%)	20(95.2%)
IJPH	18	13(72.2%)	17(94.4%)

Informed consent was documented in 230 articles (73.01%) out of 315 articles reviewed. In IJCH of 185 articles reviewed 125 (67.6%) articles reported informed consent from study participants. In IJCM of 67 articles reviewed 54 articles (80.6%) were mentioned about written consent from the participants. In IJPH of 77 articles reviewed 59 articles (76.6%) reported getting informed consent.

Institutional ethical clearance was obtained in 230 articles (71.74%) out of 315 articles reviewed. In IJCH of 185 articles reviewed 112 articles (60.5%) got ethical approval from the Institute. In IJCM of 67 articles, 56 articles (83.6%) mentioned obtaining Institutional ethical clearance. In IJPH of 77 articles reviewed 66 articles (85.7%) obtained ethical approval.

Discussion

Out of 315 articles reviewed, 226 (71.74%) articles mentioned about ethical approval from Institutional ethical committee and 230 (73.01%) mentioned about informed consent which is higher when compared to previous studies.

Chaturvedi et al. (2009) reviewed 157 articles from the Indian Journal of Psychiatry and reported that, informed consent was mentioned in 51% of studies in 2000, which gradually rose to 82% in the year 2007 and ethics committee approvals were mentioned in 2% of studies in 2000, which rose to 28% in the year 2006 and

25% of reports in 2007.

Belhekar et al. (2014) reviewed 673 articles from four national journals and found only 163 (24.2%) articles mentioned about ethical approval and 179 (26.5%) articles mentioned about informed consent.

Sabapathy SS et al. reviewed Indian physiotherapy journals from which ethical committee clearance was mentioned in 14 out of 73 studies (19.2%); informed consent was obtained in 38 out of 68 studies (55.9%), assent in 3 out of 6 studies (50%).

It is evident that practice of reporting informed consent and Institutional ethical clearance has been increased when compared to previous study results. It is also observed that there is only minimum change in reporting ethical practices over four years.

Properly documented review and approval from a formally constituted review board (national or institutional review board or ethics committee) for all studies involving humans, medical records, and human tissues/organs were required in most of the journals. But we can see from this study only around 70% of published articles were reported about consent and ethical clearance from the institute which focus on the need for stronger direction on bioethical issues in publication. Journal editors are important for the publication of scientific documents. They should

encourage authors to meet the standards as stated in guidelines and should reject research not meeting these requirements. Editors should explain the importance of ethical protection to reviewers, readers, and researchers and publish those papers that show them as important criteria in research. Though many journals including those in the study provide guidance on information to be provided regarding ethical approval and informed consent in their Instructions to Authors, it appears that these requirements are not always adhered to by authors. Journal editors should introduce effective mechanisms to ensure that this information is reported for all research conducted on human participants. It shows there is a need to train journal reviewers by editors themselves; so that, the reviewers can guide the authors at the time of review of their research articles.

Conclusions

Ethical conduct is important for any sphere of life in medical research and publication as they directly affect the humanity. No research activity involving human subjects can be conducted and proceed unless informed consent is completely sought.

Analysis of Physical Parameters in Pre-Obese Women- An Observational Study

Manali B Badave¹, G Varadharajulu²

¹Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India, ²Dean of Krishna college of Physiotherapy, Department of Neurosciences, Krishna Institute of Medical Sciences deemed to be university, Karad, Maharashtra, India

Abstract

Objective: To analyze the physical parameters in pre-obese women.

Methods: A total of 100 pre-obese women between the age group 40-59 years were randomly selected, to analyze physical parameters in them. Pre-obese was categorized according to the BMI classification (BMI- 25-29.99). Outcome measures used for assessment included physical fitness tests such as curl ups for abdominal endurance, push ups for upper body endurance, squat test for lower body endurance. For assessing upper body muscular strength free weight flat bench press was selected and to assess lower body muscle strength leg press test was selected. Sit and reach test was performed to assess flexibility. Then we observed the physical parameters scores in pre-obese women with the normal ranges.

Result: 27% of the women showed poor muscle flexibility, 45% women showed poor results for abdominal endurance, 33% showed poor results for upper body endurance, 3% women gave poor results for lower limb endurance. 17% women showed poor results for upper body muscle strength and 3% women showed poor results for lower body muscle strength.

Conclusion: On the basis of the results of this study, it can be concluded that, the lower body muscular strength and lower limb endurance was found to be normal but flexibility, upper limb muscle strength and upper limb muscle endurance was found to be poor among these pre-obese women.

Key words: physical parameters, physical fitness, pre-obese.

Introduction

With the recent development incidence of obesity is increasing dramatically among general population.¹ The prevalence of obesity has been increasing worldwide which is 39% in adults with ratio indicating that women are more likely to be obese than men.² Prevalence of obesity is 38% for males and 40% for female respectively also, prevalence for obese and pre-obese found out to be 29.7% in India.^{2,3} It is found out that 12.7% of women are pre-obese in India.⁴

It is necessary to quantify obesity; the method used to quantify obesity may include Body Mass Index (BMI). It can be calculated by dividing an individual's weight measured in kg by their height in meters squared (kg/m^2)⁵ This index is independent of age and gender.⁵

According to the classification of BMI individuals who have score ranges between 18.50-24.99 are rated as normal, >25 are overweight, 25- 29.99 are pre-obese and above 30 considered as obese.²

A variety of factors such as poor diet, genetic predisposition, physical inactivity, advancing technology, sedentary life, physiological and behavioral factors which are implicated as contributing factors to obesity.⁶ Body mass index (BMI) has been shown to be an important predictor of risk of non communicable diseases.³ There are various negative effects of obesity on health which are hypertension, type 2 diabetes mellitus, stroke, dyslipidemia, osteoarthritis, cancer, cardiovascular diseases, respiratory system problems and on mental health.⁷

Physical fitness is defined as “the ability to carry out daily tasks with vigor and alertness, without undue fatigue and with ample energy to enjoy leisure-time pursuits and to meet unforeseen emergencies.” There are few components which can measure physical fitness are endurance, muscle strength, flexibility, agility, speed, balance.⁸

Muscular endurance is defined as “a health related component of physical fitness that relates to the external force that a muscle can exert” Muscular endurance is also known as local endurance. It is the ability of a muscle to contract repeatedly against a load, generate and sustain tension, and resist fatigue over an extended period of time. The important components of muscular endurance test are low- intensity, muscle contractions, a large number of repetitions, and a prolonged time period. So, muscular endurance can be assessed by partial curl-up test, push up test, sit ups, etc.¹⁶ Cardiopulmonary endurance is also known as total body endurance. It is associated with repetitive, dynamic motor activities such as walking, cycling or upper extremity ergometry, which involve use of the large muscle of the body. Different types of test like 6-minute walk test, 12-minute walk test, treadmill test, etc. is used to find out the functional status of respiratory, cardiovascular, and skeletal muscle systems.¹⁶

Muscle strength is “a health related component of physical fitness that relates to the amount of external force that a muscle can exert.” Muscular strength can be assessed either statically or dynamically. Static strength can be assessed by variety of devices including cable tensiometers and handgrip dynamometer. The 1-repetition maximum (1-RM) has been the standard for dynamic strength assessment which includes different methods like bench press, leg press, etc.¹⁷ Flexibility is “a health related component of physical fitness that relates to the range of motion available at a joint.”¹⁸

A cross sectional study was done on obesity, physical fitness and activity levels in Cree children, they concluded that there was a high prevalence was found of overweight in population, with low physical activity and fitness level.¹⁴ Another study was done on physical fitness and physical activity in obese and non-obese youth they concluded that obese subjects had poorer performances in various tasks e.g sit up, bent arm,

shuttle run, endurance shuttle run as compared to non-obese subjects and they had higher sport index than their obese counterparts.¹⁵

Physical activity is defined as any bodily movement produced by skeletal muscles that require energy expenditure. Exercise is a subcategory of physical activity which is structured, repetitive and purposeful.¹⁰ If the person is weak, dull, and sick and he is not able to do his work efficiently and quickly. A well balanced exercise program can improve general health, endurance and also enhances emotional well being. Any healthy person may become physically unfit if he is not doing exercise regularly.¹⁰

There are certain physiological changes occurred in body in response physical activity. Physiological changes triggered by exercises includes increased requirement for oxygen and substrate in skeletal muscle are increased, as are the removal of metabolites and carbon dioxide. Along with this certain chemical, mechanical and thermal stimuli which alters the metabolic, cardiovascular and ventilator function in order to meet this increased demands.¹¹

There are various pharmacological and non-pharmacological therapies used for treatment of obesity to stay physically fit but pharmacological treatments may leads to adverse effect on body. Regular exercises maintain the physical fitness, reduce stress and enhance the mental health. Regular physical activity increases the amount of oxygen delivered to the brain, which increases capacity to do work and allows oxygen flow to the brain enables one to cognitively functions.¹³

The purpose of the study is to observe the physical parameters in pre-obese women. Moreover no study till date hence, it is necessary to study physical fitness parameters among pre-obese women.

Materials and Methodology

Study design: Observational study, sample size- 100, Place of study- Krishna hospital and medical research centre, karad, sampling method- simple random sampling, study duration- 3 months

Participants:

Inclusion criteria: 100 subjects including women

of age group 40-59years and pre- obese women with BMI score between25-29.99 were taken in the study.

Exclusion criteria: Women with psychological ailments, undergone surgery in past or pain in past 3 months, any physical injury, subjects with history of smoking, heart and lung diseases were excluded from the study.

Outcome measures: Outcome measures were recorded after the physical fitness tests were done.

1-Body Mass Index

2- Partial curl ups (abdominal endurance)

3- Maximal push ups (upper body muscle endurance)

4- Squat test (lower body muscle endurance)

5- Free weight flat bench press(upper body strength)

6-C:\Users\rksharma\Downloads\Leg press.docx
Leg press (lower body strength)

7-Sit and Reach Test (Flexibility)

Procedure: Subjects fulfilling the inclusion and exclusion criteria were included. Informed consent form was taken from each of the subjects prior to the physical fitness tests. The motive and procedure of the study was thoroughly explained to the subjects. Instructions were given to subjects about the physical fitness tests.

Their BMI were taken in order to categories them under pre-obese. To check physical parameters physical fitness tests were done which may include curl ups for abdominal endurance,push ups for upper body endurance, squat testto check lower body endurance. To check upper body muscle strength free weight flat bench press was taken and to check lower body muscle strength leg press test was taken. Sit and reach test was done for flexibility. Then we observed the physical parameters scores in pre-obese women with the normal ranges. Then data was collected and analyzed. And after that statistical analysis was done.

Results

1. Flexibility-

i) Sit and reach test

Table no.1: Interpretation: This table shows that statistically 27% pre-obese women showed poor results for muscle flexibility in sit and reach test.

Age	Findings	Frequency	Percentage
40-59	Excellent	2	2%
	Very good	10	10%
	Good	15	15%
	Fair	27	27%

2. Endurance-

i) Curl ups (Abdominal endurance)

Table no.2: Interpretations: This table shows that statistically 45% pre-obese women showed poor results for abdominal endurance in curl ups test.

Age	Findings	Frequency	Percentage
40-49	Very good	10	10%
	Good	45	45%
	Fair	45	45%

ii) Pushups (Upper limb endurance)

Table no.3: Interpretation: This table shows that statistically 33% pre-obese women showed poor results for upper limb endurance in pushups test.

Age	Findings	Frequency	Percentage
40-59	Very good	24	24%
	Good	43	43%
	Fair	33	33%

iii) Squat test (Lower limb endurance)

Table no.4 : Interpretation: This table shows statistically 3% pre-obese women showed poor results for lower limb muscle endurance in squat test.

Age	Findings	Frequency	Percentage
40-59	Excellent	1	1%
	Good	25	25%
	Above average	23	23%
	Average	21	21%
	Below average	27	27%
	poor	3	3%

4. Muscle strength

i) Flat bench press (Upper limb muscle strength)

Age	Findings	Frequency	Percentage
40-49	Excellent	5	5%
	Good	11	11%
	Average	46	46%
	Fair	21	21%
	Poor	17	17%

Table no.5 :Interpretation: This table shows that statistically 17% pre-obese women showed poor result for upper limb muscle strength in flat bench press test.

ii) Leg press (Lower limb muscle strength)

Table no.6: Interpretation: This table shows statistically 3% pre-obese women showed poor results for lower limb muscle strength in leg press test.

Age	Findings	Frequency	Percentage
40-49	Excellent	4	4%
	Good	37	37%
	Average	45	45%
	Fair	13	13%
	Poor	3	3%

Discussion

With the recent development incidence of obesity is increasing dramatically among general population.¹ It is found out that worldwide prevalence of obesity is 39% in adults with ratio indicating that women are more likely to be obese than men.² It has been reported that prevalence of preobese women is 12.7% in India. A variety of factors such as poor diet, genetic predisposition, physical inactivity, advancing in technology, sedentary life, physiological and behavioral factors which are the contributing factors for obesity.⁶

In the current study, 100 women between age group 40-59 years fulfilling the inclusion criteria were included. From which 54 subjects were between the age group of 40-50 and 46 subjects were between the age group of 50-59 years respectively. Women who are categorized under pre-obese according to the B.M.I classification (BMI- 25-29.99) were included in the studies.

The aim of our study was to analyze the physical parameters in pre-obese women such as muscle flexibility, abdominal and muscular endurance and muscle strength. Flexibility is a health related component of physical fitness that relates to the range of motion

available at a joint.¹⁸ Sit and reach test was used to check the flexibility in pre-obese women. Statistically the present study showed that, there were 27% of women showing poor results, 15% were good, 10% were very good and 2% gave excellent results.

Muscular endurance is defined as a health related component of physical fitness that relates to the external force that muscles can exert.¹⁶ curl ups test was used to check the abdominal endurance, the present study noted that 45% women showing poor results, 45% were good and 10% were very good. Push ups test was used to check the upper limb endurance, the result was found in which 33% showed poor results, 43% were good and 24% gave very good results. To check the lower limb endurance squat test was used and statistically the present study showed that, there were 3% women gave poor results, 27% were below average, 21% were average, 23% were above average, 25% were good and 1% gave excellent results.

Muscle strength is a health related component of physical fitness that relates to the amount of external force that a muscle can exert.¹⁷ Flat bench press test was used to check the upper limb strength; statistically the present study showed that 17% women showed poor results, 21% were fair, 46% were average, 11% were good and 5% women gave excellent result. Leg press was used to check the lower limb muscle strength in which the present study showed 3% women were poor, 13% were fair, 43% were average, 37% good and 4% were gave excellent results.

A study was done on physical fitness and physical activity in obese and non-obese youth. Physical fitness was assessed by the European physical fitness test battery and activity was assessed by modified version of Beacke questionnaire. They concluded that obese subjects had poorer performances in various tasks e.g sit up, bent arm, shuttle run, as compared to non- obese subjects and they had higher sport index than their obese counterparts.¹⁵

A study was done by Carmina N.G, Marshall D, Willows N on obesity, adiposity, physical fitness and activity levels in creechildren. objectives of the study were to describe the levels of obesity, adiposity, physical activity and fitness in cree children. The study concluded that there was a high prevalence of overweight in this

population with low physical activity and fitness levels.¹⁴

A study was done on effect of 2 year physical education program on physical activity and fitness in elementary school students. In which they evaluated health related physical education program for fourth and fifth grade students designed to increase physical activity during physical education classes. Result was found that physical education curriculum provides more physical activity during physical education classes.¹⁹

At the end in our study, we concluded that lower limb strength and lower limb endurance was found normal but flexibility, upper limb muscle strength and upper limb muscle endurance was poor among pre-obese women between the age of 40-59 years.

Conclusion

On the basis of this study, it was concluded that lower limb strength and lower limb endurance was found to be normal but flexibility, upper limb muscle strength and upper limb muscle endurance was poor among pre-obese women between the age of 40-59 years.

A Study to Evaluate the Effect of Proprioceptive Neuromuscular Facilitation Stretching on Balance and Gait in Spastic Diplegic Cerebral Palsy: An Interventional Study

Mansi Dabhi¹, Shweta Rakholiya²

¹MPT Neuromuscular Science, School of Physiotherapy, RK University, Rajkot, ²Assistance Professor, School of Physiotherapy, RK University, Rajkot

Abstract

Background: Cerebral Palsy is a static, non-progressive disorder that results from brain insult or injury during any of the prenatal, perinatal and postnatal stages. Proprioceptive neuromuscular facilitation integration pattern stimulates the proprioceptors with in the muscle and tendon to enhance the performance, flexibility and balance. It is generally effective in maintaining the reaction of exercise unit by increasing the co-ordination which react to the stimulation in muscular strength and flexibility. **AIM:** To evaluate the effect of Proprioceptive neuromuscular facilitation Stretching on balance and gait in spastic diplegic cerebral palsy.

Method: Total 30 Spastic diplegic cerebral palsy subjects were assessed as per Selection criteria of the study. Consent form taken from children's parents. They were randomly divided into group-A (n=15) and group-B (n=15). spastic diplegic cerebral palsy were assessed for baseline outcome measures Pediatric berg balance, WeeFIM scale ,10 Meter walk test on day 1 and after 4 week.

Group-A was given conventional treatment and Propioceptive neuromuscular facilitation stretching which include hold -relax and contract- relax for 6-second hold and 10 repetitions for 5 days/week for 4 weeks.

Group-B was given conventional treatment. Statistical analysis was done using SPSS Software.

Conclusion: Neuromuscular facilitation stretching along with conventional therapy is more effective to improve the balance and gait in spastic diplegic cerebral palsy.

Keywords: spastic diplegic cerebral palsy. Proprioceptive neuromuscular facilitation technique, Gait, Balance

Introduction

“Cerebral” refers to the brain, and “Palsy” refers to muscle weakness/poor control. Cerebral palsy (CP) is a term used to describe a problem with posture and movement that makes certain activities difficult. Someone who has cerebral palsy has problems moving his or her muscles; this is not because of muscles or nerves, these

difficulties are caused because of problems in the brain.¹ Cerebral palsy is a well-recognized neurodevelopment condition beginning in early childhood and persisting through the lifespan.²

These disorders are attributed to nonprogressive disturbances that occurred in the developing infant brain or fetal. The motor disorders of CP are often accompanied by disturbances of perception, sensation, cognition, communication, and behavior, by epilepsy and by secondary musculoskeletal problems.³

The spastic CP type is described by exaggerated deep tendon reflexes, increased muscle tone, muscle weakness, and gait affection. Nearly 70–77% of CP

Corresponding Author:

Dr. Shweta Rakholiya,

Assistant professor, School of Physiotherapy,

RK University, Rajkot. (M): 9724779333

Mail ID: shweta.rakholiya@rku.ac.in

cases were spastic CP.⁴ Spastic diplegia (SD) is a motor impairment in the upper extremities as well as the lower extremities. The constrained capacity to generate force result in activity limitation more than the spasticity did.⁶

In spastic diplegic children, abnormal gait patterns can result from disturbance of balance, muscle weakness, spasticity and skeletal deformities.^{7,8}

These patterns are characterized by lack of mobility in the lumbar spine, pelvis and hip joints and show asymmetric pelvic motion during walking. A lot of the ambulatory children with spastic diplegia were able to attain a walk in the form of a crouch gait with flexed hips, knees and ankles.⁹

The overall pooled prevalence of cerebral palsy per 1000 children surveyed was 2.95 (95% CI 2.03–3.88). Sub-group analysis for rural, urban and mixed rural-urban study population demonstrated the pooled prevalence as 1.83 (95% CI 0.41–3.25), 2.29 (95% CI 1.43–3.16) and 4.37 (95% CI 2.24–6.51) respectively.¹⁰

Proprioceptive neuromuscular facilitation integration pattern stimulates the proprioceptors with in the muscle and tendon to enhance the performance, flexibility and balance. It is generally effective in maintaining the reaction of exercise unit by increasing the co-ordination which react to the stimulation in muscular strength and flexibility.

The facilitated progression due to PNF procedures follows a hierarchical process from mobility to stability then controlled mobility to skillful movement. Studies have stated that PNF stretching is effective in improving muscle strength, flexibility, posture coordination and gait.

Method

- **Study Design:** interventional Study
- **Study Setting:** Morbi City
- **Sampling Technique:** Purposive Sampling
- **Study Population:** Spastic diplegic cerebral palsy
- **Sample Size:** 30 Subjects
- **Study Duration:** 6 months

Selection Criteria:

Inclusion Criteria:

- Children diagnosed as Spastic Diplegic cerebral palsy.
- Age bsetween 5-12 years and both gender.
- Gross motor function level I and II.
- Written consent from their parents.
- Spasticity range between 1 and 1+ grade according Modified Ashworth scale.
- Able to follow simple verbal instructions.

Exclusion Criteria:

- Uncooperative subjects.
- Uncontrolled epilepsy.
- Receiving botulinum toxin injections or surgery no earlier than 6 months before project start.
- Presence of shortening or deformities of the ankle, knee and/or hip joints that prevented the children from keeping their feet on the ground.

Procedure:

The proposal is approved by Ethical clearance for the study was obtained from the Ethics Committee, School of Physiotherapy, RK University and CTRI (Clinical trial registry – India).

Written consent was taken from subjects' parents who fulfilled selection criteria and were willing to participate in the study.

On the first visit, spastic diplegic cerebral palsy was assessed for baseline outcome measure WeeFIM, Pediatric berg balance and 10 meter walk test.

Group A (n=15): conventional Physiotherapy and Proprioceptive neuromuscular facilitation stretching which include hold -relax and contract- relax for 6-second hold and 10 repetitions and 2 minutes rest in between, for 5 days/week for 4 weeks.

Group B (n=15): conventional Physiotherapy.

Result

Data Analysis:

Descriptive statistics were used to describe sample characteristics. The significance level selected was 0.05.

Statistical Analysis:

All the statistical analysis was done by statistical package for the social science (SPSS) Statistical software version 21.0 for windows. The pre and post value were collected from both the group before and after intervention. Statistics was performed by using the

following statistical tests:

For, Pediatric Balance Scale and WeeFIM:

Intra Group: Wilcoxon signed-rank Test

Inter Group: Mann-Whitney U Test

For, 10MWT:

Intra Group: Paired T Test

Inter Group: Un-paired T Test

TABLE 1: GROUP A INTRAGROUP ANALYSIS

OUTCOME	MEAN		SD		T/Z Value	P Value
	Pre	Post	Pre	Post		
PBS	29.80	32.20	1.69	1.82	Z Value=3.456	0.001
WeeFIM	77.46	79.20	2.89	3.028	Z Value=3.341	0.001
10MWT	0.498	0.433	0.0013	0.015	T Value=5.727	0.000

The mean average for PBS improved from 29.80(pre) to 32.20(post). Similarly, for WeeFIM the mean average improved from 77.46(pre) to 79.20(post) and for 10MWT mean average improved from 0.498(pre) to 0.433(post). As per data reflects that P value is lesser than 0.05 which shows significant difference in PBS, WeeFIM and 10MWT IN Group A.

TABLE 2: GROUP B INTER GROUP ANALYSIS

OUTCOME	MEAN		SD		T/Z Value	P Value
	Pre	Post	Pre	Post		
PBS	30.53	30.60	2.29	2.38	Z Value=0.332	0.739
WeeFIM	80.40	80.20	1.88	1.52	Z Value=0.690	0.590
10MWT	0.049	0.059	0.049	0.052	T Value=0.332	0.924

The mean average for PBS from 30.53(pre) to 30.60(post) was not significantly improved. Similarly, for WeeFIM the mean average was not improved from 80.40(pre) to 80.20(post) and for 10MWT mean average from 0.049(pre) to 0.059(post) was not significantly improved. As per data reflects that P value is more than 0.05 which shows significantly not improved in PBS, WeeFIM and 10MWT.

TABLE 3: INTRA GROUP ANALYSIS

OUTCOME	MEAN		SD		Z Value	P Value
	Group A	Group B	Group A	Group B		
PBS	4.66	0.66	1.496	0.798	4.546	0.000
WeeFIM	5.26	0.200	2.016	1.146	3.3451	0.000
10MWT	0.052	0.050	0.0065	0.0045	4.253	0.001

The mean average for PBS is 4.66(post) and 0.66(post) respectively for group A and B. similarly for WeeFIM the mean 5.26(post) and 0.200(post) for group A and B. and the mean average for 10MWT is 0.52(post) and 0.050(post) respectively for group A and B. As per data reflects that P value is lesser than 0.05 which shows significant difference between both groups.

Discussion

The results of the present study showed that conventional physical therapy and Proprioceptive neuromuscular facilitation stretching is more effective to improve Gait, Balance and Functional independence in spastic diplegic cerebral palsy. Thus, the null hypothesis is rejected.

The probable mechanism by which PNF could have worked is by facilitating the neuromuscular mechanism, by stimulating the proprioceptors.

PNF increases the ROM by increasing the length of muscle and the neuromuscular efficiency. The physiological mechanism for increasing the ROM and strength may be due to autogenic inhibition, reciprocal inhibition, and stress relaxation so, it helps to lengthening the contracted structures, relax the hypertonic muscles, initiating the movements, strengthening the weak muscles and improving the control of the pelvis.

The reason for better balance and lower extremity function in PNF group may be due to the way it utilizes the different proprioceptive information for stimulating nerve and muscles function by utilizing distinct helical form pattern which is based on functional components to aid reaction of motor system located in muscles and

joints, and turn human movements into patterns for various uses such as exercise intervention. Improvement of balance ability might have resulted from facilitation of proprioceptive sense, leading to change in various supports leads to increase in stability of joints.

PNF have various exercises aim to improve stability and mobility components, once the desired stability components are achieved it mobility component further helps to improve function.

Logeshwari Selvaraj [2018] conducted study in which Proprioceptive Neuromuscular facilitation technique on trunk were Trunk exercise and PNF techniques was perfume on spastic hemiplegic cerebral palsy and concluded that the PNF technique exercises improved significantly better performance in their activities of daily living.

Chandan Kumar [2016] conducted study on Comparison between Task - Oriented Training and Proprioceptive Neuromuscular Facilitation Exercises on Lower Extremity Function in Cerebral Palsy. Concluded that both Task-Oriented Approach and Proprioceptive Neuromuscular Facilitation Exercises are beneficial in improving lower extremity function in children with cerebral palsy.

Further recommendation:

- Study can be done with other type of PNF technique
- Study can be done on other type of cerebral palsy or on other type of neurological conditions like stroke.

Conclusion

This study concluded that proprioceptive neuromuscular facilitation stretching along with conventional therapy is more effective to improve the balance and gait in spastic diplegic cerebral palsy patients.

Metabolic Syndrome: Prevalence of Its Components in Post Menopausal Females

Karanpreet Bhutani¹, Punam Rani², Arvind Kumar³, Suvarna Prasad⁴, Sunita Manhas⁵

¹Assistant Professor, ²M.Sc. Med. Biochemistry, ³M.Sc. Med. Biochemistry, ⁴Prof. & Head, Department of Biochemistry, MMIMSR, MMDU, Mullana. ⁵Associate Professor, Department of Biochemistry, MMIMSR, MMDU, Mullana

Abstract

Introduction: Metabolic syndrome is a cluster of metabolic abnormalities characterized by abdominal obesity, hyperglycemia, decreased high density lipoprotein (HDL), increased Triglycerides and high blood pressure, which predispose the individual at higher risk for both cardiovascular disease (CVD) and type 2 diabetes. Postmenopausal state is considered as a vulnerable period for developing MS.

Aims and Objectives: To study the Prevalence of metabolic syndrome and its components in postmenopausal women.

Material and Method: This study was conducted in the Department of biochemistry, MMIMSR, MMDU, Mullana, Ambala. A total of 100 postmenopausal women in the age group of above 45 years were recruited for this study after assessing their eligibility according to the selection criteria.

Biochemical Investigations: Estimation of Fasting Serum glucose was done on Erba chem 7 analyzer and Total cholesterol, HDL and Serum Triglycerides was done on Dimension® clinical chemistry system manufactured by Siemens Healthcare Diagnostics (US).

Results: The mean triglycerides and fasting serum glucose levels were significantly high (<0.001) among postmenopausal women with metabolic syndrome. Overall prevalence of metabolic syndrome was 29%.

Conclusions: Evaluating the biochemical parameters in postmenopausal women is useful for assessing the risk of developing metabolic syndrome in them. Monitoring the health status of these females can help to reduce the Prevalence of metabolic syndrome and thus the risk of developing cardiovascular disease.

Keywords: Metabolic syndrome, Postmenopausal, Components, Cardiovascular, Triglycerides

Introduction

Metabolic syndrome (MS) is a cluster of metabolic abnormalities characterized by abdominal obesity, hyperglycemia, decreased high density lipoprotein

(HDL), increased triglycerides and high blood pressure, which predispose the individual at higher risk for both cardiovascular disease (CVD) and type 2 diabetes. [1] In 2001, The Third Report of National Cholesterol Education Program Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III) (ATP III) emphasized the importance of the metabolic syndrome and provided a working definition of this syndrome for the first time. [2] Postmenopausal state is considered as a vulnerable period for developing MS, and this increased risk has been attributed to decreasing estrogen levels with an increasing risk of insulin resistance

following menopause.^[3,4] The Metabolic syndrome in postmenopausal women, in particular, needs to be given adequate attention as early as possible followed by an aggressive approach toward prevention and management. There is high prevalence of abdominal obesity, hypertension, diabetes, lipid abnormalities, and metabolic syndrome in India.^[5] Obesity correlates strongly with multiple coronary risk factors, of which it is an important determinant.^[6]

Aims and Objectives

To study the Prevalence of metabolic syndrome and its components in postmenopausal women.

Material and Method

This study was conducted in the Department of Biochemistry, MMIMSR, MMDU, Mullana, Ambala. 100 postmenopausal women in the age group of above 45 years visiting MM Super speciality hospital were considered in our study. Postmenopausal women were considered having metabolic syndrome if they had any three or more criteria of Modified National Cholesterol Education Program Adult Treatment Panel III [NCEP ATP III criteria].^[2]

Exclusion Criteria

A woman on hormone replacement therapy, with secondary hypertension and history of smoking and alcoholism were excluded from the study.

Sample Collection:

A venous blood sample was collected from all the subjects who came after 8–12 h overnight fast and was sent for fasting serum glucose, triglycerides, total cholesterol and high-density lipoprotein (HDL) cholesterol.

Biochemical Investigation

Estimation of Fasting serum glucose was done by Glucose oxidase (GOD) and Peroxidase (POD) method on Erba chem 7 analyzer.^[7] Total cholesterol,^[8] HDL,^[9] and Serum Triglycerides was done by enzymatic method^[10] on Dimension® clinical chemistry system manufactured by Siemens Healthcare Diagnostics (US).

Statistical Analysis

All the data were analyzed by using the SPSS version 20. Values were presented as Mean \pm standard deviation (SD). To test the significance between the study group and the control groups analysis was done by a student's t- test. The p-value ($p < 0.05$) was significant.

Results

A total of 100 postmenopausal women were studied. There were 29 Postmenopausal woman who were found to have metabolic syndrome. Table 1 shows Comparison of biochemical parameters of post-menopausal females with metabolic syndrome and without metabolic syndrome. The mean Fasting serum glucose levels were higher in the postmenopausal women with metabolic syndrome (142.76 ± 42.55) compared to the postmenopausal women without metabolic syndrome (99.63 ± 25.36) and the difference was statistically highly significant ($p < 0.001$). The mean total cholesterol levels were higher in the postmenopausal women with metabolic syndrome (177.55 ± 41.19) compared to the postmenopausal women without metabolic syndrome (165.92 ± 43.18) but the difference was statistically not significant (0.218). The mean serum triglycerides levels were higher in the postmenopausal women with metabolic syndrome (202.24 ± 41.30) compared to the postmenopausal women without metabolic syndrome (137.46 ± 48.11) and the difference was statistically highly significant ($p < 0.001$). The mean HDL cholesterol levels were lower in the postmenopausal women with metabolic syndrome (36.52 ± 7.17) compared to the postmenopausal women without metabolic syndrome (41.06 ± 15.69) but the difference was statistically not significant (0.139). Overall prevalence of the metabolic syndrome among postmenopausal women was 29%. The percentage prevalence of components of metabolic syndrome i.e. fasting blood sugar ≥ 100 mg/dl, Triglyceride ≥ 150 mg/dl, High-density-lipoprotein-cholesterol < 50 mg/dl, , waist circumference ≥ 80 cm, and systolic blood pressure ≥ 130 mmHg/diastolic blood pressure ≥ 85 mmHg are presented in Table 2. The percentage of these components of metabolic syndrome among postmenopausal women were 18%, 20%, 12%, 22% and 19% respectively.

Discussion

In the present study, 29% of the total 100 postmenopausal females had metabolic syndrome. Study by Deibert et al [11] showed that the Prevalence of metabolic syndrome among postmenopausal women was 36.1%.

On comparing the postmenopausal women with metabolic syndrome with postmenopausal without metabolic syndrome, it was found that mean BMI, waist circumference, systolic blood pressure and diastolic blood pressure was significantly higher in postmenopausal women with metabolic syndrome.

Study by Lobo (2008) suggested that weight increase and obesity greatly increase the Prevalence of metabolic syndrome among postmenopausal women. Changes in central obesity can cause metabolic abnormality and influence health. [12] There is a fall in the estrogen secretion among postmenopausal women resulting in assemblage of abdominal fat. Increase in systolic blood pressure and diastolic blood pressure is suggestive of risk of cardiovascular disease in postmenopausal females with metabolic syndrome.

Our study showed an increase in Fasting serum glucose, Triglycerides and a fall in High-density lipoprotein levels in postmenopausal women with metabolic syndrome. There are different studies about the menopausal effect on above biochemical parameters. Studies by Peter et al [13], and Davis et al [14] showed no effect of menopause on Triglycerides while studies by

Jensen et al [15] and Bergman et al [16] had findings similar to our study. There was a fall in High-density lipoprotein levels in postmenopausal with metabolic syndrome. It has been reported that deposition of Triglycerides leads to lipotoxicity which may be associated with β - cell dysfunction and insulin resistance.[17] Hypertriglyceridemia stimulates the enzymatic activity of cholesterol ester transfer protein, which facilitates the transfer of Triglycerides from Triglyceride – rich Lipoproteins (Chylomicrons and Very- low- density Lipoproteins) to High- density lipoprotein and Low-density lipoprotein in exchange for Cholesteryl esters [18] leading to increase in Triglycerides content of High-density lipoprotein and Low- density lipoprotein .

Kreisberg et al [19] showed that reduction in High-density lipoprotein levels should be taken as a risk factor for coronary heart disease among postmenopausal females. High waist circumference and increased triglycerides levels were the most common components of metabolic syndrome in postmenopausal females in our study. This is suggestive of an increase in the risk of cardiovascular disease in postmenopausal females with metabolic syndrome.

Conclusion

Evaluating the biochemical parameters in postmenopausal women is useful for assessing the risk of developing metabolic syndrome in them. Monitoring the health status of these females can help to reduce the Prevalence of metabolic syndrome and thus the risk of developing cardiovascular disease.

Table 1: Comparison of biochemical parameters of post-menopausal females with metabolic syndrome and without metabolic syndrome.

Parameter	Post-menopausal women with metabolic syndrome (Mean \pm S.D.)	Post-menopausal women without metabolic syndrome (Mean \pm S.D.)	p value	Significance
Fasting serum glucose (mg/dl)	142.76 \pm 42.55	99.63 \pm 25.36	<0.001	HS
Total Cholesterol (mg/dl)	177.55 \pm 41.19	165.92 \pm 43.18	0.218	NS
Triglycerides (mg/dl)	202.24 \pm 41.30	137.46 \pm 48.11	<0.001	HS
HDL(mg/dl)	36.52 \pm 7.17	41.06 \pm 15.69	0.139	NS

Table 2: Prevalence of metabolic syndrome and its components in post-menopausal females.

	Number	Percentage (%)
Metabolic Syndrome	29	29%
Fasting serum glucose ≥ 100 mg/dl	18	18%
Triglycerides ≥ 150 mg/dl	20	20%
High-density-lipoprotein-cholesterol < 50 mg/dl	12	12%
Waist circumference ≥ 80 cm	22	22%
Systolic blood pressure / Diastolic blood pressure ≥ 130 mmHg / ≥ 85 mmHg	19	19%

Sociodemographic Characteristics of Pregnancy Induced Hypertension: An Observational Study in the Kolhapur Population

Jyosthana Koppula¹, Vasudha Sawant¹

¹Junior Resident, ²Associate Professor, Department of Obstetrics and Gynaecology, Dr D. Y. Patil Hospital and Research Centre and D. Y. Patil Medical College, D.Y. Patil Education Society, Kolhapur

Abstract

Backgrounds: Pregnancy Induced Hypertension (PIH) is the foremost cause of maternal and neonatal mortality. Research suggests PIH is associated with different socio-demographic parameters. However, there is a paucity in the data regarding the socio-demographic characteristics of pregnancies affected by hypertension. This study aimed at evaluating socio-demographic characteristics of PIH in Kolhapur district, Maharashtra.

Materials and Method: Pregnant women (n=150) with Blood Pressure >140/90 mm of Hg after 20 weeks of gestation and willing to give consent were included. Those not willing for follow up, patients with history of obesity, chronic hypertension, coronary heart disease were excluded. Data collection was done using pre-designed, pre-tested questionnaire comprising of questions on sociodemographic parameters. Association between variables was calculated by chi square test and P-values < 0.05 were considered significant.

Results: Mean age of the participants was 22.57 ± 3.68 years, 81% suffered from mild PE (n=122) and 62% were primiparas (n = 93). 97% of them belonged to the rural background, and most of them were literate (n=107, 71.33%). 52% (n=82) belonged to Class I status. Neonatal outcome was normal in most (n=137), preterm births (n=18), intrauterine growth restriction (IUGR) (n=31), in neonatal intensive care unit (NICU) (n=15). Sociodemographic parameters and PIH showed no association.

Conclusion: Primipara women had higher incidence of pregnancy induced hypertension. However, pregnancy induced hypertension did not seem to have any association with the socio-demographic variables.

Keywords: Blood Pressure, Hypertension, intrauterine growth restriction

Introduction

Pregnancy related hypertension (PIH) is classically defined as a condition where systolic blood pressure (SBP) >140 mm of Hg and a diastolic blood pressure

(DBP) >90 mm of Hg is diagnosed.⁽¹⁾ As per the Canadian Hypertension Society, PIH can be referred to any one of pre-existing hypertension, gestational hypertension and Pre-eclampsia (PE), pre-existing hypertension with gestational hypertension and proteinuria and unclassifiable hypertension.⁽²⁾

Corresponding Author:

Dr. Vasudha Sawant,

Associate Professor, Department of Obstetrics and Gynaecology, Dr D. Y. Patil Hospital and Research Centre and D. Y. Patil Medical College, D.Y. Patil Education Society, Kolhapur – 416006, Maharashtra, (India), Email: vasudhaswnt@gmail.com, Tel no: 7385045684

PE and eclampsia are the primary culprits of maternal and perinatal mortality and morbidity. PIH is known to affect about 6-10% of all pregnancies.⁽³⁾ Most common pathologies related to PE are haemolysis, elevated liver enzymes and low platelet count (HELLP) or partial HELLP syndrome. Furthermore, haemorrhagic stroke and pulmonary oedema have been

reported as the primary causes of mortality in eclamptic women. ⁽⁴⁾ Other maternal short-term complications include dysfunction of the central nervous system, acute disseminated intravascular coagulation (DIC), cerebrovascular events, hepatocellular injuries, oliguria, pulmonary oedema, placental abruption, and thrombocytopenia. ⁽⁵⁾ Complications associated with PE are more prominent when in early-onset (<32 weeks of gestation) PE as compared to late-onset PE. ⁽⁶⁾ Women with PIH are predisposed to several other conditions such as hypertension, cardiovascular disease (CVD), diabetes mellitus and renal diseases later in life. ⁽⁷⁾

PIH is the most prevalent cause of maternal death in Europe. ⁽⁸⁾ It was third among the leading causes of maternal deaths in a tertiary centre in India. ⁽⁹⁾ Savitz et al showed that women who were Hispanic and Black were at a higher risk of PIH compared to white women. A reduced risk was seen in Asian women. The study also suggested a positive correlation between pre-pregnancy weight and risk of PIH. ⁽¹⁰⁾

There have been previous studies in India which have demonstrated associations of PIH with several biochemical and haematological parameters. ^(11,12) However, studies relating to PIH with socio-demographic variables are rare. As it is known that PIH is affected by socio-demographic variables, there is a need to study this aspect of PIH across different regions of India, and thereby developing strategies to prevent it. ⁽¹³⁾ Here, we studied the socio-demographic characteristics of women suffering from PIH in tertiary care centre in Kolhapur district of Maharashtra.

Methods

The prospective observational study was undertaken at the Department of gynaecology and obstetrics, at a tertiary care hospital, Kolhapur, for a period of two years. A total of 150 women were selected by random sampling method and enrolled in the study, post the approval from the institutional ethical committee. An informed and written consent was obtained from them. All pregnant women with BP>140/90 mm of Hg after 20 weeks of gestation and giving consent were included in the study. Those not willing for follow up, patients with history of obesity, chronic hypertension, coronary heart disease, impaired renal failure, Smokers and alcoholics were excluded.

The data was collected using predesigned and pretested questionnaire comprising of two parts. The first part had details of socio demographic characteristics like name, age, residence etc. Second part included the general physical and detailed systemic examination findings. Sociodemographic variables were classified based on modified Kuppuswamy classification. ⁽¹⁴⁾ Severity of PIH were classified based on symptoms, signs, and other investigations.

The data was analysed on MS-Excel package 365. The qualitative variables were expressed in terms of percentages. Quantitative variables were categorised and expressed in terms of percentages or in terms of mean and standard deviations. Association between variables was calculated by chi square test. P-values below 0.05 were considered significant.

Results

The mean age of the participants in the study ranged from 18-32 years with a mean age of 22.57 ± 3.68 years. A significant number were ≤ 25 years of age ($P= 2.20e^{-16}$). There were 112 patients suffering from mild PE (SBP 140-149, DBP 90-99 mmHg), 24 from severe PE (SBP 150-159, DBP 100-109 mmHg) and 4 from eclampsia (SBP ≥ 160 and DBP ≥ 110 mmHg). Participants in the study group were classified according to their socio-demographic parameters in order to assess their impact on the incidences of PIH.

Majority of participants in the study were between 21-25 years of age ($n=66$), followed by women between 18-20 years. A significant proportion of the sample (62%, $n=93$) were primiparas ($P=5.31e^{-5}$) and 97.33% ($n=146$), belonged to rural background ($P=2.20e^{-16}$). There were 6% ($n=9$) of patients who had a history abortion, and 2.67% ($n=4$) had a history of still birth in the past.

The mean SBP was 149.11 ± 9.31 mm of Hg and mean DBP was 90.67 ± 2.50 mm of Hg. About 22.67% had SBP and 2% ($n= 3$) of them had more than 180 mm of Hg. Likewise, 6.67% ($n=10$) of the patients had diastolic blood pressure more than 100 mm of Hg in the present study. Maximum number of women were affected with mild PE ($n=122$, 81.33%), 24 had severe PE (16%) whereas 4 of them (2.7%) suffered from eclampsia.

More than half (54.67%, n=82), of the participants were of Class-I, i.e. upper class . A significant fraction of the sample was poorly educated (middle school or below, $P=3.47e^{-13}$). As many as 136 patients showed PIH related symptoms. The most common symptom was pedal oedema (n=40), followed by abdominal pain (n=31) and epigastric discomfort (n=22). A complete account of the symptoms has been depicted in figure 1. However, no association between PIH (PE and

eclampsia) and sociodemographic variables was noted. Chi-square test between PIH and the variables, returned a P-value >0.05 .

Most women had normal deliveries (91.33%, n=137), while 13 had Lower segment Caesarean section (LSCS). Mean birth weight of the babies was 2.57 ± 0.44 kgs. A total of 65 neonates (43.5%) presented complications (figure 2).

Figure 1. An account of the PIH symptoms in participants

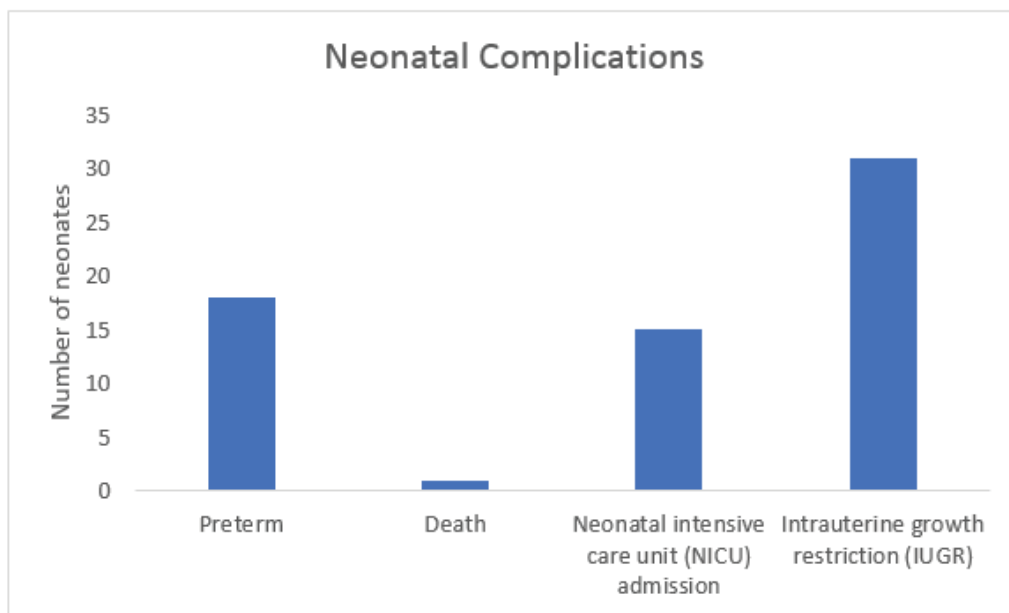

Figure 2. Distribution of neonatal complications

Discussion

PIH is one of the leading causes of foetal and maternal mortality all over the world. The estimates of the mortalities are much higher in developing countries of Asia (varying between 20-80 %), than the rest of the world.^(15,16) PIH is affected by a number of factors, sociodemographic being one of them. In India, the incidence of PE was estimated to be 8-10 % of the total pregnancies.⁽¹⁷⁾ Although, studies emphasizing the biochemical factors and PIH have been numerous, reports relating to the effect on socio-demographic variables have been few.^(12,18) As demographics can impact PIH, region-specific studies will help in preventive measures

Concurrent with the present study, the mean age of women in PIH group was 23.8 years in a study by Manjusha et al, in the Pune district of Maharashtra. Additionally, a significant number were ≤ 25 years ($P=2.20e^{-16}$).^(19, 20) However, in a particular study in north India by Mehta et al, incidences of PIH was found in women >25 years of age.⁽²¹⁾ In the present study, only 4.67% ($n=7$) were >30 years of age. This bias could be explained as a lesser prevalence of pregnant women above 30 years in the studied region. However, in Iran, a considerable number of participants were above the age of 35 years.⁽²²⁾ In a survey on maternal hypertension, there were 32% Chinese and Filipinos, 37% Koreans, and 49% Japanese mothers who were above 35 years suggesting ethnic differences between PIH age groups.⁽¹³⁾

PIH was classically proposed as a disease of the first pregnancy.⁽²³⁾ Herein, it is reported that a significant number ($P=5.31e^{-5}$) of women were primiparas (62%). This is consistent with several other previous studies who reported number of incidences of primiparas ranging from 52-73%.⁽¹⁹⁻²¹⁾ Previous literature suggests, risk of PE in primiparas in almost twice is higher than those in multiparas⁽²⁴⁾. However, a recent report also suggested that the data for the impact of parity in PE were conflicting and both nulliparas and multiparas were predisposed to PE risk⁽⁵⁾

Herein, a significant number of women ($P=2.20e^{-16}$) belonged to a rural background. A study by American Society of Nephrology states that women in rural areas have increased incidence of PIH.⁽²⁵⁾ Studies by Jena et al and Bangal et al also report similar findings in

the eastern and western regions of India respectively.^(26,27) Conflicting trends were reported for Africa where rural women in Nigeria .^(28, 29) Factors like poverty, poor availability of health care facilities and lack of awareness regarding PIH in the rural population could be responsible for the higher incidence of PIH in the rural population.

Likewise, education and socio-economic status has also been shown to be associated with the incidences of PIH.⁽³⁰⁾ A major population of women were poorly educated (middle school or below, $P=3.47e^{-13}$) although we did not find any significant association between education and PIH similar to Ramesh K et al.⁽²⁰⁾ In studies outside India illiterate and poorly educated women were seen to be at a higher risk of PIH.^(13,30) In India however, literate women are more predisposed to the risk of PIH and is explained by the rising levels of stress at work and college.^(21,20,30,31) This is also in part linked to the knowledge and awareness regarding their health issues and PIH in women. Many cases of PIH among illiterate women go unnoticed and unreported due to their ignorance.^(31,12) Likewise, low socioeconomic status has been linked to increased risk of PIH, which is in contrast this study, wherein a significant population despite belonging to the upper class suffered from PIH.^(12,31,20) As most patients belonged to the rural background, lack of proper healthcare facilities in spite of being economically sound, could be a plausible explanation for this.

As regards the symptoms, pedal oedema has been reported to be one of the main symptoms in patients with pregnancy induced hypertension, concurrent with our study. Other prevalent symptoms include headache and blurred vision and epigastric pain.⁽³²⁾ Patients suffering from PIH have also been shown to present several neonatal complications like IUGR, pre-term births and even death of the neonates in few cases.⁽³³⁾ Our study was in line with these and a considerable number of neonates had IUGR while a few were also preterm births.

Over-all the study demonstrated that PIH was more prevalent in women who are below 25 years, belong to rural areas, primipara and poorly educated. There seems to be a need to improve awareness among women about their health during pregnancy. Also, as a major part of India is covered by rural population, more

women healthcare centres at rural level are needed to be established to provide accessible healthcare facilities to these women in their locality. Our study provides a broad idea about the factors related to PIH. Similar studies with a larger sample size and/or multi-centres would be able to give a clearer picture of all the parameters affecting PIH.

Conflicts of Interest: The authors declare that they have no conflict of interest.

Utilization of Antenatal Care Package among Women of Urban Slums

Shruti. Kardalkar¹, Mayur S. Sherkhane²

Senior Resident, Department of Community Medicine, Gulbarga Institute of Medical Sciences and Hospital, Gulbarga, Karnataka, India, ²Professor, Department of Community Medicine, SDM College of Medical Sciences and Hospital, Dharwad, Karnataka, India

Abstract

Background: Antenatal period is an essential phase in shaping health care of the nation. Complete antenatal package includes minimum of three antenatal visits, two tetanus toxoid injections during the pregnancy, or received one tetanus toxoid injection during the pregnancy and at least one in the three years prior to the pregnancy, and received iron and folic acid tablets for 100 days. Utilization of complete antenatal package is pivotal for every pregnant woman and is influenced by socio-demographic factors. **Objectives:** To study the pattern of utilization of antenatal care package and factors influencing it among pregnant women of urban slums. **Methods:** Cross sectional study was done and data was collected by house to house survey after taking consent, using a pre-designed and pre-tested proforma. **Results:** Majority of 40.44% were in the age group of 18-25 years, 36.89% had completed primary education and 53.78% belonged to lower socioeconomic class. 39.56% women had availed the complete ANC package. Primigravida, literates and homemakers had utilized complete ANC package more effectively. ($p < 0.05$) Utilization of the complete ANC package was less among lower socioeconomic status women and labourers. **Conclusion:** Though women had undergone antenatal visits regularly but there was disparity in utilizing the complete ANC package, which should be focussed and emphasized on a larger perspective so as to build a healthy motherhood.

Key words: Antenatal Package, Health-care, Literacy, Pregnant, Slum, Urban, Women.

Introduction

To attain Every Woman Every Child vision and the Global Strategy for Women's, Children's and Adolescents' Health, innovative, evidence-based approaches to antenatal care (ANC) is required. The World Health Organization (WHO) envisions a world where every pregnant woman and newborn receives quality care throughout the pregnancy, during childbirth and postnatal period. ANC imparts a key platform for health-care functions, which is defined as "the care

provided by skilled health-care professionals to pregnant women and adolescent girls in order to ensure the best health conditions for both mother and baby during pregnancy." The components of ANC include risk identification, prevention and management of pregnancy related or concurrent diseases and health education and health promotion.¹

Global estimates indicate that only half of all pregnant women receive recommended amount of ANC package.² Nevertheless, the utilization of complete ANC package is not ubiquitous in India which was reflected during the National Family Health Survey 4 (NFHS-4), where only 21% of pregnant women had availed the services completely.^{2,3} In Karnataka, the utilization rates of full ANC care was 32.8% as per NFHS 4.⁴

Utilization of ANC services is of paramount importance for reducing maternal mortality in India.^{2,5,6}

Each day in 2017, approximately 810 women died from preventable causes related to pregnancy and childbirth. Between 2000 and 2017, the maternal mortality ratio (MMR, number of maternal deaths per 100,000 live births) dropped by about 38% worldwide. 94% of all maternal deaths occur in low and lower middle-income countries. The MMR in low income countries in 2017 was 462 per 100 000 live births versus 11 per 100 000 live births in high income countries. Sub-Saharan Africa and Southern Asia accounted for approximately 86% (254 000) of the estimated global maternal deaths in 2017. Sub-Saharan Africa alone accounted for roughly two-thirds (196 000) of maternal deaths, while Southern Asia accounted for nearly one-fifth (58 000).⁷ In India maternal mortality accounts to 130/100,000 live births for the year 2014-16.⁸

WHO new antenatal care model increases the number of contacts/visits a pregnant woman has with healthcare providers throughout her pregnancy from four to eight. Focusing on a positive pregnancy experience, these new guidelines seek to ensure not only a healthy pregnancy for mother and baby, but also an effective transition to positive labour, childbirth and ultimately to a positive experience of motherhood.⁹

ANC is an essential component in the primary health care services of a country, which aims for a healthy society.¹⁰

Ensuring appropriate ANC services is of paramount importance in safeguarding maternal and newborn health, in India where health risks results from the vicious cycle of malnutrition, poverty as well as literacy status of the family.¹¹ In developing nations, though there is adequate provision of maternal health services but there is dearth in effective utilization. Thus, the present study was conducted with objectives of assessing the utilization of complete antenatal care package and the factors influencing in availing these services among pregnant women residing in urban slums.

Methodology

Study design:

A community based, cross-sectional study was conducted for a period of one year in the urban slums. The study was carried out by interviewing women in the

age group of 15-45 years, who delivered three months before the start of the study residing in urban slums, which is the field practice of Urban Health Training Centre attached to a tertiary care hospital.

Voluntary consent:

As the study was community based, the women were enrolled in the research after obtaining written informed consent on voluntary basis.

Sampling method:

The overall sample size was calculated as 225, using the formula $4pq/L^2$, where p is the prevalence 64% (According to World Health Organization, globally 64% of women receive ANC complete package)¹ q=1-p and L the permissible error, taken as 10%, the sample size worked out to be 225 at 5% alpha error. The total population of urban field practice area is 30,000. With an average family size of five members, 6000 families were residing in the study area. To achieve the required sample size, every 10th house was considered and only one woman from each family was included in the study, as she was considered to be representative of the selected family. Further for confirmation of the services utilized and to avoid recall bias, only those women were selected who had mother card with details of ANC and services availed.

Sampling procedure:

House to house survey was carried out by the investigators, by doing systematic random sampling (every 10th house was considered), if there was no study participant in the 10th house, then as per the procedure followed in systematic random method, the next houses were considered (i.e. 11th, 12th and so on). Later, as per the protocol systematic sampling method was continued considering 20th, 30th house and so on till the required sample size was achieved. Anganwadi workers and medico social workers played a pivotal role in establishing rapport with the study participants. One woman was selected from each house and she was considered as representative of the family. No other woman was selected from the same family, so as to avoid replication of the data and recall bias.

Inclusion and exclusion criteria: Women in the age group of 15-45 years, who had delivered three

months before the start of the study and residing in the study area for more than one year and who gave consent on a voluntary basis to participate in the study were included. Only the present pregnancy was considered for the study. Women who did not comply with the inclusion criteria were excluded.

Complete ANC package: Complete antenatal package includes those women who had a minimum of three antenatal visits, at least two tetanus toxoid injections during the pregnancy, or received one tetanus toxoid injection during the pregnancy and at least one in the three years prior to the pregnancy, and received iron and folic acid tablets for 100 days or more.⁷

Data collection:

A community based, cross-sectional study was conducted for a period of one year in the urban slums. Data was collected by interviewing 225 women in the age group of 15-45 years, who delivered three months before the start of the study using a pre-designed and pre-tested semi structured proforma, which included socio-demographic profile, and the various aspects of antenatal care. The questionnaire used in the study was translated to vernacular language and validated by the investigators. The data collection was restricted to the index pregnancy, to avoid recall bias and the mix-up of replies regarding earlier deliveries, if any. A house-to-house survey was done, case identification was carried out with the help of medical social and anganwadi workers equipped with the proforma. The case load was cross-checked to reassure that the cases were not missed. Data was collected after signing a written informed consent form on voluntary basis and confidentiality was assured.

Data analysis was done using SPSS software version 22.0. Descriptive statistics, Odds ratio and 95% Confidence interval were calculated. Chi-square test was applied to find an association between two attributes and $P < 0.05$ was considered as statistically significant.

Results

A total of 225 pregnant women participated in the study. The socio-demographic characteristics of the study participants were as follows. A majority of 40.44% were in the age group of 18-25 years. 72% of

the women belonged to Muslim community, 36.89% women had completed primary school education and 53.78% belonged to lower middle class socio-economic status [(SES), Modified B. G. Prasad's Classification 2019-India].¹²

Table.1, illustrates antenatal details of study participants, where in 60.44% women had registered their pregnancy at government hospital. Majority of the women 50.66% had registered their pregnancy in first trimester and 46.67% of women had taken 3 antenatal visits. Two doses of TT injection were taken by 72% women and intake of iron and folic acid with calcium tablets was recorded among 38.67% of the women.

Table 2 depicts the complete utilization of complete ANC package. It was noticed that 39.56% of the study participants had utilized the complete ANC package which included 3 or more visits, 2 TT injection doses, Iron and folic acid tablet intake for a minimum of 100 days.

Table 3 describes the association between socio-demographic characteristics and complete ANC package utilization. The utilization of complete ANC package among primigravida was 58.27% in contrast to 9.30% multigravida and was statistically significant ($\chi^2=53.29$, $df=1$, $OR=13.6164$, $95\% CI=6.1064-30.3628$, $p < 0.05$). This shows that primigravida were more apprehensive about the events occurring during ante natal period, so the utilization rate was higher in them. 61.41% of literates had used the complete ANC package when compared to 11.22% of illiterates, which was statistically significant. ($\chi^2=58.2863$, $df=1$, $OR=0.1613$, $95\% CI=0.0386-0.1635$, $p < 0.05$), connoting that education of the women played a significant role in availing the complete ANC package efficaciously. When socioeconomic class was considered, less than 50% of the study participants had utilized the complete ANC package who came from lower socio economic status. This shows that lower socioeconomic class women were not aware of the benefits of availing the complete ANC package. In the occupation category, 57.81% homemakers had used the complete ANC package in comparison to 10.98% pregnant women who were labourers and this difference was statistically significant. ($\chi^2=45.8595$, $df=2$, $OR=11.1152$, $95\% CI=5.1146-24.1562$, $p < 0.05$) ANC visits led to loss of daily wages of the labourers

and hence the package was not efficiently utilized by the women.

Table 1. Antenatal details of study participants (n=225)

** As per Modified BG Prasad classification 2019.¹²

Discussion

The present study was aimed at assessing the utilization pattern of complete antenatal care package and also to evaluate the causable factors affecting it.

The overall utilization of complete ANC package as a whole was 39.56% in the present study. This low rate of utilization was attributed to factors like literacy, gravida of the women, occupation, sociocultural factors and

socioeconomic status subject to awareness, availability and accessibility of the services.

In the present study, it was found that 40.44% of the women were in the age group of 18-25 years, which was similar to a study done in Belgaum, Karnataka by Paudel DP et al.,¹³ where 54.6% of the women belonged to 20-24 years of age.

A study done by Jerath et al.,¹⁴ in urban slums of Delhi, 44.4% had registered pregnancy in first trimester, which was similar to the present study where 50.66% women availed ANC in first trimester.

In the present study, 43.56% of the study participants were illiterates and 58.67% belonged to nuclear family, which was alike to the results of a study done in Gujarat by Bhimani RN et al.,¹⁵ where 43.92% were illiterates and 42.93% lived in nuclear families.

In a study done by Jogia PD et al.,¹⁶ Junagadh, Gujarat, 80% of study participants were Hindus majority were homemakers, 56% were primigravida, whereas in the present study 72% were Muslims, 56.89% were homemakers and 61.78% were primigravida.

In a study done by Sarkar TK et al.,² in West Bengal it was observed that 90.26% had availed three or more than three antenatal visits, 55.8% had consumed iron and folic acid tablets for >100 days, 89.6% had taken 2 doses of tetanus toxoid injection, whereas the present study findings revealed that 46.67% had taken 3 antenatal visits, 38.67% had consumed iron and folic acid for a minimum of 100 days and 72% had taken two doses of tetanus toxoid injections.

The present study findings revealed that 39.56% had utilized the complete ANC package, which was significantly associated with literacy, primigravida and homemakers. This was in resemblance to findings of a study done in Gujarat where 46.03% had availed complete ANC package and was significantly associated with literacy, employment status of women and socioeconomic status.

Conclusion

ANC bestows opportunity to communicate with and support women, families and communities at an essential phase of a woman's life. Although the services

are feasible, affordable and accessible but the complete ANC package utilization remains in a dismal state.

The communication and support of ANC are vital not only in saving lives, but enhances health-care utilization and quality of care. Women's positive experiences during ANC lays foundation for healthy motherhood in the community and nation as a whole.

Acknowledgement: We express our sincere gratitude to all the women who participated in the study spending their precious time.

Ethical Clearance: As the study was community based, the women were enrolled in the research after obtaining written informed consent on voluntary basis.

Awareness about Diabetes: A Comparison between Population of Urban Areas and Urban Slums.

Mayank Garg¹, Prerna Mohan Saxena², Raju K Parasher³

¹Physiotherapist, All India Institute of Medical Sciences, New Delhi, India, ²Assistant Professor, Amar Jyoti Institute of Physiotherapy, New Delhi, India, ³Director, Amar Jyoti Institute of Physiotherapy, New Delhi, India

Abstract

Background: Developing countries like India are witnessing a huge rise in the cases of diabetes mellitus (DM). Education is one of the key components in its management. By assessing awareness levels, suitable awareness programs can be organised.

Objective: This study aimed to find awareness regarding DM and compare it among those living in urban areas and urban slums.

Methodology: In a cross-sectional study design, a Diabetes Awareness Questionnaire was prepared by the researchers to assess awareness levels. 400 subjects (200 each from urban areas (UA) and urban slums (US)) were selected. The mean of responses was calculated. Chi-square test was used to compare means of two groups.

Results: 41.5% of population of US and 80.5% of population of UA knew that there was reduced insulin production in DM. 37.5% and 80.5% of population knew normal fasting blood glucose level in US and UA respectively. 72.5% and 74% from US and 84% and 80.5% from UA knew that increased urination and increased thirst, respectively, were initial symptoms of DM.

Conclusion: Overall the level of awareness in both US and UA was found to be low. Thus, there is a need for more diabetes awareness programs as it can lead to prevention and better management of the disease.

Keywords: Diabetes, Awareness, Urban slums, Urban areas.

Introduction

Diabetes mellitus (DM) has become a global epidemic. In India, there are 69.1 million people with DM and this is going to increase in the coming years.¹ DM is rampant, especially in the developing nations², and most cases are now falling in the younger age group.^{3,4} Lifestyle habits from urban cities have started to

replicate in semi-urban and rural areas thereby affecting people across different strata of society.⁴

DM is associated with complications that hamper quality of life significantly. With scarce resources to deal with the problem, DM is a huge burden on the healthcare industry.³ Yet awareness about DM is poor among diabetics and non-diabetics.^{4,5}

Various researchers have assessed awareness regarding DM and almost all have used a questionnaire to extract information. Singh et al, 2012 studied rural population of northeast India and found that only 21.4% of them knew of a disease called DM⁶ whereas the CURES-9 study found this to be 75%.⁷ The awareness regarding symptoms, management and other aspects has been found to be low in most studies. Murugesan et

al, 2007 found low levels of awareness in both diabetic and non-diabetic population. However, diabetics had better knowledge about symptoms and preventive aspects of DM than non-diabetics.⁸ Sabri et al, 2007 studied 240 diabetics in rural and urban areas and found that urban residence, higher education level and higher socioeconomic status were associated with high awareness levels.⁹ Khapre et al, 2011 also found that rural population had poorer knowledge in comparison to urban population. Most people were aware of signs and symptoms of DM but lacked awareness regarding risk factors, management and complications.⁴

Mathew et al, 2012 studied 500 adults in south India and found low awareness on major risk factors for DM.¹⁰ Educational-level and presence of family history of diabetes were the most important factors associated with knowledge of DM.^{9,10} Education is one of the key components in ensuring better treatment and control of DM and evidence has showed that poor knowledge is associated with poor disease management.⁴

Owing to small sample size and heterogeneity of our population, the results cannot be generalised.³ Also, the number of questions asked have been inadequate to get a comprehensive idea about awareness levels. No study has been done in urban slums where a significant population resides. Thus there is a need to find awareness levels in urban areas and urban slums of a city like Delhi which is seeing a huge rise in the prevalence of DM. This study aimed to find awareness levels regarding DM in people living in urban areas and urban slums of Delhi and compare the same in these two groups.

Method

Identification and selection of trials

Table 1: Characteristics of population

	Total population (N=400)	UA (N=200)	US (N=200)
Mean Age (in years)	39.4	41.4	37.4
Diabetic (in %)	41	57.5	24.5
If any family member had DM (in %)	18.5	25	12

The present study was a non-experimental cross-sectional study in which a Diabetes Awareness Questionnaire (in both Hindi and English) having questions related to general information, initial symptoms, risk factors, management options, complications and sources of information of DM was developed. 400 subjects (200 each from urban areas (UA) and urban slums (US)) with age above 18 years and with no reading disability and/or cognitive impairment participated in the study. The subjects of UA were approached through Resident Welfare Associations (RWAs), out-patient department and camps set up in these areas while those of US were approached through Community Based Rehabilitation (CBR) workers working at CBR centers set up by Amar Jyoti Charitable Trust, New Delhi at these places. A sample of convenience was used.

Procedure

Subjects were approached for the study. After receiving their informed consent, they provided basic demographic details and answered questions of the questionnaire. The data was subsequently tabulated for analysis and was analysed using Stata 14 software. Mean was calculated for all the responses. Chi-square test, wherever applicable, was used to compare means of two groups (US and UA). A p-value of less than or equal to 0.05 was considered to be significant.

Results

Of the total population, 41% was diabetic (57.5% from UA and 24.5% from US). The results have been shown in Table 1, 2 and 3.

The table 2 shows the %age of population who said ‘yes’ for the particular parameter (for instance: 61% of the total population believes that there is reduced insulin production in DM).

*- For normal fasting blood sugar level, the depicted %age in the table is the %age of population who chose the correct range of blood sugar level.

#- Statistically significant difference present using chi-square test ($p \leq 0.05$).

Table 2: Knowledge about DM on various parameters (all values in %age)

Parameter	Total Population	UA	US
A. General Information about DM			
Reduced Insulin Production#	61	80.5	41.5
Increased blood sugar	89.75	94	85.5
Normal fasting blood sugar level*	59	80.5	37.5
B. Symptoms			
Frequent urination#	78.25	84	72.5
Increased thirst	77.25	80.5	74
C. Risk Factors			
Overweight#	68	85.5	50.5
Age	45.75	45.5	46
Family history#	37	26	48
Poor dietary habits	60.5	60.5	60.5
Lack of physical activity	49	49	49
D. Complications			
Blurring of Vision#	58	35.5	80.5
Frequent Infections#	24.75	9.5	40
Foot Ulcers#	39	27.5	50.5
Numbness in hand/foot#	46	20	72
Loss of body part#	36	17.5	54.5
E. Management			
May require Insulin	53	53	53
Manage Weight#	41.75	25	58.5
Exercise Regularly	72	72	72
Make Dietary Changes	70	61	79

The table 3 clearly shows that top 3 sources of information for UA were ads on TV/radio, posters and doctors and while those for urban slums were family/friends, doctors and ads on TV/radio. Internet was not a major source in both UA and US.

Table 3: Sources of Information regarding DM (all values in %age)

Source	Total Population	UA	US
Doctor/Health Care Professional	55.25	44	66.5
Family/Friends	53.75	34.5	73
Ads on TV/Radio	56	56	56
Newspaper/Magazine	34	32.5	35.5
Internet	16.75	14	19.5
Posters on roadside/hospital	45	45	45
Health Camps	41.5	32.5	50.5

Discussion

According to our knowledge, this is the first study to have studied awareness regarding DM in Delhi's urban areas and urban slums. We found that people had some basic knowledge about DM and its symptoms and this may be due to advertisements and articles seen more often in media these days. However, awareness regarding risk factors, complications and management options was found to be low. This is in agreement with results of previous researchers viz. Muninarayana et al 2010, Satyawali et al 2016 and others.^{5,11,12}

When compared to urban slums, people of urban areas were somewhat better with respect to general information about DM; were almost similar with respect to symptoms and management options; and were less aware with respect to risk factors and complications. However, a deeper understanding of the disease is missing in both the groups. Deepa et al 2014 studied population of 4 different geographical locations of India and found that awareness was significantly lower in rural areas than in urban areas.¹³

Studies have shown that awareness can improve when education is imparted. In a study done in southern India, short term training on non-communicable diseases (specially DM) was imparted to teachers who in turn educated high school students. An assessment 6 months post training showed significant improvement in health perception and lifestyle changes (viz. avoiding junk food, playing outdoor games) among teachers

and students (Selvam et al 2017).¹⁴ Fezeu et al 2010 also found that awareness was good in areas where education on DM was imparted during last 4 years.¹⁵ In urban slums, where people remain undiagnosed and infrastructure is inadequate, community health workers can play a positive role in educating and strengthening public health interventions.¹⁶ Limaye et al (2017) found that providing virtual assistance in form of mails and messages reduced obesity prevalence at 1 year in IT company employees.¹⁷ So such assistance can also be sought in today's digital world.

As far as sources of knowledge regarding DM are concerned, our results clearly indicate the importance of physician in providing information. Srivastava et al also found doctor to be major source of information to caregivers of diabetic patients as they educate about management and complications.¹⁸ Thus there is a need to make this patient-physician interaction stronger by giving more time to patients, using handouts and written instructions instead of verbal communication. Effective communication leads to adoption of healthy lifestyle and subsequently improved self-care.¹⁹ Media in form of TV/radio shows and newspaper articles can also play a vital role.

Almost all researchers have used questionnaires which can have open-ended or the more feasible close-ended questions. In open-ended questions, response depends upon the recall ability of the interviewee. In closed-ended questions, guess work and response bias

may exist as respondents tend to give more answers in 'yes' in order to seem more aware.^{7,20} Our questionnaire had most questions closed-ended and this could be one reason for greater awareness regarding risk factors and complications in urban slums than in urban areas.

To tackle diabetes and reduce its complications, there is a need to strengthen existing programs. One such program, The National Program for Control of Diabetes, Cardiovascular Disease and Stroke covers the entire country and aims to promote healthy lifestyle; generate awareness; screening and early detection; and provide timely and affordable treatment.²¹ Young students and women could take initiatives and form small chains where they can teach other thus spreading awareness in the entire community.

Conclusion

India is the diabetes capital of the world but is not ready to face the challenges it imposes owing to low awareness levels among its people. Education can be the first step in prevention of diabetes as it would encourage people to adopt healthy lifestyle thereby lowering the burden of disease.

Climatic Variation Water Quality Assessment of Selected Temple Ponds in Kanchipuram

Meenakshi Perumal¹, Sriram Gopalsamy²

¹Assistant Professor, Department of Civil & Structural Engineering, ²Professor, Department of Mechanical Engineering, Sri Chandrasekharendra Saraswathi Viswa Mahavidyalaya, Enathur, Kanchipuram, Tamilnadu, India

Abstract

Kanchipuram is the holiest city in Tamil Nadu, India. It has more number of Temple ponds, ponds having water has been selected for the study of climatic variations under physico chemical and biological parameters of water. The period of the study is pre monsoon march 2019 and post monsoon January 2020. The following parameters pH, electrical conductivity, dissolved oxygen, total dissolved solids, chlorides, sulphates, total hardness, calcium, magnesium, ammonical nitrogen, total nitrogen, total phosphate, total silica and biological parameter Total coliform count has been considered in the analysis. The results were linked with ISI-IS: 2296-1982 standards for surface water. The result shown that dissolved oxygen in all seventeen temple ponds has been greater than the standard limit in both the season. The remaining physico chemical, biological parameters were within the limit comparing with class B,C,D,E standard. Analysing the results the temple pond water appropriate in both the climate for bath, swim, fish culture, irrigation, etc. Climatic variation cannot cause the major changes in the pond water.

Key Words: Temples, Pond water, Parameters, Physico chemical, Biological

Introduction

Living mechanism on the earth planet is possible with the presence of water. On the total earth surface 72 percentages have been covered with water. Distribution of water about ninety six percentages as sea water remaining in the form of glaciers, ground water¹. Water quality is the most significant in surface water aquaculture because water quality value disproportions can cause pressure, reduced growth, and mortality of the culture species. The temple tanks are old-fashioned rainwater storage structures built near to the temples in India for use by the public². There are residences around the temples, temple tanks. In olden times, the water in the temple tank was utilized for drinking purpose also, at present used for bathing and washing. These tanks facilitated in recharging the shallow open wells positioned in households in and around the tank. The effect of this system ground water quality is can be established. Now a day temple tank has fallen into disorder. Houses were constructed around the tanks, which polluted, preventing ground water from leaching

in. Pollution is the most important problem as a seventy percentage of shallow water resources and ground water resources have been contaminated by organic, inorganic and biological pollution³. Limnology is the study of the practical connection and productivity of fresh water affected biotic groups by the physical, chemical and biological environmental factors⁴. This present study in pond water was aimed to assess the pollution level and how the climatic variation affects the deterioration of water quality due to pollution.

Method

i. Study Area: Kanchipuram is 75 kms from Chennai, it is one of the seven holy cities in the country. In Kanchipuram, temples are constructed with pond and without a pond. At present due to environmental impacts few temple ponds having water. Preliminary survey shows seventeen temple ponds having water. These ponds selected as sample points. The latitude and longitude values measured with the GPS device. The names and location of the temple ponds (sample points)

as shown in Table 1.

ii. Sample Collection

Pond water samples have been collected by hygienic bottles. The bottles were completely washed while collecting the water samples and properly labeled. The obtained results were compared with as per ISI-IS: 2296-1982 tolerance limits. Based on the tolerance limits the classifications of water given as following Class, A - Drinking water source without conventional treatment, after disinfection, B - Outdoor bathing, C - Drinking

water source with conventional treatment followed by disinfection, D – fish culture, wildlife propagation, E – irrigation, industrial cooling, controlled waste disposal.

Results

To determine the pollution level in the seventeen ponds the water sample was analyzed with the physico chemical and biological parameters. These parameter values of seventeen sample points in pre monsoon are shown in Table 2 and post monsoon are shown in Table 3.

Table 1: Names and location of seventeen temple ponds (sample points)

S.NO	Pond No.	Name of The Temple	Level of Pond Water		Latitude	Longitude

Illustrations (Figures)

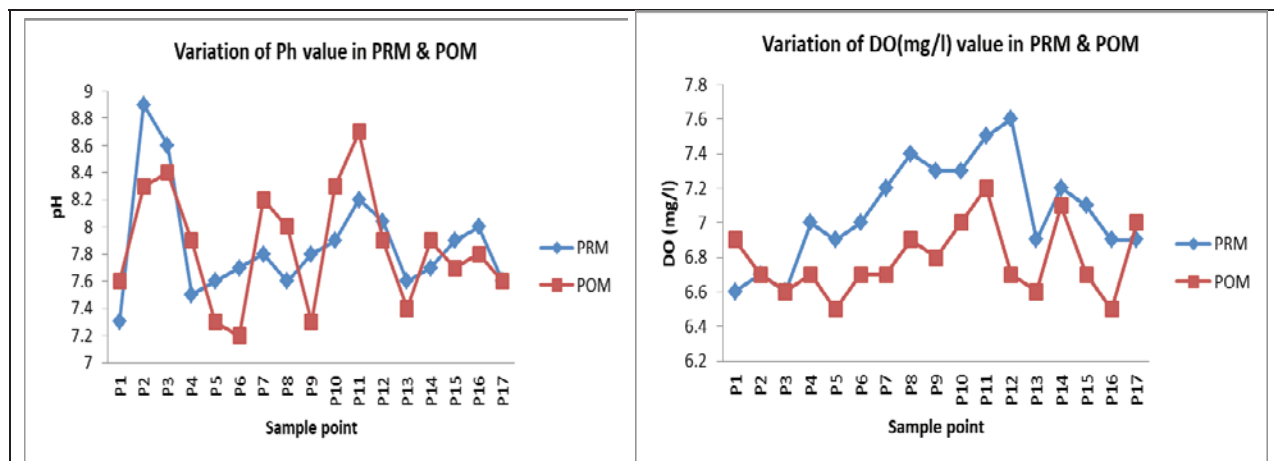

Figure 1: Variation of pH value, DO value in Pre monsoon & Post monsoon

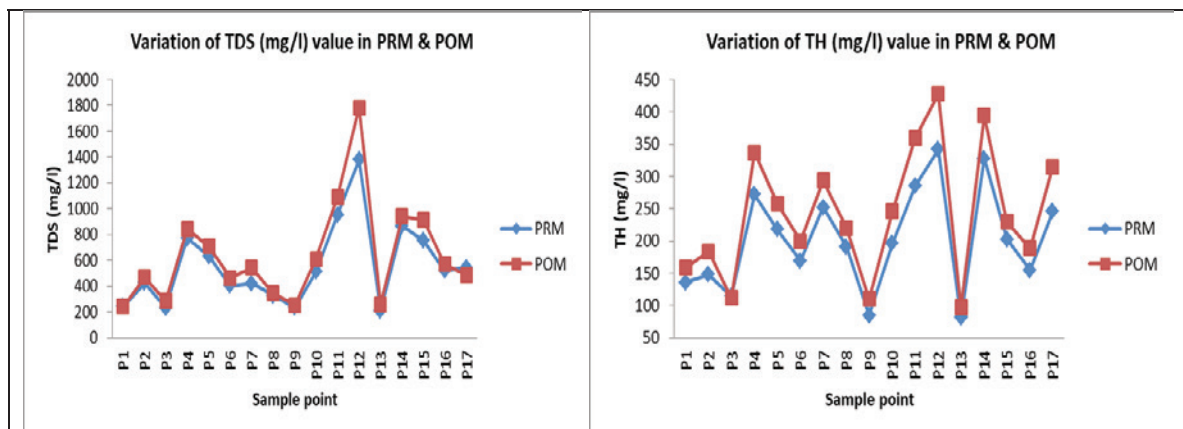

Figure 2: Variation of TDS value, TH value in Pre monsoon & Post monsoon

Discussion

i. pH

pH is an important environmental factor. It is the scale of acidity and alkalinity of any water. It is the effect of exchanges of various ingredients in the solution⁵. In the present study pH noted in the sample point ranges from 7.3 to 8.9 in pre monsoon and 7.6 to 8.3 in post monsoon. This higher pH value due to rise in temperature by the improved rate of photosynthesis causing in the greater consumption of carbon dioxide. Variation of pH values in pre monsoon and post monsoon are shown in Figure 1. Climatic variation shows minor changes.

iii. Dissolved Oxygen

Dissolved oxygen is important for growth of each fauna. In precipitation and dissolution of biological materials dissolved oxygen plays a major part⁶. In the present study dissolved oxygen, noted in the sample point ranges from 6.6 mg/l to 7.6mg/l in pre monsoon and 7.2mg/l to 8.7mg/l in post monsoon. The greater values of dissolved oxygen because of lower water temperature and great photosynthetic activities. Variation of dissolved oxygen values in pre monsoon and post monsoon shown in Figure 1. Climatic variation shows minor changes.

iv. Total Dissolved Solids

Total dissolved salts composed of some inorganic salts Calcium, Magnesium, Potassium, etc. It composed of some organic material in minor quantity⁷. In the present study, the total dissolved solid values are lies between 232 -1380 mg/l in pre monsoon and 242 -1090 mg/l in post monsoon. It is the important criterion for water quality determination. Climatic variation of TDS values in pre monsoon and post monsoon are shown in Figure 2. Climatic variation shows minor deviation, decreased value of TDS in the post monsoon comparing to pre monsoon is solids diluted in rain water.

v. Chlorides

Chlorides are the anions were present in all natural waters in different concentrations. The source of chlorides in surface water is leaching of sedimentary rocks, discharge of domestic and industrial wastes, etc. In the present study, the chloride values lie between

54-486 mg/l in pre monsoon and 67-526 mg/l in post monsoon. Chloride enters water by the solvent action of water on salts present in the soil⁷. Climatic variation shows minor deviation. Considering class A the value greater, other classes it satisfies the limit.

vi. Sulphate

The sulphate mixed with surface water from top hills, flow through rocks and mixed in water bodies during precipitation, low concentration from decomposition of organic matter⁷. In the present study, the sulphate values vary from 27–369mg/l in pre monsoon and 33-342 mg/l in post monsoon. Considering class A – E standard the sulphate value satisfies the limit.

vii. Electrical Conductivity

Electrical conductivity is the one way to assess the clarity of water. The ionic power as conductivity is a measure of total ions⁸. The ionic power of a sample water depends on the ionization of solutes and other ingredients melted in it. In the present study, the Electrical conductivity varies from 388 – 2230 μ hos/cm in pre monsoon and 430 – 3012 μ hos/cm in post monsoon. Climatic variation shows the minor deviation in the values.

viii. Total Hardness

Hardness is the calcium and magnesium salts combines with bicarbonates, and carbonates, it gives the temporary hardness and with sulfates, chlorides and others anions of a mineral acids producing permanent hardness⁸. In the present study, the total hardness varies from 81-328 mg/l in pre monsoon and 97-428 mg/l in post monsoon. Variation of total hardness values in pre monsoon and post monsoon are shown in Figure 2. Climatic variation shows the minor deviation in the values.

ix. Calcium

Calcium is a significant mineral in natural water⁸. Calcium plays an essential role in the biological productivity of the lakes and ponds. In the present study, the calcium varies from 16-72 mg/l in pre monsoon and 19-87 mg/l in post monsoon. Considering class A – E standard the calcium value satisfies the limit. The water is suitable for domestic use.

x. Magnesium

Magnesium is one of the main ingredients in natural waters and is a energetic component of chlorophyll⁸. In the present study, the magnesium varies from 11-42 mg/l in pre monsoon and 12-48 mg/l in post monsoon. The water is suitable for domestic use.

xi. Ammonical Nitrogen and Total Nitrogen

Every organism requires nitrogen in the elementary process of life to synthesize protein necessary for progression and reproduction⁹. Ammonia melts in water to formulate ammonium hydroxide and hydroxyl ions these ammonium ions are engaged by aquatic autotrophs with preference over nitrates, thus avoiding it to reach to toxic levels¹⁰. In the present study, the ammonical nitrogen varies from 2.7- 9.2 mg/l in pre monsoon and 1.9 – 10.6 mg/l in post monsoon. In the present study, the total nitrogen varies from 7.9 – 21.8 mg/l in pre monsoon and 6.7 – 26.5 mg/l in post monsoon.

xii. Total Phosphate

Phosphorus is the limiting nutrient in the primary production of fresh waters. Phosphate is a significant nutrient for the maintenance of the fertility of water group. In the present study, the total phosphate varies from 3.5 – 17.3 mg/l in pre monsoon and 3.8 – 14.3 in post monsoon. The greater values of phosphate can be due to speedy evaporation and mineralization of decomposed constituents in pond water.

xiii. Total Silica

Silica is also called as silicon dioxide, it is the compound of the two most plentiful elements in the earth crust, silicon and oxygen, SiO₂. The silica presence in natural water is 5 to 25 mg/l, in some areas 100mg/l is also present. Silica is greatly important in helping to stop osteoporosis and in helping increase bone strength. In the present study, the total silica varies from 6.8 – 36.4 mg/l in pre monsoon and 7.6 – 32.7mg/l in post monsoon.

xiv. Total Coliform Count

The coliform bacteria are nonpathogenic bacteria that arise in the feces of warm-blooded animals. A coliform bacteria increase creates waterborne disease. A positive total coliform is an indication of pollution

in water. In the present study, the total coliform count varies from 400 – 2100 MPN in pre monsoon and 450 – 2600 MPN in post monsoon.

Conclusion

In the climatic variation investigation study concluded that some of the physico-chemical parameters pH, EC, TDS, chlorides, sulphates, total hardness, calcium, magnesium, ammonical nitrogen, total nitrogen, total phosphate, total silica were found within the permissible limits. Dissolved oxygen parameter beyond the permissible limit. The greatest value of the DO is useful for fish growth. The pond water contains biological parameter Total coliform count; it is greater in some pond water. The results indicating organic pollution. Climatic variation cannot cause the major changes in the pond water. The temple pond water appropriate in both the climate for bath, swim, fish culture, irrigation, etc. To tolerate the ecosystem and aquatic life in the pond water there should have awareness programs related to protection of the pond so that aquatic life saved in future.

Living with Urostomy: Patient's Perspective

Meenal Sharma¹, Sukhpal Kaur², Amlesh Seth³, Prabhjot Singh⁴

¹Ph.D Scholar at National Consortium by INC and RGUHS, ²Lecturer, National Institute of Nursing Education, PGIMER, Chandigarh, ³Head of Department, ⁴Associate Professor, Department of Urology, AIIMS, New Delhi

Abstract

The diagnosis of bladder cancer and necessity of urostomy is profoundly life changing. This qualitative study was conducted in order to assess lived experiences of patients who had received urostomy due to bladder cancer or any other urinary pathology. The sample included 30 patients with urostomy admitted in the Urology ward, AIIMS, New Delhi. Purposive sampling was used and data was collected using semi structured interviews. Narrative data was analysed using Colaizzi's steps of analysis for qualitative data. Ten themes emerged from the analyses which were further categorized into sub themes. The theoretical framework of the themes and subthemes defined the phenomenon of living with urostomy in entirety.

Key words: *Qualitative research, Lived Experience, Bladder cancer, Urostomy, Colaizzi's Steps of Qualitative Analysis*

Introduction

Urostomy is a procedure that reroutes the flow of the urine out of the body.¹ Urostomy surgery may be required for many reasons, the most frequent indication being bladder cancer, which is the second most common urologic malignancy.² Of all bladder cancers, 10-20 percent is the muscle invasive type which is classically treated with cystectomy and urostomy.³

Creation of a urostomy significantly alters elimination pattern and can have both physical and psychological effects. The most common physical complications with urostomy are infectious, gastrointestinal, wound related and genitourinary. The physiologic complications involve changes of the stoma and peri-stomal skin including dermatitis, pain, bleeding, necrosis, prolapse, stenosis, herniation, infection and retraction of the stoma.^{4,5}

Many urostomy patients have emotional, social and sexual problems. Urostomy patients are concerned about the effect of the stoma on their ability to carry

out activities of daily living. Ostomy surgery is a life-enhancing procedure that restores a vital bodily function, but it's not easy to accept.⁶

Nurses involved in the care of patients with a stoma should have an understanding of the reasons for stoma creation, and the types of stoma and appliances available. Issues related to diet, sexual relationships and self-image should also be discussed with patients.^{7,8}

There have been significant advances in stoma appliances and an increase in nurses specialising in stoma care. Despite this, a large proportion reportedly up to 75% of patients continue to experience adjustment problems, which suggest that improvements in stoma management are by themselves not enough to enhance functioning.⁷ This inspired the examination of problems of urostomy patients in this study.

Objective: To explore the lived experiences of the patients living with urostomy.

Materials and Method

Research Design and Sampling

A phenomenological qualitative research design was used. Sample size was limited to 30 when data saturation occurred. Purposive sampling was used to select patients who had undergone radical cystectomy and ileal conduit

Corresponding Author:

Ms Meenal Sharma

Ph.D Scholar at National Consortium by INC and RGUHS

surgery. Patients after 5 days of the surgery, above 18 years of age and willing to participate in the study were enrolled.

Research Tools

1. Demographic Profile Sheet:-

The demographic profile sheet was used to collect socio-demographic data of patients. Content validity was obtained from the experts.

2. Semi-Structured Interview Guide:-

An interview schedule was developed which listed the open ended questions to explore the experiences of the urostomy patients. It was validated by experts.

Data Collection

The study was conducted from January 2018 to July 2018. The willing participants were explained about the study and informed consent was signed. Anonymity, confidentiality and privacy of patients were maintained. Face to face interview was conducted by the researcher with a fairly open framework. An interview session lasted 10-30 minutes and was audio taped with the consent of the patient. Field notes were maintained. The place for interview was a private room in the urology ward. Active attention was given to the body language, posture, facial expressions and voice intonation of the participants. Short pauses and silences were dealt with patience as they helped the patient to understand their feelings and put them into words. Emotional support was extended when patient got distraught and cried during the interview.

Data Analysis

The demographic data was analysed using descriptive statistics in SPSS. Statistical tests used to describe the data were frequency distribution, mean and standard deviation.

Qualitative analysis was done simultaneously with data collection. Recorded interviews were transcribed verbatim and translated into English by the researcher and rechecked by translator. Colaizzi's steps of qualitative analysis were used for analysis. The data was read and re-read numerous times to identify the significant responses. A total of 623 significant responses

were extracted from the interviews. Meanings were formulated for these significant responses. In total 808 meanings were identified and grouped under 10 themes as some of the responses were not exclusive but were interrelated and overlapping. Formulated meanings were coded in a MS Excel sheet to extract common themes which were further categorized into sub- themes. The derived theoretical framework integrated participants description to achieve comprehension of the experience of living with urostomy.

Results

Demographic description of sample

The sample composed of primarily male participants 90% (n=27) with average age of 57±11.61 years. Urinary bladder cancer was the primary disease in 28 patients, with only two female patients having urinary bladder metastasis. Majority of the patients had radical cystectomy and ileal conduit with or without nephroureterectomy, prostactectomy and lymph node dissection. The mean weight of the participants was 62±9.97 kgs and mean height was 173.2±9.6cms. Most of the patients were not employed 53.3% (n=16). A large proportion of the patients 36.6% (n=11) belonged to lower income group. A striking number of patients 60% (n=18) have smoked or chewed tobacco before diagnosis.

Qualitative Analysis

Ten themes emerged from the lived experiences of the urostomy patients which were further divided into sub themes. [Number] in brackets is the number of significant responses for the particular theme and sub theme. *Italicised sentences* are the expressions of the participants. Following themes were identified.

1. Knowledge regarding urostomy

Most of the patients confirmed lack of knowledge regarding urostomy [36].

...*"I don't know how to wear or change bag and also how to manage if a leakage occurs."* Patient 6

Due to lack of knowledge, patients experienced dependence on the health care staff for changing urostomy bag [14]. Some patients expressed readiness to learn urostomy care [19].

...*"I want to know about the diet, how to change the urostomy bag and what is the frequency of bag changes and also can I lay in prone position?"* Patient 20

2. Physical problems

Patients experienced numerous physical problems related to their disease, treatment and urostomy. Weakness [20] and fatigue [25] was present in most of the patients

...*"I feel very much physically weak. I face difficulty in daily activities."* Patient 1

Skin problems around urostomy were fairly common [9]. Most of the patients had pain and oozing at surgical site [15] thus increasing the risk of infection. [4] Urine leakage from the urostomy was a difficulty faced by almost all the patients [23]. Continuous lying down in bed also caused discomfort [5].

...*"Because of constant lying down on the bed, I have developed bed sores on my back."* Patient 13

Patients had difficulty in maintaining hygiene due to surgical incision and urostomy [6]. Surgical creation of ileal conduit requires resection of ileal segment causing digestive problems in the patient postoperatively like abdominal bloating [18], stomach ache [15], nausea, vomiting [1], and loss of appetite [23], constipation [4] and diarrhoea [1].

...*"I was distressed by stomach ache and gas for which they gave medicine and now it's better."* Patient 25

3. Psychological Problems

Mental tension [15] and depression [17] were evident followed by feelings of hopelessness [4], helplessness [24] and dependency [12].

...*"It feels as if half of my life has slipped out of my hands."* Patient 1

...*"Yes, mental tension is there. It is better to die than to suffer from this."* Patient 3

Most of the patients were middle aged males and sole earner for the family. They were highly stressed due to the failure to meet family role [22].

...*"We are helpless for my son's education. Even if I*

sell my land, then where will we go? I dreamt of making him a doctor (Pause)." Patient 23

Patients had fear of urine leakage from urostomy [7] and were anxious [6] and embarrassed because of the urostomy [16].

...*"I feel sometimes, that why has this happened in front of my children. Now, they will have to even tie my pyjama. I feel ashamed because of that."* Patient 20

Some patients also expressed anger [11].

...*"Everyone has to die one day, but it should not be so early in my case."* Patient 27

Feelings ranged from disbelief, confusion and ambivalence towards urostomy [14]. Some patients vehemently denied mental stress [12] to avoid stressful disclosure with the researcher, while some were unwilling to communicate on certain questions [3]. Conversely, some patients talked optimistically about urostomy and were hopeful of the future [43]. Positivity was also noted by in terms of readiness to change to a healthy lifestyle [16].

...*"This operation saved my life otherwise I would have died. So, whatever has happened is for good."* Patient 28

...*"Isn't there is something which can be fitted inside the body. It would be better, if it is not visible outside."* Patient 22

4. Impact on daily activities

Patients reported difficulty in performing their daily activities [9]. Sleeping was disturbed in some of the patients [5].

...*"Yes, the sleep is stressful, I worry that it may leak and spoil the bed."* Patient 27

Doubts related to diet were common [16]. Travelling was deeply impacted because of urostomy [21]. Patients were concerned about bag leakage [10] and practical difficulties in driving [8]. Dressing was also a matter of concern for most of the patients like ability to wear undergarments and their regular clothes [23].

...*"If I wear pants below the stoma, it is not very comfortable, so, I try to wear it above the stoma. The*

pants have to be stitched according to the stoma.” Patient 27
can I do?” Patient 2

5. Social Problems

Many of the patients restricted their social activities. They were concerned about extra preparations needed for urostomy [26].

...*“If there is a function somewhere, I won’t be able to attend as I will have to keep supplies with me.”* Patient 23

Most of the patients felt social stigmatization because of the urostomy and recognized the lack of social support system [22].

...*“People will wonder that what disgusting problem I am suffering from. My neck will be hung in shame.”* Patient 11

6. Family Problems

Family functioning was greatly disturbed. Most of the patients perceived anxiety and stress in the family members [7] and were aware of the caregiver’s burden on their attendants [5].

...*“Everybody has been caring for me from last 1 year. There has been lot of tension in the family.”* Patient 10

Most of the patient were male and were experiencing sexual difficulties but they were not comfortable enough to discuss it with the researcher except few [5].

...*“I have very much problems. I can’t talk about sex right now. Please ask about it later.”* Patient 23

...*“I am not able to maintain sexual relations with my wife (nonverbally messages not to talk about sexual problems),”* Patient 26

7. Occupational Problems

Patients were anxious about their inability to do heavy work [21] and were uncertain of whether occupation can be continued. Financial consequences of incapability to work were a cause of turmoil.

...*“I am sitting idle for about 3 years now. My work is done partly by my children, so I am able to live. What*

8. Financial Problems

Majority of the patients with few exceptions had strained finances [14] and was worried about additional expense of urostomy [23].

...*“The main problem is monetary expenses. The supplies are very costly.”* Patient 26

Few patients were unable to procure supplies for urostomy and struggling for daily needs [5].

...*“Sometimes, the bag bursts. If by chance we don’t have money to buy bag that day, then my clothes are drenched in urine whole day.”* Patient 3

9. Religious and Spiritual Problems

Some patients quoted the need to change to spiritual lifestyle considering they have got a second chance at life because of urostomy [5]. In contrast, urostomy was considered causing impurity of body because of bodily contact with urine by some [14]. Patients were emotionally stressed because they couldn’t offer prayers [2].

...*“In our religion, even if a drop of urine touches the body then prayers are not offered. We have to be totally pure to pray. (Eyes well up with tears).”* Patient 16

10. Health Care Issues

The patients from remote areas were stressed because of the inaccessibility of health care near their home [7]. Some patients experienced distress due to delayed care because of limited health care staff and resources [6].

...*“Staff is very less here.”* Patient 23

Most of the patients had faith in capability of health care team [3].

...*“They have done really good for me. Whatever happened with me has been good so far.”* Patient 24

The detailed description of the themes and sub themes facilitate vision of the overall experience of living with urostomy. Researcher observed that the

experiences of different patients were as varied as their personalities, demographics and social circumstances, but were unified by their common struggle of living with urostomy.

Discussion

In the last 30 years, much has been done to improve the quality of life for patients with stoma. In spite of these, however, even today it is a very difficult to live with urostomy. Literature describes the numerous problems of urostomy patients. The present study also confirmed these issues.

The findings of the present study are consistent with other researchers who have discussed physical problems of urostomy patients.⁸ In the present study some of the physical problems were problems due to location of urostomy. Skin problems and urine leakage was a major issue. Patients also described lots of digestive problems.

Around one-quarter of stoma patients experience clinically significant psychological symptoms postoperatively.⁹ In this study, mental tension and depressive feelings were present in most of the patients. Patients had fear of urine leakage and were embarrassed of the urostomy and declared it as retribution for their bad conduct. Socially, urostomy patients found themselves vulnerable to other's reaction to the urostomy, thus restricting their social activities.¹⁰ In general, family and friends can be an immense source of support which was also narrated by most of the patients in the study.¹¹ Ostomy surgery may affect the patients' sexual relationship with their intimate partner which was also the case in present study.¹²

Most of the participants belonged to lower economic group with few exceptions. It was difficult for them to bear the burden of disease and urostomy. Another important finding relates to religious issues. As with many religions, it is important to be clean, especially when praying. This was regarded as the worst effect of the urostomy by some patients. Study participants expressed faith in the health care professionals although they were aware of the shortage of the health care staff and resources.

In this qualitative study, researcher was able to establish a trusting relationship with most of the patients.

Interview offered the patients an opportunity to express their thoughts, feelings and beliefs without being judged. Patients acknowledged the interview to be therapeutic. The findings of this study cannot be extrapolated to wider populations because qualitative research results cannot be tested for statistical significance.¹³ However, the findings are useful for health care providers when creating a supportive environment to improve quality of life of urostomy patients.

Conclusion

Living with a urostomy takes significant adjustment in daily living. A detailed knowledge can facilitate health care personnel to understand the problems of these particular patients and design the health care accordingly. Motivation of the patient to take independent care of their urostomy will lead to better self care efficacy and psychosocial adjustment.

A Comparative Study of Abdominal Versus Non – Descent Vaginal Hysterectomy in a Tertiary Care Centre

Mihir Kumar Sarkar¹, Arindam Halder¹

¹Associate Professor, CSS, Kolkata

Abstract

Objectives: Hysterectomy means surgical removal of uterus. Both abdominal and non-decent vaginal hysterectomies are quite popular and acceptable methods among the gynecologist.

To evaluate the appropriate route of hysterectomy (abdominal or vaginal) in our hospital population for benign disease by comparing peri-operative and post-operative complications.

Materials and Method: As per the inclusion and exclusion criteria, 100 cases admitted to the gynaecology unit hysterectomy for benign diseases were randomly selected, out of which 50 cases underwent NDVH (non- descent hysterectomy) and 50 cases underwent AH (abdominal hysterectomy). The parameters evaluated were operating time, I loss, postoperative pain and other postoperative complications.

Results: The results were indicative towards vaginal hysterectomy being a better surgical modality with lesser operating I blood loss, postoperative pain and other postoperative complications.

Conclusion: With adequate vaginal access, good uterine mobility and technical skill, vaginal hysterectomy can performed on a non-prolapsed uterus, with an additional advantage of shorter duration of surgery, intraoperative com| postoperative morbidity and shorter hospital stay. Hence, stating it to be a better surgical alternative to at hysterectomy.

Keywords: Postoperative pain; Abdominal Hysterectomy; Non-Descent Vaginal Hysterectomy

Introduction

Hysterectomies are the most common elective surgeries in gynaecology; and can be performed by abdominal, vaginal or laparoscopic method. Vaginal hysterectomy has distinct health and economic benefits. Both abdominal and vaginal hysterectomies hold their own positions in the gynaecological field.¹

Charles Clay in Manchester performed the first abdominal hysterectomy in 1843. Vaginal hysterectomy

was performed first by Soranus of Ephesus in 120 AD.²

Criteria such as the uterine size, mobility, accessibility and the pathology confined to the uterus (no adnexal pathology or known or suspected adhesions) are mostly the incorporating factors for vaginal hysterectomy.³

Extrauterine disease such as adnexal pathology, severe endometriosis or adhesions may preclude vaginal hysterectomy. Following abdominal hysterectomy patients are might be at higher risk of depression, anxiety.⁴ This study was performed to evaluate appropriate route of hysterectomy (abdominal for our women with benign disease and comparing perioperative and postoperative complications with vaginal hysterectomy).

Dr Arindam Halder

Associate Professor, Department of Obstetrics and Gynaecology, Chittaranjan Seva Sadan College of Obstetrics, Gynaecology and Child Health
Kolkata, E –Mail :halderarindam1978@gmail.com

Materials and Method

The study was undertaken over a period of 12 months May 2017-April 2018 at CSS, Kolkata. The study was approved by Institutional Ethical Committee. Written informed consent was taken from the participating patients. Total number of 130 cases requiring hysterectomy for diseases were randomly selected out of which 65 underwent NDVH and 65 cases underwent AH. Patients selected as per the following inclusion and exclusion criteria.

Inclusion criteria

- 1) Fibroid Uterus
- 2) Abnormal uterine bleeding (AUB)
- 3) Chronic cervicitis
- 4) Adenomyosis
- 5) Postmenopausal Bleeding

Exclusion criteria

- 1) Uterine size more than 12 weeks of gravid uterus
- 2) Restricted uterine mobility
- 3) Prolapsed uterus
- 4) Patients with complex adnexal mass
- 5) Patients with previous 2 or more LSCS

After taking a thorough history and clinical examination, patients were subjected to routine investigations. Operating time for NDVH was calculated from incision at cervico-vaginal junction to the completion of closure of vault. Operating time for AH was calculated from incision on the abdomen to closure of skin incision.

Blood loss was estimated by preoperative and postoperative (day 2) haemoglobin and hematocrit measurement. Intraoperative complications such as injury to bowel/bladder or ureter and haemorrhage were noted.

Postoperatively all patients were given same antibiotic prophylaxis with adequate analgesia and fluid replacement. Complications like wound infection, vault

hematoma, febrile morbidity, hemorrhage were kept into consideration. Hospital stay was calculated as number of days in hospital after the surgery including the day of surgery.

Postoperative pain was documented as per the visual analogue scale. VAS (Visual Analog Scale) was assessed by asking participants to rate the severity of pain on a 10 cm scale ranging from 'no pain' to 'worst pain'.

Data analysis was done using the SPSS (Statistical Package for the Social Science) Version 17 for window. The t test was used to find significant difference of age, parity, comorbidity, duration of operation, blood loss. MW (Mann Whitney) test was used to find the Significant difference of pain score between AH and NDVH. A probability value of 0.05 was accepted as the level of statistical significance.

Results

The mean age of women in our study was 48.74 years in NDVH, which was higher when compared to AH with a mean age of 46.12 years. ($P < 0.05$)

In maximum number of patients who underwent the surgeries, the underlying pathologies were consistent with first being AUB followed closely by fibroids.

The mean duration of surgery in both the groups were calculated and AH was much lengthier operation than NDVH (AH 72.30 minutes vs NDVH 42.16 minutes, $p < 0.001$). This was a statistically significant finding in this study.

Intraoperative blood loss was higher in the AH group where it amounted to 141.80 ml viz a viz NDVH where the average loss of blood was 43.96 ml. This was statistically significant ($p < 0.05$).

In the 130 surgeries performed the complications were as follows: one case had ureteric injury in AH group, one case had bladder injury in NDVH group and one case had bowel injury in AH group and these were not statistically significant.

Postoperatively pain was measured using the visual analogue scale on day 1, 2 and 3 in which the scores for the patients who underwent AH were always higher than that of NDVH and the difference was statistically

significant($p < 0.001$).

Postoperative complications like febrile morbidity, wound infection, burst abdomen, wound gaping and paralytic ileus were more following AH compared to NDVH but the difference was not statistically significant.

Discussion

The prospective cohort study was carried out to study the indication for abdominal and vaginal hysterectomy for non-descent uterus and to compare postoperative complications in vaginal and abdominal routes of hysterectomy. Advantage and disadvantage for

abdominal and vaginal hysterectomy for non-descent uterus were also studied.

Mean age was more among the cases that underwent NDVH compared to AH in the study group. Mean age in NDVH was 48.74 years and in AH was 46.12 years.

Similar finding was also observed in a study by Asnafiet al.⁵ The mean age of patients who had undergone vaginal hysterectomy was 58.5 ± 12 years and 44.69 ± 7.9 years for abdominal hysterectomy.⁵

In this study AUB, fibroid, PID (Pelvic inflammatory disease) and adenomyosis were common indications for hysterectomy. Abdominal hysterectomy was preferred for fibroid and endometrial hyperplasia, and Non-descent vaginal hysterectomy was preferred for PID and AUB. Similar finding was observed in a study conducted by S Bharatnur (2010) where they studied the comparative risks of complications of abdominal and vaginal hysterectomies and concluded that DUB, Fibroid and chronic cervicitis were common indications for hysterectomy. Other indications were adenomyosis and cervical polyp.⁶

The mean duration of surgery was significantly less among NDVH as compared to AH cases in the study group. Mean duration was 42.16 min in NDVH and 72.30 min in AH. Similar finding were observed in a study conducted by Chen et al where the operation time in VH (mean time 65.2 min) group was significantly shorter than in the abdominal hysterectomy (mean time 95.6 min) group.⁷ S Bharatnur also noted that mean operating time was more in abdominal hysterectomy than in vaginal hysterectomy (AH 101 ± 27.1 min, VH 65 ± 26.2).⁶

Mean blood loss was significantly less amongst NDVH cases as compared to AH. Mean blood loss was 43.96 ml in NDVH and 141.80 ml in AH. Chen et al compared outcomes of vaginal and abdominal hysterectomy in women also concurred with their results showing intraoperative blood loss to be significantly less in the vaginal hysterectomy (mean 30.4 ml) group compared with the abdominal hysterectomy (mean 70.3 ml) group, complication showed that one ureteric injury and one bowel injury was present in AH case, while one bladder injury was seen in NDVH.

N. Fatima et al found that bladder injury occurred in one case in VH (1.9%) and in four cases in AH (2.3%). Ureter injury occurred in one (0.6%) case in AH group. Authors concluded that vaginal hysterectomy is associated with quicker recovery, early mobilization, and shorter hospitalization, less operative and postoperative morbidity when compared to abdominal hysterectomy.⁷

Mean hospital stay in days was significantly less among NDVH as compared to AH. Mean hospital stay was 3 days in NDVH and 4.14 days in AH. Similar finding observed in a study conducted by Chen et al with hospital stay length in the vaginal hysterectomy (mean hospital stay 4.5 days) group being significantly shorter than in the abdominal hysterectomy (mean hospital stay 6.3 days) group.⁸

Even in cases of cervical cancer, different studies have found out that vaginal hysterectomy is better than abdominal procedure, In a study by Zang S et al; LARVH is a suitable alternative to ARH for early-stage cervical cancer, which shows less blood loss, shorter catheterized and hospital stay, and similar survival outcomes.⁹ In a study by Dawood et al, they concluded that patients who required a hysterectomy for benign lesions having a moderate-sized uterus can be offered vaginal route for surgery rather than abdominal due to better peri and postoperative care of the patients.¹⁰

Conclusion

The present study was undertaken to provide objective evidence to assist gynaecological surgeons in their selection of the most appropriate method of hysterectomy and to provide data to permit patients to make an informed decision about their preferred type of hysterectomy. With adequate vaginal access, good uterine mobility and technical skill, vaginal hysterectomy can safely be performed on a non-prolapsed uterus, with an additional advantage of shorter duration of surgery, lesser intraoperative complications, lesser post-operative morbidity and shorter hospital stay. Hence, it can be concluded that NDVH supercedes over AH with patient's favourable outcome and must be the choice of operative procedure amongst the two surgeries.

Conflict of Interest : The author declare that they have no conflict of interest.

Prof., Department of CSE, Faculty of Engineering, University of Lucknow, Lucknow, UP, India, ⁴Assistant Professor, Department of CSE, BNCET, Lucknow, UP, India, ⁵Assistant Professor, Department of CSE, KMC Urdu-Arbi Farshi University, Lucknow, UP, India

Abstract

Diagnosis of psychiatric disorder is intricate clinical entity that could pose challenges for clinicians involving both accurate identification and effective timely diagnosis. These battles have prompted the evolution of multiple machine learning approaches to help improve the management of the disorder. These methods use clinical, anatomical and physiological information and symptoms obtained from neuroimaging and from clinical investigation to make diagnosis system that may identify psychiatric patients as compared to non-psychiatric patients and predict diagnosis results. This review paper introduces a background on psychiatric disorder, imaging and machine learning methods. This review paper also discussed about the methodologies of previous studies which have implemented imaging and machine learning in the diagnosis of psychiatric disorder and give directions for future use of machine learning techniques in psychiatric-related studies.

Key Words: Machine Learning, Psychiatric Disorder, Neuroimaging, Magnetic Resonance Imaging.

Introduction

Machine Learning (ML) is a branch of computer science that uses software and data analysis to develop programs that perform a task. For example, a computer can be taught to play chess, or a computer program can be trained to identify cats or dogs in a series of images. When doctors are looking for ways to diagnose patients who have a mental illness, machines can be used to do so by using ML software. It is interesting to note that ML software is not a new idea.

ML algorithms can efficiently leverage cohort information to create classifiers and assess the sensitivity and specificity of parameters connected to diagnostic validity to the initial and revised diagnostic test tools. ML algorithms have been employed to shorten several

scales, like the Social Responsiveness Scale (SRS) for behavioural differentiation between autism and attention-deficit/hyperactivity disorder (ADHD)¹.

Some of the areas where computers will play large role in the psychiatric field are not a surprise to those who study psychology. For example, after the development of Positron Emission Tomography (PET), the use of the PET scanner has been the basis for testing the effects of pharmaceuticals such as the antidepressant drugs like Prozac on the brain. Using the PET scanner, researchers are able to see the amount of serotonin being released into the brain. This is a very important aspect of drug treatment and development.

Magnetic resonance imaging (MRI) is an emerging technology that has enabled doctors to get a detailed view of a patient's brain as it functions and what is going on when a patient is undergoing a medical procedure.

Comorbidity is complex situation and it's hard to understand in the interpretation and diagnosis of

Corresponding Author:

Dr. Sapna Singh

E-mail: sapanasinghmg@gmail.com

psychiatric disorder. The notion of comorbidity was originally operationalized by Feinstein² when he had been worried with the medicating confounds of treating patients with disorders like rheumatic fever who concurrently suffered from multiple ailments. Conceptualising comorbidity, nevertheless, has not established so simple and considering by the Feinstein², not having a legitimate definition has contributed to it depicting a heterogeneous expression in the lack of its nosology. What's more, it's used synonymously with multimorbidity, though the latter is much more commonly known if the majority of disorders are non-defined within their own right, together with comorbidity compared, found as a coexistence of ailments³. In addition, in psychiatry, psychology, and mental health counselling; comorbidity was known as the existence and identification of more than one diseases happening in a person at precisely the exact same moment⁴. Here we reflect about the definition and reference it because the coexistence of not just two or more ailments but additionally, diseases which may be described as chronic and even though they may be pathologically associated with one another, they also behave independently⁵.

There are numerous conventional statistical approaches to examine if this routine suggests the greater chance of comorbidity of the above mentioned, however they take certain inherent limitations⁶. ML has revealed particular benefits in analyzing potential predictors concurrently in an impartial fashion, notably its capacity to spot patterns of data within useful attributes such as the prediction of an outcome of interest. Several researchers implemented ML methods on different medical data and information to examine whether comorbidity are significant longitudinal predictors of impaired cognition⁷.

ML can be used to check the capacity of every MRI step as an important biomarker for psychiatric diagnosis⁸. ML is made up of set of processes used to develop prediction models from empirical data to produce precise predictions about new information. Based upon the information three potential kinds of learning could be utilized, such as supervised learning, semi-supervised learning, and unsupervised learning. Supervised learning is done if all the information is tagged; semi-supervised learning is done whenever there is unlabeled data combined with tagged information; and,

unsupervised learning is done once all the information is unlabeled. Learning methods can be classified into linear and nonlinear procedures. Linear methods are more straightforward, while nonlinear methods are more elastic in character. Classification-based methods try to classify the information by different and categorical labels, whereas regression-based processes fit the data to a constant function and so work with constant tags to the information. For unsupervised learning, the approaches are mostly categorized as clustering approaches that set the information into clusters according to inherent similarities. Most of the researches have used supervised learning procedures to implement methods in their models⁹.

A major change in the field of Psychiatry and Neuropsychiatric is the potential use of technology to make diagnosis faster. We all need to realize that it can take time to find out what the root cause of a problem is. Using a computer, machine learning software with MRI and PET scanners can make a diagnosis faster and more accurate than the traditional methods.

This review paper stating the ML techniques applied with the use of fast and high performance computers and the use of latest digital technology for supporting the doctors for the diagnosis purpose and we can get reliable diagnosis. Section 1 is presenting the introductory view about the psychiatric disorder and about the ML techniques for psychiatric diagnosis in this paper. Section 2 present the reviews of different ML work in the area of psychiatric diagnosis. Finally the Section 3 presenting the conclusion and presenting the need of the wide scope of ML application in psychiatric diagnosis.

Related Work

ML approaches are sensitive to ease inference in the single-subject degree, and may identify spatially dispersed patterns in the mind which may be undetectable using set comparisons. Recently, an increasing number of studies have applied ML approaches to neuroimaging data to forecast and describe psychiatric ailments^{10,11}, in addition to Post Traumatic Stress Disorder (PTSD) With a Multivariate Voxel Pattern Investigation (MVPA) or supervised ML¹²; an individual can classify psychiatric disorder in person neuroimaging data. In keeping with this belief, it's been indicated further the multivariate patterns of mind changes detected by system learning

might be exceptionally sensitive to operational changes in the brain as a consequence of psychiatric disorder, and thus can facilitate the translation of neuroimaging in the chair to the bedside.

Sato et al.¹³ Implemented technique which includes four phases. In the first phase, SNPs together with the most discriminating info between the nutritious controls and schizophrenia sufferers are chosen to build a support vector machine outfit (SNP-SVME). In the second and third phase, Voxels from the fMRI map leading to classification are chosen to create yet another SVME (Voxel-SVME). In the fourth phase, the above three models are all combined to one module by means of a vast majority voting strategy to produce a last choice (Mixed SNP-fMRI). Experimental results demonstrate that better classification accuracy was attained by mixing genetic and fMRI information than using either alone, suggesting that genetic or mind function representing distinct, but partly complementary facets, of schizophrenia etiopathology. This study indicates an efficient means to reassess biological classification of people with schizophrenia, which can be potentially helpful for identifying diagnostically significant markers for the disease.

After emotional injury, why do some just some pieces of the traumatic event reunite as intrusive memories while some don't? Intrusive memories are crucial to cognitive behavioural therapy for post-traumatic anxiety disease, and an aetiological comprehension is justified. Clark et al.¹⁴ presented investigations using multivariate pattern analysis (MVPA) plus also a machine learning classifier to research if peri-traumatic brain stimulation managed to forecast later intrusive memories (i.e. until they'd occurred). To supply a methodological foundation for knowing the context of the recent outcomes, Clark et al.¹⁴ first demonstrate how functional magnetic resonance imaging (fMRI) through an experimental analogue of injury (an injury movie) via a potential event-related design managed to catch a person's subsequent intrusive memories. Results revealed widespread increases in brain activation at communicating when seeing a scene from the scanner which would later reunite as an intrusive memory from the actual world. All these fMRI results were duplicated in another study. Employing MVPA and also a machine learning classifier, it had been possible to forecast afterwards intrusive memories

around participants using 68% precision, and within a participant with 97% precision; i.e. that the classifier could identify from numerous scenes people who would later reunite as a intrusive memory. In addition, we report here mind networks crucial in intrusive memory forecast. MVPA unlocks the prospect of decoding brain action to rebuild idiosyncratic cognitive events with regard to understanding and forecasting mental health symptoms.

There are no neuroanatomical biomarkers of anorexia nervosa (AN) Accessible to create clinical Inferences in a single subject level. Lavagnino et al.¹⁵ provide results of a multivariate ML system using structural neuroanatomical scan information to distinguish a patient from matched healthy controls in a single subject level. Neuroanatomical volumes were pulled using the FreeSurfer applications and enter into the Least Absolute Shrinkage and Selection Operator (LASSO) multivariate ML algorithm. LASSO has been trained to spot book individual topics as a patients or wholesome controls. What's more, the model estimated that the probability that a single theme belonged to the A group according to a single scan. The model accurately predicted 25 from 30 subjects, translating into 83.3% accuracy (sensitivity 86.7 percent, specificity 80.0 percent) ($p < 0.001$; χ^2 evaluation). The predicted probabilities revealed a linear connection with drive for thinness clinical trials ($r = 0.52$, $p < 0.005$) and with body mass index (BMI) ($r = -0.45$, $p = 0.01$). The model attained a Fantastic predictive precision and drive for thinness revealed a powerful neuroanatomical Signature. These outcomes imply that neuroimaging scans combined with ML techniques have the potential to supply Information for an individual topic level that may be related to clinical results.

Cognitive behavioural treatment for psychosis (CBTp) entails assisting patients to understand and reframe threatening examinations of the psychotic experiences to decrease distress and boost operation. Whilst CBTp is successful for all, it isn't effective for many patients and the variables predicting a fantastic outcome remain poorly known. ML is a highly effective approach which enables new predictors to be identified within a manner that is qualitative, which may inform understanding of these mechanics inherent therapeutic interventions, and finally make predictions about

symptom development in the individual patient level. Thirty-eight patients having a diagnosis of schizophrenia finished a societal affect activity during functional MRI. The models predicted progress in psychotic ($r=0.63$, respectively $p=0.003$) and Profession ($r=0.31$, respectively $p=0.05$) symptoms after CBTp, but maybe not at the treatment-as-usual category ($n=16$). Psychotic symptom development has been called by neural responses to threat-related influence across sensor motor and frontal-limbic areas, whereas affective symptom development has been called by neural responses to fearful faces just in addition to prosocial influence across sensor motor and rectal areas. These findings imply that CBTp probably enhances psychotic and affective symptoms in people endorsing more threatening evaluations and mood-congruent processing biases, respectively that can be researched and reframed as a member of their treatment. This study enhances our comprehension of the neurobiology of therapy response and offers a base that will hopefully result in greater accuracy and tailoring of these interventions provided to patients¹⁶.

Neuroimaging studies have yielded considerable improvements in the understanding of neural systems pertinent to the development and persistence of dependence. Nevertheless, these improvements haven't researched widely for diagnostic precision in human subjects. Mete et al.¹⁷ create a statistical approach, with a ML framework, to properly classify brain pictures of cocaine-dependent participants along with wholesome controls. Within this analysis, a frame acceptable for educating possible brain areas that differed between the 2 groups was designed and implemented. Single Photon Emission Computerized Tomography (SPECT) images acquired through a saline extract in 3 cohorts of two - 4 week abstinent cocaine-dependent participants ($n=93$) and wholesome controls ($n=69$) were utilized to create a classification version. A data theoretic-based attribute selection algorithm was initially conducted to decrease the amount of voxels. A density-based clustering algorithm was then utilized to form spatially attached voxel clouds in three-dimensional space. A statistical classifier, Service Vectors Machine (SVM), was subsequently used for participant classification. Statistically insignificant voxels of spatially connected brain areas were eliminated iteratively and classification accuracy was reported via the iterations. A lot of the 30 chosen clusters are

highly pertinent to this addictive process, including areas pertinent to cognitive management, default style network associated self-referential believed, behavioural inhibition, and contextual memories. Relative Behaviour and hypo activity of regional cerebral blood circulation in brain areas in cocaine-dependent participants are introduced with corresponding amount of importance. The SVM-based strategy successfully categorized cocaine-dependent and healthy control participants with voxels chosen with info theoretic-based and statistical approaches from participants' SPECT data. The areas present within this study align with mind areas reported from the literature. These findings support the potential use of brain imaging and SVM-based classifier from the analysis of substance use disorders and furthering an understanding of their underlying pathology.

Conclusion

When the issue of psychiatric study was that there was insufficient information. Now, with all the speed of technological improvements that have happened in the current century at neuroimaging, we're at risk of becoming overwhelmed by a quantity of information which the individual brain, helped only by conventional statistical procedures, can't assimilate and incorporate. We suggest a set of alternatives to 21st century psychiatry's data overload problems is supplied by machine ML and specifically from a branch that's now often referred to as statistical learning. Besides these statements, prototypes learnt by ML techniques may assist in better understanding the features of each course. The percentage of these with the identification of psychiatric disorder in different medical data has been little.

Hospitalized Morbidity & Utilization of Beds in a Rural Health Training Centre

Mohite RV¹, Kshirsagar VY²

¹Assist Professors, Dept of Community Medicine, ²Professors, Dept of Pediatrics,
Krishna Institute of Medical Sciences Karad, Maharashtra, India

Abstract

Background: Morbidity consumes a substantial portion of health care resources in a hospital. The overload in hospital ward remains a major source of concern in many countries, including India, for policy makers. The availability of beds is perhaps the single most important factor in determination of the hospital utilization in a country. **Objective:** To determine the pattern of hospitalized morbidity, hospital bed utilization by different morbidity and length of stay in the Rural Health Training Centre (RHTC). **Observation:** A total of 528 patients were admitted in RHTC of which max, 53% were females with mean age of male and female patients were 48.15yrs (SD=19.22) and 40.39yrs (SD=16.64) respectively. Max, 22.9% patients were in age group 26-35 years. Max. 38.6% hospitalized morbidity was mainly due to viral fever followed by gastroenteritis, 21.5% and among the total anaemic admissions, higher proportion, 70% was belonged to females. Length of stay due to hospitalised morbidity range from one to four days of which max length of stay was seen in age 46 to 55 yrs and mainly due to enteric fever.

Overall bed occupancy rate due to hospitalized morbid condition during study period was 54.92%. Bed occupancy rate was high, 17.91% due to viral fever followed by gastroenteritis, 15.05%, and enteric fever (10.38%) respectively. However, maximum length of hospital stay ,4 days was mainly due to enteric fever and variation within disease about the length of stay in hospital is found significant. **Conclusion:** Hospitalized utilization in rural area is mainly due to infectious diseases and need efforts to sensitize the poor and neglected sector of rural community to access the health care services for positive health.

Keywords: Morbidity, bed utilization, length of stay, RHTC

Introduction

Morbidity consumes a substantial portion of health care resources in a hospital. The overload in hospital ward remains a major source of concern in many countries, including India, for policy makers. The availability of beds is perhaps the single most important factor in determination of the hospital utilization in a country. ^[1]

In India, shortage of hospital beds is a huge problem, the average bed population ratio being 9 per 10,000 populations in comparison with the world average of 27 per 10,000 during 2000-2009. As the demand for health care increases, a high efficiency on limited resources is necessary for affordable high-patient service levels. ^[2,3]

A possible way to minimize the problem of scarcities of beds is to look for variation in bed utilization by different causes across the country and plan services accordingly. This information also provides the basis for patient care and bed management in a hospital. There are many factors affecting bed utilization, namely the allocation of beds, patient placement and patient admission policies, etc.^[4] Similarly, in Indian communities, the access of health care services and

utilization of hospital bed influenced by factors such as social, economic, educational and cultural characteristics of people as well as attitude and habit towards medical profession. The present study aimed to know the habit of rural Indian community towards utilization of hospital beds from Rural Health Training Centre (RHTC).

Materials and Method

It was a descriptive study with retrospective analysis of records conducted in the in-patient Department of Rural Health Training Centre (RHTC), Kasegaon, under Dept. of Community Medicine, Krishna Institute of Medical Sciences (KIMS), Karad provide primary health care services to needy and poor people free of cost. The study involved the analysis of records of patients admitted for a period of year 2014. Data was extracted from the admission and discharge registers maintained at RHTC. This centre has 10 in-patient beds (5 General & 5 ANC). Only planned surgeries are done under consultation with KIMS, Karad. Critical cases & infectious diseases (e.g Cholera etc.) are not admitted in this hospital, they are referred to tertiary health care centre (KIMS Karad). A Medical Officer is available for consultation round-the-clock. All the patients coming to this hospital are working in farm and farm related occupations. Before conducting this study, approval was obtained from the Institutional Ethics Committee.

The investigators abstracted all the medical

records from the in-patient department records using a pre-designed data collection tool. The information obtained included morbidity (illness or events that lead to hospitalization) and clinical & therapeutic details (history of illness, physical examination, laboratory investigation, diagnosis, duration of illness and length of stay in hospital).

Average length of stay: The average period (days) of stay in the hospital per admitted patient⁵.

Bed Occupancy rate: Percentage of occupancy of hospital beds. [5]

The primary condition requiring hospitalization was noted as the main diagnosis. The patients admitted to general ward were utilized for present study; however ANC beds were excluded from present study. All the data collected was entered in to the Excel sheet & analyzed by applying statistical tests i.e. Proportion, Averages and tests of significance (Chi-square test).

Results

A total of 528 patients were admitted in RHTC during a year 2014 of which 248 and 280 belonged to male and female gender with mean age 44.2 years and ranges between 16 – 85 years with mean age of male and female patients were 48.15yrs (SD=19.22) & 40.39yrs (SD=16.64) respectively.

Table 1: Distribution of the study population according to age group & Gender

Age group (Yrs)	Frequency (%)			χ^2	P
	Male	Female	Total		
16 – 25	48 (45.2) (19.3)	58 (54.7) (20.7)	106(20.0)	28.2	0.0001*
26 – 35	41 (33.8) (16.5)	80(66.1) (28.5)	121(22.9)		
36 – 45	40 (37.7) (16.1)	66 (62.2) (23.5)	106(20.0)		
46 – 55	31 (64.5) (12.5)	17(35.4) (06.0)	48(09.0)		
56 – 65	27(57.4) (10.8)	20 (42.5) (07.1)	47(08.9)		
66 – 75	55 (61.7) (22.1)	34 (38.2) (12.1)	89(16.8)		
76 – 85	06(54.5) (02.4)	05 (45.4) (01.7)	11(02.0)		

Table 1 revealed that max, 22.9% patients were in age group 26-35 years followed by 20% each in 16-25 and 36-45 years respectively. Among male and female patients max, 22.1% and 28.5 % were from age group 66-75 yrs and 26-35 yrs respectively. There is significant association between hospitalized morbidity patterns of gender with respect to age as reported by $p < 0.05$ at 95% confidence level.

Table 2: Distribution of study population according to occupation

Occupation (Male)	Frequency	%	Occupation (Female)	Frequency	%
Farmers	99	39.9	Housewife	206	73.5
Service	37	14.9	Service	27	09.6
Student	21	08.4	Student	11	03.9
Factory worker	17	06.8	Labour	36	12.8
Ex-serviceman	07	02.8			
Labour	67	27.0			

Table 2 shows max; 39.9.2% male patients were farmer followed by labours, 27% whereas max, 73.5% female were engaged with household duties followed by 12.8% as daily wedge labours.

Figure 1: Distribution of study population according to socio-economic status & Gender

According to fig 1, max, proportions of male (65%) and female (55%) patients were belonging to upper socio-economic class whereas significantly few male patients (2.2%) were belonging to lower class compared

to female patients (18.50%) according to modified B.G. Prasad socio-economic classification(2018) and the difference in proportions were found statistically significant ($\chi^2 = 14.30, p = 0.008^*$).

Table 3: Distribution of study subjects according to Disease and Gender

Morbidity	Frequency (%)			χ^2	P
	Male	Female	Total		
Respiratory diseases	28 (42.4) (11.2)	38 (57.5) (13.5)	66(12.5)	21.2	0.007*
Gastroenteritis	68 (59.6) (27.4)	46 (40.3) (16.4)	114 (21.5)		
Viral fever	88 (43.1) (35.4)	116 (56.8) (41.4)	204(38.6)		
Enteric fever	37 (60.6) (14.9)	24 (39.3) (08.5)	61(11.5)		
U.T.I	09 (39.1) (03.6)	14(60.8) (05.0)	23(04.3)		
Anaemia	18(30.0) (07.2)	42 (70.0) (15.0)	60(11.3)		

Max. 38.6% hospitalized morbidity was mainly due to viral fever followed by gastroenteritis, 21.5% and among the total anaemic admissions, higher proportion, 70% was belonged to females. Among males, higher admission rate, 35.4% was seen due to viral fever followed by gastroenteritis, 27.4% and enteric fever, 14.9% however; in females, 41.4% due to viral fever followed by gastroenteritis, 16.4% and anaemia by 15% respectively. The proportion of admissions due to gastroenteritis and enteric fever was seen higher in males 27.4% and 14.9% as compared to females. The gender and hospitalized morbidity was significantly associated to each other as denoted by p value which is <0.05 at 95% confidence interval (Table 3).

Table 4: Distribution of study subjects according to length of stay in hospital

Age group (in years)	Length of stay (in days)				Student t test	P
	Minimum	Maximum	Mean	S.D		
16 – 25	1	3	1.45	0.60	3.59	0.001*
26 – 35	1	3	1.91	0.79		
36 – 45	1	3	2.65	0.74		
46 – 55	1	4	1.87	1.12		
56 – 65	1	3	1.80	1.12		
66 – 75	1	3	1.52	0.87		
76 – 85	1	1	1.00	0.00		

According to table 4, patients with age group 46 to 55yrs stayed for maximum duration, 4 days in hospital as compared to other age groups. Mean duration of stay in hospital among male (1.95 ± 0.89) was more as compared to female (0.56 ± 0.56) patients and difference was found statistically significant (t value 3.59, $p < 0.001$).

Table 5: Distribution of study subjects according to Bed- days utilization

Morbidity	Length of stay				Bed days occupied	Proportion of bed days occupied/1820 (%)	ANOVA	p
	Min.	Max.	Mean	S.D				
Respiratory diseases	1	3	1.2	0.57	79	4.34	16.49	0.001*
Gastroenteritis	1	3	1.9	0.62	274	15.05		
Viral fever	1	3	1.6	0.64	326	17.91		
Enteric fever	3	4	3.1	0.40	189	10.38		
U.T.I	2	3	2.6	0.54	60	3.29		
Anaemia	1	2	1.2	0.49	72	3.95		

Overall bed occupancy rate due to hospitalized morbid condition during study period was 54.92%. Bed occupancy rate was high (17.91%) due to viral fever followed by gastroenteritis (15.05%) and enteric fever (10.38%) respectively. However, maximum length of hospital stay (4 days) was mainly due to enteric fever and variation within disease about the length of stay in hospital is found significant ANOVA ($F=16.49$, $p < 0.001$) (Table 5).

Discussion

Present study revealed that maximum proportions of patients admitted to RHTC were in age group 26 to 45 yrs with high proportion of females i.e. 53%. The max, proportion of male and female patients admitted was with good economic status with mean age, males and female was 48.15yrs (SD=19.22) and 40.39yrs (SD=16.64) respectively. A study conducted by Rahman M et al⁶ in Dhaka observed that 80% respondents were age of 16-45 yrs and max, 60% were females with max, 61.42% respondents were found good socio-economic status. Similar findings also observed by Hussain S et al⁷ in Karachi, Pakistan. Study conducted by Ashok Kumar T et al⁸ in south India also observed that hospitalization proportion among female was more i.e.53.1%. It indicates that immunological status among rural female population is poor may be due to high prevalence of anaemia, poor nutritional status and

may be household anxiety also. Socio-economic status influences people to seek medical services as directly associated with education and positive attitude, however fear of loss of wages, negative attitude and illiteracy affect the hospitalization by poor even though health care services provided by free of cost.

Our study observed that max. 38.6% patients were admitted due the Viral fever followed by 21.5% Gastroenteritis and 12.5% Respiratory diseases respectively. Proportion of patients admitted for diseases like Urinary Tract Infection, Enteric fever and Anaemia range 4.3% to 11.5%. Rahman M et al⁶ also found that viral fever was prominent morbid condition, 53.5% for hospitalization followed by Arthritis-22.5% and Diarrhoea -8.5%. Similar morbidity pattern also observed by Hussain S et al⁷ i.e. 26.53% respondents were suffered from respiratory infections. This is mainly due to rural residence, exposure to various allergic particles as well as field activities and consumption of untreated water from irrigated fields. However study conducted in Saudi by Abdullah I et al⁹ observed 60% hospitalization due to respiratory infections which was mainly due to summer study period and maximum use of cold items.

The average length of hospital stay in our study range from one to four days, similar observation i.e. 3.2 days reported by Alan J. Crockett et al¹⁰ in South Australian

hospital. However study conducted by E.Ravi Kiran^[11] in South India observed 6 to 12 days and difference was mainly due to geographical variations, study setting and subjects.

Conclusion

Communicable diseases are still big problem in rural India which leads to hospitalization, similarly women's health is again need to be highlighted and services should be rendered as per need and health status of community.

Variation in Blood Pressure and Pulse in Inter-arms and Its Management

Naresh Vashist¹, Raveen Chauhan²

¹Pharmacy Practice, Shoolini University, Bajhol, Distt. Solan, H.P, India & Pharmacist, Health & Family Welfare Department, Himachal Pradesh, India, ²Assistant Professor, Department of Pharmaceutical Sciences, Shoolini University, Bajhol, Distt. Solan, H.P, India

Abstract

Background: Blood pressure is vital sign, along with heart rate, oxygen saturation, respiratory rate and body temperature. Blood pressure, in normal adult, is approximately 120/80 mmHg. Difference between measured systolic and diastolic pressures is called pulse pressure. Pulse pressure is due to cardiac output. Blood pressure should be measured in both arms at first visit because differences exist and measurement in only one arm may lead to under diagnosis of hypertension. Confirmation of an inter-arm difference requires a method of repeated simultaneous measurement, to avoid overestimation of prevalence.

Method: Apparatus used is digital sphygmomanometer. Blood pressure and pulse rate is measured of both arms, thrice each time, concordant readings are considered and noted for this purpose of blood pressure and pulse rate in different age groups persons.

Result: Total Persons investigated of different age groups = 1126, Males = 517, Females = 609, total SBPV in range of 0-10mmHg =936, 11-20mmHg=178, 21-30mmHg=12. DBPV in range of 0-10mmHg=1097, 11-20mmHg= 26, 21-30mmHg=3. PV=26, 0-10mmHg=1109, 11-20mmHg=15, 21-30mmHg=2. Diseased persons=325, Normal persons=801.

Conclusion: Variation in blood pressure and pulse rate in inter-arms observed in different age groups from 0-10mmHg to 21-30mmHg. More variation may show cardiovascular disease in individual. Total person investigated are 1126 out of which 801 are normal and 325 are suffering with hypertension, diabetes, hypertension with diabetes and hypotension. Maximum variation is found in 0-10mmHg in systolic blood pressure, diastolic blood pressure and pulse which is not showing significant diseases and minimum in 21-30mmHg which is showing cardiovascular diseases and their probabilities.

Keywords: Digital sphygmomanometer; systolic blood pressure, diastolic blood pressure, pulse rate.

Introduction

Blood pressure is vital sign, along with heart rate, oxygen saturation, respiratory rate and body temperature. Blood pressure, in normal adult, is

approximately 120 millimetres of mercury systolic, and 80 millimetres of mercury diastolic means “120/80 mmHg”.¹ Difference between the measured systolic and diastolic pressures is called pulse pressure. The pulse pressure is due to cardiac output. The magnitude of the pulse pressure is usually attributed to the interaction of the stroke volume of the heart, the ability to expand of the arterial system—largely attributable to the aorta and large elastic arteries—and the resistance to flow in arterial tree.² The inter-arm difference in blood pressure was discovered first by Osler in 1915.³ The blood pressure should be measured

in both the arms at the first visit to avoid differences exist and under diagnosis of hypertension.^{4,5} Confirmation of an inter-arm difference requires a method of repeated simultaneous measurement to avoid overestimation of prevalence.^{6,7} Both arms measurement of blood pressure is important to prevent the misdiagnosis of hypertension due to normal differences in blood pressure in inter-arms.⁸ When both arms are measured, it has been suggested that simultaneous measurement of both arms seems preferable since sequential measurement of blood pressure overestimates the prevalence of systolic inter-arm difference.⁹ A systolic blood pressure difference in inter-arms is one risk marker that is easily measured clinically with no additional equipment. Differences in inter-arms can cause errors in blood pressure interpretation and management when not recognized.¹⁰⁻¹⁴ The new clinical guideline for hypertension from the National Institute for Health and clinical Excellence considers less than 10mmHg inter-arm difference as normal and attributes more than 20 mm Hg to underlying vascular disease.¹⁵ An inter-arm difference in blood pressure of 10-20 mm Hg, suggesting

15% of the population with hypertension.¹⁶ The recent European Guideline on Hypertension gives a more precise description of this by stating that in the event of a significant (>10mmHg) and consistent Systolic Blood Pressure difference in inter-arm, the arm with the higher Blood Pressure values should be used.¹⁷ Stergiou et al. pointed out that clinical blood pressure measurements had a standard deviation of differences between two sets of measurements of 10.4mmHg, systolic.¹⁸

Material and Method

The apparatus used is digital sphygmomanometer. The blood pressure and pulse rate is measured of both the arms, thrice, the concordant readings are considered and noted for this purpose of blood pressure and pulse rate in different age groups persons. The data is collected from different rural areas by collecting the people on some fixed places or by visiting in different rural areas. The cuff is tied in the upper region of the arms and the instrument is put on the level of the chest.

Table-1: SBPV, DBPV and PV in Normal and Diseased persons in different age groups:

Discussion

Total persons whose blood pressures and pulse rates are detected with the help of digital sphygmomanometer are 1126 out of which 517 are males and 609 are females, in different age groups. The normal persons are 801 and the diseased subjects are 325 which are suffering from hypertension, diabetes and hypertension with diabetes. In age group 10-20, total persons investigated are 18, the SBPV from 0-10 mmHg variation is in 18 persons, DBPV is in 18 and PV is in 18 persons where as 0 subject is in the 11-20 mmHg variation and in 21-30 mmHg variation. In age group 21-30, total persons are 76, the SBPV from 0-10 mmHg variation is in 63 persons, DBPV is in 75 and PV is in 75, in 11-20 mmHg variation, 13 SBPV, 1 DBPV and 1 PV, in 21-30mmHg variation, persons are nil. In age group 31-40, 144 are total persons out of which 0-10 mmHg variation SBPV is in 125, DBPV is in 142, PV is in 140. In 11-20 mmHg variation SBPV 19, DBPV 2, PV 4. In age group 41-50, total persons are 248, in 0-10 mmHg variation SBPV are 219, DBPV are 247, PV are 247, in 11-20 mmHg variation, SBPV are 27, DBPV and PV is 1, in 21-30 mmHg variation, SBPV are 2, DBPV and PV is 0. In age group 51-60, total persons are 273, in 0-10 mmHg,

SBPV are 230, DBPV are 265, PV are 273, in 11-20 mmHg, SBPV are 41, DBPV is 8 and PV is 0, in 21-30 mmHg, SBPV are 2, DBPV and PV is 0. In age group 61-70, total persons are 202, in 0-10 mmHg variation SBPV are 157, DBPV are 195, PV are 198, in 11-20 mmHg variation, SBPV are 41, DBPV are 6 and PV are 3, in 21-30 mmHg variation, SBPV are 4, DBPV and PV is 1 each. In age group 71-80, total persons are 136, in 0-10 mmHg variation SBPV are 102, DBPV are 128, PV are 130, in 11-20 mmHg variation, SBPV are 30, DBPV are 6 and PV are 5, in 21-30 mmHg variation, SBPV are 4, DBPV are 2 and PV is 1. In age group 81-90, total subjects are 25, in 0-10 mmHg variation SBPV are 19, DBPV are 24, PV are 25, in 11-20 mmHg variation, SBPV are 6, DBPV is 1 and PV is 0, in 21-30 mmHg variation, SBPV, DBPV and PV is 0. In age group 91-100, total persons are 4, in 0-10 mmHg variation SBPV are 3, DBPV are 3, PV are 3, in 11-20 mmHg variation, SBPV, DBPV and PV is 1 each, in 21-30 mmHg variation, SBPV, DBPV and PV is 0 each. Various diseases significantly influenced the increase in Blood Pressure as showed by Weinberg et al.¹⁹ that an inter-arm Systolic Blood Pressure difference is common and associated with a significant increased risk for future

cardiovascular events, even inter-arm difference is modest. Igarashi et al. reported that inter-arm difference in blood pressure might regard as a simple marker for coronary and peripheral artery diseases.²⁰The mean blood pressure difference for left-arm and right-arm was higher in some cases but found statistically insignificant as reflected in the reportings of Pesola et al.²¹Imaging evidence at lower levels of inter-arm difference such as 10 or 15 mmHg is scarce and inconclusive.²²The differences in inter-arms are associated both with wider pulse pressures.²³

Management:

Further studies of the measurement and implications of an inter-arm difference are needed. The effect of the full protocol in reducing apparent prevalence suggests that future epidemiological studies of inter-arm difference must adopt a similar robust repeated simultaneous measurements approach to avoid overestimation of prevalence.²⁴It is recommended that digital sphygmomanometer should be made for measurement of the blood pressure of inter-arms on the same time to avoid the error of variation of blood pressure and pulse rate. The accuracy of the readings is detected. The apparatus may have two cuffs to tie both sides and should be attached to a single instrument. The readings on the monitor should be different for both arms with one conclusive reading on the screen.

Conclusions

The variation in inter-arms in SBPV and DBPV and pulse variation is observed when detected with digital sphygmomanometer, thrice in each arm and concordant readings are noted each time. Variation in blood pressure and pulse rate in inter-arms observed in different age groups from 0-10mmHg to 21-30mmHg. More variation may show the cardiovascular disease in individual. Total person detected are 1126 out of which 801 are normal and 325 are suffering with hypertension, diabetes, hypertension with diabetes and hypotension. Maximum variation is found in 0-10mmHg in systolic blood pressure, diastolic blood pressure and pulse which is not showing significant diseases and minimum in 21-30mmHg which is showing cardiovascular diseases and their probabilities.

Abstract

Introduction- FNAC is a valuable tool in the preoperative assessment of breast masses with a primary goal to separate malignant from benign masses.

Material and Methods- This study was conducted on 300 cases presenting with breast lump during the last 3 years in a tertiary care hospital of Western Uttar Pradesh. FNAC was performed in all the cases and smears were analysed and categorised according to NBSBSP classification. Cytohistologic correlation was done wherever possible.

Results- Age of patients ranged from 8 years to 74 years with mean age of 32.4 years and female to male ratio of 20.08:1. Majority of aspirates were in C2- benign category followed by C5 malignant, C4 suspicious and C3 atypical respectively. Maximum number of aspirates were reported as fibroadenoma 42.27 % followed by fibrocystic disease 33.7%. 9.12% were diagnosed as malignant lesions of which infiltrating ductal carcinoma (89.65%) was the commonest.

Conclusion- FNAC is a safe, cost effective, highly sensitive and specific outpatient procedure useful in early diagnosis and management of breast lesions and at times obviating the need of surgery. Borderline (gray zone) lesions should be followed up.

Keyword- Breast lump, FNAC, Gray zone lesions.

Introduction

Breast lump is the most common presentation in most of the breast diseases. The triple assessment of breast disease by clinical examination, mammography and Fine Needle Aspiration Cytology (FNAC) has been reported as 100% accurate in diagnosis of breast disease¹. FNAC is a valuable tool in the preoperative assessment of breast masses with a primary goal to separate malignant from benign masses as malignant

requires radical therapy and benign can be managed conservatively².

FNAC of breast lump has various benefits over open tissue biopsy. It is highly sensitive ranging from 82% to 97.5% and with specificity of >99%, easy to perform, minimally invasive and cost effective that can be performed at outpatient department with results available within shorter time and helps in planning of treatment in the breast lump^{3,4}. We can also perform molecular ancillary techniques, that is progesterone receptor (PR) and estrogen receptor (ER), proliferation antigen (Ki67) and DNA pattern analysis^{5,6}.

FNAC helps in differentiating benign from malignant but there are certain diseases in which the morphological features are overlapping such as cellular fibroadenoma, proliferative breast disease with atypical

hyperplasia, papillary lesions and low grade carcinoma making them difficult to be categorised.

However, to overcome this difficulty a standard system of reporting breast FNAC was given by National Health Service Breast Screening Program (NHSBSP)⁷ comprising of categories C1 to C5. C1-Inadequate, C2-Benign, C3-Atypical, probably benign, C4-Suspicious, C5-Malignant. C3, C4 categories consists of gray zone lesions and these are further subjected to biopsy.

The present study was conducted to evaluate the spectrum of breast lesions on aspiration cytology, to classify them according to NHSBSP and to identify the borderline cases.

Material and Methods

This study was conducted on 300 cases presenting with breast lump during the last 3 years in a tertiary care hospital of Western Uttar Pradesh. Inclusion criteria were cases presenting with palpable breast lump and breast lesion detected on radiology.

The cases with nipple discharge without palpable breast lump were excluded from the study.

FNAC of palpable breast lump was performed with a 22-24 gauze disposable needle attached to a 10 ml disposable plastic syringe fitted in syringe holder and sample was obtained by to and fro motion.

Smears were prepared and half slides were fixed in 95% ethyl alcohol for Haematoxylin & Eosin (H & E) and Papanicolaou(PAP) stain and remaining were air dried for Leishman-Giemsa stain.

FNAC smears were studied in detailed for findings of inflammation, benign breast disease, suspicious and malignant lesions and they were classified according to NHSBSP,2011⁷. The cytomorphological features of borderline lesions (gray zone) were analysed specifically to establish a criteria which would help in classifying these lesions.

For cytohistopathological correlation, formalin fixed paraffin embedded H & E stained sections were studied.

Results

A total of 300 cases presented with breast lump, of which bilateral disease was seen in 18 cases therefore 318 breast lumps were observed.

Table 1 : AGE AND SEX WISE DISTRIBUTION

Age Group (In Years)	Females		Males		Total (%)	
	Number	Percentage (%)	Number	Percentage (%)	Number	Percentage (%)
1-10	1	0.33	0	0	1	0.33
11-20	52	17.33	1	0.33	53	17.67
21-30	95	31.67	7	2.33	102	34
31-40	79	26.33	0	0	79	26.33
41-50	42	14	2	0.67	44	14.67
51-60	11	3.67	2	0.67	13	4.33
61-70	7	2.33	0	0	7	2.33
71-80	0	0	1	0.33	1	0.33
TOTAL	287	95.67	13	4.33	300	100

Age of patients ranged from 8 years to 74 years with mean age of 32.4 years. Majority of patients were in third decade 34% (102/300) cases, followed by 26.33% and 18% in 4th and 2nd decade respectively. There were 95.67% (287/300) female and 4.33% (13/300) males. Female : Male ratio was 22.08:1 (Table 1).

TABLE 2 : CATEGORISATION OF CYTOLOGICAL DIAGNOSIS

CYTOLOGICAL CATEGORY	TOTAL NUMBER OF ASPIRATES	PERCENTAGE (%)
C1	17	5.35
C2	246	77.35
C3	11	3.46
C4	15	4.72
C5	29	9.12
TOTAL	318	100

Majority of aspirates were in C2- benign category followed by C5 malignant, C4 suspicious and C3 atypical respectively.(Table 2).

17 out of 18 bilateral cases showed similar cytological category C2 on both sides while in one case categories were different C4 in right side and C5 in left side.

TABLE 3: SPECTRUM OF BENIGN LESIONS – C2

C2 CATEGORY		NUMBER OF ASPIRATES	PERCENTAGE (%)
Non proliferative breast disease	Fibrocystic disease	83	33.7
Proliferative breast disease without atypia	Epithelial hyperplasia	03	1.22
Benign Tumours	Fibroadenoma	104	42.27
	Benign phylloides tumour	01	0.41
	Intraductalpapiloma	01	0.41
	Lactational adenoma	04	1.63
Non-neoplastic and miscellaneous	Acute mastitis / abscess	13	5.28
	Galectocele	12	4.90
	Gynaecomastia	07	2.84
	Duct ectasia	06	2.45
	Chronic mastitis	04	1.63
	Fat necrosis	03	1.22
	Granulomatous inflammation	03	1.22
	Retention cyst	01	0.41
	Epidermal cyst	01	0.41
	TOTAL	246	100

Out of benign cases maximum number of aspirates were reported as fibroadenoma 42.27 % followed by fibrocystic disease 33.7% (Table 3).

TABLE 4 : SPECTRUM OF MALIGNANT LESIONS - C5

C5 CATEGORY	NUMBER OF CASES	(PERCENTAGE) %
Infiltrating Ductal Carcinoma	26	89.65
Infiltrating Lobular Carcinoma	01	3.45
Mucinous (Colloid) carcinoma	01	3.45
Medullary Carcinoma	01	3.45
TOTAL	29	100

29 out of 318 (9.12%) breast FNACs were diagnosed as malignant lesions. Majority of cases were infiltrating ductal carcinoma (89.65%). (Table 4).

TABLE 5 : CYTO-HISTOPATHOLOGICAL CORRELATION

CYTOLOGICAL CATEGORY	CYTO-HISTOPATHOLOGICAL CORRELATION		TOTAL
	YES	NO	
C2	35	1	36
C3	3	1	4
C4	6	1	7
C5	8	0	8
TOTAL	52	3	55

Out of 318 aspirates, histopathological sections were available in 55 aspirates (17.29%). FNAC findings correlated with histopathological diagnosis in 52 cases and 3 aspirates showed discrepancy. (Table 5).

One case was diagnosed as benign on cytology, on histology it turned out to be infiltrating ductal carcinoma with insitu component. Another case was diagnosed as cystic lesion with occasional atypical cells this also turned out to be infiltrating ductal carcinoma with extensive cystic changes with haemorrhage. Third case was given as suspicious for malignancy on cytology, on histology it was diagnosed as fibrocystic disease with florid epitheliosis and focal atypical changes. Considering histopathology as gold standard for diagnosis the p value for cytohistopathological correlation was significant (p value < 0.05). Overall sensitivity was 87.5%, specificity

97.4%, positive predictive value 95%, negative predictive value 94.5% and diagnostic accuracy was 98.3%.

Discussion

FNAC plays an important and essential role in the management of patients with breast lesions and also offers a great potential for prediction of patient's outcome, disease response to therapy and assessment of risk of developing breast cancer.⁸

Female sex and increasing age are the strongest risk factors for breast cancer.⁹In present study, age of the

patients ranged from 8 years – 74 years with the mean age of 32.4 years. Majority of the patients were in 3rd decade 34% (102/300 cases), followed by 26.3 % in 4th decade. Similar findings were observed by Khandaza et al.¹⁰

There was female preponderance (95.67 %, 287/300 cases) with F:M ratio of 22.08:1. This was in accordance with various studies^{2,11,12} which reported F:M ratio ranging from 14:1 to 24.5:1

Breast lump was the commonest clinical presentation, as it was the inclusion criteria, followed by pain and fever in 20.67% (62/300) and 7.67% (23/300) cases respectively. Chandanwale et al² and Shirley et al¹² also observed that lump was the most common presenting symptom in their studies observed in 100% and 67.8% respectively.

Cytological categorization from C1-C5 category for FNAC breast is a cost effective and practical procedure for early diagnosis of breast cancer.¹³ In the present study we observed that benign lesions were the most frequent accounting for 77.3% cases followed by malignant lesions in 9.1% of cases. Similar findings were observed by Bajwa et al.¹³

The most common benign lesion (C2) in our study was fibroadenoma 42.27% (104/246) followed by fibrocystic disease 33.7% (83/246). Fibroadenoma was also the most common lesion observed in the study by Chandanwale et al² 49% (49/100) and Echezoh et al¹⁴ 45% (45/100).

26 / 318 aspirates were categorized as gray zone lesions, 11/318 (3.4%) showed epithelial hyperplasia with atypia (C3) and 15/318 (4.7%) were reported as suspicious of malignancy (C4). Histological correlation in borderline lesions was available in 11/26 cases. 3/4 cases of C3 category were consistent with diagnosis of atypical epitheliosis and 6/7 cases were consistent with malignancy.

Our percentage of C3 was in between percentage reported by Challa et al,¹⁵ and Sankaya and Dongre¹⁶ who reported it to be 3.3% and 3.6% whereas percentage of C4 was comparable to Sankya and Dongre¹⁶ who reported it in 3.5% cases. According to Arul et al 2016¹⁷ diagnosis of C3 and C4 categories are difficult as they do

not have strict criteria for diagnosis.

In the present study, 9.12% (29/318) cases were diagnosed as malignant breast lesions. In a study conducted by Yalavarthi et al,¹⁸ 13.5% (45/334) cases were diagnosed as malignant.

In the present study cyto-histological correlation was available in 55 cases, showing that FNAC had 94.5% diagnostic accuracy, 87.5% sensitivity and 97.4% specificity of diagnosing various breast lesions.

The sensitivity ranging from 80-99.4% and specificity upto 100% have been reported the past.¹⁹⁻²²

Though FNAC is a reliable tool for diagnosis of breast lesions false negatives and false positives may occur. In the present study False negative was observed in (2/55, 3.6%) and false positive in one case i.e. 1.8%. The false negative and false positive have been reported ranging from 1.7% to 13.3% and 0.6% to 6.5% respectively in the past.²³⁻²⁹

Inadequate aspirates reported in the past ranged from 8-13.3%.³⁰⁻³³ Inadequate smears in the present study were 5.35%. Our observations were lower as compared to other studies this could be due to less number of cases in the present study. As histological correlation was not available in these cases, the possibility of malignancy cannot be excluded. NHSBSP⁷ surveys highlights that further clinical correlation and diagnostic modalities should be used in all cases with inadequate aspirates before considering them benign.

Conclusion

FNAC is a safe, cost effective outpatient procedure useful in early diagnosis and management of breast lesions and at times obviating the need of surgery. In the present study most of the non neoplastic inflammatory and benign lesions were managed conservatively.

We observed a high sensitivity and specificity for diagnosis of malignant lesions with minimal false negatives and false positives. In cases with discrepancy further clinical, laboratory and radiological correlation should be sought. Borderline (gray zone) lesions should be followed up.

Ethical Clearance- Taken from institutional ethical committee.

Invitro Study to Assess the Impact of Chelating Agents on Microhardness of Primary Radicular Dentin

Needhika Chhibber¹, Arun Kumar², Deepmala³

¹Registrar, Oral Medicine and Radiology, Indira Gandhi Government Dental College, Jammu, ²MDS, Department of Periodontology & Oral Implantology, ³BDS, House Surgeon, Indira Gandhi Government Dental College, Jammu

Abstract

Background: To evaluate the effect of two irrigating solutions on microhardness of radicular dentin of primary teeth.

Methods: 10 buccolingual sections of roots of decoronated primary teeth were mounted in plaster, randomly divided into two groups of 5 specimens each according to the irrigant used: group1 (5.25% sodium hypochlorite with 17% EDTA) and group 2 (2-6% citric acid). Dentin microhardness was measured before and after irrigation at apical, middle, cervical levels of the roots with a Vickers indenter.

Results: There was a statistically significant difference in the microhardness values of radicular dentine before and after irrigation with both the agents. More reduction was seen with Citirc acid as compared to EDTA with statistically significant difference (p=0.001).

Conclusion: Chelating agent when used as irrigants bring about a significant reduction in microhardness of radicular dentine in primary teeth.

Keywords: Citric Acid, EDTA, Hardness test, Smear Layer

Introduction

Smear layer is a dense coating of residues obliterating the dentinal tubules, produced as a result of instrumentation.^(1,2) Removal of this smear layer can be done with the use of chelating agents. Although they improve the quality of obturation but, they may have the disadvantage of significant reduction of microhardness in primary root canals. The present study was conducted to evaluate the effect of two chelating agents namely, 5.25 % sodium hypochlorite with 17% EDTA and 6 % Citric acid used as irrigating solutions, on microhardness of radicular dentin in primary teeth.

Materials and Method

The study was carried out in the Department of OMR after approval by the Institutional Ethical Committee. 10 freshly extracted human primary teeth (anterior and posterior) that were indicated for extraction, having atleast one root with 2/3rd root length were selected for the study. The teeth were decoronated at the cemento enamel junction and the roots were sectioned buccolingually. These root halves were then embedded in blocks of plaster of Paris with the dentin facing upwards. The specimens were divided into 2 groups on the basis of the irrigant used i.e. Group I (5.25% sodium hypochlorite and 17% EDTA) and Group II (6 % citric acid).

For every specimen three separate indentations were made at the cervical, middle, and apical levels of the root with a Vickers diamond indenter using a 200g load and a 10s dwell time. Microhardness value was obtained pretreatment which gave the mean baseline Vicker hardness number (VHN). The specimens were then

irrigated according to their respective groups. Group I- Continuous application of 17% EDTA & 5.25 % sodium hypochlorite was done for 3 minutes on each specimen. Group II – The individual specimens were treated with 6 % citric acid for 3 minutes.

Specimens were rinsed in distilled water after application of the irrigant and blotted dry. Vickers hardness number was again recorded post treatment and the change in microhardness was calculated.

Statistical Analysis

The data was analysed using SPSS software version 24.

Results

The mean baseline Vickers microhardness value for primary radicular dentin was found to be 51.69 ± 11.14 and 50.49 ± 15.85 VHN, in Group I and II respectively. Post-treatment mean VHN value was 33.28 ± 6.87 and 24.65 ± 6.39 in Group I and II respectively. When pre and post-treatment value was compared statistically among group 1 and 2, it was found to be statistically significant. 6% Citric acid caused greater percentage reduction in dentin microhardness than 17 % EDTA used with 5.25 % sodium hypochlorite and the pairwise comparison showed this reduction to be significantly different (p -value <0.05) as shown in Table 1 .

Table 1: Comparison of the microhardness between the two groups

Groups	Pre-Treatment (Mean \pm SD)	Post-Treatment (Mean \pm SD)	P-value*
Group 1	51.69 \pm 11.14	33.28 \pm 6.87	<0.01
Group 2	50.49 \pm 15.85	24.65 \pm 6.39	<0.01
p-value**	0.76	0.004	

*paired t-test applied, ** independent t-test applied

Discussion

Use of irrigating solution is an essential part of endodontic treatment. It renders the canals sterile, lubricates them for easy passage of files and removes the smear layer. It has been observed that a heavy smear layer is usually seen in the specimen's irrigated with saline solution alone. It produces a sludge layer made up of residual debris that cause occlusion of the dentinal tubules.⁽³⁾ Thus the use of chelating agents is recommended for removal of smear layer.

17 % EDTA as a final rinse in primary teeth for 3 minutes was found by Torabinejad VS to efficiently remove the smear layer from root canal walls.⁽⁴⁾ Sodium hypochlorite, in a 5.25% concentration, is antimicrobial, effective solvent of necrotic tissue, helps debride the root canals, and is nontoxic to the periapical tissues.⁽⁵⁾ Gotze GDR et al in 2005 found the effect of sodium hypochlorite and citric acid (CA) association in

removing smear layer (SL) of primary teeth. They stated that the efficacy of these auxiliary chemical substances was that they allowed better penetration and adaptation of the filling material to the root canals and helps in better disinfection of root canals.⁽⁶⁾

6 % Citric acid is a powerful antimicrobial agent and has been quite effective in removal of the smear layer. Salama FS et al in 1994 observed that 6% citric acid for 15 or 30 sec is quite effective in removing all the components of the smear layer of the root canals of the primary teeth and has recommended the use of 6% citric acid as an effective irrigant for smear layer removal in primary teeth.⁽³⁾ Though 6% concentration of Citric acid is considered as a weak concentration for chelating action but sufficient for removal of smear layer in primary teeth. Yet, in the present study significant reduction in microhardness was seen.

Hariharan et al showed that EDTA when used as a root canal irrigant in primary teeth, removed the smear layer but adversely affected the dentinal tubules through the conjugation of tubules, erosion of peritubular dentin and break down of intertubular dentin.⁽²⁾ The use of these agents on permanent teeth is advantageous although similar effects on primary teeth may be undesirable as they have a much reduced radicular dentin thickness. The average thickness of dentin in primary teeth is 0.52+0.24 Gpa.⁽⁷⁾

Chelating agents are preferably used in the permanent teeth for their advantage of smear layer removal but their effect on primary radicular dentin may be detrimental as they decrease its microhardness, ultimately decreasing the strength and affecting the mechanical properties of the tooth.

It can be assumed that reduction in microhardness might lead to faster resorption of roots, thus causing earlier exfoliation of primary teeth. It is thus recommended that additional studies should be conducted on finding the outcome and long term effect of these irrigants.

Conclusion

A significant reduction in the microhardness was seen on using 17% EDTA & 5.25% sodium hypochlorite and citric acid as root canal irrigants when compared with pretreated radicular dentin.

6% Citric acid produced greater reduction in microhardness as compared to 17% EDTA and 5.25% sodium hypochlorite and the results so obtained were statistically significant.

A Study to Compare the Effect of Respiratory Muscle Stretch Gymnastic (RMSG) and Diaphragmatic Breathing on Pulmonary Function Test among Geriatric Population– An Interventional Study

Nikhil Aggarwal¹, Nidhi Ved²

¹ Assistant Professor Chandigarh University, Mohali, ² Assistant Professor RK University, Rajkot- Gujarat- India

Abstract

Introduction : Aging is the universal phenomenon, India is the Second Largest country in the world with 72 million elderly person in 2011. It is suspected that it will be 172 millions by 2031. People above the age of 60 years are consider as Geriatric. Aging is associated with decrease in lung compliance and Thoracic Mobility. Kyphotic curvature of spine occurs due to aging, which increases AP diameter of the thorax. Increase in AP diameter of thorax alters the curvature & optimal length of Diaphragm and decreases its force generation capacity. Also due to poor posture Shoulder Quadrant muscle undergoes Shortening due to which pump handle and bucket handle movement do not occur properly, ultimately reducing the Thoracic Mobility & Flexibility. So there is a need to improve Pulmonary function among Geriatric Population.

Aim : To compare the effect of respiratory muscle stretch gymnastic (RMSG) and diaphragmatic breathing on pulmonary function test among geriatric population

Objectives : (1) To find out the effect of RMSG on FEV1, FVC and FEV1/FVC ratio in geriatric population

(2) To find out the effect of diaphragmatic breathing on FEV1, FVC and FEV1/FVC ratio in geriatric population

(3) To compare the effect of RMSG & diaphragmatic breathing on FEV1, FVC and FEV1/FVC ratio in geriatric population.

Method: Subjects who fulfil exclusion and inclusion criteria were selected by purposive sampling and were assigned to group A and group B by simple random sampling. They were explained about the study, its usefulness and written consent were taken. 60 subjects were divide into two Groups: Group A: 30 subjects were given RMSG Group B: 30 subjects were given Diaphragmatic Breathing.

Results: Data were analyzed using software SPSS version 20. Paired t-test was applied within the group and Unpaired t-test was applied between the two groups. Pre-treatment and post-treatment FVC, FEV1 and FEV1/FVC ratio was analyzed, it showed statistically significant (P value < 0.05) difference in both the group but when comparison was done between two groups, it was statistically non-significant (P value > 0.05).

Conclusion: Respiratory Muscle Stretch Gymnastic and Diaphragmatic breathing both were effective in improving pulmonary functions in geriatric population after performing breathing techniques for consecutive 3 days (once a day). But there was no significant difference between the two Groups in improving pulmonary function in geriatric population.

Key words: FVC, FEV1, FEV1/FVC ratio, geriatric population, RMSG

Introduction

According to census 2011 - India is the second largest country in the World with 72 million elderly person. People above 65 years of age are considered as Geriatric. Aging leads to: Loss Of Elastic Recoil of lung, Hyperinflation, Increases in Residual Volume, Alteration in Optimal Length of Diaphragm, Decreases Strength Of Respiratory Muscle.^{1,2}

Kyphotic curvature of the spine increases with Age which increases AP Diameter of thorax & Shoulder Quadrant muscle undergoes Shortening due to which Pump Handle & Bucket Handle Movement do not Occur Properly ultimately reduces thoracic Mobility.^{2,3}

RMSG Includes 5 Technique :⁴

1. Elevating & Pulling Back the Shoulder
2. Stretching the Upper Chest
3. Stretching the Lower Chest
4. Stretching the Back Muscle
5. Elevating Elbow

Diaphragmatic Breathing is a technique in which patient was asked to breath by the optimal use of Diaphragm.^{4,5} It involves Slow & Rhythmic Breathing. Pulmonary Function Test in form of FVC FEV1 & FEV1/FVC ratio was taken as an outcome Measure. ^{5,6,7}

Till now various respiratory techniques are used to improve pulmonary function among Geriatric but no study have been found which shows the effect of RMSG on Pulmonary functions among Geriatric Population. So the Need of the Study was to find out whether RMSG was effective in Improving pulmonary functions among Geriatric Population and than to Compare it's effect with Diaphragmatic breathing among geriatric population

Aims and Objectives

- To Find Out the Effect of RMSG on FVC, FEV1 and FEV1/FVC ratio among Geriatric Population.
- To Find Out the Effect of Diaphragmatic Breathing on FVC, FEV1 and FEV1/FVC ratio among Geriatric Population.
- To Compare the Effect of RMSG and

Diaphragmatic breathing on FVC, FEV1 and FEV1/FVC ratio among Geriatric Population.

HYPOTHESIS

H₀- There is no significant difference between the Effect of RMSG and Diaphragmatic breathing on FVC, FEV1 and FEV1/FVC ratio among Geriatric Population.

H₁- There is a significant difference between the Effect of RMSG and Diaphragmatic breathing on FVC, FEV1 and FEV1/FVC ratio among Geriatric Population

Methodology

- Research Design: Comparative Interventional Study

- Sample Size: 60 Subjects

- Sample Source: Rajkot- Gujarat-India

- Inclusion Criteria:

Age: Subjects > 65 years

Gender: Both Male and Female

Subjects who understands & follow the command

- Exclusion Criteria:

Subjects doing meditation or yoga or exercise on regular basis.

Subjects with the history of smoking.

Subjects with neurological, Cardiorespiratory or Musculoskeletal disorders related to

spine which may affect respiratory mechanics.

Uncooperative Subjects & Subjects who denied for Participation.

- Instrumentations:

- o Instruments and Tool used:

- § Spirometer (Helios 401)

- § Pen

- § Paper

- § Data Collection Sheet

- § Consent Form
- § Towel
- § Cotton
- § Spirit
- § Mouthpiece
- § Nose clip
- § Plinth
- § Pillow
- § Stopwatch

PROCEDURE

Subjects those who fulfill the study's inclusive and exclusive criteria and give their consent form were included in the study. Prior to testing, the subjects were familiarized with the testing procedure.

Subjects were divided into 2 Group Group A was Given RMSG & Group B was Given Diaphragmatic Breathing. Pre & Post Pulmonary Function Test was taken as per the standard guideline of American Thoracic Society.

PFT (Pulmonary Function Test- FVC, FEV1, FEV1/FVC) measurement procedure:⁷

- Pre and post pulmonary function test was taken as per the standard outlined by American Thoracic Society. Subjects were given comfortable position on table without back support and foot resting on the floor, a soft nose clip was placed to prevent air escaping from nose and test was performed.

- For measurement of FEV1, FVC and FEV1/FVC ratio, patients were asked to take the deepest breath as much as possible than place the mouthpiece in mouth with lips sealing it and immediately exhale hard and fast for as long as possible, preferably atleast 6 seconds followed by a rapid inspiration from the mouthpiece.

- Three trials were given for each procedure and best trial was selected. The trial was considered "unacceptable" if it showed evidence of cough, early termination of expiration or inconsistent effort.

After collection of data, pre and post value for FEV1, FVC and FEV1/FVC were analyzed by statistical software and results were found.

Group A was given RMSG Technique: ⁴

RMSG Includes 5 Technique :

1. Elevating & Pulling Back the Shoulder
2. Stretching the Upper Chest
3. Stretching the Lower Chest
4. Stretching the Back Muscle
5. Elevating Elbow

These breathing techniques was given for 7 consecutive days (once a day).

Group B was given Diaphragmatic Breathing Technique: ^{5,6}

- Subjects were ask to sit in semi fowler's position.

- They were told to place their hand below the anterior costal margin and feel the movement occurring. Then the subjects were told to breathe in slowly and deeply through the nose allowing the abdomen to rise slightly and then relax and exhale slowly through the mouth.

- These breathing technique was performed for continuous 5 minutes such that patient takes 6 to 8 deep breath per minute.

- These breathing technique was given for 7 consecutive days (once a day).

Result

Statistical Analysis

Study design: Comparative study.

Statistical software: The statistical software named SPSS 20.00 was used for data analysis. Microsoft Excel and Word were used to generate graphs and tables.

Test: The normality of data was checked by using Shapiro-Wilk test which shows data was of parametric type. Comparison between with groups was done by

unpaired t-test.

Level of significance (p value) was set to 0.05

Table 1 Intra group comparison of FVC, FEV1 and FEV1/FVC ratio for GROUP A- RMSG.

Parameters	Mean ± Std. Deviation		t	p	Result
	Pre	Post			
FVC(l)	1.89 + 0.29	2.18 + 0.30	-4.993	<0.05	Significant
FEV1(l)	1.70 + 0.28	1.87 + 0.24	-2.863	<0.05	Significant
FEV1/ FVC (%)	88.15 + 6.16	88.90 + 4.73	-1.492	>0.05	Non-Significant

Table 2 Intra group comparison of FVC, FEV1 and FEV1/FVC for GROUP B– Diaphragmatic Breathing.

Parameters	Mean ± Std. Deviation		t	p	Result
	Pre	Post			
FVC(l)	2.08 + 0.34	2.27 + 0.34	-4.271	<0.05	Significant
FEV1(l)	1.91 + 0.27	1.98 + 0.26	-4.572	<0.05	Significant
FEV1/FVC (%)	88.71 + 5.02	88.73 + 4.45	-2.028	>0.05	Non- Significant

Graph 1 Comparison of mean difference of FVC, FEV1 and FEV1/FVC ratio between Group A and Group B.

Figure 1 Patient Performing RMSG Exercises

Discussion

The result of these study supports the null hypothesis. In group-A significant difference was found in pre & post FVC and FEV1 but no significant difference was found in pre and post FEV1/FVC ratio. In group B significant difference was found in pre & post FVC and FEV1 but no significant difference was found in pre and post FEV1/FVC ratio. Inter Group comparison of Group A and Group B suggested that there was no significant difference for FVC, FEV1 and FEV1/FVC ratio between the two Groups.

RMSG is based on theory of Lapasle's law – Ventilation of Lung depends upon the Length of Respiratory muscle. Maximal Force is Generated by the respiratory muscle when they are in their Optimal Length. As Geriatric have alteration in the Optimal length of respiratory muscle (Diaphragm & Intercostal muscle).^{3,13}

When RMSG is given Muscle Spindle Stimulates & Sends Signals to Alpha motor Neuron, as a result of

which Extradfusil fiber of Muscle Spindle Contracts. The more the muscle contracts, the more it will relax according to the frank starling law. Hence by Giving RMSG, Optimal Length of the respiratory Muscle can be reached.¹³

Nidhi ved et al stated that RMSG have beneficial effect on pulmonary function among Menstruating women when RMSG was given for consecutive 3 days(Once a day).

Some studies suggested that diaphragmatic breathing increases the lung compliance and reduces the airway resistance. The reason behind it is believed that during diaphragmatic breathing the maximum deflation of lungs occurs, which is an important physiological stimulus for the release of surfactant and prostaglandin into the alveolar spaces, surfactant reduces the surface tension and improves the lung compliance, allowing the lung to inflate more easily and reduces the airway resistance.⁸

According to **Sheetal Panwar et al and Prem kumar yadav et al** during diaphragmatic breathing pulmonary pressure continues to rise due to increase in venous return to the heart, these increase in pulmonary pressure may provide an adequate driving force to propel the blood to the upper most part of the lung where ventilation of the air is more, this results in more perfusion from top to bottom and improves ventilation perfusion ratio.^{8,9}

The present study show statistically significant results for Diaphragmatic breathing exercise, supporting to these **Kyochul Seo et al** stated that there was a significant increase in tidal volume, inspiratory capacity, inspiratory reserve volume and breathing capacity in experimental group (Diaphragmatic group) than the control group after performing 30mins session for 3 times a week for 4 week in male smokers.¹⁰ **Karina m et al** demonstrated that Diaphragmatic breathing shows positive result in improving lung volumes, respiratory motion, SPO2 and also in reducing respiratory rate among both COPD and Healthy individual while Pilate breathing do not show any changes among COPD but improves lung volume and SPO2 among healthy individual.¹²

In harmony with the result of present study **Prem Kumar Yadav et al** suggested that diaphragmatic breathing significantly increases FVC, FEV₁, PEFR, MVV, FEV₁/FVC ratio and TV in 50 healthy adults who performed diaphragmatic breathing exercise for 3 months. However, FEV₁/FVC ratio was more significant in male than female while FVC was more significant in female.⁸

Conclusion

Respiratory Muscle Stretch Gymnastic & Diaphragmatic Breathing both were effective in Pulmonary function test among geriatric Population. But there was no significant difference between two groups after performing breathing technique for consecutive 7 days among geriatric Population.

Clinical relevance

Results suggest that both the techniques i.e. Respiratory Muscle Stretch Gymnastic and Diaphragmatic breathing showed statistical significant

difference in pulmonary functions after performing breathing technique for consecutive 7 days among geriatric Population. Hence both the technique can be alternatively used as an adjunct with other techniques for improving pulmonary functions in individual who have reduce lung volumes and capacities.

Limitation

- Blinding was not done in the study.
- Sample size was relatively small.
- Study duration of the treatment protocol was short

Further recommendations

- Study can be done with large sample size.
- Treatment can be given for longer duration with follow up.
- Other pulmonary function parameters and outcome measures like PEFR, Chest expansion can be used.
- Different populations who have reduced lung volume and capacities can be studied.
- Study can be done with control group.
- Blinding could be done in future study.

The Effect of X Box 360 Kinect-Virtual Reality Intervention on Balance and Gait Training In Stroke Patient”: An Interventional Study

Nikita Girishbhai Shobhana¹, Shweta Rakholiya²

¹MPT Neuromuscular Science, ²Assistance Professor, School of Physiotherapy, RK University, Rajkot

Abstract

Background: Kinect- based Virtual Reality training that includes auditory and visual stimulation, feedback information, repetitions of the same motion that performing rehabilitation exercises. **Aim:** To Evaluate the effect of XBOX 360 Kinect-Virtual Reality training on balance and gait in patient with chronic stroke. **Methodology:** Consent was taken from all 30 subjects for participating in the study. Baseline measurements berg balance scale, 6 min walk test and gait parameters will be taken. Patients randomly have divided into 2 groups. Group A: conventional PT (n=15) 60 min and Group B: conventional PT with Virtual reality XBOX 360 Kinect (n=15) 60 min. After they will be assessed for post outcome measures. **Conclusion:** there is conclude that virtual reality X box 360 with physical therapy is more effective then only physical therapy for improve balance and gait in chronic stroke patients.

Key Words: Stroke- balance and gait activity -XBOX 360-Virtual reality.

Introduction

Stroke, is the second largest cause of death and a major cause of disability & handicap. ^(10,11) In people recovery of functional ability after stroke is variable and between 30 – 60% of people remain dependent on other for some activities of daily living. ⁽⁵⁾ Key functional task such as ability to walk has been identified by patient as being of great significance. Approximately 50 – 80% of patient will regain some degree of walking ability after stroke. ⁽⁹⁾

VR is an advanced technology that can display 3D visual images that change rapidly in response to instruction from the user which appears to provide an answer to this challenge due to its well-known assets including opportunity for experiential active learning,

the ability to objectively measure behavior in challenging but safe and ecologically valid environments, while gradually increasing the complexity of task and decrease the support provided by clinicians ⁽¹⁾. A number of researchers have integrated VR into assessment & rehabilitation of cognitive process, such as visual perception & executive function, and into training of activities of daily living.

One key benefit is VR’s more naturalistic or “real – life” environments. ⁽¹¹⁾ The environment is usually referred as being ‘Immersive’ in which user has a strong “sense of presence” by using video capture system where the user view them self or an avatar in the scene. In a Non Immersive VR the user interacts with degrees with environment. In addition, VR can be tailored according to the need of the client ⁽¹⁾

VR-based systems that use sensor technology to monitor whole-body movements can elicit patients to perform high-intensity and high-energy movements. Kinect- based systems (Microsoft Corp, Redmond, WA) reduce the demand on staff time for intervention and increase patients’ motivation toward rehabilitation.

Kinect- based VR training that includes auditory and visual stimulation, feedback information about “winning” or “losing,” and repetitions of the same motion can provide a variable rehabilitation tool that reduces barriers to individuals performing rehabilitation exercises.⁽¹⁾

The most recently released Xbox Kinect system has an RGB camera and a dual infrared depth sensor for the automatic detection of limb and body position and motion. The system uses these elements to capture data to create a 3-dimensional human body model in real time, called an avatar, which allows for patient to use their own body as the controls to play a game. The reliable visual feedback from the on-screen player’s avatar may provide accurate feedback on movement⁽¹⁾.

Although the Kinect gaming system has been shown to be of therapeutic benefit in rehabilitation, the applicability of Kinect-based VR training to improve motor function in patients following the occurrence of a stroke has not been evaluated.⁽¹⁾

Methodology

- **Study type:** Interventional Study
- **Study setting:** Rajkot city
- **Sample size:** 30
- **Study duration:** 6 weeks.

CRITERIA FOR SELECTION

Inclusion Criteria:

- Age: 40 – 60 years.
- Gender: male and female
- Chronic stroke patient: more than 6 months
- Could walk independently or with a guide (with or without an assistive device) for 10 m.
- With a MMSE rating >24.

Exclusion Criteria:

- Uncooperative patient.
- Subjects with any progressive, critical or long term illness, an unstable cardiovascular, musculoskeletal

or neurological condition, demonstrate inability to follow instructions.

Procedure

- 30 subjects were selected as per selection criteria.
- Then Informed consent obtained from the patients.
- Patient randomly divided into group A and group B.
- Group A - conventional Physical Therapy with Virtual reality XBOX 360 Kinect^(1,3,4). (n = 15)
- Group B - conventional Physical Therapy⁽¹⁾. (n = 15)

GROUP A

Patients was exposed to two software for XBOX 360 kinect.

1. Kinect Sports.

Kinect Sports consists of 6 sports, including Bowling, Boxing, Track and field, Table tennis, Volleyball and Soccer (football). Players can also play improving mini-games. The game includes interactive cut scenes, music that plays in replays and highlights while playing the sports.

2. Kinect Adventure:

Kinect Adventures uses full body motion to allow the player to engage in a variety of mini games, all of which feature jump-in, jump-out multiplayer play. Each mini game lasts about three minutes. While most of the mini games are co-operative in two player mode, Reflex Ridge is a competitive game. The object of all the mini games is to get the highest number of adventure pins, which are collected in different ways.

GROUP B

ROM exercises, Balance training, Gait training: 3 days per week, 60 min

Outcome measures

Berg Balance Scale.

6 Min Walk Test.

Gait parameters - step length, stride length, cadence

Pre intervention, baseline characters BBS, 6 min walk test, gait parameters of both groups were matched using statistical tests.

Results

The effect of Virtual reality using XBOX 360 Kinect on postural control and gait calculated and entered in MS-EXCEL. It analyzed and graphs were made in MS-EXCEL sheets. Before beginning with analysis,

The data was analyzed in SPSS version 21.0 windows was used for the statistical analysis. Accordingly, paired t test was used for Intra group analysis for 6 min walk test and gait parameters and Wilcoxon test for BBS and Unpaired t Test for Inter group analysis and p-value less than 0.05 were considered statistically significant.

Table 1 GROUP A INTRA GROUP ANALYSIS

Outcome Measure	Pre Mean	Post Mean	PRE Standard Deviation	POST Standard Deviation	P-value
BBS	43.73	50.13	4.11	3.70	0.000
6 MWT	53.06	62.53	4.46	4.73	
STEP LENGTH	43.86	59.53	5.39	8.36	
STRIDE LENGTH	85.33	108.13	10.54	14.62	
CADENCE	87.2	102.46	10.54	10.94	

Intra group analysis of group A in Table 1 suggest that there is significant difference in all the outcomes after 6 weeks of Virtual reality X box 360 and conventional therapy.

Table 2 GROUP B INTRA GROUP ANALYSIS

Outcome Measure	Pre Mean	Post Mean	PRE Standard Deviation	POST Standard Deviation	P-value
BBS	44.06	48.6	4.19	3.35	0.000
6 MWT	52.8	59.26	3.25	3.55	
STEP LENGTH	44	55.53	3.56	5.12	
TRIDE LENGTH	82	91.13	6.33	6.05	
CADENCE	87.46	95.8	8.83	7.60	

Intra group analysis of group B in Table 2 suggest that there is significant difference in all the outcomes after 6 weeks of conventional therapy.

Table 3 INTER GROUP ANALYSIS

Outcome Measure	Group A Mean	Group B Mean	Group A Standard Deviation	Group B Standard Deviation	T value	P-value
BBS	50.13	48.60	1.29	1.40	3.77	0.001
6 MWT	62.53	59.26	2.38	2.92	3.07	0.005
STEP LENGTH	59.53	55.53	3.81	3.04	3.28	0.003
STRIDE LENGTH	108.13	91.13	10.01	3.70	4.95	0.000
CADENCE	102.46	95.80	3.90	3.67	5.01	0.000

Inter group analysis in table 3 suggest that group A shown significant improvement than group B. There is more significant improvement in balance and gait in patients with chronic stroke.

However, for the BBS, 6 min walk test and gait parameters the intervention group demonstrated significant improvement as compared with the control group.

Discussion

In the result of the study, group A - shows more significant difference than group B. Previous studies have reported improved upper extremity function in patients with stroke following use of VR gaming systems. ⁽¹⁾ **Hsin-Chieh Lee** suggested, VR balance training by using Kinect for Xbox games plus the traditional method had positive effects on the balance ability of patients with chronic stroke. The VR group experienced higher pleasure than the ST group during the intervention. ⁽²⁾ **Pohl**, concluded that the stroke related impairments are powerful modifiers of performance in a 6-minute walk test. Motor deficits of lower limb and decrease balance contribute to the distance travelled by an adult in 6 minutes. ⁽⁶⁾ **Albert de Graaf** investigated

the in-depth research as there have been several motion tracking devices introduced by gaming industry, like **Nintendo Wii**, PlayStation 3 eye and Microsoft XBOX 360 Kinect & if these techniques can be used for home based upper extremity rehabilitation. The results are promising and test results show that the techniques meet the requirements and already proved to help in rehabilitation.⁽⁷⁾ VR training may have contributed to the improvements in balance and gait function observed in the participants by encouraging more interest, concentration on the task, fast response, repetition of exercise, motivation for patients, provide feed to patients during exercise and other side alternative to programs of repetitious exercise that are often performed in front of a mirror that can provide low intrinsic motivation^(1,2) In the present study, a combination of 2 games (the Kinect Sports and the Kinect adventure) was used for stroke patients. The programs required active movements, and the participants usually performed the active movements of the hip, knee, or ankle, as well as the lower extremity. There measure BBS, 6 min walk test and gait parameters scores. That the VR had a positive effect on improving participation in balance and gait. Group B had 15 patients performing conventional physiotherapy in this ROM, Balance training in weight bearing and weight

shifting exercises weight bearing with reach out, and in Gait training walking forward, backward, sidewalk, obstacle walk. Which all exercises are done in VR with feedback and in form of game so patient become motivation and feedback and also they also like to do exercise with game.

Balance and gait is improved in virtual reality group reason could be Virtual reality training is given in simulated environment providing visual input like subject can recognize their body on screen through Kinect and can move body part in order to play different games, auditory input were also provided, subjects were instructed for each game and continuous live feedback of their progress are provided through speakers, they were appreciated for their gains in every move, Somatosensory feedback is also provided to subjects by keeping hand on patients paretic arm to move it in right direction and also through trunk belt which gives feedback for, appropriate movements in different directions which work on proper dissociation of trunk during game. Therefore, all three components necessary to improve balance are provided in VR technique. Which shows significant improvement in balance post visual feedback, the structure of the brain can be enhanced using visual feedback in virtual reality to augment interconnected, distributed cortical regions. It is suggested that visual information can provide a potent signal for the reorganization of sensorimotor circuits. Subjects therefore performed well in order to win every game which improves their balance automatically, equally they were appreciated for their every gain that boosted their confidence and they performed well in every next session.

In group A there was significant improvement in BBS score, 6 min walk test and step length, stride length, cadence. There was more improvement in VR training with convention in stroke patients in balance and gait. So null hypothesis is rejected. There was not any effect on balance and gait in stroke patients by Virtual Reality intervention through XBOX-360 Kinect that was null hypothesis which was rejected. Virtual reality very useful for motor learning and rehabilitation program. Therefore, Virtual reality using x box 360 Kinect can be used as one of the best therapy for rehabilitation program.

Further recommendation:

Study can be done to know effect of Virtual reality Xbox 360 exercise in patients with Parkinsonism or other neurological disorders.

Conclusion

Virtual reality training using X box 360 Kinect as effective therapeutic approach for improving balance and gait in stroke patients in rehabilitation. Their level of experienced by VR group was higher than conventional physical therapy group. So there is conclude that virtual reality X box 360 with physical therapy is more effective then only physical therapy for improve balance and gait in chronic stroke patient.

A Study to Correlate the Vertical Jump Test and Wingate Cycle Test as a Method to Assess Anaerobic Power in Football Players

Parul A. Rakholiya¹, Arti Gadesha²

¹ MPT in Musculoskeletal and Sports Physiotherapy], Assistant Professor, Shri Bhartimaiya College of Optometry and Physiotherapy, Surat, ²MPT in Cardio-Pulmonary Physiotherapy, Consultant Physiotherapist at Raghuvir Physiotherapy and Diabetic Education Center, Rajkot

Abstract

Background and Objectives: Anaerobic energy production is extremely important in football as it provides energy at a very high rate during periods of intense activity in a match. The Wingate cycle ergometer test and vertical jump tests have been used to assess anaerobic power in athletes for the purpose of providing vital information regarding anaerobic performance of athletes for given sports. The objective was to correlate vertical jump test with Wingate anaerobic test as a method to assess anaerobic power in football players.

Method: 100 football athletes with mean age of 17.18 +1.95 (SD) years were selected. Anthropometric measurements, the vertical jump test and Wingate cycle ergometer test were performed. Peak and mean anaerobic power were determined.

Results: Data were analyzed by using SPSS software 14.00 by Pearson Correlation coefficient which showed significant moderately positive correlation between peak power ($r = 0.220$, $p < 0.05$) & mean power ($r = 0.263$, $p < 0.05$) of vertical jump test and Wingate test.

Conclusion: The result suggested that vertical jump tests can be accept as field measures of anaerobic power instead of laboratory-based Wingate anaerobic test in football players.

Key words: Vertical jump test, Wingate Anaerobic test, Anaerobic peak and mean power, football players.

Introduction

Physical and physiological characteristics of football players required high level of anaerobic power, aerobic capacity, speed, muscular strength, agility and flexibility.¹ During a 90-minute game, elite-level players run about 10 km at an average intensity close to the anaerobic threshold (80–90% of maximal heart rate). Within this endurance context, numerous explosive bursts of activities are required, including jumping, kicking, tackling, turning, sprinting and changing pace and sustaining forceful contractions to maintain balance and control of the ball against defensive pressure.²

Anaerobic energy production is extremely important in football as it provides energy at a very high rate during periods of intense exercise in a match. The concentration

of lactate in the blood is frequently used as an indicator of anaerobic energy production in football.³

The Wingate anaerobic test (WAnT) and vertical jump tests have been commonly used tests to assess anaerobic power in athletes for the purpose of providing vital information regarding anaerobic performance of athletes for various sports.⁴

Wingate Anaerobic Test has been used to assess anaerobic-fitness levels and the effectiveness of anaerobic-training programs for a variety of power sports including football, basketball, tennis, and track and field.⁵

Activities of this intensity and duration rely heavily on anaerobic metabolic pathways, namely the ATP-

PC pathway and the glycolytic pathway. Previous researchers indicated that, during a 30-second Wingate Anaerobic Test, the energy contribution of the ATP-PC pathway is 28%, of the glycolytic pathway is 56%, and of the aerobic pathway is only 16%. Due to the specificity of the Wingate Anaerobic Test for measuring components of anaerobic capacity, it would seem logical to use this test to measure anaerobic power.⁵

The vertical jump test is widely used as field tests for assessment of explosive strength of lower limbs in many sports. Such methods are frequently studied considering their confidence and validity in volleyball and football players.⁶

During a Vertical jump test; the aim of the performer is to attain maximum vertical displacement of the body's center of mass (i.e. vertical height) in each consecutive jump over a period of time. Since the vertical displacement during a jump is mainly dependent on the mechanical power output during the push-off phase, the measurement unit used to express Vertical jump test performance is mean power expressed in Watt, this can be easily estimated with the formula described by Harman's formula.⁷ Harman's formula is reliable and valid for calculation peak power and mean power for vertical jump test.⁸

Bosco et al. reported that the highest average power output during the Vertical jump test is achieved during the first 15s and then declines progressively until the termination of the test. Additionally, the average mechanical power output for the first 15s period has been found to be highly correlated ($r = 0.86$) with fast twitch muscle fiber distribution (FT), while the power output during the successive 15s periods demonstrated a lower correlation with FT (15-30s, $r = 0.72$). During a vertical jump test, power output required to attain maximal jump height and complete a single test is reached between one and two seconds which suggests that only the adenosine triphosphate- phosphocreatine (ATPPC) energy system is utilized since the test duration is so short.⁴

There are limited studies shows correlations of vertical jump test with Wingate anaerobic test to measure anaerobic power in football players. So, the need of study was to correlate vertical jump test with Wingate anaerobic test as a method to assess anaerobic power in football players.

Methodology

Source of data: Various schools, colleges and sports institute

Study design: Correlational study

Sampling technique: Simple convenient sampling

Sample size: 100 football players

Study duration: 2 days

Selection Criteria:

Inclusion Criteria:

- Age group: 14-20 years
- Healthy male football players.
- Athlete playing football more than 1 year for 5 times in a week.
- Football players participating in competitions at school, college or club levels.

Exclusion Criteria:

- History of any cardiovascular, musculoskeletal, neurological problem, metabolic disorder.
- Smoker or ex-smoker
- Athletes having history of Trauma
- Athletes with regular participation in any other athletic activity
- Uncooperative athletes

Materials to be used:

Cycle ergometer (monarck ergomedic 894E), Measure tape, Wall, Chalk stick.

Measurement Procedure:

The proposed title and procedure have been approved by ethical committee members. Football players from various school, colleges and sports institutions were screened and amongst them those who fulfilled inclusion and exclusion criteria were requested to participate in study. 100 subjects were selected from them by convenient sampling method. Procedure, potential risks

and benefits were explained in brief and written consent was taken from all.

Study duration was of 2 days for each participant.

Day 1:

Vertical Jump Test:

Prior to the vertical jump test, the athletes were led through an 8-10-minute warm-up. The athletes' tip of middle finger was marked by therapist. Athlete was asked to stand aside of the wall, keeping both feet remaining on the ground, reaches up as high as possible with one hand and marked the wall with the tips of the middle finger (M1). From a static position the athlete was asked to jumped as high as possible and mark the wall with the chalk on his finger (M2). The distance between M1 and M2 was measured and recorded by the therapist. The test was repeated 3 times. Best of three of recorded distances was considered and those values were used to assess the athlete's performance by using Harman Formula.

Harman et al (1991) established equations for peak and average power.⁸

Peak power (W) = $61.9 \times VJ \text{ (cm)} + 36.0 \times \text{mass (kg)} + 1822$

Average power (W) = $21.2 \times VJ \text{ (cm)} + 23.0 \times \text{mass (kg)} - 1393$

Day 2:

The Wingate Anaerobic test:

The Wingate anaerobic test was performed on a computerized Monarck Cycle ergometer (Monarck ergomedic 894E). The athletes were asked to perform a warm up for 10 minutes. To eliminate the possibility of fatigue after the warm up, a brief rest period followed by the warm-up before testing was given. The seat height was adjusted in such a way that so that no more than 5° of flexion was possible when the leg was fully extended.

The data for each subject were entered into the preinstalled Wingate Power software program. Prior to the initiation of the test, the pre-determined workload was placed in the ergometer's basket. The resistance was calculated as 7.50 % of the subject's body weight.

Each subject pedalled the cycle without resistance before test begun for 2 minutes to building up to maximal revolution per minute to overcome the initial inertia of the ergometer. Once the required pedalling speed as calculated was reached, the resistance was added instantaneously by automatic dropping of the weight rack by the machine.

Peak power and mean power were calculated and recorded in watts (W) using software power program.

Statistical Analysis

Statistical analysis was done by using SPSS 14 version for windows software. Pearson Correlation test were used to determine the degree of correlation between peak power and mean power of Vertical jump test and Wingate anaerobic test.

Results

Table 1: Correlation of Peak power and mean power between vertical jump test and Wingate anaerobic test in football players

	N	Mean	SD	r value
WAnT peak power (W) [Pearson correlation sig.]	100	268.35	+97.14850	0.220 0.028
Vertical jump test peak power (W) [Pearson correlation sig.]	100	7492.67	+709.01990	
WAnT mean power (W) [Pearson correlation sig.]	100	205.5334	+82.66076	0.263 0.008
Vertical jump test mean power (W) [Pearson correlation sig.]	100	1141.6200	+274.70086	

Above table 1 shows correlation of peak and mean power between Wingate anaerobic test and vertical jump test. Mean value of peak power of Wingate anaerobic test is 268.35 (W) and that of vertical jump test is 7492.67 (W). Pearson correlation of peak power of vertical jump test with peak power of Wingate anaerobic test demonstrate a positive correlation ($r = 0.220$, $p < 0.05$) which shows moderately positively correlated. Mean value of mean power of Wingate anaerobic test is 205.5334(W) and that of vertical jump test is 1141.6200(W). Pearson correlation of mean power of vertical jump test with mean power of Wingate anaerobic test demonstrate a positive correlation ($r = 0.263$, $p < 0.05$) which shows moderately positively correlated.

Graph 1: Correlation of Peak power between vertical jump test with Wingate anaerobic test in football players

Graph 2: Correlation of mean power between vertical jump test and Wingate anaerobic test in football players

Discussion

The major finding of study was to correlate peak and mean power of vertical jump test with that of Wingate

anaerobic test. The result shows moderately positive correlation between peak power of vertical jump test with Wingate anaerobic test ($r = 0.220$, $p < 0.05$) and also shows moderately positive correlation between mean

power of vertical jump test and Wingate anaerobic test ($r = 0.263$, $p < 0.01$) there by supporting the experimental hypothesis. These findings demonstrate validity of vertical jump test as a field test as a measure to assess anaerobic power in football players.

Accurate anaerobic power assessment is paramount for athletes, as many sports involve rapid rest to high intensity exercise transitions such as sprinting and jumping movements. In addition, many team sports require participants to produce maximal or near maximal sprints of very short durations (e.g. 1–7 s). For example, majority of sprints performed during a soccer match are less than 20m in distance or approximating 3.5s to complete. The sudden release of large amounts of energy to produce such high intensity performances can be provided in main by non-mitochondrial energy pathways involving ATP–PCr degradation and glycolysis.¹⁰

Stauffer KA et al, was found a significant correlation ($r = 0.85$) between peak power measured during the Vertical Jump and Wingate anaerobic power tests, demonstrate validity of the Vertical Jump as a field test of anaerobic power. Both tests rely heavily on ATP/PC energy system contributions to produce/sustain maximal anaerobic power.¹⁰

According to **Beckenholdt et al.**, anaerobic tests should be performed specifically for skill or sport being tested, since a high degree of specificity has been found among various anaerobic tests. The VJT is more specific in sports where jumping ability and explosive power is mainly utilized because of its compatibility with the action of the muscle groups involved. However, although height was found to be significantly correlated with maximal power in units relative to body mass, the WAnT prevails as an indicator of the rate at which muscle power can be generated from the splitting of energy rich phosphagens and glycogenolysis because of its high reliability and validity in assessing anaerobic power.¹¹

Apostolos T. et al, confirmed the differences in mean power values (both absolute and relative to body mass) elicited during two tests, with the relative power values of the VJT being almost double than those recorded for the respective WAnT. Prior assessments of a 30s VJT and 30s WAnT reported mean relative power values of 18.3 ± 5.28 W.kg⁻¹ vs 6.86 ± 1.21 W.kg⁻¹ and 1258 ± 462

W vs 622 ± 167 W. **Hoffman et al.** measured power outputs of 43.3 ± 6.9 W.kg⁻¹ and 9.5 ± 1.0 W.kg⁻¹ for a 15s VJT and a 30s WAnT respectively.¹¹

Bosco et al. described this phenomenon to the stretch-shortening cycle (SSC) present throughout VJT. SSC is believed to allow muscles to store potential energy, thus resulting in power outputs considerably higher than the chemo-mechanical values. The output produced during the jumping test incorporates also the recovery of mechanical energy stored in the elastic elements of the lower limbs. The potential energy stored in muscles due to the eccentric action has a substantial effect in jumping exercises, but it is negligible in cycling, where the muscles are contracting primarily concentrically.¹¹

Second is, Newton's second law indicates that greater forces will result in greater accelerations. As acceleration increases the required forces also increase; therefore, achieving high velocities, power outputs, and jump heights is dependent upon high force production results in high anaerobic power.¹²

The differences between cycling vs. jumping modes of anaerobic power assessment may also relate to the significant differences observed in power outputs between the tests. By recruiting a greater muscle mass (both legs acting simultaneously and the inclusion of upper-body musculature), the jump test appeared to result in a significantly greater power expression. Moreover, the greater power outputs observed in the jump test may also be related to a greater recovery of mechanical energy that is stored in the elastic elements of the body during the countermovement.⁴

Moreover, it was also found that subjects with more height and or weight exhibited capacity to generate greater power outputs while performing VJT and WAnT. Height and weight used in present study for prediction equation for anaerobic power in VJT. This finding suggests positive correlation between height / weight and power output.¹⁰

The result of study showed that there was moderately positive correlation between peak and mean power of vertical jump test with Wingate anaerobic test. So, vertical jump test can be used as a field test instead of laboratory-based Wingate anaerobic test in football

players.

Limitations of study are small sample size, only male athletes and result cannot be generalized to all population because study age group is between 14-20 years.

Further recommendation will be correlation of vertical jump test with Wingate anaerobic test in other sports, both genders can be tested and different age group can be considered.

Conclusion

The present study concluded that vertical jump tests can be used as field measures of anaerobic power instead of laboratory-based Wingate anaerobic test in football players.

Acknowledgement

Authors acknowledge the immense help received from the all football players. The authors are also grateful to God and Parents.

A study to Assess the Effectiveness of Jacobson's Progressive Relaxation Technique on Anxiety among Elderly People of Aged 60-70 Years in Selected Old Age Homes at New Delhi

Pauline Sharmila¹, R Sree Raja Kumar², Sonia Mehta³

¹Principal, ²Professor, ³Post graduate Student, School of Nursing Science and Research, Sharda University, India

Abstract

Introduction: The elderly who are residing in the old age homes may have the chances of experiencing anxiety as they are away from their children and succumb to health problems. The purpose of the study was to reduce the anxiety among elderly by making them experience Jacobson's progressive muscle relaxation technique.

Objectives:

1. To assess the level of anxiety among elderly people aged 60- 70 years.
2. To assess the effectiveness of Jacobson's progressive relaxation technique on anxiety among elderly people aged 60-70 years.
3. To find out the association between anxiety and selected demographic variables among elderly people aged 60-70 years.

Materials and Method: A Quantitative research approach was used and the research design adopted for the present study was quasi-experimental pre-test and post-test design. The target population for the study was elderly people in selected old age homes in New Delhi. Sample size was 60. The tool taken for the study was Hamilton Anxiety Scale. Purposive sampling technique was used.

Result: There was severe anxiety in 90% of the aged before the administration of the relaxation technique which reduced to 30 % after the intervention. This study concluded that Jacobson's progressive muscles relaxation technique was effective in reducing anxiety among elderly people.

Key words: Level of anxiety, Jacobson's progressive muscle relaxation technique, elderly people, old age homes.

Background of the Study

"If you want to conquer the anxiety of life, live in the moment"

The world's population is aging rapidly. Between 2015 and 2050, the proportion of the world's older

adults is estimated to almost double from about 12% to 22%. In absolute terms, this is an expected increase from 900 million to 2 billion people over the age of 60. Older people face physical and mental health challenges which need to be recognized. Over 20% of adults aged 60 suffer from a mental or neurological disorder and 6.6% of all disability (disability-adjusted life years-DALYs) among people over 60 years is attributed to mental and neurological disorders. These disorders in older people account for 17.4% of Years Lived with Disability (YLDs).¹

Email:- pauline.sharmila@sharda.ac.in

The most common mental and neurological disorders in this age group are dementia and depression, which affect approximately 5% and 7% of the world’s older population, respectively. Anxiety disorders affect 3.8% of the older population, substance use problems affect almost 1% and around a quarter of deaths from self-harm are among people aged 60 or above.²

The term anxiety has become a part of our everyday life. The concepts of anxiety may differ according to the individual’s state of contexts and interpretations. It is recognized that certain amount of anxiety is desirable, productive and can facilitate the individuals to grow but when the anxiety exceeds it disturbs the normal functions and the human body undergoes a number of autonomic physiological changes such as perspiration, restlessness, discomfort, palpitation and tightness in the chest.³

Aging is a natural process and an inevitable one. Elderly are in a crucial phase where the physiological, psychological and socio-cultural changes in contribute to developing anxiety.

Anxiety is a normal emotion ⁴ and all human beings develop it as a means of protection from danger and threat. Persistent or extreme anxiety can seriously decrease the quality of life and can be a sign of other problems, such as depression, dementia, physical illness, or side effects

of prolonged drug treatment. Anxiety can be a symptom associated with many medical disorders common in older adults, including heart disease, lung disease, thyroid and other endocrine problems, neurologic illness, dietary problems (e.g., excess caffeine intake or vitamin B12 deficiency), psychological illnesses, and side effects to medications.⁵

Studies have shown that generalized anxiety disorder is more common in the elderly, affecting 7% of seniors, than depression, which affects about 3% of seniors. Surprisingly, there is little research that has been done on this disorder among elderly as reported by a research study.⁶

Methodology

Research Approach

Quantitative research approach was used in the present study to assess the level of anxiety among the elderly people undergoing Jacobson’s progressive muscle relaxation technique in selected old age homes in New Delhi.

Research Design

A Quasi-experimental pre-test and post-test design was used in this study .

Table 1. Tabular presentation of the research design

Group	Pre-test	Intervention	Post-test
Experimental group(elderly people)	O1	X	O2
Control group(elderly people)	O3	-	O4

O₁-Pre-anxiety assessment among the Experimental group

O₂-Post- anxiety assessment among the Experimental group

X- Implementation of Jacobson’s progressive relaxation technique to the Experimental group

O₃-Pre- anxiety assessment among the Control group.

O₄- Post- anxiety assessment among the Control group

Independent variable

Jacobson’s progressive relaxation technique.

Dependent Variable.

Level of anxiety.

Setting

This study was conducted in Nyi Dunia & Ashriwad old age homes.

Population

In this study, the population includes elderly people aged 60-70 years.

Target population:

The target population consist of elderly people those who are suffering with anxiety.

Accessible population:

The accessible population consist of elderly people those who are residing at selected old age homes in New Delhi.

SAMPLE

Elderly people having anxiety who were residing in Nyi Duniya & Ashriwad old age home.

SAMPLING TECHNIQUE

In this study, purposive sampling technique was used to select the sample.

SAMPLE SIZE

60

CRITERIA FOR SAMPLE SELECTION**Inclusion Criteria**

Ø Elderly people who are residing in the selected 2 old age homes.

Ø Elderly who are willing to participate in the study.

Ø Elderly Males and females who are aged 60-70 years.

Ø Elderly people who are able read and speak Hindi.

Exclusion Criteria

Ø Elderly persons who are not able to perform relaxation techniques.

Ø Elderly persons who are disoriented.

Ø Elderly who are taking anti-anxiety drugs.

Ø Elderly people who are having any physical deformities

Development of Tool

The research instrument was developed by doing study from the literature review. The primary and secondary sources of literature were reviewed to develop the appropriate tool. Validity was obtained from Nursing professors, Statistician and an Ayurvedic doctor. Their opinions and valuable suggestion were incorporated in the tool and it was finalized by the guide.

Description of the Tool

Tool 1: Demographic proforma.

Tool 2: Hamilton anxiety scale.

Tool 1- Demographic Proforma.

The instrument was developed by the researcher. The tool was used to collect the background information of the participants. The tool had items such as age, gender, educational status, religion, duration of stay in old age home, source of information and any physical or mental illness.

Tool 2- Hamilton anxiety scale.

In this study, Hamilton anxiety scale was used to assess the anxiety level among elderly. In this scale, 14 items were given with a total score of 56. Each item had 0-4 score level. 0= No anxiety, 1 = mild anxiety, 2=moderate anxiety, 3=sever anxiety, & 4=very severe anxiety.

Content Validity

To ensure the content validity of the tool, the tool along with the letter requesting opinion and suggestion from experts and criteria checklist were given to nine experts in the field of pediatrics, psychiatry and community department. The experts were requested to give their opinion regarding agreement or disagreement in terms of relevance, accuracy and appropriateness. Language validity was established by Hindi language experts.

Language Validity

The language validity was established by translating the tool to Hindi and retranslating to English by language experts.

Reliability

The reliability of the tool was recognized by administering the tool to 6 samples who were residing in the old age home, Guru Vishram Viridh ashram.. The reliability coefficient was calculated by split half method and using spearman brown prophecy formula. The reliability coefficient obtained was ($r = 0.80$).

Discussion

A study to assess the effectiveness of Jacobson's Progressive relaxation technique on anxiety among elderly people of aged 60-70 years in selected old age homes at New Delhi.

The findings regarding sample characteristics

The results of the study show that in the experimental group the majority of samples (53.3%) belonged to the age group of 60-62 , (60%) of the sample were female, majority of samples were either widow/widower, 18 (60%) belonged to Hindu religion, most of samples were having their education status (60%) up to primary school , majority of the sample had the source of information 27 (90%) from mass media, most of samples were residing in old age homes 14 (46.7 %) <1 year, and 16 (53.3%) samples were not suffering from any physical or mental illness. In the control group the majority of samples were 22 (73.3%) were belong to age group of 60-62 year of age, 19 (63.3%) of the sample were female, majority of sample marital status was 13 (43.3%) widow/widower, 11 (36.7%) belonged to Hindu religion, most of sample were having education status to 13 (43.3%) primary school education , majority of the sample were getting of source of information 30 (100%) from mass media, most of sample were residing in old age homes 19 (63.3 %) <1 year, 12 (40.0%) sample were not suffering from physical or mental illness.

Objective 1: To assess the level of anxiety among elderly people aged 60-70 years.

Frequency and percentage distribution of the level of anxiety among the elderly people in

experimental and control group

In Experimental Group

- Majority of the elderly people (53.3%) were in the age group of 60 to 62 years age.

- 40% of the elderly were males and 60% were females.

- Most of the elderly people (60%) had only primary school education.

- The majority of elderly people (60%) belonged to Hindu religion.

- 33% of the elderly were either Widow or Widower.

- 90 % of elderly had received health information through mass media.

- 46.7% of the elderly were staying for < 1 year.

- 53.3% of elderly people had no physical & mental illness.

In Control group

- 73.3% were in the sage group of 60 to 62 years.

- 36.7% of the elderly were males and 63.3% were females.

- 43.3% had only primary school education.

- 36.7 % were following Hinduism.

- 43.3% were either Widow or Widower.

- 30 % of elderly were receiving health information from mass media.

- 63.3% of the elderly were staying in the old age home for < 1 year.

- 40 % of elderly people had neither physical & mental illness.

Objective 2:

Compare the pre-test and post-test level of anxiety among elderly people in experimental group and control group.

The Level of anxiety among elderly people was assessed using Hamilton anxiety scale. The pre-test score in the experimental group revealed that 27 (90%) were found with severe anxiety, 3 (10%) had very severe anxiety and in control group 29(96.7%) were found with

severe anxiety & 1(3.3%) had very severe anxiety. The post-test score of the experimental group showed that 21 (70%) had moderate anxiety, 9 (30%) had Severe anxiety and in control group 28(93.3%) were found with severe anxiety & 2(6.7%) had very severe anxiety.

Figure 1:- Pre-test anxiety level among elderly of experimental group

Figure 2:- Post-test anxiety level among elderly in experimental group

Figure 3:- Pre-test anxiety level among elderly in control group

Figure 4:- Post-test anxiety levels among elderly in control group

Effectiveness of the Jacobson’s progressive relaxation technique on anxiety.

The mean anxiety score among elderly in experimental group during pre-test was 28.07 with standard deviation of 1.911 and post-test was 23.53 with a standard deviation of 1.717. In this group the mean difference between pre& post-test score was 4.54.

It was found that there was a significant difference between the mean pre-test and mean post-test anxiety level in experimental group which clearly indicated that t- calculated value $t=17.784$ is more than t-table value at 0.05 level of significance, hence null hypotheses were rejected and research hypotheses were accepted. Progressive muscles relaxation technique was found

to be effective in reducing anxiety level among elderly people.

Objective 3: Association between the anxiety level and selected demographic variables

There was no statistically significant association found between anxiety level and the selected demographic variables such as elderly age ($p = .117$), gender ($p = .745$), religion ($p = .888$) marital status ($p = .813$), education ($p = .474$), source of information ($p = .144$), duration of stay in the old age home ($p = .580$), and any physical or mental illness ($p = .533$).

The above results indicate that there was no significant association was found between post-test anxiety levels with selected demographic variables in experimental group. Hence it found that Null Hypotheses H02 was accepted.

Conclusion

This study has shown that the administration of Jacobson's progressive muscles relaxation technique was effective in reducing anxiety among elderly people aged 60-70 years in experimental group. There was no significant association between the post-test scores of anxiety level with selected demographic variables in experimental group. These kinds of relaxation techniques should be regularly given to the elderly to experience reduction in the levels of anxiety which can improve their quality of life.

Determinants of Depressive Disorder among Elderly Stroke Patients in the Northeast of Thailand

Peyanut Jantavaree¹, Pannee Banchonhattakit², Rujira Duangsong³, Rajda Chaichit⁴

¹Doctor of Public Health Program, Faculty of Public Health, ²Associate Professor, Dr, Faculty of Public Health, ³Assistant Professor, Dr, Faculty of Public Health, ⁴Assistant Professor, Dr, Faculty of Dentistry, Khon Kaen University, Thailand

Abstract

Background: Stroke is the 2nd leading cause of death and 3rd rank of disability in the world including Thailand as well. This research aimed to determine the trend and investigate factors associated with depressive disorder among elderly stroke patients in the Northeast of Thailand.

Method: This cross-sectional study was conducted among 612 elderly stroke patients who were multistage random sampling from four provinces of the Northeast of Thailand to response to a structured questionnaire. Multiple logistic regression was performed to identify the factors influenced on depressive disorder of elderly stroke patients in the Northeast of Thailand.

Result: Among the total of 612 elderly stroke patients, 77.61% (95%CI: 74.10-80.85) had depression disorder. Factors that were associated with depressive disorders among elderly stroke patients were; impaired daily activities (adj.OR=15.82; 95%CI: 8.36-29.91), low access to health service (adj.OR=6.01; 95%CI: 3.20-11.28), rehabilitation at home (adj.OR=4.56;95%CI:2.52-8.24), unemployment (adj.OR=2.02; 95%CI: 1.20-3.36) when controlling other covariates including age, education, income, chronic disease, duration of illness and health insurance.

Conclusion: More than two-third of elderly stroke patients had depressive disorders. Limitation in performing daily activities, poor access to health services, inadequate rehabilitation and unemployment were associated with depression among elderly stroke patients in the Northeast of Thailand.

Key words: *Depressive disorders, Elderly, Northeast of Thailand, Stroke*

Introduction

Stroke is the world 2nd leading cause of death and 3rd rank of disabilities. Globally, approximately 6.7 million people were died because of stroke and more than 3 in 4 deaths occurred in middle and low-income countries¹. The risk is increasing with age among both males and females². Stroke was also the main cause of disability and dependency needed from other people because on nervous system. The patients who survive from stroke

will have long term effect on physical deficiency³, loss of sight, speech, or movement and decrease brain ability⁴.

In Thailand, stroke was the 2nd leading cause of death. Between 2011 and 2015, the mortality rates of stroke were slightly increased from 30.0 to 43.3 per hundred thousand population⁵ of which 80% was ischemic stroke whereas the rest 20% was cerebrovascular disorder⁶. The Ministry of Public Health reported that 1.4 times increased of hospitalization due to stroke between 2007 and 2013⁷. The Northeast of Thailand, the biggest region number of elderly and over in 2016 was 3,117,763 or 14.21% with the ratio between elderly males and females was 1 to 1.2⁵. Being in the elderly age, they are mostly encounter various problems related to changes especially

Corresponding Author:
Panee Banchonhattakit
E-mail: panban@kku.ac.th

physical and psychological deterioration which made them weak and ill⁵. If they suffer chronic diseases such as stroke, mental disorders could be more prevalence. Depressive disorder influenced on stroke patients as well as other diseases such as hypertension, diabetes, cancer and substance abuse⁸. After the stroke, from 3 months to 3 years, there were more than 1 in 3 of the patients had depression of which the prevalence was up to 25%. Most of them were at the extreme level, 24 % of them had emotional expressions such as angry, irritable, anxious, sad, fear, hopeless and suicide leading causes⁹. Stroke patients who had experience with depression are burden on family and their society because of ignoring follow up, treatments, and rehabilitation. Therefore the more slowly and more severity of healing of the illness can be made¹⁰. The impact of depression effected on physically, mentally and socially, as a result, the quality of life of patients has decreased¹¹.

Little is known on depression among elderly stroke patients especially in the Northeast part of Thailand. Therefore, the objective of this study was to determine the pattern of stroke and investigate the factors associated with depression among elderly stroke patients in the Northeast of Thailand.

Material and Method

Study Design

This cross-sectional study was conducted among 612 elderly stroke patients who were recruited by using a multistage random sampling from four provinces of the Northeast of Thailand including Khon Kaen, Roi Et, Maha Sarakham and Kalasin provinces. The inclusion criteria were persons aged 60-year-old or above, lived in Northeast of Thailand and were diagnosed as had stroke, and were ongoing treatments for more 4 weeks. The elderly stroke patients who were critically ill or could not communicate with the researcher were excluded from the study. The depression assessment was used by 9 questions-depression screening test in native of Isan (Northeast) dialect developed by Suwana

Arunphongphaisan in 2006¹² was used to identify the depressive disorder.

Data Analysis

A simple logistic regression was used to identify the association between each independent variable and depressive disorders. The independent factors that had p-value <0.25 were processed to the multivariable analysis using the multiple logistic regression to identify the association of all determinants and depressive disorder when controlling the other covariates. The magnitude of association was presented as adjusted odds ratio (Adj.OR), 95% confidence interval (CI). P-value <0.05 was a statistically significant level.

Results

Among the total of 612 elderly stroke patients, 56.05% were females with the average age 67.92 ± 6.31 years old. Most of them were married (71.57%) and finished primary school (87.65%). More than half were unemployment (57.19%) with the median monthly income of 10,000 Baht. As high as 62.91% were in debt, and 20.10% of the respondents borrowed from the informal sectors. More than half of the respondents (55.56%), almost all had chronic disease (88.56%) of which 45.57% had hypertension and 44.10% had diabetes. Almost all were ischemic stroke patients (94.61%). Most of them had stroke less than 5 years (65.20%), almost all rehabilitation at home (86.27%). In addition, almost all of them had universal health insurance (88.73%). However, about half had poor access to health services (50.16%). In addition, most of them did not smoke and drink alcohol, 72.39% and 65.36%, respectively. 86.60% of them were able to practice some daily activities.

There were 77.61% of the elderly stroke patients in the Northeast of Thailand had depressive disorder. However, most of the had mild depressive disorder (73.85%) whereas less than five percent had moderate to severe depressive disorder (Table1)

Table 1. Number and percentage of depressive disorder among elderly stroke patients in the Northeast of Thailand (n=612)

Depressive disorder	Number	Percent	95%CI
No (< 7points)	137	22.39	19.14 - 25.89
Mild (7-12 points)	452	73.85	70.18 – 77.29
Moderate (13-18 points)	21	3.43	2.13- 5.19
Severe (\geq 19 points)	2	0.33	0.03- 1.17

The multiple logistic regression indicated factors that were associated with depression among elderly stroke patients were; could perform only some daily activities (adj.OR= 15.82; 95%CI: 8.36-29.91), had poor access to health services (adj.OR= 6.01; 95%CI: 3.20-11.28), were rehabilitated at home not at a hospital (adj.OR=4.56;95%CI:2.52-8.24), unemployment (adj.OR=2.02; 95%CI: 1.20-3.36) when controlling other covariates including age, education, income, chronic disease, duration of illness and health insurance. (Table 2)

Table 2: The multivariable analysis of factors associated with depressive disorder among elderly stroke patients in the Northeast of Thailand, using the GLMM model presenting odds ratios, adjusted odds ratios, 95%CI and P-value (n=612)

Factors	Number	% Depressive disorder	OR	adj. OR	95%CI	P-value
Be able to perform daily activities						<0.001
Could perform all activities by themselves	82	23.17	1	1		
Could perform only some activities by themselves	530	86.04	20.43	15.82	8.36- 29.91	
Access to Health service						0.007
Good	307	60.26	1	1		
Poor	305	95.08	12.74	6.01	3.20 - 11.28	
Rehabilitation						0.007

Home	528	82.77	5.81	4.56	2.52-8.24	
Employment status						0.007
Employed	262	65.27	1	1		
Unemployed	350	86.86	3.51	2.02	1.2-3.36	

Discussion

Two-third of elderly stroke patients in the Northeast of Thailand had depressive disorder (77.61%), the finding of our this study was in line with a systematic review and meta-analysis on depression after stroke which reported the prevalence of stroke was ranking from 25 to 79%¹³. It was also similar with the finding from a study in Bangladesh where the prevalence of depression was 70%¹⁴. The possible reasons might be that when stroke occurs, it can be the main cause of disability and dependency which needed helps from other people³. The depressive disorder might also more prevalent from the long-term effect on physical deficiency, hearing problem, and decrease brain ability⁴. These conditions make them feel depress to be burden of their family¹⁰. In addition, the long duration of illness while not being self- help will be an opportunity to increase the level of depression. Due to stroke, if the body condition cannot return to normal, impact on their job or daily activities will lead them to lack self-esteem, self-negative and as the result, stress can develop into depression¹⁵.

This study observed that be able to perform only some daily activities by themselves were strongly associated with depression disorder among elderly stroke patients in the Northeast of Thailand. It was similar with the result from a study in Bangladesh which report that those who unable to perform daily activities by themselves had 14.9 time higher chances to have depression than those who can perform daily activities by themselves¹⁴. It might be that when elderly got stroke patient, they suffered various consequences especially, physical and psychologically deterioration which made them to weak and ill⁵.

Poor access to health services had influence on depression among these elderly stroke patients. This finding was supported by a study on depression predictor¹⁶. Even though almost all of them had health insurances, they still bared the opportunity costs. The expenses on traveling, food, accommodation, and medical expenses beyond the insurance coverage. In addition, most of them need someone to take them to the hospital, they had problems on accessibility to health services¹⁷, of which their health problems would not properly solve. Therefore, they are prone to chronic stress and depression.

Rehabilitation at home, not at hospital was strong associated with depressive disorder. It could be explained that the effectiveness of rehabilitation at home is lower than in the hospital which have better equipment, health personnel and training protocol. Therefore, their disability and dependency will be prolonged. This finding was in line with a study in China which found that low levels of state self-esteem, social support satisfaction and functional ability were associated with depression among Chinese stroke survivors six months after discharge from a rehabilitation hospital¹⁸.

Among elderly stroke patients in the Northeast of Thailand, unemployment was also associated with depression. This result was support by a study among African post-stroke depression which observed that unemployment had influence on depression¹⁹. Some of the occupational characteristics were related with differences occupation type. Social values and activities required physical competency. In case of stroke, physical disability and movement are affected. As the result, loss of the ability to perform duties was occurred, and economic burden within family was eminent.

Conclusion

Almost two-third of elderly stroke patients in the Northeast of Thailand had depressive disorder. The limitation in daily activities, poor access to health services and rehabilitation as well as unemployment were associated with depression among elderly stroke patients. Relevant sectors should strengthen accessibility to health services especially rehabilitation. Special attentions should be for those with limitation in performing daily activities as well as those with financial hardship.

Acknowledgement

The authors would like to express our sincere appreciation to all elderly stroke patients for their times and information. Special thanks to the Faculty of Public Health, Khon Kaen University, Khon Kaen University, Thailand for the supports.

Influence of Family, Peer Factors and Comprehensive Sexuality Education on Teenage Pregnancy in the Northeast of Thailand: A Case Control Study

Phandita Sukhumal¹, Thiti Sungworawongpana², Wongs Laohasiriwong³

¹Doctor of Public Health Program, Faculty of Public Health, Khon Kaen University, ²Dr, Faculty of Nursing, Khon Kaen University, ³Associate Professor, Dr, Faculty of Public Health, Khon Kaen University

Abstract

Background: More than one third of teenage pregnancies was found in the Northeast of Thailand. The objective of this research was to examine the influence of personal, family, peer factors, sexuality attitude, and the comprehensive sexuality education (CSE) on teenage pregnancies in the Northeast of Thailand.

Methodology: This case control study was conducted with the 1:3 proportion of case and control. The case were 60 teenage aged 15-19 years old, lived in the Northeast of Thailand, and delivered a baby less than 1 years. The control was 180 teenagers aged between 15 and 19 years old in the same region but never pregnant. Multiple logistic regression analysis was used to identify factors associated with teenage pregnancy presenting adjusted odds ratio and 95% confident Interval for the magnitude of association. P-value of <0.05 was statistically significant cut point.

Result: Among 240 teenagers, 60 were teenage pregnancy with the mean age of 17.09±0.63 years old, whereas 180 teenagers were the control group with mean age of 16.83±0.56. The multiple logistic regression analysis indicated that had no to one brother (adj.OR=5.08; 95%CI: 2.28-11.35), had friend lived with her boyfriend (adj.OR=4.97; 95%CI: 2.33-10.58), had average level of sexual attitude (adj.OR=4.68; 95%CI: 2.82-10.79), had average level of CSE (adj.OR=4.56; 95%CI: 2.93-10.52) were associated with teenage pregnancy, when controlling other covariates.

Conclusion: Family and peer factors, sexual attitude, as well as comprehensive sex education had influence on teenage pregnancy in the Northeast of Thailand. Effective comprehensive sex education is in need to help improve sexual attitude especially among those lived in the vulnerable family and peer environment. Families should closely supervise their children on sexuality, gender roles and social norms.

Key words: *Environment, Family, Northeast of Thailand, Peer, Teenage Pregnancy*

Introduction

Teenage pregnancy means pregnancy in a woman aged 10-19 years (WHO). About 16 million girls aged 15 to 19 (11%) and some one million girls under 15 give birth every year-mostly in low- and middle-income countries

(95%)¹. Many of teenage pregnancy and childbirth are not planned and unwanted, of which are more likely occurred in poor, uneducated and rural communities. Pregnancy and childbirth complications are the second cause of death among 15 to 19-year-olds globally². Some three million unsafe abortions among girls aged 15 to 19 take place each year, contributing to maternal deaths and to lasting health problems. Early childbearing increases the risks for both mothers and their newborns. In low- and middle-income countries, babies born to mothers under 20 years of age face a 50% higher risk of being

Corresponding Author.
Thiti Sungworawongpana
E-mail: kansun@kku.ac.th

stillborn or dying in the first few weeks versus those born to mothers aged 20-29. The younger the mother, the greater the risk to the baby. New-borns to teenage mothers are also more likely to have low birth weight, with the risk of long-term effects. Teenage pregnancy can also have negative social and economic effects on girls, their families and communities. Many girls who become pregnant must drop out of school. A girl with little or no education has fewer skills and opportunities to find a job. This can also have an economic cost with a country losing annual income a young woman would have earned over her lifetime if she had not had teenage pregnancy^{1,2}.

In Thailand, there were increasing proportion of teenage mothers from 12.9% to 15.3% between 2004 and 2016. Infants of young mothers had various disabilities, especially gastroschisis and prematurity^{3,4}. There were increasing risk of low birth weight among babies of young mothers⁴. In addition, failed attempts at self-induced abortion can have negative health outcomes for infants⁵. Lack of skills, family planning, and knowledge about sex had made teenage had premarital sexual relationship and unplanned pregnancy. Living with both parents was reported as reducing risk behaviour in teenage age 13-20 years⁶ as well as reduction of crime, violence, and use of drugs and alcohol⁷. Family member had influence on sexuality and pregnancy of teenage such as had teenage pregnancy sister and or mothers as well as had separated parents⁸. Financial hardship and low paid occupation also increased the risk of teenage pregnancy⁹. Peer factors such as had pregnant friends were associated with teenage pregnancy¹⁰. UNICEF Thailand, 2015 reported the influences of modernizing society norm and social sections toward premarital sex which shifting the direction to acceptable of premarital sex in Thai society which reported endorsed by 40% of male teenagers and 36% of female teenagers¹¹. Lack of communication about sex between parents and teenagers as well as limited parental supervision creates an environment where teenagers may decide to have sex without proper protection. Some girls who performed well in school and did not exhibit other risk behaviors were more likely to become pregnant since they did not have sufficient knowledge and skills to assert and protect themselves in sexual situations¹².

The Thai government finalized the Strategic Plan

for Teen Pregnancy Prevention and Solutions for fiscal years 2015-2024 and issued an Act for prevention and solution of the teenage pregnancy problem, B.E.(2016). This Act aiming at protecting the reproductive rights of individuals, clearly defining the roles and responsibilities of different agencies, improving the delivery of services, improving Comprehensive Sexuality Education (CSE) in schools for the prevention and solution of teenage pregnancy problem

The Bureau of Reproductive Health reported that 12.9% of all Thai pregnancies were among women under 20 years of age, of which the proportion of teenage pregnancy was highest in the Northeast region (37.2%)¹³. Therefore, better understanding of the factors that differentiate sexually experienced between teenagers who become pregnant from those who did not will help relevance sectors to develop more effective programs to reduce teenage pregnancy. This study was aimed to identify influence of personal characteristics, family and peer factors, sexuality knowledge and attitude as well as CSE on teenage pregnancy in the Northeast of Thailand.

Material and Method

Study Design

This unmatched case control study was conducted among teenage women in the Northeast of Thailand. The sample size in this study was calculated by the following formula¹⁴. The proportion of case and control of 1:3. The case were 60 teenager aged 15-19 years old, lived in 3 provinces of the Northeast of Thailand, and delivered a baby within less than 1 years, literate, and willing to participated. The control were 180 teenagers, aged between 15 and 19 years old in the same region, never pregnant as well as literate, and willing to participated. Both case and control filled the self-administered questionnaire.

Data Analysis

Simple logistic regression was used to identify the association between each independent variable with teenage pregnancy. The factor that had p-value less than 0.25 were the proceeded to the multivariable analysis. Multiple logistic regression analysis was used to identify factors associated with teenager pregnancy when controlling the effect of covariates, presenting adjusted odds ratio (adj.OR) and 95% confident Interval. The

statistically significant level was set at p-value <0.05.

Results

The mean age of the case was 17.09±0.63 years old whereas the control was 16.83±0.56 years. Just about half of the cases (33.33%), but most of the control (75.56%) study high school. Half of the case was marriage without registration but almost all the control was single (98.89%). More than half of cases were unemployed (56.67%) whereas 94.44% of control were students. Only about half of cases lived with parents (51.67%) but 72.78% of the control did.

Concerning family factors, almost all the case's family income was lower than the average family income of the Northerners in year 2018 (20,271 Baht/month), whereas as only 68.33% among control. About half of cases had 1-2 siblings, but it was 70.00% among control. Most of the cases had 0-1 brothers, whereas 59.44% of control had 2-3 brothers, 61.67% of the cases had 2-4 sisters, 52.22% of control had 0-1 sister. Most of the cases and control were 2nd and 5th children of their parents. Most of case and control did not have teenage

pregnancy sibling. Similar proportion of case and control had no teenage pregnancy mother.

Peer factors, most of the case had only 3-5 close friends while 61.67% of the control had more than 5 close friends. Majority of cases had married friend while 68.33% of control had friend who were single. Most of cases had a friend lived with boyfriend, but 71.67% of control had friend who did not live with their boyfriends. Half of cases had pregnant friend whereas 71.11% of control had non pregnant friends.

Concerning knowledge, attitude and CSE. Knowledge on sexuality which covered reproductive health, contraceptive methods and pregnancy were assessed and compared among cases and control. Similar proportion of case and control had highest of knowledge, followed by average level of which 61.67% among case and 58.34% among control. The most of cases had average level of attitude on sexuality, but 61.67% of control had highly appropriate attitude sexuality. In addition, the most of cases had average level of CSE whereas 62.22% of controls had high level of CSE.

The individual independent variable was test of association on teenage pregnancy using a simple logistic regression. The factors which had p-value<0.25 were proceeded to the multivariable analysis using multiple logistic regression. These factors were, family income, number of brothers and sisters, number of brothers, number of sisters, sequence of offspring, had teenage pregnancy mother, number of close friend, had friend

at school, had married friend, had friend lived with boyfriend, had pregnant friend, sexuality attitude level, and CSE level. After the multivariable analysis the final model indicated that had 0-1 brother, had friend lived with a boyfriend, had average level of attitude toward sexuality, had average level of CSE were associated with teenage pregnancy when controlling other covariates.

Discussion

The result showed that number of brothers, had friend lived with boyfriend, sexual attitude level, and CSE were associated with teenage pregnancy in the Northeast of Thailand. Roles of family factors, teenagers who had 0-1 brothers had a significantly higher chance to get pregnant than those who had 2-3 brothers. Had no, or only one brother, the teenagers would not be familiar with boys. In addition, they might have the one that sincerely takes good care of them, provided advice and protected them². However, our result was inconsistent with the research of factors associated with adolescent pregnancy in a rural district of Kalasin province, Thailand reported that the number of brothers was not significant factor with adolescent pregnancy. It might be that in Thai culture when a girl has brothers, she will meet her brother's friend and might develop relationship with the girl. If more brothers, the girl would have more

chances to meet more brother's friend which increase the risk of pregnancy among the girls if her brother/ and or family did not supervise them properly.

With reference to peer factors, teenage women who had a friend lived with her boyfriend, had a significantly higher risk to get pregnant than the teenager who had no friend lived with a boyfriend. The sexual behaviors of a close friend has more effect on teenager behaviors since they need acceptance from friends. Therefore, they try to copy attitude, value and actions. In addition, normative influence means the group of friends had social pressure to force them². Peer network had heavily weighted toward a close friend, so close friend predicts girls perception of pregnancy norms with statistical significance on adolescent pregnancy¹⁵.

Concerning sexual attitude level, teenager women who had average level of sexual attitude had significantly

higher chances to get pregnant than teenagers who had high appropriate sexual attitude level. It was similar with the result of many studies which found that personal attitude and attitude towards sex and pregnancy of adolescences were associated with teenage pregnancy. The social-norms where adolescent pregnancy is seen to be a negative sight in the community^{16,17}. This study observed 61.67% of control had highly appropriate attitude whereas only 67% of cases had. Social impact on adolescent's attitude of which the social force may change their lifestyle to fit the social expectation, therefore a poorly developed or ambiguous attitude may direct people to rely on and to very effect by, which can influence individuals attitude and decision-making process influencing power. Teenage women who has average level of CSE had a significantly higher odds to get pregnant than teenagers who had high CSE. It was supported by that 60.00% of control had high level of CSE where almost all of cases had only average level (81.67%). Therefore, cases were less likely to have good knowledge and attitude on risk of pregnancy as well as protected themselves from unprotected or forced sexual relationship.

Conclusion

Family and peer factors, sexual attitude, as well as CSE were associated with teenage pregnancy. Effective CSE is in need to help improve sexual attitude especially among those who lived in vulnerable family and peer environment. School should improve teaching methods on CSE for a better outcome on sexuality knowledge, appropriated attitude and practices to prevent teenage pregnancy. Families should closely supervise their children on sexuality, gender roles and norms. Two ways communication is essential among parents and children especially on sexuality.

Endometrial Estrogen and Progesterone Receptor Expression and Blood Vessel Density in Abnormal Uterine Bleeding

Pradyot Singh¹, Mamta Gupta², Rani Bansal³, Davender Swarup⁴, Mitali Singhal⁵

¹Postgraduate Student, ²Associate Professor, ³HOD, ⁴Professor, ⁵Assistant Professor, Department of Pathology, Subharti Medical College, Swami Vivekanand Subharti University, Meerut

Abstract

Background: The aim of present study was to analyse endometrial estrogen and progesterone receptor expression and blood vessel density in cases of abnormal uterine bleeding.

Material and Method: The present study was conducted on specimens received from 266 patients presenting with abnormal uterine bleeding in reproductive age group (18-45 years) on endometrial biopsies and hysterectomy specimens. The intensity and distribution of ER, PR was evaluated using a semi-quantitative method Allred score. Also density of blood vessels /10 HPF was evaluated.

Results: Neoplastic cases were found among 9.4% (25) of the subjects whereas non-neoplastic lesions were present in 90.6% (241) of the subjects. Mean Allred scoring of estrogen and progesterone receptor in glandular component was highest among endometrial carcinoma. Mean Allred scoring of estrogen receptor in stromal component was highest among Hyperplasia without atypia (5.13±1.58). Mean progesterone receptor in stroma component was highest among Hyperplasia without atypia followed by disordered maturation and endometrial carcinoma.

Conclusion: The results of the present study showed that ER and PR expression are useful investigations. There expression varies in various causes of abnormal bleeding. Future studies with clinical trials could be done to try medical treatment of AUB.

Keywords: Abnormal uterine bleeding, Endometrial Carcinoma Estrogen receptor, immunohistochemistry, hyperplasia, Progesterone receptor

Introduction

Abnormal uterine bleeding (AUB) is the commonest presenting symptom in gynaecology. It occurs in 9-14% of women between menarche and menopause^{1,2}, significantly impacting quality of life and imposing financial burden³. The classification is based on the acronym "PALM- COEIN", which stands for polyp,

adenomyosis, leiomyoma, malignancy and hyperplasia, coagulopathy, ovulatory dysfunction, endometrial, iatrogenic, and not classified³.

Estrogen and progesterone receptors belong to the nuclear steroid receptor superfamily the effect of these steroid hormones are thought to be mediated through these receptors. The ER and PR IHC expression and distribution pattern may play an important role in endometrial function and pathogenesis⁴. The study of these receptors distribution in the endometrial glands could open the gate for medical treatment of cases of AUB and avoid unnecessary surgical intervention. The cause of the bleeding may be due to potentiation of the hormonal action through change in their receptor levels⁵. Also there is positive correlation between the endometrial angiogenesis and menstrual disorders. The

ORCID ID- <https://orcid.org/0000-0002-0761-3614>

alternation in blood vessel morphology and density also plays a significant role. Hence the present study was conducted to analyse endometrial estrogen and progesterone receptor expression and blood vessel density in cases of abnormal uterine bleeding.

Materials and Method

The present prospective cross-sectional hospital based study was conducted on specimens received from patients with abnormal uterine bleeding presenting with AUB in reproductive age group (18-45 years). The sample size for the present study was 266. The source of data for this study were patients undergoing endometrial biopsy/hysterectomy for complaints of abnormal uterine bleeding presenting in reproductive age group (18-50 years) over a period of 2 years. In the present study IHC was performed among 50 subjects, out of which 25 were neoplastic and 25 were non-neoplastic as control. The subjects were selected according to the following criteria:

Inclusion criteria: Hysterectomy and endometrial samples of reproductive and peri-menopausal age groups having abnormal uterine bleeding and patients presenting with menstrual irregularities like, irregular cycles, excessive and prolonged menstrual bleeding.

Exclusion criteria: Inadequate samples, patients with provisional diagnosis of infertility and women on hormone replacement therapy, oral contraceptive pills, intrauterine contraceptive devices or steroidal and non-steroidal anti-inflammatory medications.

Sample handling: Grossing and processing was done on the Hysterectomy specimens and endometrial tissues received. Specimens were fixed in 10% formal saline and then processing was done. Endometrial tissue was fixed as a whole while the hysterectomy specimen was cut and fixed overnight. The tissues were processed routinely to obtain 4-5 m thick paraffin sections and stained with Haematoxylin and Eosin. Lesions were categorised according to PALM-COIEN.

Sections stained by H & E stain were used for dating of endometrium. Findings were correlated with clinical history to formulate cause of abnormal uterine bleeding. Overall vascularity of endometrium in functionalis layer was judged by counting average number of blood vessels in 10 HPFs. Number of vessels was evaluated

in all cases on high power using 4µm sections stained with Haematoxylin and Eosin and the photomicrographs were taken at 40x magnification.

Antibody: Primary antibody used for ER and PR was Monoclonal mouse Anti-Estrogen Receptor clone ID5 (Sentier) and Monoclonal mouse Anti-Progesterone Receptor clone PR88 (Sentier) respectively. Expression of ER and PR receptors was observed in endometrial lining and stroma⁴.

Scoring criteria: The intensity and distribution of ER and PR was evaluated using a semi-quantitative method - Allred score. In Allred system of scoring, score 0-5 was given to cells depending on the proportion of cells which were stained (proportion score [PS]) and score 0 -3 depending on the intensity of staining (intensity score [IS]). Allred score is (PS + IS = AS)⁶.

Statistical Analysis

Data collected was tabulated in an excel sheet. The mean and standard deviation of the measurements per group were used for statistical analysis (SPSS 22.00 for windows; SPSS inc, Chicago, USA). Statistical difference between was determined using chi square test and the level of significance was $p < 0.05$.

Results

In the present study, endometrial biopsy and hysterectomy specimen were obtained from 76.3% and 23.7% of the total specimen (266) respectively.

Among the neoplastic cases, Hyperplasia without atypia, Atypical Hyperplasia and endometrial carcinoma was reported among 80%, 12% and 8% of cases respectively. Disordered maturation, Secretory/ Progesterone effect, Proliferative/Oestrogen effect, Non-secretory endometrium, Polyp, Adenomyosis, Leiomyoma and Endometritis were found among 44.81%, 22.41%, 13.28%, 4.98%, 4.56%, 5.39%, 3.32% and 1.24% of the non-neoplastic cases respectively (Table 1).

0-9 blood vessels / 10HPF was revealed among 14.1% of the non-neoplastic cases as compared to 4% of neoplastic cases. 40-49 blood vessels/10 HPF was found among 84% and 17.4% of the neoplastic and non-neoplastic cases respectively (Table 2).

In the present study, average blood vessel density was highest among Hyperplasia without atypia (42.60±3.21) followed by Polyp (38.80±3.78), Endometrial Carcinoma (38±0) and Atypical Hyperplasia (36.71±4.78). The least average blood vessel density was found among disordered maturation (20.17±3.81) followed by different phases of endometrium in context of leiomyoma (22.36±4.16) and non-secretory endometrium (24.51±4.98) as shown in Table 3.

In the present study, mean Allred scoring of estrogen and progesterone receptor in glandular component was highest among Endometrial Carcinoma (7±0, 7.67±2.92) followed by Hyperplasia without atypia (6.33±0.58, 7.67±2.92) respectively. Mean Allred scoring of estrogen and progesterone receptor in stromal component was highest among Hyperplasia without atypia i.e. 5.13±1.58, 6.90±2.92 respectively as shown in Table 4.

Discussion

The present study was conducted to evaluate endometrial estrogen and progesterone receptor expression and blood vessel density in cases of abnormal uterine bleeding. In the present study, maximum AUB cases were in the age group of 31-40 years (45.96%). The mean age of the study subjects was 39.1 ± 6.3 years (range 22-50 years). These results were in accordance with the study done by Singh P et al⁷ who revealed that cases presenting with AUB were of 36-45 years of age which accounted for 74.73%. Mean age of presentation was 37.9 years. Mostafa AM et al⁸ reported that mean age of the females of the control group was 34.81 years (range 27-40).

In the present study, among the neoplastic cases, Hyperplasia without atypia, Atypical Hyperplasia and endometrial carcinoma was reported among 80%, 12% and 8% of the subjects respectively. These results were in accordance with the study done by Baghel P et al⁹. She reported simple hyperplasia without atypia among 12 cases (5.6%), whereas with atypia was seen only in 3 cases (1.40%). The most common patterns in the present study were disordered maturation followed by Secretory/Progesterone effect and Proliferative/Oestrogen phase. These results in accordance with the study done by Tiwari A et al¹⁰ who found disordered proliferative endometrium was most common (12%) other than normal endometrial patterns.

In the present study, mean blood vessels were highest among Hyperplasia without atypia (42.60 ± 3.21) followed by polyp (38.80 ± 3.78). The least mean blood vessels was found among disordered maturation (20.17 ± 3.81) followed by endometrium in case of leiomyoma (22.36 ± 4.16). Makhija D et al¹¹ in their study revealed that the endometrial blood vessels showed characteristic changes in various phases of menstrual cycle. They were concentrated more in basal layer in the proliferative phase and were distributed more in functional layer in the secretory phase. The average blood vessels per HPF were 4.471 ± 0.095 in complex hyperplasia and 6.38 ± 0.78 in pill endometrium. Mean blood vessels per HPF were 3.9 ± 0.16 in proliferative and secretory phase and 3.73 ± 0.38 in Non secretory cases.

In the present study, overall it was observed that ER and PR expression were higher in neoplastic as compared to non-neoplastic cases. Similar results were reported by Armando A et al¹² in their study. High expression in the glandular epithelia indicates a higher sensitivity of these structures to steroid hormones, which may be responsible for the development of benign polyps in the presence of low serum estrogen levels, while malignant polyps appear to be developed by a different etiology.

In our study, there was a significant increase in ER and PR expression in the endometrial glands in patients with AUB. Patients with AUB had a significant higher endometrial thickness and ER and PR levels in the endometrium. Therefore examination of estrogen and progesterone receptor expression is more important than the biochemical examination of the hormone itself because it gives an idea about the actual effects of these hormones. Therefore, it is a useful investigation on which clinical trials could be done to try medical treatment of AUB in reproductive age group.

Conclusion

The results of the present study concluded that endometrial ER and PR expression in endometrium helped in establishing its trend in and providing insight in the pathogenesis of abnormal uterine bleeding. The examination of estrogen and progesterone receptor expression is more important than the biochemical examination of the hormone itself because it gives an idea about the actual effects of these hormones in tissues. The blood vessel density showed the possibility of quantifying microscopically the morphologic alterations that occur in blood vessels in pathological process and predict angiogenesis in AUB. However morphometric evaluation will aid to better diagnosis and treatment in cases of AUB. Therefore ER, PR expression and blood vessel density are useful investigations on which clinical trials could be done to try medical treatment of AUB in reproductive age group.

Physical, Psychosocial Determinants and Quality of Life of Elderly in the Northeast of Thailand

Prapat Thammawongsa¹, Wongs Laohasiriwong^{2*}

¹Faculty of Public Health, Khon Kaen University, Thailand, ²Associate Professor, Dr, Faculty of Public Health, Khon Kaen University, Thailand

Abstract

Background: Rising of elderly population is one of a major public health's concerns. This research aimed to describe physical and psychosocial determinants and identify their association with Quality of Life (QOL) of the elderly population in the Northeast of Thailand.

Method: This cross-sectional study was conducted among 1,113 elderly, who aged 60 years old and older, were multistage random sampling from four provinces of the Northeast of Thailand to response to a structured questionnaire interview. Generalized linear mixed model (GLMM) was performed to identify the influence of physical and psychosocial determinants on QOL of elderly in the Northeast of Thailand.

Result: Among a total of 1,113 elderly individuals, 54.27% (95%CI: 51.29–57.22) had good QOL, follow by 45.10% (95% CI: 42.15–48.08) with moderate QOL. Factors that were associated with having good QOL among elderly population were; received highly respected as a valuable person (adj.OR= 4.23; 95%CI: 3.12-5.74), had good social support on accessibility to information (adj.OR= 3.12; 95%CI: 2.24-4.35), had no stress to minimum level of stress (adj.OR= 2.87; 95%CI: 1.92-4.27), had no physical limitation such as fall/ urinary incontinence/ constipation/ eating difficulties/ hearing/ eyesight/ mobilization/ sleeping disorders/ memory loss (adj.OR = 2.25; 95%CI: 1.66-3.06), rural residence (adj.OR= 2.00; 95%CI: 1.44-2.77), and accessibility to health care facility (adj.OR= 1.98; 95%CI: 1.48-2.70). Another significant covariate was being a younger elderly group (60-69 years old) (adj.OR= 1.84; 95%CI: 1.37-2.47).

Conclusion: Majority of elderly in the Northeast of Thailand had good QOL. Both physical and psychosocial determinants had influence on QOL the elderly population. Interventions on community to increasing respect as well as communication with elderly are essential especially for the older elderly groups.

Key words: *Elderly, Physical, Psychosocial, Quality of Life, Social Capital*

Introduction

Thailand has been entered into society since 2000-2001 with had elderly people more than 10 percent of Thai population¹ Moreover, by 2023 Thailand will get into elderly society completely by having 20 percent of population are elderly people². The Northeast of Thailand, the country's biggest region, number of elderly

people who aged 60 years and older was 3,117,763, accounting for 14.21% of the population with the ratio between elderly males and females was 1 to 1.2³. There have been various changes in term of physical, mind, and social among elderly⁴. Being in the elderly age, there are many challenges and problems from deterioration of both physical and psychological aspects which made them weak and ill. Health conditions observed among elderly were that only 3.3% of them had great health, 42.4% had good health, 38.3% had moderate health, 13.9% had poor health, and 2.1% had seriously ill health¹. Chronic non-communicable diseases have most impact on elderly especially on burden on health care and expense.

Physical and psychological health problems are related with quality of life (QOL)². WHO defines QOL as an individual's perception of their position in life in the context of culture and value systems in which they live and in relation to their goals, expectations, standards and concerns⁵. It is a broad ranging concept affected in a complex way by the person's physical health, psychological state, personal beliefs, social relationships and their relationship to salient features of their environment⁶⁻⁸. Many factors were associated with QOL among middle and elderly people including personal, political, and economical factors⁹. In addition, social interaction, dependency problem, and health problem were considered as factors influenced on QOL¹⁰. Elderly with good connection and received well support from society¹¹ had better QOL than those with poorer supports. In addition, losing social interaction could result in social deprivation¹².

At present there is no comprehensive study on the roles of physical and psychosocial determinants on QOL among elderly population especially in the Northeast of Thailand. The objective of this study describes the physical and psychosocial determinants and QOL of elderly as well as investigate the influence of physical and psychosocial determinants on QOL of elderly population in the Northeast of Thailand.

Material and Method

Study Design

This cross-sectional study was conducted among 1,113 elderly who were recruited by using a multistage random sampling from four provinces of the Northeast of Thailand including Khon Kaen, Udon Thani, Nakhon Ratchasima and Ubon Ratchathani provinces proportional to size of the population. The inclusion criteria were those aged 60-year-old and over, lived in Northeast of Thailand during the data collection. The elderly who critically ill were excluded from this study. A self-administered structured questionnaire consisted of 4 parts including demographic and socioeconomics, physical factors, psychosocial determinants, and QOL was used for data collection.

Data Analysis

A simple logistic regression was used to identify association of each independent variable with QOL. The independent factors that had p-value < 0.25 were processed to the multivariable analysis using the generalized linear mixed model (GLMM) to identify the association between physical and psychosocial determinants, and QOL when controlling the effect of other covariates, of which 4 provinces were selected to include as random effects. The magnitude of association was presented as adjusted odds ratio (adj. OR), 95% confidence interval (CI) and p-value < 0.05 as statistically significant level.

Results

Among the total of 1,113 elderly, 54% were females with the average age of 70.23 (± 7.55) old. Most of them finished primary education (88.41%), and 63.97% were married. Almost all lived with others (92%). The median monthly income was 2000 (600:50,000) Baht, of which majority relied on monthly government welfare and had not enough income. More than one-third did not work whereas more than 60% reported that they need to work.

In term of physical determinants, almost half of participants were overweight and obesity (46.35%), and 43.31% had chronic disease. The most common chronic diseases suffering they were hypertension (30.55%), and type 2 diabetes (16.62%). Almost all could perform daily functions dependently. More than a quarter having difficulties of eyesight (27.67%) followed by eating difficulties (19.68%), memory loss (19.41%), and sleeping disorder (19.04%). Concerning psychosocial determinants most of them had no and minimum stress (81.40%), and no and minimal depression (82.39%). Most of them received average to high levels of social support. Only 3.23% reflex inconvenience in travelling to health care facilities. About three quarters had family member accompanied them to health facilities, and 63.25% were satisfied with health services. More than half of the participants had good QOL, followed by fair level (Table 1).

Table 1. Number and percentage of quality of life (QOL) among participants in the Northeast of Thailand (n=1,113)

QOL Level	Number	Percent	95%CI
Poor	7	0.63	00.25 - 1.29
Fair	502	45.10	42.15 - 48.08
Good	604	54.27	51.29 - 57.22

The GLMM indicated factors associated with having good QOL among elderly population. These factors were; highly respected and admiration, had good level of accessibility to information, had no stress to minimum level of stress, had no physical difficulties (fall/ urinary incontinence/ constipation/ eating difficulties/ hearing/ eyesight/ mobilization/ sleeping disorders/ memory loss), lived in rural areas, convenience in traveling to health care facilities and younger elderly group (60-69 years old) when controlling the effect of provinces and other covariates including sex, occupation, health behaviors, chronic disease, depression, health insurance. (Table 2)

Discussion

Majority of elderly participants of this study had good QOL (54.27%). This finding is in line with the result of other studies on QOL among elderly which reported that 60.37% of primary elderly age (60-69 years old) had good QOL while 47.43% of middle elderly (70-79 years old) and lately elderly (80 and over) (47.43%) had good QOL^{13,14}. The possible reasons that could explain these situations were that the elderly aged 60-69 years old still perform normal physical functions therefore they were more likely to satisfy with their life than the older elderly who suffered physical limitations¹⁵⁻¹⁷. When the elderly had health problems, most of them were irritated and sorrowful that lead to stress therefore, caring from people surrounding them can make them feel better. This study observed that being admired and considered as valuable person were strongly associated with having good QOL among elderly in the Northeast of Thailand. It was similar with the result from other studies which expressed that supporting from society is one of the forces that had impact on QOL of the elderly^{18, 19}. In addition, elderly need supports to be able to self-reliance when having health problems²⁰. Elderly who lived in warm family with love care, respect, and help from family members made them had better life satisfaction which resulted in good QOL²¹. The context of Thailand, taking care elderly who are parents or grandparents is considered as gratitude behavior²². Therefore, the elderly was satisfied. In addition the long term care for elderly is one of an importance strategy of the Ministry of Public Health Thailand, in the preparation to be readiness for the elderly society, involving collaboration of various sectors of society^{18,23}. Supporting elderly to access the information in their societies had influenced on their QOL as well. Elderly who could access to information have better opportunity to access to public welfare, joining events as well as health care, minimized misunderstanding on information which have impact to both their physical and psycho social health²⁴. In addition power of information could make them have more confidence in travelling to various places as well as health facility¹⁸. No and minimal levels were associated with having good QOL of elderly people. This result was supported by previous studied which stated that having good mood had effect on elderly mind¹⁵ and mental health is main factor that had impact on elderly's QOL^{25,26}

The Northeast of Thailand is the region that the working age population migrated to work in Bangkok and other regions sending money home for their parents. Many elderlies had children who were working in various urban settings to earn money to support family especially their parent who mostly lived in rural areas. The elderly who lived in rural settings with the support from the other family members and communities as well as lifestyle and culture of caring and sharing could enjoy their life better than those lived in urban settings resulted in better QOL¹⁸.

Conclusion

More than half of elderly population in the Northeast of Thailand had good QOL. Both physical and psychosocial determinants were associated with QOL among these elderly population. Social interventions to improve respect as well as communication with elderly are essential especially for older elderly group.

Assessing the Awareness of Usage of Mouth Washes among the General Population and Patients Undergoing Orthodontic Treatment-A Questionnaire Study

Prasanna Arvind T.R¹, S. Aravind Kumar²

¹Postgraduate Student, ²Professor and HOD, Department of Orthodontics, Saveetha Dental College, Saveetha Institute Of Medical and Technical Sciences, Chennai, India

Abstract

Introduction: Usage of mouthwashes and its different variants is on the rise due to their ease of use and simplicity as well as the relative comfort it gives the user on maintaining oral hygiene. However this must be balanced with the understanding that mouthwashes are merely adjunctive aids for maintaining oral hygiene and must be balanced with proper brushing and flossing to express its full effects. This study aims to assess the awareness of usage of mouthwashes among the general population and patients undergoing orthodontic treatment and attempts to differentiate between different needs for usage of mouthwashes.

Materials and Methodology: A questionnaire survey containing 16 questions was prepared which contained questions regarding the information about the subject and their knowledge about the usage of mouthwashes, its types, uses and side-effects. The questionnaire was prepared using Google forms and was sent to 149 subjects through mail and by sharing the link of the survey. The subjects included patients from varied age groups as well as the general population and patients undergoing active orthodontic treatment

Results and Conclusion; Most of the subjects who took the test and were using mouthwashes as a part of daily oral hygiene were aware of its usage patterns and conditions. The main reason for using mouthwashes was bad breath followed by prevention of dental caries. Awareness in gargling time, different conditions was higher in orthodontic patients as well as increased care towards their oral hygiene

Keywords: Mouthwashes, General population, Orthodontic treatment, Knowledge

Introduction

As the old saying goes, The oral cavity is the mirror to a person's health. Maintaining good oral hygiene involves adequate brushing with a proper technique and flossing in the interdental regions to remove food debris and plaque⁽¹⁾

Dental health awareness should be stated at a very young age. Children should be taught the importance of

keeping their teeth healthy and clean^(2, 3). Consequences of poor oral hygiene and poor food choices should be explained to effectively remind the children of the need to brush their teeth after every meal and avoid sweet treats as much as possible⁽⁴⁾.

In adults, the dental health awareness should be assessed by their dentists. Awareness about dental health will help them in understanding what practices should they need to reinforce to have a healthy and strong teeth⁽⁵⁾. Different dental treatments are now made available to cosmetically enhance the appearance of teeth, correct orthodontic problems as well as in restoring teeth. Alleviating fear or anxiety related to lack of knowledge regarding the procedure is one of the mitigating factors and this must be resolved as soon as possible⁽⁶⁾.

A mouthwash or rinse does not replace a regular and proper oral hygiene routine of twice-daily tooth brushing and daily flossing. The main function of most mouthwashes is to freshen breath and that said, some mouthwashes such as fluoride rinses, can help protect the teeth from decay by shielding them from acids produced by plaque bacteria ⁽⁷⁾. Patients undergoing orthodontic treatment, might have an increased concern and awareness about the status of their teeth and appearance and it would be interesting to note their viewpoints towards usage of mouthwashes, both from a social as well as commercial point of view⁽⁸⁾. This study aims in instilling such dental awareness over the use of mouthwashes among adults in the general population as well as patients undergoing orthodontic treatment.

Materials and Methodology

This is a knowledge aptitude practice survey assessing the awareness of general population and patients undergoing orthodontic treatment towards the usage of mouthwashes. The survey was prepared using Google forms and was sent to the participants using the web link of the survey. 149 subjects were included in this study. The survey consisted of sixteen questions out of which 4 were compulsory and 13 were not compulsory. Out of the 149 subjects, 64 were patients undergoing orthodontic treatment and the remaining 85 were from the general population and included varied groups. Since this test was used to check the awareness of mouthwashes among people, subjects who had relatives or friends undergoing orthodontic treatment could also answer questions regarding the usage of braces and its comfort levels.

Results

1) Do you use mouthwashes?

150 responses

Figure 1: Assessment of usage of mouthwashes

2) Have you used any mouthwash for the below listed conditions?

144 responses

Figure 2: Content-driven mouthwash use(contd)

3) Are you aware of the need for mouthwashes during orthodontic treatment?

129 responses

Figure 3: Adjunct with orthodontic treatment

4) Are you aware of the side-effects of improper oral hygiene during orthodontic treatment?

110 responses

Figure 4: Possible side-effects

5) If yes, then are you aware of

130 responses

Figure 5: Possible side-effects(contd)

6) Are you aware that usage of tea, coffee, and other beverages must be restricted when using anti-plaque mouthwashes?

150 responses

Figure 6: Dietary restrictions

Discussion

The questions were framed in such a way that the initial few questions inquired about the usage of mouthwashes and the subsequent reasons for either using or not using it. Since this survey focused on assessing the awareness regarding mouthwashes, people who did not use mouthwashes too could participate in the survey by answering the other questions. The questions then gradually moved towards assessing the knowledge of subjects in using mouthwashes and the time required to gargle, expectorate etc. The interest of subjects towards their oral hygiene was assessed with some aptitude questions along with a little medical history and then the survey finally moved towards assessing the beneficial effects as well as a few side-effects a few 'must-knows'.

The first question was framed to determine the number of subjects using mouthwashes. 38.9% of the subjects replied yes and 28.2% replied no while 32.9% replied occasionally⁽⁹⁾. The second and third questions focused on why the subjects were either using or not using mouthwashes. 63.7% of the subjects replying no mentioned that they were taking care of their oral hygiene regularly which was a satisfying number. 21.6% saw no need in using mouthwashes while 7.8% considered it to be expensive for daily needs and 6.9% were not aware of mouthwashes and other adjunctive oral hygiene aids which despite being a small number does not portray favorably^(10,11). In patients replying in the affirmative for

usage of mouthwashes, the main reason for using them was for eliminating bad breath as 52.4% would attest to. 35.2% considered it as a part of daily oral health care and hygiene which despite being an encouraging number needs further improvement⁽¹²⁾. 6.7% used it for reducing dental decay and 5.7% used it for cosmetic reasons such as teeth whitening. In the fourth question, 44.2% of the subjects replied that they had used a mouthwash with a doctor's prescription while the remaining 55.8% did not which could also imply that they were not too fond of mouthwashes as well as the fact that they were not active participants in maintaining good oral hygiene⁽¹³⁾. In the fifth question, the awareness towards the ingredients and contents of the mouthwash as well as in using it was questioned with 58.9% replying that they read the instructions given in the label of the mouthwash^(14,15). 25.5% were not too fond of strictly complying with conditions and used it for gargling after brushing. This indicated poor awareness towards compliance methods and also indicated a slight slack in reading instructions and complying to protocol and procedures⁽¹⁶⁾. 15.6% used mouthwashes to their own wishes and did not strictly adhere to any specific timing with convenience being their chief concern. It is important to read the label on any brand of mouthwash. Different brands have different concentrations, and some may recommend dilution with water⁽¹⁷⁾. If the label does not tell you to dilute, then the full benefit of the mouthwash may not be expressed if the ingredients are at a lower level. One

of the keys to using mouthwash correctly is to swish it in your mouth for the correct amount of time⁽¹⁸⁾. Read the product label. Most mouthwashes recommend that you swish the product around in your mouth for 30 seconds to one minute then spit it out. The sixth question focused on whether the subjects read the contents of the mouthwash properly. 72.6% replied yes while 27.4 % replied no. The seventh question lists the conditions for using mouthwashes and bad breath (halitosis) leads the list with 58%. The next condition in the list is preventing dental caries with 19.6%. Fluoride mouth rinses are mostly given for preventing dental caries. Mouth ulcers constitute 13.3% while sensitivity contributes to 9.1%. The eighth question deals with the number of times mouthwash is used in a day. 41.3% use it only once in the morning, while 31.5% use it irregularly and 27.3% use mouthwashes twice a day. The ninth question deals with awareness about different conditions for which mouthwashes can be used. 58.4% replied yes while 41.6% replied no. The absence of an overwhelming majority in this condition is a cause of concern as it indicates lack of awareness about the indications for using a mouthwash and is mostly used as a fad or routine in most cases. The tenth question deals with patients undergoing orthodontic treatment and attempts to understand their opinion on usage of mouthwashes during active appliance therapy. 51.6% replied yes while 48.4% replied no. The lack of a big difference between both the answers is slightly misleading since it could also indicate ignorance on part of the patient or lack of education on part of the orthodontist⁽¹⁹⁾. At any case, mouthwashes are not a must in orthodontic treatment with fluoride rinses being the most commonly prescribed mouthwashes. The eleventh question is revealing on part of the patients for using mouthwashes. 50% of patients have voted for reducing foul odour and freshening up breath with oral hygiene and appearance being the chief concern. 28.3% have answered with maintenance of oral hygiene being easier since it can remove food debris and plaque and prevent accumulation of bacterial load. 15.1% have replied with preventing dental decay⁽²⁰⁾. This could be put down to either awareness about the composition of the mouthwashes they are using which is a positive sign or sheer mental training about the treatment from the part of the orthodontist. 6.6% have replied with mouthwashes giving a psychological effect which could be explained as the placebo therapy. The

twelfth question tries to gain an insight into the patients self awareness about his treatment pattern as well as oral hygiene awareness. 62.4% replied with dental decay and cavities which was a positive sign while 23.9% were concerned with the damaging effects to their teeth and appearance while 13.8% were concerned about its effects to the functioning of the oral cavity with sensitivity being a chief complaint⁽²¹⁾. The thirteenth question asks about the side effects of mouthwashes with 51.7% replying yes and 37.6% replying no which is a damaging number. People who were aware of its side effects were however quite knowledgeable with respect to its signs and were conscious of the limitations of mouthwashes⁽²²⁾. The final question attempts to reveal the mindset of positively-motivated people in using mouthwashes with 50.7% replying with bad breath indicating that halitosis and oral hygiene maintenance awareness is still not up to required standards in most of the population and greater efforts are required to instill a greater sense of awareness among the general population as well as patients undergoing orthodontic treatment.

Conclusion

Orthodontic treatment is widely acknowledged and accepted in everyday dental practice due to the positive effects it has on the dentofacial complex^(3, 4). With fixed orthodontic appliances, clinicians can offer patients the establishment of functional occlusion, improvement of oral health, and esthetic improvement of the dentofacial complex. Anomalies in the development of the face and jaws as well as orthodontic treatment can influence oral health⁽⁷⁾. Deviations from an ideal arrangement and position of teeth (lack of space, tooth rotation or open bite, a deep bite, and cross-bite) facilitate dental plaque accumulation⁽⁸⁾. It has to be pointed out that malocclusion is not a primary etiological factor but an auxiliary factor, which facilitates dental plaque accumulation. The main principle of orthodontic therapy is to correct tooth and jaw position and, thus, indirectly improve the health of the periodontium and durability of teeth⁽¹⁰⁾.

There is a need to incorporate more oral hygiene programs in future. Extra attention should be given in educating and motivating the patients on oral hygiene practices during orthodontic treatment in a proper manner and this could be beneficial in maintaining proper oral hygiene⁽³⁾. Maintaining good oral hygiene

procedures during fixed appliance therapy is important for gingival health and to prevent the development of white spot lesions ⁽⁶⁾. Mouthwashes can only control plaque if the brushing technique employed is efficient. In this study, 28% of males and 52% of females use mouthwash, which has a combined value of 40%. This value is close to a research done by Baheti and Toshniwal, ^[8] in which 57.4% of the population used mouthwash. In the same research, 36% of people used mouthwash after every meal, which is in contrast to our research with 12%. From the above study, it is clearly understood that women understand the usage of mouthwash better compared to men.

All procedures carried out with hydrogen peroxide in the mouth with the purpose of whitening the teeth should be performed directly by a dentist who has been properly trained to prevent the oral mucosa from receiving this product during the procedure ⁽⁷⁾. The time and method of use require caution in order to decrease, to the minimum, the undesirable effects of hydrogen peroxide on tooth tissues and restorations. Whitening strips and other tooth bleaching products are all hydrogen peroxide-based. Should mouth washing with hydrogen peroxide be occasionally done, touching the oral mucosa once a year or every six months, it would cause minor co carcinogenic effects ^(10, 12). However, should it be done every day or every week, as an antiseptic used to help with oral hygiene, it would become a protocol that is highly reckless to health! Websites, blogs and social network profiles that recommend the procedure should be immediately sued by the government! Esthetics comprises harmony between shape, size, position and color ⁽¹⁴⁾. If we take a closer look at some people's smile and notice red gingival and lips with extremely white teeth, the diagnosis of excessive use of hydrogen peroxide is inevitable: artificiality is evident. Extremely white teeth and red gingival and lips create a quite artificial picture from an esthetic standpoint!

Abstract

The knowledge of variations in the branching pattern of Left Coronary artery is an important factor in the study of coronary heart disease and mostly it is the left which is commonly involved. With the adaptation of sedentary life style and increasing stress, Coronary artery disease has become the major cause of death and coronary angiography is has become a routine for cardiologists & radiologists. This study is done to determine the branching pattern, mean length and mean outer diameter of the trunk of the Left Coronary artery using Silicon Cast technique. A Plastinate material that is Silicon is used in this study for luminal casts, this is first of its kind in India and it's a new innovative technique for studying the arterial patterns. The present study was carried out in 110 fresh hearts, 90 males and 20 females with a mean age of 66.0 years, which were collected from the mortuary of the Forensic department of Mysore Medical College and JSS Medical College, Mysore, South India for a period of 2 years. The Silicone material was injected into the Coronary arteries; the cast was removed and the fine branching pattern of the left Coronary artery was studied and measured using Vernier digital calipers. The left Coronary artery arose from the left posterior aortic sinus in most number of cases. The mean outer diameter of the trunk at the point of origin was 3.51 ± 0.71 (range 2 – 5.8mm). The mean length of the trunk of left Coronary artery was 10.04 ± 3.27 mm (range 4-18.5mm). Most of the branching pattern was bifurcation (62.72 %) and trifurcation (33.63%) was observed, tetrafurcation was found to be in 3.63% of cases only, no cases of pentafurcation was seen .This study will help in interventional studies by cardiologist and radiologists during diagnostic and therapeutic approach in Coronary vascular diseases.

Key words: Heart vessels, Left Coronary artery, Silicon cast, Vascular pattern.

Introduction

The Human heart is supplied by the Coronary arteries. The right and left Coronary arteries arise

Corresponding author:

Najma Mobin

Associate Professor, Department of Anatomy, JSS Medical College, JSS Academy of Higher Education & Research, Bannimantap, Mysuru, Karnataka State, India, Bannimantap, Mysuru, Karnataka State, India, Phone number to: +91 9845881326 Email: drnajmamobin786@gmail.com

from the aortic sinus of Valsalva, the right arises from the anterior aortic sinus and the left from the left posterior aortic sinus, the right posterior aortic sinus is devoid of any orifice hence, known as non-coronary sinus ¹. The Left Coronary artery (LCA) has a wide range of morphological variability with respect to its diameter, length and branching pattern of its main trunk. Normally, the LCA after arising from the left posterior aortic sinus of ascending aorta, it passes between the pulmonary trunk & left auricle, where it divides into two branches: the Left anterior descending branch (LAD) and Left circumflex branches (LCx). In 2% of cases these two branches may arise separately from the

same sinus. Furthermore, the LAD branch gives left diagonal, left conus and septal branches. The circumflex gives atrio-ventricular, sinuatrial nodal, left marginal and posterior interventricular artery and Kugel's artery². Many angiographic studies have been done in the previous literature showing considerable variations in the branching pattern of LCA in different populations & races. But even the angiographic measurements of LCA was found to be less accurate than those seen in post-mortem pathologic studies, due to their under estimation by the effects of rotation angulation and foreshortening³. A correlation between the branching pattern of Left coronary artery and atherosclerosis present in its branches or the presence of a complete left bundle branch block has been noted⁴. Variations of the branching pattern of Left coronary artery has been studied by various previous authors, its branches showing bifurcation, trifurcation, tetrafurcation and pentafurcation has been noted among various populations. With the recent changes in the life style and increased stress among the South Indian population, coronary heart diseases are on the high rise, a number of therapeutic procedures like angiography and coronary by-pass surgeries are being done on day to day basis in every hospital, therefore our study aims at identifying the vascular pattern of Left coronary artery using Silicon casts among the South Indian population. Such a study of the vascular pattern of Coronary arteries using Plastination technique like Luminal Silicon casts has been done for the first time in India.

Materials and Method

A total of 110 adult cadaveric normal human hearts were collected 90 males (82%) and 20 females (18%) with average mean age of 66 years. The hearts were obtained from the mortuary from the department of Forensic medicine of JSSMC & MMCRI, Mysuru, South India for a period of 2 years. There was no history & evidence of cardiovascular diseases. Ethical clearance was granted by the Institutional Ethical Committee of JSSMC.

Dissection method: The arch of aorta was identified and about 15cms above the sinutubular junction it was

incised transversely, the three sinuses were identified, a vertical incision was made along the tubular wall of non-coronary sinus for clear visualization of the coronary ostia.

Silicon cast method: The Silicone gel was used as Plastinate material and was injected using a gun under controlled pressure into the Left Coronary artery ostia; the heart was then put in HCl Solution for the cardiac muscle to get corroded and the cast was removed carefully. The Silicon cast was left to dry and measurements were taken. The diameter and length of the trunk of Left coronary artery was measured using digital Vernier calipers and noted. Variations in the branching pattern like bifurcation, trifurcation, tetrafurcation and pentafurcation of the main trunk of left coronary artery were noted in the Silicon casts.

Statistical analysis was done using SPSS software. Means and standard deviations were done for continuous variables and nominal variables were described in terms of percentages.

Results

The Aortic valves in all 110 specimens were normal and had three cusps.

Mean diameter of the trunk of LCA: The mean diameter of LCA was 3.51mm (range 2 – 5.8mm).

Mean length of the main trunk of LCA: The mean length was 10.04 mm (range 4 – 18.5 mm).

Branching pattern of LCA: Bifurcation was seen in 62.72 % (69/110); Trifurcation in 33.63 % (37/110), Tetrafurcation in 3.63% (4/110), No cases of pentafurcation were seen.

(Refer Table no: 2) (Refer Figures no: 1 & 2)

Small & Long length of main trunk of LCA: The percentage of small trunk length (less than 5mm) was 5.45% and of long trunk length (more than 15mm) was found to be 7.27%.

Discussion

The Coronary artery disease is one of the major causes of death among the urban population of South India. The main trunk of the LCA usually does not give any branches but terminates into a left anterior descending artery (LAD) and a left circumflex artery (LCx). There were no variations with regards to the origin of the LCA from the Aortic sinus in our study. Reig & Petit revealed the average length of the main trunk of LCA to be 10 ± 5.52 mm (range 2 – 23mm)

⁵. Anil Kumar et al reported in his study conducted in 78 cadaveric hearts the mean diameter of trunk of LCA as $4.34\text{mm} \pm 2.01\text{mm}$ and the mean length as $10.2 \pm 3.5\text{mm}$ ⁶. Venkateshwer et al reported among 110 cadaveric hearts of South Indian population the diameter of the trunk of LCA to be 2 – 6mm and the length to be 15 – 25mm ⁷. In our study the mean diameter of the trunk of LCA was found to be $3.51 \pm 0.71\text{mm}$ (range 2 – 5.8mm) and the mean length of the trunk of LCA was $10.04 \pm 3.27\text{mm}$ (range 4 – 18.5mm) (Refer Table no:1). Gazetopoulos et al showed a relationship between the lengths of the main trunk to the degree of atherosclerosis in its branches. He reported that in shorter trunks of LCA, the atherosclerotic lesions appeared early and progressed faster at the higher levels of severity and can cause myocardial infarction more frequently than in the cases of longer length of the trunks ⁴. The length of the trunks is also very important in the positioning of the cannulas during aortic valve surgeries & during myocardial perfusion. Studies conducted by Bhele et al showed that when the length of the common trunk of LCA is less than 5mm then it can be considered as short and if it is more than 15mm then it can be considered as long common trunk ⁸. In our study the percentage of short trunks (less than 5mm) was 5.45% and percentage of long trunks (more than 15mm) was 7.27%. Priti et al reported the mean length of LCA to be $11.42 \pm 4.98\text{mm}$ (range 0.5 – 21.5mm) in 60 cadaveric hearts among North Indian population ⁹. Kalpana et al reported the mean length of the main trunk of LCA to be between 6 – 15mm ¹⁰. Studies by Kulkarni et al revealed the mean length of the trunk to be 7mm (range 5 – 10mm). The LCA was bifurcated in 60% cases, trifurcated in 35% and tetrafurcated in 5% cases ¹¹. Previous studies have shown morphological variability in the branching pattern of LCA. The most common type of branching pattern of LCA reported was bifurcation. In our study also bifurcation type of branching pattern was the commonest followed by trifurcation & tetrafurcation (Refer Table no:3). There was comparatively lower incidence of tetrafurcation in our study (3.63%). The incidence of tetrafurcation in the literature ranges between 2.5 – 11%. The occurrences of pentafurcation of LCA was not well documented. In our study also cases of pentafurcation were not found. Lakshmiprabha et al conducted study on 55 cadaveric hearts by dissection method among South Indian population, the LCA was bifurcating in 54.54%,

trifurcated in 41.82% and tetrafurcated or pentafurcated in only 1.82% cases ¹². Our findings are very similar to the studies conducted by Kulkarni et al ¹¹, in our present study the LCA was bifurcated in 62.72 %, trifurcated in 33.63 % and tetrafurcated in only 3.63 %, no cases of Pentafurcation was found (Refer Table no: 2 & 3) (Refer Figure no: 1 & 2). The LCA is the major source of blood supply to the heart. Kalbfleisch & Hort conducted study on the regions irrigated by the Coronary arteries using postmortem angiography which showed that 68.8% of cardiac muscle mass is irrigated by LCA and 79% of the left ventricular muscle mass. Therefore, any obstruction in the LCA & its branches reduces blood flow to the ventricular myocardium leading to atherosclerotic disease; this has more serious complications than those of the Right Coronary artery ¹³.

Conclusion

Due to high rise in the cases of Coronary artery disease in south India it's very important to know the branching pattern of Left Coronary artery for early diagnosis & treatment. Therapeutic procedures like angiography & by-pass surgeries requires sound anatomical knowledge with respect to the branching pattern of the coronary arteries, this can diminish many technical complications during catheterization and prevent false interpretations of the angiograms of coronary arteries by the radiologists and cardiac surgeons. In the present study exploring the coronary arterial pattern with the use of Silicon casts is first of its kind in India. Such an innovative method can be used to study the arterial pattern of various other viscera and can be useful for future studies by the researchers.

Post-Menopausal Sex Hormones in Relation to Type 2 Diabetes Mellitus

Priya Alva¹, Shilpa Shetty², Aditi Bhandary³, Laxmi Manjeera⁴, Neetha Nandan⁵, Suchetha Kumari⁶

¹ Msc, Research Scholar, ²Phd, Research Assistant, ³Assistant Professor, Department of Medicine, ⁴Head of the Department of Obstetrics and Gynaecology, Neetha Nandan⁵, M.D, Associate Professor, Department of Obstetrics and Gynaecology, ⁶Professor, Department of Bio-Chemistry, Nitte Deemed to be University

Abstract

Sex Hormone binding globulin is a glyco protein that transports the sex steroids to their target tissue. The concentration of free steroids in the circulation depends upon the availability of serum SHBG. Low SHBG is associated with hyperinsulinemia, T2DM, and cardiovascular risk. **Objective:** The objective of the study was to determine the correlation of SHBG with hormone levels, insulin and BMI in post- menopausal women with type 2 diabetes mellitus (T2DM). **Research Design and methods:** One hundred and five postmenopausal women with diabetes and eighty five postmenopausal women without diabetes were recruited for the study. Height, weight, BMI, was measured. Insulin, SHBG and sex steroids were measured by enzyme linked immunosorbent assay (ELISA). **Results:** The mean concentration of SHBG was higher in control group 25.21 (16.1- 43.7), than the diabetic postmenopausal women 20.65 (12.54-33.46) $p < 0.05$. A significant inverse association was observed between insulin resistance, free testosterone and BMI. **Conclusion:** In postmenopausal women with type 2 diabetes mellitus low levels of SHBG is observed which shows an inverse correlation with insulin resistance, free testosterone and DHEA leading to hyperandrogenicity and hyperinsulinemia .

Key words: SHBG, Estradiol, Testosterone, DHEA, Post- Menopausal women, Diabetes Mellitus.

Introduction

Women experience abrupt hormonal changes, mainly the reduction in the level of endogenous Estrodiol and relative excess of androgen during menopausal transition. These hormonal changes increase the prevalence of metabolic syndrome in post-menopausal women when compared with a woman of fertile age ¹⁻³. Insulin resistance characterised by abnormal glucose, obesity and dyslipidaemia ⁴⁻⁷ marks the origin of metabolic syndrome ⁴⁻⁷. Sex Hormones and their transport protein known as Sex Hormone Binding Globulin possess a major role in the pathophysiology of T2DM ⁸.

SHBG is a carrier protein for sex steroids mainly estrogen and testosterone regulating its bioavailability in the circulation. Reduced level of SHBG and its relation with T2DM and metabolic syndrome have been demonstrated by some of the epidemiological studies ^{9, 10}. However, studies on the role about the sex hormones in postmenopausal women with T2DM is limited. Therefore the current study aimed to correlate SHBG with sex hormones in post- menopausal population with T2DM. We hypothesized that reduced SHBG may contribute to the pathogenesis of T2DM in postmenopausal women in relation to sex hormones by modulating the sex steroids.

Methodology

This case control study was performed on 105 postmenopausal women with previous history of diabetes aged 45-65 years, recruited from the outpatient department of K.S.Hegde Charitable Hospital,

Mangalore. 85 healthy non –diabetic postmenopausal women served as control .Subjects with thyroid disorder, liver and renal disease were excluded from the study.

The study protocol was approved by the Central Ethics of Nitte Deemed to be university. Informed consent was obtained from all the recruited subjects after explaining the nature and purpose of the study.

Anthropometric Measurement: Body height and weight were measured. BMI was calculated as weight in kilograms (kg) divided by height in meters squared (m²)

Biochemical Analysis: Fasting venous blood were collected from each subject after 12 hours fast using plain tubes which was then centrifuged for serum. The separated serum from each sample was divided into two separate tubes. Serum was stored at -20 centigrade for the analysis of testosterone, estrodiol, SHBG, DHEA and insulin. Glucose and lipid profile were analysed immediately after sample collection.

Plasma blood sugar, triglyceride(TG) and HDL-CHO were measured by Semi automated biochemistry analyser(Star 2 plus). SHBG, insulin and sex-hormones was analysed by ELISA (Diamitra,Italy).

Insulin resistance were calculated using homeostasis model assessment (HOMA-IR). Free testosterone was calculated from serum total testosterone and SHBG using an online calculator.

Statistical analysis: All the analysis were performed using SPSS version 12. For a Normally distributed data, descriptive statistics were used and reported as Mean + Standard deviation. Otherwise the reports are expressed as Median (25th, 75th) percentile. Association of SHBG with insulin and other metabolic variables were assessed with Spearman’s correlation.

P-value < 0.05 was considered statistically significance.

Results

Descriptive Characteristic

Table 1 presents descriptive statistics between the case and control subjects. Among the postmenopausal women, diabetic (case)group had significantly higher fasting blood sugar, insulin, BMI when compared with a control subjects. Cholestrol, Triglycerides, LDL-C was increased and HDL-C was decreased in postmenopausal diabetic women.

Table 1:Baseline characteristics of the post-menopausal women with and without diabetes

	Case (n=105)	Control(n=85)	p - Value
Age (years)	59 (54,3)	54 (51,57)	<0.001
Weight (Kg)	59.9 +12.5	56.0 + 10.4	<0.001
BMI (wt in kg/ ht in m2)	26.32 + 5.21	24.1 + 3.93	<0.001
FPG (mg/dl)	142(122,175)	99 (89,106)	<0.001
Insulin	21.4(3.02, 30.9)	3.74(1.77, 7.70)	<0.001
Homa ir	7.67(0.83, 14.3)	1.0 (0.42, 1.80)	<0.001
Cholestrol	159 (138,189)	148 (123, 174)	
Triglyceride	125 (95,162)	118 (94, 150)	
HDL -C	43 (36,51)	51 (42 , 58)	
LDL-C	93(72,145)	74 (54, 95)	
VLDL-C	26 (20 , 32)	23 (18 ,31)	

Results are presented as mean + SD for data that were normally distributed median[2th,75th percentile] for non-normally distributed data. BMI,body mass index;FPG fasting plasma glucose; Homa-IR, homeostasis model assessment for insulin resistance.

SHBG and Sex steroids

The steroid hormone and SHBG data are listed in Table 2. SHBG concentration differed markedly between the groups, with significantly lower levels (median 20.65 nmol/L) in diabetic postmenopausal

women than healthy (25.21 nmol/L) control women. (Table 2). Total testosterone and free testosterone were higher in case group but it was not significantly different. Dehydroepiandrosterone (DHEA) was significantly raised in case subjects (1.50 ng/ml) when compared with control post-menopausal women.

Table 2: SHBG and Hormone levels between the groups

Hormones	Case	Control	p-value
SHBG(nmol/l)	20.65 (12.54, 33.46)	25.21 (16.1, 43.7)	<0.05
Testosterone (nmol/l)	1.11 (0.45, 1.62)	0.90 (0.47, 1.61)	NS
Estradiol(nmol/l)	0.276 (0.08, 0.35)	0.29 (0.17, 0.39)	NS
DHEA (ng/ml)	1.50 (0.45, 1.60)	1.09 (1.03, 1.95)	<0.01
Free Testosterone	0.0245 (0.011, 0.03)	0.016 (0.15, 0.67)	NS

SHBG, sex hormone binding globulin; DHEA, Dehydroepiandrosterone.

Correlation between SHBG and the hormones

SHBG was significantly inversely correlated with fasting blood glucose, body mass index, insulin resistance, free testosterone and DHEA among women with Type 2 Diabetes (Table 3). No association was observed in healthy control postmenopausal women (data not shown). SHBG was positively correlated with testosterone and estradiol which was not significant.

Table 3: Correlation between SHBG with Blood glucose, Insulin, Homa-IR and Sex Steroids in postmenopausal diabetic women.

	Spearman Correlation	p-value
FBG	-0.297	0.002
BMI	-0.26	0.006
HOMA-IR	-0.223	0.04
Testosterone	0.051	NS
Free Testosterone	-0.320	0.001
Estradiol	0.103	NS
DHEA	-0.291	0.03
Cholesterol	-0.154	NS
Triglyceride	-0.166	NS
HDL-C	0.040	NS
LDL-C	-0.173	NS

Discussion

We evaluated the association of SHBG with sex steroids in diabetic postmenopausal women and their healthy control. SHBG relates inversely to BMI and insulin resistance in diabetic postmenopausal women. It is in consistence with a previous data that low circulating SHBG is associated with abdominal fat^{11,12,13} along with hyperinsulinemia, glucose intolerance with a risk of type 2 diabetes and cardiovascular diseases in postmenopausal women^{14,15,16,17}. Moreover the accumulation of adipose tissue coincide with the onset of menopause may also explain partly the increased risk.¹⁸

In women before or after menopause, androgenic profile shows to be associated with abdominal obesity with the rise in free testosterone level and reduced concentration of circulating SHBG¹⁹.

Moreover it was found that free testosterone is strongly associated with hyperinsulinemia and hyperglycemia in post-menopausal women with metabolic syndrome. In our study we did find higher level of free testosterone in diabetic group of women but it was not strongly significant. Further we did observe a strong negative correlation with SHBG and free testosterone in diabetic women.

In recent years several clinical studies have proved the inhibitory effect of hyperinsulinemia on SHBG production from the liver. SHBG is known as transport protein for sex steroids, its reduced concentration increases the bioavailability of free steroids. Thus free testosterone available in the circulation alters the glucose homeostasis among the diabetic subjects. Thus supporting the androgen function in the metabolism of glucose Numerous studies reported the mechanism by which androgen and insulin resistance may be connected. Abdominal obesity may itself lead to hyperandrogenism by converting adrenal androstenedione to testosterone via 17- β -hydroxysteroid oxidoreductase in abdominal adipose tissue which preferably results in hyperinsulinemia²⁰.

Drastically low SHBG concentration in women was found to be associated with adverse blood lipid profile^{21, 22}. In our study, SHBG was positively correlated with HDL-C. Several previous studies suggest the influence of SHBG on HDL metabolism. This effect possibly

may be due to estradiol – testosterone imbalance or the relationship between hyperinsulinemia and SHBG, where insulin may be the regulatory factor for both SHBG and HDL. Insulin acts as an inhibitory factor for the production of SHBG by human hepatoma cells [HEP G2]²³. Further activity of hepatic lipase synthesized by hepatocyte increases which has a major role in HDL-C metabolism causing the Apo B conversion containing lipo-protein into minor LDL, and thus the depletion of HDL cholesterol levels²⁴.

An increased concentration of dehydroepiandrosterone (DHEA) is observed in diabetic women when compared with control subjects and we did found a strong negative correlation with SHBG among diabetic women. DHEA has been associated with impaired fasting glucose in a crosssectionally studied data²⁵. After menopause adrenal glands constantly produces the precursors steroids like DHEA and androstenedione in a huge amount there by altering the androgen estrogen ratio^{31,32}. This explains that DHEA may be converted to higher concentration of testosterone which again alters the glucose levels in diabetic women.

Estrodiol is considered to be an amplifier of SHBG. Its concentration supresses after menopause. In this study Estrodiol level were positively correlated with SHBG . This relation was in accordance with a previous study which support that Estrodiol is an important determinant of SHBG concentration in blood in post-menopausal women²⁶. In women the relationship between estrogen and insulin resistance is U-shaped where increased and reduced levels are associated with insulin resistance and diabetes.

In conclusion this study indicates that 1) there is a significant difference in the blood concentration of SHBG in diabetic women when compared with healthy control subjects 2) SHBG levels are correlated positively with Estrodiol and negatively with BMI, Insulin resistance, Free testosterone leading to hyperinsulinemia and hyperandrogenecity. Thus understanding the association between SHBG-sex steroids-Diabetes will contribute to know the actual mechanism and thus the prevention of T2DM in postmenopausal women at risk

Effectiveness of Foam Texture Versus Sand Texture on Balance with Diabetic Polyneuropathy Patients: A Comparative Study

Priyanka Parmar¹, Shweta Rakholiya²

¹MPT Neuromuscular Science, ²Assistant Professor, School of Physiotherapy, RK University, Rajkot

Abstract

Background: Diabetic polyneuropathy (DPN) is a chronic, symmetric, length-dependent sensorimotor polyneuropathy, people with peripheral neuropathy caused by diabetes often experience balance disorder. Foam texture and sand texture improve balance by providing increased stimulation of sensory receptors of the plantar surface of the foot. **Aim:** To find out the effect of foam texture versus sand texture on balance with diabetic polyneuropathy.

Method: a total of 30 subjects age 35 to 70 years (male and female) having diabetic polyneuropathy were included in the study on the basis of selection criteria. Patients have been divided into 2 groups. Group A received balance and conventional exercise on foam texture and group B received balance and conventional exercise on sand texture (30 minutes, 5 times /week, 6 weeks) Outcome measures have been taken on day 1 and after 6 weeks. the data was analyzed using. SPSS 21.

Conclusion: This study concluded that balance exercise on foam texture shows significant improvement in balance in diabetic polyneuropathy patients.

Keywords: Diabetic polyneuropathy, foam texture, sand texture.

Introduction

Diabetic polyneuropathy (DPN) is A chronic, symmetric, length-dependent sensorimotor polyneuropathy and is present in up to 50% of patients with both diabetes type 1 and type 2. ⁷ This pattern of disease onset might suggest that sensory neuronal cell bodies in dorsal root ganglia (DRG) are targeted.² Patients with DPN develop gradual and insidious damage to the distal terminals of sensory neurons first, with symptoms of tingling, pain or loss of sensation in their toes.²

The WHO estimated that 422 million people worldwide were living with diabetes in 2014. The lifetime prevalence of approximately: 50 % ². Patients have lack of accurate proprioceptive information from

the lower extremities in DPN patient has resulted in postural instability during different static and dynamic situations, therefore, they are at A high risk for falling.^{5,6} People with peripheral neuropathy caused by diabetes often experience balance disorder. ⁶

Sensory impairments of the limbs may lead to the balance problem.⁴ due to balance impairment patients have complained of fear of falling.⁶ Foam texture and sand texture significantly improve the postural stability due to providing increased stimulation of sensory receptors of the plantar surface of the foot. ^{1,4} And this textures enhanced somatosensory feedback. ^{1,4}

Method

- **Type of Study:** Comparative Study
- **Time/ Duration of Study:** 6 Months
- **Place of Study:** Various Hospitals in Rajkot
- **Sample Size:** 30

Selection Criteria:

Informed in Detail the Whole Procedure of Study to The Patients and Consent Taken prior to the procedure. 30 Subjects Divided into 2 groups. Balance assessed by the time up and go test and modified fall efficacy scale. Group A included 15 participants underwent the balance exercises on foam texture for 20 minutes and conventional exercise for 10 minutes while group B included 15 participants underwent the balance exercises on sand texture 20 minutes and conventional exercise for 10 minutes.

Inclusion Criteria:

- 35 To 70 Year Age, Male and Female Both
- Type1 and 2 Diabetic Mellitus Who Had the Ability to Stand On Both Feet and On One Leg
- Medically Diagnosed with Diabetic Polyneuropathy.

Exclusion Criteria:

- Diabetic Ulcers in Either Foot
- Lack of Blood Sugar Control
- Internal Ear Infections
- Other Nervous System Impairments (Except Neuropathy) Or Other Diseases Affecting Balance,
- Musculoskeletal Problems Such as Vertebral Column and Limb Deformity,
- History of Repeated Ankle Sprains in The Year Before, Severe Pain Influencing Balance
- Lower Limb Fractures

TUG and MFES assessed the first day and after 6 weeks

RESULT:

DATA ANALYSIS:

Descriptive statistics were used to describe sample characteristics. The significant level selected was 0.05.

STATISTICAL ANALYSIS

SPSS version 21 for windows was used for the statistical analysis.

There are two outcome measures.

1. time up and go test paired t-test – intragroup analysis and independent t-test – intergroup analysis
2. modified fall efficacy scale The Wilcoxon Signed Rank Test - Intragroup analysis and Mann-Whitney U Test - Intergroup analysis.

Procedure

The trail was registered in the clinical trial registry (CTRI /2019/09/028007) and ethical clearance was taken from the ethical committee, school of physiotherapy,

TABLE 1: GROUP A (FOAM TEXTURE) INTRA GROUP ANALYSIS

Outcome Measure		Mean	Standard Deviation	Value	P- Value
TUG	PRE	17.801	2.916	T=6.977	0.000
	POST	14.546	2.554		
MFES	PRE	5.466	1.407	Z=-3.439	0.001
	POST	8.066	1.032		

Intragroup analysis of group A in Table 1 suggests that there is a significant difference in both measurement (TUG AND MFES) after 6 weeks of Balance exercises on foam texture.

TABLE 2: GROUP B (SAND TEXTURE) INTRA GROUP ANALYSIS

Outcome Measure		Mean	Standard Deviation	Value	P-Value
TUG	PRE	17.746	2.531	T=10.583	0.000
	POST	15.969	2.503		
MFES	PRE	6.066	1.099	Z=-3.626	0.000
	POST	7.266	1.032		

Intragroup analysis of group B in Table 2 suggests that there is a significant difference in both measurement (TUG and MFES) after 6 weeks of Balance exercises on sand texture.

TABLE 3 INTERGROUP ANALYSIS

Outcome Measure	Mean		Standard Deviation	Value	P Value
	A-POST FOAM	B-POST SAND			
TUG	14.546	15.969	1.806	T=2.715	0.01
MFES	8.066	7.266	1.093	Z=-1.976	0.04

Intergroup analysis is suggesting that group A showed significant improvement than group B. There is a more significant improvement in balance in patients with diabetic polyneuropathy.

Discussion

The purpose of the study was to compare the effectiveness of balance exercise on foam texture Vs balance exercise on sand texture on balance in diabetic polyneuropathy patients. In the study TUG and MFES were taken to analyze the balance and confidence level while performing ADL. The results show improvement in the balance in both groups. but balance exercise on foam texture was more significantly improved Than sand texture. So the null hypothesis is rejected. Balance training is known to be very effective in the rehabilitation of diabetic polyneuropathy when incorporate with sensory input are challenging and progressively induce the patient to use lower limb somatosensory inputs to maintain balance. Both group's post-training showed improvement in balance. Training on the foam texture shows that more displacement in the body center of mass than sand texture. The information got from vestibular,

visual and proprioceptive and mechanoreceptors in the muscles and joints afferents processed by the central nervous system with motor command^{3,4,6}

The current study showed that there was a significant difference between group scores of TUG and MFES. Sensory input integration is very important for maintaining equilibrium during walking and found improves postural adjustment mechanism, which directly influences on balance. And there was an improvement in independence in mobility, and fairly good static balance and low risk of fall. Foam texture is effective on balance and this article support it:

Akkradate Siriphorn reported that balance training performed on a foam texture significantly improved postural stability in Healthy Young Adults. **Hatton** al suggested that Standing on textured surfaces to develop the therapeutic benefits of textured surfaces as an intervention to improve the balance in healthy older

adults. **Anna Lucy** Concluded that The effect of textured surfaces had a significant influence on postural stability and lower limb muscle activity. **Hj Shin** reported that Therapeutic Effects on sea sand effectively improved balance and decrease pain and fatigue. **Marialuisa Gandolfi** reported for the first time that exercise performed in different sensory contexts may significantly improve dynamic balance in multiple sclerosis patients. The mechanism behind the effectiveness of foam texture balance exercise is proprioceptive information from the lower extremities in DPN patients has resulted in postural instability during different static and dynamic situations. Foam texture improves balance by providing increased stimulation of sensory receptors of the plantar surface of the foot when the loss of balance was imminent and it enhanced somatosensory feedback. And it became challenging than sand texture. A limitation of the study that the Patients were not fitting properly in inclusion-exclusion criteria. Due to the lengthy procedure of the rehabilitation process, Patients were not following the six-week protocol continuously. To make sure that patients performing the exercise properly Supervision needed to be done while treating patients.

Conclusion

Balance exercise on foam texture and sand texture shows significant improvement on balance in diabetic polyneuropathy patient but there is a more significant improvement in foam texture so this study concluded that foam texture effective than sand texture on balance in diabetic polyneuropathy patients.

Knowledge, Compliance and Determinants of Use of Standard Precautions for Infection Control among Health Care Workers – A Teaching Hospital Based Study

Priyanka Sharma¹, Pooja Goyal¹, Raina Chawla³, Rashmi Ahuja¹, Manisha Meena¹, Annu Sharma⁴, Shobhit Srivastava⁵

¹Assistant Professor, Department of Obst & Gyne, ²Associate Professor, Department of Community Medicine, ³Associate Professor, Department of Obst & Gyne, ⁴Specialist Gynecologist, ⁵Final MBBS Student, ESIC Medical College & Hospital, Faridabad, Haryana, India

Abstract

Introduction: Standard Precautions, which are easily implementable and universally acceptable interventions, can help reduce the transmission of infections in the health care setting. However, knowledge and compliance with regard to Standard Precautions remains unsatisfactory.

Materials and Method: This cross sectional study was conducted on 200 health care workers (HCWs) at ESIC Medical College & Hospital, Faridabad. A self-administered structured questionnaire with specific subsections to assess knowledge, attitude and practice of Standard Precautions was used for data collection. Regression analysis was used to analyze the relation between knowledge, attitude and compliance. Chi Square test was used to determine relation between various determinants and the knowledge and practice of Standard Precautions.

Results: Mean knowledge, attitude and compliance scores among HCWs were 11.47 ± 4.16 , 7.09 ± 1.46 and 10.72 ± 2.57 respectively. A moderately positive correlation was observed between knowledge and attitude scores ($r=0.421$, $p<0.001$). Mean knowledge scores were higher for females, higher professional posts, those with previous Hepatitis B immunization and those with history of recent occupational exposure. Compliance scores were higher for females, for those with more professional post and in those with history of recent needle stick injury. A significantly greater number of females ($p=0.02$), trained HCWs ($p=0.003$), doctors & nurses ($p=0.003$), Hepatitis B immunised personnel ($p=0.003$) and those with history of recent occupational exposure ($p<0.001$) within the past 1 year had satisfactory knowledge scores. Similarly, significantly more number of female HCWs ($p=0.004$), nurses ($p=0.001$), experienced HCWs ($p=0.01$), and those with history of recent needle prick injury ($p=0.04$) achieved satisfactory compliance scores.

Conclusion: The knowledge and compliance of Standard Precautions is generally poor. Pre- induction and periodic in- house training in Standard Precautions should be mandatory for all health care workers along with compulsory Hepatitis B immunization to reduce the risk of occupational exposure in the health care setting.

Introduction

Standard Precautions are a set of easily implementable infection prevention interventions based on the principle that all blood and body fluids are potential sources of infection regardless of diagnosis, presumed infectious

status or health care setting.¹ These broadly include hand hygiene, use of personal protective equipment, safe handling of sharps and provision of a protective environment.² The prevalence of health care associated infections is 7.6% in the developed and 10.1% in the developing world.³ 40% of Hepatitis B and C infections and 2.5% of all HIV infections in health care workers (HCWs) are occupationally acquired. 90% of these occur in developing countries.⁴ The reasons for low adherence to Standard Precautions include limited knowledge, lack of appropriate facilities and staffing, non-availability of funds and high patient load. Awareness and compliance were significantly associated with training in Standard Precautions.⁵ Reasons for poor adherence to Standard Precautions include work stress, time constraint, lack of supply of personal protective equipment, lack of display of guidelines and emergency situations.⁶ Assessment of the prevailing knowledge, notions and practice of Standard Precautions is thus mandatory to identify knowledge deficits and plan effective interventions specifically tailored to local needs for effective infection control.

Objectives

1. To assess the knowledge, attitude and compliance of Standard Precautions among HCWs
2. To identify determinants of knowledge and practice of Standard Precautions in HCWs

Methodology

Study setting and participants

A cross sectional study was conducted in August 2018 on HCWs working at ESIC Medical College, Faridabad to assess the knowledge, attitude and practices and identify determinants which influence the knowledge of and compliance to infection control. A sample size of 197 was calculated with 95% confidence interval and 5% margin of error. This was rounded up to 200 HCWs. Ethical approval was taken from the Institutional Ethics Committee. Participants were selected by simple random sampling from an institutional list of health care workers. All doctors, nursing staff, laboratory/OT technicians and nursing orderlies/porters and house-keeping staff employed full-time in the hospital were eligible to participate in the study. Those who refused to participate were excluded.

Study Tool

Data was collected through a self-administered questionnaire based on CDC¹, NHS⁷ and WHO⁸ guidelines for Standard Precautions. The structured questionnaire comprised of 4 main sections- one each on demographic data, knowledge, attitude and compliance related questions. The questionnaire was tested for content validity by experts in Standard Precautions and for internal consistency (Cronbach's alpha = 0.72). After informed consent, the questionnaire was administered to participants. For those with language-related difficulties, translation was provided. The demographic details in Part I included data on age, gender, professional post held, marital status, prior training in Standard Precautions, total job experience, history of immunisation against Hepatitis B and needle prick injury. In Part II, 10 multiple choice questions tested knowledge of Standard Precautions. One point was awarded to each correct answer. No points were awarded for incorrect answers. In order to reduce guessing and chance selection of an option, questions were designed so that a question could have multiple correct answers. The knowledge score ranged from 0-20. Part III comprised of 10 questions that tested attitude towards Standard Precautions use. A correct response was given 1 point and an incorrect response was given no points. Attitude score ranged from 0 to 10. Part IV comprised of 15 multiple choice questions testing compliance to Standard Precautions. Correct response was awarded one point and no points were given for incorrect response. Score ranged from 0 to 15.

Statistical Analysis

For any HCW, knowledge, attitude or compliance score of $\geq 70\%$ was considered satisfactory and $< 70\%$ was considered unsatisfactory. Data was checked for completeness and consistency and was statistically analysed using SPSS 17.0 software. Frequencies and percentages of demographic variables, and average scores with Standard Deviation (SD) for knowledge, attitude and compliance of Standard Precautions were obtained. The knowledge, attitude and compliance among HCWs was evaluated vis-a-vis demographic variables, h/o training in Standard Precautions, immunization and h/o needle prick injury. Chi Square test was used to measure association between the categorical variables and $p \leq$

0.05 was considered significant. Regression analysis was used to investigate the association between knowledge, attitude and practice of Standard Precautions.

Results

The baseline characteristics of the study population are detailed in Table 1. Only 68.5 % had received complete Hepatitis B immunization. Of these, 33 (52.4%) HCWs were occupationally exposed in the past 1 year. Only 56.5 % of the HCWs had received prior training in Standard Precautions. Amongst the exposed, majority (56.3%) were untrained in Standard Precautions ($p=0.001$).

Only 28%, 36% and 54.5 % of the HCWs attained satisfactory knowledge, attitude and compliance scores respectively. (Figure 1)

The mean knowledge, attitude and compliance scores among HCWs were 11.47 ± 4.16 , 7.09 ± 1.46 and 10.72 ± 2.57 respectively. A significant moderate positive correlation was observed between mean knowledge and attitude scores ($r=0.421$, $p<0.001$).

Females had significantly higher mean knowledge scores ($p=0.01$). Mean knowledge scores were also significantly higher ($p=0.006$) for higher professional posts held. Also, mean knowledge scores were significantly higher in HCWs who had received prior Hepatitis B immunization ($p=0.024$). Similarly, scores were significantly higher in those with occupational exposure in the preceding year ($p=0.003$). No significant difference in scores was seen with respect to age, marital status, years of experience and prior training in use of Standard Precautions.

Mean compliance scores were significantly higher for females ($p=0.001$). They also increased significantly with higher professional post ($p<0.001$). Mean scores were higher in those who received a needle prick in the preceding year. ($p=0.003$)

Mean attitude scores were significantly higher for older ($p<0.001$) and married HCWs ($p=0.012$). Mean attitude score was also better in those who had received prior training in use of Standard Precautions ($p=0.001$) and in those who had sustained needle prick/ sharps injury in the previous 1 year ($p=0.004$).

Further, after grouping HCWs as per satisfactory and unsatisfactory knowledge, attitude and compliance scores, determinants of good performance under each of these categories were then analysed.

A significantly greater number of female HCWs ($p=0.02$), trained HCWs ($p=0.003$), doctors & nurses ($p=0.003$), Hepatitis B immunised personnel ($p=0.003$) and those with history of recent occupational exposure ($p<0.001$) within the past 1 year had satisfactory knowledge scores. (Figure 2) Similarly, significantly more number of female HCWs ($p=0.004$), nurses ($p=0.001$), experienced HCWs ($p=0.01$), and those with history of recent needle prick injury ($p=0.04$) achieved satisfactory compliance scores. (Figure 3)

Table 2 demonstrates data regarding compliance to certain key components of Standard Precautions in our subjects and compares it with data from other authors.^{6,9,10,11,12}

Figure 1. Distribution of HCWs vis-à-vis Satisfactory and Unsatisfactory Scores

Figure 2. Determinants of “Satisfactory” Knowledge of Standard Precautions amongst HCWs

Figure 3. Determinants of “Satisfactory” Compliance to Standard Precautions amongst HCWs

Discussion

Mean per cent knowledge, attitude and compliance scores (in per cent) were 57.3%, 70.9%, 71.46%. Knowledge of Standard Precautions in HCWs was found to be very unsatisfactory. Attitude and compliance scores were satisfactory. The discrepancy in knowledge and practice, and the observed upward trend in scores from knowledge to attitude to compliance could be result with a social desirability bias amongst the participants. The actual compliance is likely to be lower amongst HCWs. A similar discrepancy in mean knowledge and practice scores is detailed in another study.⁵ In a study conducted on Iranian subjects, the mean knowledge, attitude and practice scores were 83.5%, 72.4% and 73.4% respectively. Only 45% HCWs were found to possess 'Good' knowledge. Despite a high mean compliance score in HCWs, only 45.5% were able to attain a compliance score of >70%.¹³

A moderately positive correlation was observed between knowledge and attitude scores but not among other parameters. Mean knowledge scores were higher for females, higher professional posts, those with previous Hepatitis B immunization and those with history of recent occupational exposure. Compliance scores were higher for female HCWs, for those with higher professional posts and those with history of recent needle prick injury. In the previously quoted Iranian study, knowledge scores were higher in married HCWs (40.28 v/s 36.17, $p=0.01$). Practice scores were similarly higher in married HCWs (35.15 v/s 32.00, $p=0.002$) and in trained professionals (35.45 v/s 31.81, $p=0.01$).¹³ Other researchers have noted that the odds of having adequate knowledge of as well as compliance to Standard Precautions were significantly greater in older HCWs, in those with more years of service and higher professional post held. Also, increasing age and history of Hepatitis B immunization improved odds of good knowledge but did not significantly affect compliance.⁹

We observed that use of gloves, hand hygiene and personal protective equipment has achieved acceptable, but not ideal levels. With respect to sharp handling and disposal, we lag behind other comparable studies.^{6,9,10,11,12} (Table 3)

Amongst our subjects, 32.5 % reported a needle stick/sharps injury in the preceding year. This is lower

than studies in other teaching hospitals where incidence ranges from 47%- 53%.^{5,14,15,16}

68.5% of HCWs were immunized against Hepatitis B. Of the 63 non immunized individuals, 42.7% had sustained a needle prick injury in the past 1 year alone. This suggests that there is a need to specifically target younger HCWs, newer recruits and those at lower professional rungs by quality induction and periodic in- house training and orientation of HCWs. Similarly, Hepatitis B immunization could be made mandatory before induction to duty and active 'mop-up' immunization drives could target non immune in- house candidates.

It was noted that training in Standard Precautions had significantly improved attitude towards use of Standard Precautions. However, there was no appreciable difference in knowledge or compliance amongst trained and untrained HCWs which indicates a need for improvement in the quality and content of training.

We encountered a participation bias and over representation of doctors in the sample due to reluctance in other HCWs to participate. Also, the observed disproportion between knowledge and compliance scores (social desirability bias) could be avoided by introducing an OSCE or clinical observation component in future studies.

Conclusion

The knowledge and compliance of Standard Precautions is generally poor amongst a majority of health care workers. The factors responsible for poor knowledge and compliance include male sex, younger age, less years of service, lower professional post and lack of prior training of Standard Precautions. There is a moderate correlation between knowledge of Standard Precautions and attitude towards compliance. It is concluded that pre- induction and periodic in- house training in Standard Precautions should be mandatory for all health care workers along with compulsory Hepatitis B immunization to reduce the risk of occupational exposure in the health care setting.

Parental Awareness of Musculoskeletal Health Consequences Due to Overweight Bag in Primary School Students

Rachhanaa Satish Pawaskar¹, Snehdeep S Patil²

¹Resident, ²Associate Professor, Department of Community Medicine, D.Y.Patil Medical College, Kolhapur, Maharashtra

Abstract

Background: Musculoskeletal discomfort is high in school going children in Kolhapur. The primary trigger for the discomfort is heavy school bags as identified through previous studies. Despite the Government of Maharashtra's resolution to limit the school bag weight, a significant load reduction is lacking. Here we assessed the awareness and corrective measures regarding the weight of the school bag in parents and school authorities in primary school children.

Materials and Methods: In this Cross sectional, prospective study, five schools, namely—A, B, C, D, E were selected based on feasibility. Two hundred and one consenting parents of students belonging to class 1 (6-7 year) from each school filled out a pre-tested questionnaire to assess their awareness. Statistical analysis of the response was calculated through chi-square test ($P < 0.05$).

Results: Predominant weight carried by school children exceeded 10% of their body weight (mean total weight: 3.891 ± 1.96 kg; gross weight: 3.014 ± 1.63 kg; $n=154$). Prevalence of musculoskeletal discomfort was 52.7%. Style of carrying the school bag significantly influenced development of discomfort ($P=0.002$). School authorities ($n=5$) and parents were aware of the Government resolution ($n=183$). But parents neither considered the weight of the bag at the time of purchase ($n=148$) nor helped their children pack their school bags ($n=137$).

Conclusion: While there is increased awareness in parents and school authorities, there is lack of action. Corrective measures in terms of behavioural attitudes in parents and school authorities is necessary to bring about the expected changes.

Keywords: Musculoskeletal discomfort, school backpacks, parental awareness, load carriage

Introduction

A popular topic of health concern in school going children is growing musculoskeletal discomfort and a high prevalence in Kolhapur has been previously observed in primary and middle school children. ⁽¹⁾ The

predominant cause for discomfort is heavy school bags. ⁽²⁻¹⁰⁾ On an average, school children carry heavy loads for a period of 12 years and prolonged stress on the vulnerable spine is a predisposing factor for adolescent spinal discomfort. ⁽⁹⁾

In order to alleviate the carry load, Government of Maharashtra recommends safe load limit for the school students as less than 10% of their body weight. ⁽¹¹⁾ Despite extensive studies regarding the detrimental effects of excessive schoolbag weight carriage ^(4,12,13) and Government resolutions to tackle the same there persists a lack of awareness and implementation at the grass-root level which is the primary contributor for the high prevalence of musculoskeletal health problems. ⁽¹⁴⁾

Corresponding author:

Hence, the aim of the study was to assess the levels of parental awareness on musculoskeletal discomfort in their children and over-all involvement in the choice and weight of school bag in primary school children of age 6-7. To the best of our knowledge, this is the first report of parental awareness of musculoskeletal discomfort in the age group of 6-7 years.

Materials and Methods

All procedures were followed in accordance and on receiving approval from the Institutional ethical committee and with Helsinki Declaration of 1975, as revised in 2000. Data collection commenced after receiving approval and consent from the respective school authorities and parents. Consent forms were sent with the students. Of the 234 consent forms distributed, 201 were returned.

The cross-sectional study was conducted in 5 schools (A, B, C, D, E) in the city of Kolhapur in August 2015 based on feasibility. The study sample size was extracted from the previous study and was limited to only students in the first grade. Time for data collection spanned over a period of one week and the questionnaires were distributed to the students with an instruction to have it filled by their parents. Post submission of the filled questionnaire and the consent forms, a surprise visit was made to the respective schools. Bags were weighed using a standard weighing scale and recorded as Gross weight and Total weight.¹

All first graders who were day scholars, between the age of 6-7 and whose parents had given consent were included in the study. Children who complained of orthopaedic problems, or having ankle deformities, or leg length discrepancy or wheelchair bound were excluded from the study. The primary tools for assessment were a weighing scale ($\pm 100\text{g}$) for objective testing and pre-tested questionnaire.

The preliminary questionnaire was validated through a pilot study involving 20 primary school students belonging to class 1.⁽¹⁾ Contents of the questionnaire was broadly divided into 2 parts: general information of the students and Body Discomfort chart (BDC) to record the site of discomfort. Given the difference in the medium of teaching, the original English questionnaire was translated to Marathi. Time taken to fill up the

questionnaire was less than 10 minutes.

Data collected were entered in MS Excel and categorical variables were represented as percentage and frequency. Proportion difference between the variables were compared through Chi-square test ($P < 0.05$).

Results

High parent participation at 85.9% was noted as assessed by the return of the filled-out questionnaires. The gender distribution among the school children is presented in Table 1. The mean weight of the students was 18.41 ± 3.87 kg. Average height of the children was 111.70 ± 7.81 cm. None of the students were consuming any growth supplements. The mean weight and gross weight the school bags were noted as 3.891 ± 1.96 kg and 3.014 ± 1.63 kg, respectively. Predominantly, weight of the school bag was greater than 10% of body weight in all schools ($n=154$) except for school D, wherein it was comparable. Prevalence of musculoskeletal health problems, as assessed through BDS, in students of school A, B, C, D and E was 77.1%, 87.1%, 45.8%, 0% and 64.1 %, respectively. Prevalence of musculoskeletal health problems was 52.7% ($n=106$); neck and shoulder region pain or discomfort were the most common.

Style of carrying the school bag had a significant association with the development of musculoskeletal discomfort ($P=0.002$). Children who carried their school bags on one shoulder and low slung were more prone to experiencing musculoskeletal discomfort than the those who carried their bags high slung and, on both shoulders (Table 2).

Mode of travel had a significant association with discomfort. It was observed that unit increase in the gross school bag weight doubled the likelihood of experiencing discomfort (OR 2.268, $P=0.000$). Students who walked to school ($n=23$) were 5 times more likely to experience discomfort than the ones who travelled by car ($n=7$), rickshaw ($n=140$) and bus ($n=13$) (OR 5.545, $P < 0.046$).

Awareness of Government of Maharashtra resolution of school bag weight load

All the schools included in the study were aware of the Government of Maharashtra resolution to alleviate

musculoskeletal health problems in school students. Most of the schools (n=3), reviewed the timetables to mitigate musculoskeletal discomfort in students. Surprisingly, majority of the schools (n=4) did not educate the students on weight and size of the bag. However, to mitigate the school bag load, school C provided lunch and water, and School D provided locker facilities for students. All school authorities reviewed their timetables and promoted daily physical activities in students (Table 3).

Most parents were aware of the GoM resolution of school bag weight (n=183). Of this, only 53 parents took into consideration the self weight of the school bag at the

time of purchase. Majority of the parents did not consider the bag weight (n=148). This significantly contributed to musculoskeletal discomfort ($P < 0.05$). Interestingly, when parents bought a school bag considering the child's choice and weight (n=104), musculoskeletal discomfort was significantly reduced ($P = 6.08e^{-12}$). At the same time, there was a significant association between parents who helped their child pack the bags and musculoskeletal discomfort ($P = 2.2e^{-16}$). These children (n=64) did not complain of musculoskeletal discomfort. It is of great interest that most parents confirmed that their child was experiencing musculoskeletal discomfort (n=99) (Table 4) but did not consider that helping their child pack the school bag.

Discussion

Parent's awareness plays a critical role in avoiding musculoskeletal discomfort in children. Majority of the parents were unaware of the contents of the school bag and such studies have been focused on older children and not on children in the age group of 6-7 years.⁽¹⁵⁾ The gap in understanding on the load carried by younger children between the age of 6-7 y and parental awareness is explained here. Despite high parental awareness on load restriction, the average weight carried exceeded 10% of the total body weight. This implies that apart from awareness, parental involvement is crucial: there is a significant impact on load carriage only when parents participate in packing the bag. Even when parents were aware of the child's discomfort, measures to alleviate the same were not evident. Therefore, parental involvement should not be a one-time event during choosing a bag but, a daily routine where they assist their child pack his/her bag. This could significantly alleviate musculoskeletal discomfort in young children.

Highest and average weight carried by students of age 8-13 years is reported to 7kg and 5kg, respectively.⁽¹⁶⁻¹⁸⁾ Although weight carried was varied, the biomechanical impact of the load was significant in all studies.⁽¹³⁾ This implies that carrying a load over 10% of body weight is the primary trigger for musculoskeletal discomfort despite the weight variation.

Manner of carrying the backpack was identified as an important gap in the previous studies (meta analysis). The significant difference observed here between the styles, reflects the importance of right carriage and is influenced by the duration of load carriage. Style of carrying a school bag influences gait kinetics and double strap backpacks improved gait parameters.⁽¹⁹⁾ Heavy backpacks is identified as a significant cause of injuries and the innocuous initial signs are observed as pressure marks (swelling and redness) over the shoulder and neck region where the straps rest. Neck pain or stiffness and upper back pain are common complaints during the academic year and absent during summer holidays.⁽¹⁶⁾ This is linked to carrying heavy school bags and could progress to muscle fatigue.⁽²⁰⁾ On an average, previous studies have concluded that students carry an average of 15% of their body weight.⁽¹⁴⁾ High prevalence of musculoskeletal discomfort in the schools studied is

alarming and requires immediate attention.

Despite the GoM initiative to reduce backpack weight of school going children, there is lack of implementation of the same as evident from measures taken by 2 schools. Surprisingly, children attending government and Marathi medium schools were carrying a lighter load than those attending private schools as compared to CBSE schools which demand heavy textbooks and notebooks as per the curriculum.¹

While carrying school bags is indispensable, active involvement from the parents and school authorities is the key to alleviate the growing problem of musculoskeletal disorders in the young. In conclusion, although, school authorities and parents were aware of musculoskeletal health problems in primary school students, preventive measures were not enforced entirely. Awareness did not reflect as action, therefore behaviour changes in both parents and teachers is necessary.

Retention of Various Pit and Fissure Sealants in Deciduous Teeth. A Systematic Review

Rachna Mulani¹, Aditi Mathur²

¹BDS (MDS Pediatric and Preventive Dentistry) ²Reader, Department of Pediatric and Preventive Dentistry, Dr.D.Y.Patil Vidyapeeth, Pimpri, Pune, Maharashtra, India

Abstract

Background: Dental caries is one of the most prevailing oral health diseases in children. Most of these dental caries occur in the deep pits and fissures. Pit and fissure sealants have been traditionally used for preventing dental caries. These are the materials which fill the fissures and making it self-cleansable.

Objectives: To assess the retention rate of various pit and fissure sealants used in deciduous teeth

Intervention: Pit and fissure sealants

Results: A preliminary search yielded a total of 153 studies through Google scholar and search strategy used in PubMed. 7 articles giving 11 estimates were included for qualitative synthesis. All materials were light cured. Retention rate of fluoride releasing sealants and ACP sealants were superior to other sealants.

Conclusion: Pit and fissure sealants have a good retention in primary dentition. Sealants are very well accepted and prove to be effective in preventing occlusal caries found in the large number amongst children. Use of sealants in primary dentition will surely prevent the damage to erupting permanent dentition due to developing caries in the former.

Keywords: Pit and fissure sealants, deciduous teeth, retention rate, fluoride releasing pit and fissure sealants

Introduction

Inspite of being a preventable disease and advancement in the caries detection systems, dental caries still continue to be a common childhood disease. The prevalence of ECC differs according to the group, and a prevalence of up to 85% has been reported for disadvantaged groups.¹ Even though it is largely a preventable condition, ECC remains one of the most common childhood diseases.

Pits and fissures are progressively susceptible to dental caries on the grounds that the life systems

favours plaque accumulation; these zones are regularly inaccessible and close for any oral cleanliness measures to be successful. By filling such anomalies with flowable therapeutic material (pit and fissure sealants) the tooth turns out to be less morphologically susceptible.² This is particularly suggested in younger patients with erupting teeth.

Sealants structure mechanical boundaries that seclude the pits, furrows, and deformities in the gnawing (occlusal) surfaces of the teeth from the dental plaque and dietary constituents. They additionally can also fill irregularities developed in smooth surfaces. Though application of pit and fissure sealants require skilled personnel, patient tolerance and is a technique sensitive procedure compared to that of topical fluorides but the potential benefits outweigh the difficulties encountered. The success of pit & fissure sealants, one of the most important tools in preventive dentistry, is directly

Pimpri, Pune- 411018

Maharashtra, India

associated with the material's ability to remain on the tooth surface⁴⁻⁷. Many systematic reviews have been conducted on the effectiveness of pits and fissures on permanent dentition but no pooled evidence of its effectiveness in terms of retention was found regarding primary dentition. Thus this systematic review was initiated with an aim to assess the effectiveness of pit and fissure sealants with respect to retention rate in primary dentition in children.

Materials and Method

Eligibility Criteria

Inclusion and exclusion criteria were fixed and the studies were screened based on the criteria mentioned below:-

Inclusion criteria:

1. Studies done to assess the retention of various pit and fissure sealants in primary dentition.
2. Study designs like randomized controlled trials, clinical trial, prospective clinical studies, and comparative studies done with pit and fissure intervention in one of the group.
3. Studies in English or studies in other languages where translation to English is possible
4. Studies published from the year 1st January 2001 to 31st November 2019.

Exclusion criteria:

1. Studies excluded were reviews, case reports, case series, conference proceedings.
2. Letters to editor, short communications, pre-

clinical and in- vitro studies were also excluded.

PIO from can be referred as:-

1. **Patient Population:** Children with primary dentition
2. **Intervention:** pit and fissure sealants
3. **Outcome:** retention (total loss, partial loss, no loss)

Information Sources

A search strategy was developed using keywords related to pit and fissure sealants in primary dentition. Data was searched through the database, PubMed and Google scholar from 1st January 2001 till 31st November 2019. Cross references were checked for relevant articles, grey literature was also searched on various pit and fissures retention data when applied on deciduous teeth. Hand searching of articles was done when the full texts.

Search

The comprehensive data search was performed in PubMed and Google scholar. While carrying out the search through PubMed the filters were put for the dates of publication as 1st January 2001 till 31st November 2019. The filter on article type was set for comparative study, randomized controlled trial, clinical study, clinical trial, controlled clinical trial and species as humans with best match option for sorting. No language restrictions were put and studies that could no be translated in English were excluded. The keywords for search were decided by reviewing the literature.

The search strategy used in PubMed for searching articles was as follows:

Search strategy

Sr. no.	Search strategy	Articles in hit	Articles selected
1	pit and fissure sealant AND deciduous dentition AND retention	16	11
2	fissure sealants AND primary teeth	20	7
3	dental sealants AND milk teeth	5	1
4	primary teeth AND tooth sealant AND survival	17	5
5	(pit and fissure sealants OR dental sealant OR fissure sealant) AND (deciduous dentition OR primary teeth OR deciduous teeth OR milk teeth) AND (survival OR retention)	48	19
6	glass ionomer sealant AND primary teeth	32	10
7	baby teeth AND tooth sealant AND survival	10	2
8	baby teeth AND tooth sealant AND survival	3	1
9	baby tooth AND pit and fissure sealant AND retention	1	1
10	Others	1	1
	Total	153	58

A total of nine search strategies were formed. Google search was carried out but no search strategy was used for searching articles in Google scholar. Google Scholar yielded only one article which was found to be relevant according to the eligibility criteria.

Results

This systematic review yielded a total of 152 articles through PubMed search strategy and one through Google scholar. After screening 7 articles were selected for analysis. Pit and fissure sealants were intact in all the studies in more than 40% of the treated teeth. The complete retention rate ranged from 43% to the highest of 77%. Partial loss of the sealants was evident in 15.1% to 34.9% of the treated primary teeth while the total loss of sealants was observed in a maximum of 24.4% treated teeth. No complete loss of sealant was found in study conducted by Corona SA et al which used Fluoroshield resin sealant. When it came to assessing the retention there are various standardized criteria present in the literature. Tom and Ryge, color coverage caries sealant evaluation system and ICDAS criteria for retention were used in the include studies. From this systematic review it can be concluded that pit and fissure sealants

are effective in primary teeth and should be considered by the clinician for children with a high caries risk to improve their quality of life.

Discussion

Summary of Evidence

The incidence of caries in the occlusal surfaces of the teeth constitutes more than two-thirds of all caries types.³ Pit & fissure sealant have been used widely for prevention of occlusal caries but there are still no guidelines regarding their use in primary teeth.

Literature reports various studies which have been conducted to assess the retention rate of pit and fissure sealant on permanent dentition. But the retention of sealants in primary dentition still remains a point of debate. This systematic review makes an attempt to report the retention rate of pit and fissure sealant in primary dentition. **Corona SAM et al** conducted a split mouth clinical trial to evaluate the retention rate of a flowable restorative system used as a pit-and-fissure sealant compared with a conventional filled resin sealant Fluoroshield and Flow-It! for a 1-year period. At 6- and 12-month intervals, both materials showed no total loss

for 12 months. Flow-It! Sealants presented a higher retention rate at both 6-month and 1-year evaluations. The authors concluded that the flowable restorative system yielded optimal retention on primary molars. Its retention rate was significantly higher than that of the conventional pit-and-fissure sealant on primary teeth. A retrospective clinical trial conducted by **Ram D et al** to describe the retention rates of a compomer sealant Dyract with non-rinse conditioning placed in three paediatric dentistry practices. 317 sealants were applied in 220 primary molars of 176 children aged 2.5–13 years. Dyract Seal has a lower retention rate than conventional sealants. **Chadwick BL et al** conducted a placebo controlled individual randomised control trial to determine the efficacy of a glass ionomer fissure sealant placed on primary molars in pre-school children at high risk of developing dental caries can decrease the incidence of dental caries. All the children were re-examined once at varying intervals between 12 and 30 months. The overall retention rate in these children for the fissure sealant was 18.7% at a follow-up of 13 months which was quite low. The study concluded that the intervention as used in this population had no effect on caries incidence and it cannot be recommended as a clinical procedure as the retention rate was very low. **Maher MM et al** conducted a randomised split mouth study to assess the retention of pit and fissure sealants in primary teeth after phosphoric acid-etching technique and self adhesive technique. Lower retention rate of 64% and 51% at 12th months versus 82% and 73% at 6 months were found with phosphoric acid etching and self-etch adhesive technique respectively. It was concluded that replacing phosphoric acid-etching with self-etching adhesive Adper Prompt L-Pop does not compromise sealant retention in primary teeth after a 1-year period. **Unal M et al** conducted a split mouth randomised control trial to evaluate the clinical success of three fissure sealants; amorphous calcium phosphate (ACP) containing resin-based sealant Aegis, fluoride-containing resin based sealant Heliobond F, Heliobond Fissure sealants on primary teeth. Follow-up was conducted at 1,3,6,12,18 and 24 after Fissure sealants application. Success rates for retention of sealant material according to 24 months' follow-up were 95.7%, 91.8% and 87.8% for Aegis, Heliobond and Heliobond F respectively. It was concluded that resin based sealants containing ACP or fluoride are more retentive than conventional resin based

sealants. **Honkala S et al** conducted a study to measure the caries preventive effect of sealants applied to occlusal surfaces of primary molars compared to fluoride varnish applications and to assess the retention rate of sealants after 1 year. The follow-up examinations were conducted after 1 year. After 1 year follow up, varnished surfaces were significantly more likely to develop new caries lesions than the sealed ones. 73.0% of the sealants were completely retained and 15.1% partially retained. It was concluded that sealing fissures is better in preventing occlusal caries lesions in primary molars. **Joshi S et al** conducted a split mouth clinical trial to evaluate the clinical performance of high viscosity GIC sealant applied with or without additional light curing in children with early childhood caries. On the basis of the application technique, selected teeth in the study group were further allotted to group A with sealant application with additional light curing and group B with sealant application without additional light curing. It was observed that in Group A that is GIC sealant with additional light curing, the retention rate at 12 months was 44.2% and in Group B that is GIC sealant with no additional light curing it was 43%. It was concluded that retention by high-viscosity GIC sealant applied with or without additional light curing was found to be similar.

Since the review was assessing retention in primary dentition thus the age range in the included articles was from 2.5 years to 13 years. Maximum studies reported had children recruited between the age of 4 to 7 years. The sealant materials used in these studies were all different. Fluorshield resin sealant, Dyract seal light cured self adhesive compomer; glass ionomer sealant, Clinpro light cured sealant and used amorphous calcium phosphate containing resin-based sealant, fluoridated and non-fluoridated sealants. All the sealants used were light cured. All the sealants were placed on either 1st primary molar or 2nd primary molars; maxillary or mandibular. The follow-up period of the studies varied from a minimum of 1 year to a maximum 3 years. Overall follow-up period was short in the included studies. To assess the retention of sealants it is very essential to follow the patients for a long time to have a reliable data for evidence.

Conclusion

Within the limitation of the study it can be concluded

that pit and fissure sealants have a good retention in primary dentition. Sealants are very well accepted and proved materials which prevent the occlusal caries found in the large number amongst children. Thus this can surely be used in primary dentition to prevent caries development in them and also to prevent the damage to erupting permanent dentition due to developing caries in the former. Over all this, it cannot be overlooked that the evidence does not report retention rates from a single retention assessment tool rather there is lack of use of such tools in the literature thus reliability on such evidence should be made with caution.

A Cross Sectional Study to Evaluate Tree Plantation and Gardening as an Intergenerational Bonding Activity amongst Geriatric Population

Rahul Netragaonkar¹, Amrut Arun Swami², Shruti Amrut Swami³

¹Associate Professor, ²Assistant Professor, Dept. of Community Medicine, DVVPPF's Medical College, Ahmednagar, Maharashtra, ³Assistant Professor, Dept. of Rasashastra & Bhaishajya Kalpana, Bidar Vidya Kendra R. Akka Mahadevi Ayurvedic Medical College, Bidar, Karnataka

Abstract

Background: Life expectancy among the elderly has been improving for many decades all over world, the emotional and mental wellbeing of the geriatric people is at stake because of the younger people migrating to the urban areas or even abroad for work, and older people staying alone at their homes.

Few days can be spent by older – younger people together to plant trees. And this intergenerational bonding activity can give a sense of satisfaction and mental wellbeing to the older adults.

Objectives:

1. To find out how older people spend time with younger generations
2. To evaluate if older people are interested in gardening and planting trees as an intergenerational activity.

Methods: We conducted a survey on 120 older people in the community attached to our college, we enquired about the different means by which the older people spend time with the younger generations and if they will be interested in gardening or planting trees together with the younger generations.

Results: There were a total of 120 participants, 60 males and 60 females. Mean age was 68.49 ± 6.83 years. Majority of them interacted with the younger generations daily (55.83%). Chit chatting, managing business and telling stories to children were the common things done together. Majority (70%) felt that they spent enough time with the younger people, while few were not spending time at all with their younger generations (5.83%). 79 participants never planted a single tree (65.83%). 107 participants felt that planting trees is necessary (89.17%) while 104 participants (86.67%) would like to do gardening or planting trees with their younger generations.

Keywords: Intergenerational Activities, Geriatric Mental Health, Tree Plantation

Introduction

Life expectancy among the elderly has been improving for many decades the reason being

advancement of health sector and overall improvement in per capita income of the people all over world,^[1] and there is evidence that the physical health of the elderly has also been improving with these advancement.^[2-4]

The emotional and mental wellbeing of the geriatric people is at stake because of the increasing urbanization, and younger people migrating to the urban areas or even abroad for work, and older people staying alone at their hometowns.

In the global Sustainable Development Goals [5], goal 13 is Climate Action, “take urgent action to combat climate change and its impacts”. It’s a responsibility which is equally shared by the governments and all the people living on the earth. All the efforts how much ever minimal they may be should be counted as minute steps towards environmental betterment.

Planting and growing trees is one of the major responsibilities we have today on us. [6] All people should come together to help build our green zones inside and nearby cities and villages. Older people have much time left with them, younger people have energy. If all these generations spend some time together, then planting and growing trees can be easily done. People can maintain small gardens at home, every home can have a small nursery of its own where they can grow saplings of the common regional trees, even fruit trees like Mango, Papaya, Custard Apple, Guava. Weekends and few days in the vacations can be spent by older – younger people of the house together to plant these trees near to our houses, residential areas or near to cities. Planting trees have a large potential to conserve energy in urban areas. [7]

When the younger people who live in cities come to visit their parents in the villages, if they spend time together in planting these trees, it will be memories to cherish for both the generations. When the children are away, older parents can remember them while taking care of these trees, when the old people are dead, the children can remember them while eating fruits from these trees. And most importantly every tree that is planted and grown will be a one-step ahead on the path of environmental betterment.

We had conducted this study to see what things older people do with the younger generations and weather they will be interested in planting trees.

Literature Review

AL Park et al [8] studied the impact of intergenerational activities on general wellbeing of older adults. They suggested that geriatric people who are involved in intergenerational activities of any form are healthy both physically and mentally as compared to those people who are left to live alone. They concluded that the geriatric people should be involved in daily

activities in home or in society to improve their overall wellbeing.

CN Reisig et al [9] studied the perception of geriatric people of wellbeing after intergenerational experiences with youth, they also concluded that the intergenerational activities are important for geriatric physical and mental health.

Faer M et al [10] conducted a large project on intergenerational activities between the adolescents, young adults and older adults. They reported that not only the older people but also the adolescents and young adults are benefited from these intergenerational activities and they recommended different social and community activities to be planned and executed on a regular basis. Their project brought together different age-distinct, high risk, ethnically similar populations in an intergenerational, reciprocal support mechanism that addressed those negative factors that affect high-risk behaviour and decisional processes in adolescents and physical and mental functioning in the elderly.

Many authors have raised a concern about the mental and physical wellbeing of geriatric people. [11-13] Some of them suggested the importance of intergenerational activities in improving the overall health of the geriatric people. [14 – 17]

Objectives:

2. To find out how older people spend time with younger generations
3. To evaluate if older people are interested in gardening and planting trees as an intergenerational activity.

Methods

We conducted a survey on 120 in the community attached to our parent medical college, where we enquired about the different means by which the older people spend time with the younger generations and if they will be interested in gardening or planting trees together with the younger generations.

Ethical Clearance for the institutional ethics committee has been taken to carry out this study.

Inclusion Criteria:

1. Old age people of both sexes and age more than 60 years
2. Residents of medical college and hospital area for more than 6 months

Exclusion Criteria:

1. Unmarried people
2. Those who are not willing to participate

Sample Size:

According to a study conducted by **GK Ingle et al** ^[18] the proportion of old age people more than 60 years will be 7.7%,

According to a study conducted by **GK Ingle et al** ^[18] the proportion of old age people more than 60 years will be 7.7%,

So, $p = 7.7\%$

Using formula for sample size (n) calculation,

$$n = \frac{4 \times p \times q}{e^2}$$

Where, $p = 7.7\% = 0.077$

$q = 1 - p = 0.923$

Taking e, absolute error of 5%, $e = 0.05$

$$\text{So, } n = \frac{4 \times 0.077 \times 0.923}{0.05 \times 0.05}$$

$$n = 113.71 \approx 114$$

A minimum of 113 patients will be included in the study, rounding it up to 120 patients.

Sample size = n = 120

Sampling Technique: Convenience Sampling

Statistical methods: A simple questionnaire was prepared and a pilot study was conducted with 20 geriatric participants, the questionnaire along with the results were put forth the institutional research cell to validate the questionnaire. The validated questionnaire in google form format was used to collect the data from the geriatric people in the nearby community. Data was entered in Microsoft excel, qualitative data is shown in numbers and percentages and quantitative data in mean

and SD. Charts and graphs are used to show the results.

Results

There were a total of 120 study participants, 60 males and 60 females. Mean age was 68.49 ± 6.83 years.

Majority of them interacted with the younger generations daily (55.83%) followed by 3 to 4 days a week (30%).

Table 1: Frequency of quality time spent with the younger generations

Frequency of quality time spent	Number	%
Daily	67	55.83%
3 to 4 days a week	36	30.00%
1 to 2 days a week	9	7.50%
Once or twice a month or Less	8	6.67%
Total	120	100%

General chit chat (56.67%), managing family business and farms (35%) and telling stories to grandchildren (32.50%), doing Pooja – Bhajans (10%) were the common things done by the participants with their younger generations.

Table 2: Common intergenerational activities done together

Common activities done together	Number	%
General chit chat	68	56.67
Managing family business / Farm	42	35.00
Telling stories to grandchildren	39	32.50
Pooja - Bhajan	12	10.00
Going for a walk	8	6.67
Gardening	4	3.33
Others	9	7.50

Majority (70%) felt that they spent enough time with the younger people, some felt that it was not enough (24.17%) while few were not spending time at all with their younger generations (5.83%).

**Fig 1: Opinion about younger people spending time with older people**

64 participants didn't have their own garden (53.33%), 79 participants never planted a single tree (65.83%). 107 participants felt that planting trees is necessary (89.17%)

Fig 2: Participants response regarding gardening & tree plantation

104 participants (86.67%) would like to do gardening or planting trees with their younger generations, 9 responded that they might do it (7.50%) while rest 7 showed no any interest (5.83%) in doing gardening or planting trees as an intergenerational activity. Upon one month follow up, we found that 16 families (13.33%) actually did the activity.

Fig 3: Choosing gardening and tree plantation as an intergenerational activity

Discussion

Various intergenerational activities have different impact on the people. We may look to attitudinal and behavioural measures for indicators of intergenerational community solidarity. Attitudes of youth towards elders are heterogeneous and may be positively or negatively affected by familial and nonfamilial intergenerational contact. [19, 20]

Y Fujiwara et al [21], in their study launched a new intervention study called REPRINTS in which senior volunteers were engaged in an activity of reading picture books to children. At the follow-up, social network scores (frequency of contact with grandchildren and others around the neighbourhood) and self-rated health was improved for majority of the individuals who did this activity most intensively as compared to those who did not. They concluded that this specific intergenerational activity helped in improving the mental and physical health of the older adults.

AL Park et al [8] studied the impact of intergenerational activities on general wellbeing of older adults. They recommended intergenerational activities for better health of the elderly.

CN Reisig et al [9] studied the perception of geriatric people of wellbeing after intergenerational experiences with youth while **Faer M et al** [10] conducted a large project on intergenerational activities, both of them recommended there should be intergenerational activities to maintain the health and wellbeing of people, both young and old.

We found out that majority of the participants interacted with the younger generations daily (55.83%) followed by 3 to 4 days a week (30%). General chit chat (56.67%), managing family business and farms (35%) and telling stories to grandchildren (32.50%), doing pooja – Bhajans (10%) were the common things done by the participants with their younger generations.

With increased urbanization and globalization, there is a reduced contact and also a marked reduction in the intergenerational bonding activities due to the migration of younger people for jobs in other cities. [22]

Whatever time these older people get to spend with their younger generations, should be spent in memorable

productive activities. What else can be more productive than planting trees together? The older generations can utilize their time in growing and nurturing saplings and trees at and around home, the younger generations can contribute their energy to plant these saplings in nearby areas.

We found out that 64 participants didn't have their own garden (53.33%), 79 participants never planted a single tree (65.83%). 107 participants felt that planting trees is necessary (89.17%). This indicates that with a little motivation and dedication these people can get involved in gardening and planting trees, which is the most important thing in today's era. [23]

Conclusion

Our study concludes that there are deficiencies in the intergenerational bonding activities. Various innovative and fruitful intergenerational activities should be developed, acted upon and followed to improve the physical, mental and social wellbeing of people from all the generations including old age people. Gardening and planting trees is one of such activity which people find important and are ready to follow.

Limitations:

Being a time bound study, follow up was not possible to check how many participants are actually involved in gardening and tree plantation as an intergenerational activity. A prospective study should be done to evaluate the impact and acceptance of this activity for intergenerational bonding.

Spectrum of Congenital Heart Diseases in a Tertiary Care Centre, Mysuru, Karnataka

Rajani H S¹, Narayanappa D², Sunilkumar S³

¹Associate Professor, ²Professor, ³Associate Professor, Department of Pediatrics JSS Medical College, JSS Academy of Higher Education and Research Mysore, India

Abstract

Background: Congenital heart disease (CHD) is one of the common congenital lesions and the most common cause of heart disease in children. According to the World Health Organization, the incidence of CHD in India is 15% of all the cardiovascular disease.

Objective: To know the spectrum of congenital heart disease in a hospital set up.

Methods: A hospital based prospective study was carried out over a period of 16 months (Jan 2018– April 2019). All children below 14 years of age who were admitted with CHD confirmed by echocardiographic study were included in the study. Detailed history was collected. The age, sex, clinical presentation and echocardiographic findings were documented in a predesigned proforma.

Results: The total number CHD diagnosed were 113 and were more common among males (59.3%). The commonest type of acyanotic CHD in our study was atrial septal defect (ASD) (31.8%) and cyanotic CHD was tetralogy of Fallot (7.9%). The major clinical findings were the detection of tachpnoea (54.2%) followed by murmur(38.4%) , tachycardia (33.9%) .

Conclusions: Most CHD were diagnosed in infancy with tachypnea being the most common presentation with 73.5% of CHD were acyanotic CHD.

Keywords: Congenital heart disease, children, spectrum,

Introduction

Congenital heart disease (CHD) is defined as “a gross structural abnormality of the heart or intra-thoracic great vessels that is actually or potentially of functional significance”¹. The magnitude of the problem is considerable and is largely unrecognized, understated, and underestimated. The reported incidence of CHD is 8-10/1000 live births. The incidence of CHDs in India is increasing, probably due to increased birth rate, early and more accurate diagnosis because of diagnostic modalities, increased awareness amongst parents due

to the effects of social media^{2, 3}. The frequency of different major forms of CHD also differs greatly in various studies. The clinical presentation of CHD also varies according to the type and severity of the defect. The purpose of this study was to know the spectrum of heart diseases in children.

Material and Method

A hospital based prospective study was carried out in a teaching hospital to determine the spectrum of CHDs. The study was conducted for a period of 16 months from Jan 2018 to April 2019. All patients within the age range of 0-14 years, admitted in pediatrics department as well as the neonatal and paediatric intensive care units, newborns in postnatal wards with echocardiography diagnosis of CHD were included in the study.

Correspondence Author:

Dr. Rajani H S

Associate Professor, Department Of Pediatrics
Jss Hospital Mahatma Gandhi Road, Mysore 570004
Email: rajanihs@jssuni.edu.in

Patients from neonatal intensive care unit were subjected to echocardiography due to the appearance of murmur, cyanosis and tachypnea. Newborns in postnatal wards were screened for CHD based on presence of any one of 7 clinical parameters like family history, associated dysmorphism or congenital anomalies, respiratory distress, cyanosis, murmur, feeble peripheral pulses, tachycardia and pulse oximetry reading of less than 95% or more than 3 % difference between upper limb and lower limb between 24-72 hours of age.

Children diagnosed with CHD were analyzed further. Preterms with PDA were followed up and not included in this study if it closed spontaneously within the period of hospital stay or by managing conservatively. The presence and the type of CHD was confirmed by echocardiography. The data of all patients regarding age of presentation, gender, signs and symptoms, clinical features and echo findings were documented in a predesigned proforma.

Results

A total of 113 cases diagnosed with CHD were included in the study. 54.9% were newborns and 35.4% were between 1 month and 1 year of age. Males (59.3

%) were more commonly affected than females with the male to female ratio is of 1.5:1[Table 1 and 2].

Out of 113 patients, 52 (31.8%) were diagnosed with Atrial septal defect (ASD) which was the commonest type of CHD in our study, followed by 21(18.6%) patients of Ventricular septal defect (VSD), ASD with patent ductus arteriosus (PDA) and tetralogy of Fallot (TOF)(7.9%) in that order. (Table 3).

The commonest cyanotic CHD was TOF (7.9%) and was the third in frequency in our study (Figure 3). The major clinical findings were the detection of tachypnea (54.2%) followed by murmur (38.4%), tachycardia (33.9%), failure to thrive (12.4%) and cyanosis (11.3%) (Table 4).

In this index study, out of total 113 cases, the isolated acyanotic CHD was 83(73.5 %) and cyanotic was in 24(21.2 %).

Among the risk factors, bad obstetric history like previous abortions, still births, sibling deaths was noted in 18%, consanguinity in 10.2%, maternal gestational diabetes in 9% and pregnancy induced hypertension in 6.8 %.(Table 4)

Table 1: Age and sex distribution of children with congenital heart diseases

Types of CHD	Females	Males	Total (%)
Newborns	28	34	62(54.9)
1-12 months	13	27	40(35.4)
1-5 yrs	1	5	6(5.3)
> 5 yrs	4	1	5(4.4)
Total (%)	46(40.7)	67(59.3)	113 (100%)

In our study higher prevalence of CHDs in males (64%) as compared to female (36%)

Discussion

CHD is the most common congenital problem in children accounting for nearly 25% of all congenital malformations. and one of the major causes of infant mortality⁴. A recent systemic review pointed out that the highest prevalence of CHD reported from Asia (9.3 per 1000 live birth) and the least from Africa (1.9 from 1000 live birth)⁴. In contrast to other developed country, there are few Indian studies showing the prevalence of CHD. Available Indian studies had reported a wide variation in prevalence of CHD from 2.25 to 26 per 1000 live birth^{5,6}. There are few scattered study from north and south part of country but there is a paucity of data from this part of country.

Congenital heart disease were more common in newborns and between 1 month-1year (35.4%) similar to the study at other parts of our country⁷. In our study, the highest number of cases (90.3%) was seen in infancy as newborns were included in the study. In the present study, 54.2% of the patients presented with tachypnea followed by murmur (38.4%) and tachycardia (33.9%) similar to other studies where tachypnea was common presentation⁸.

The commonest type of acyanotic CHD was ASD (36.3%) which is quite a different observation compared to other Indian data^{5-7,9,12}. This may be attributable to over-diagnosis of patent foramen ovale as ASD as asymptomatic newborns were screened and included in the study. PDA was the third in the list (5.3%) among acyanotic CHD in our study. Tetralogy of Fallot was the commonest type of cyanotic CHD (7.9%) as reported by the several studies⁹. Some studies showed the male

preponderance of 2.08:1 and 1.78:1 similar to our study (1.5:1)^{10,11}.

In a study done in Mysore between 2001 and 2004 showed a prevalence of 10.65 per 1000 live births with VSD the most common CHD, followed by ASD, TOF and PDA¹³.

In this era, where we have the most accurate diagnostic modalities, any clinical suspicion of CHD should be confirmed by echocardiography. More doctors should be trained in diagnosing CHD by echocardiograph, so that CHD can be detected and treated earlier there by reducing morbidity and mortality. Fetal echocardiography should be advised liberally to the expectant mothers when one of the siblings is known to have complex CHD, family history of CHD or any other risk factors are present.

The prevalence of CHD is not uniform across the country as studies are done under different settings. Hence, it is important to determine the exact prevalence and case burden of congenital heart disease so that appropriate changes in health policies can be recommended.

Abstract

Introduction: Very few community-based studies are centered on the native population of India and to our best knowledge this study is the first of its kind that aims to throw light on the chewing patterns and its effect on patients suffering from OSMF in the indigenous population of Andaman and Nicobar. This study aims to correlate between tobacco associated adverse habits and prevalence & severity of OSMF in indigenous population of Andaman and Nicobar Islands.

Material and Method: The study was conducted in Port Blair, Andaman in June 2014. The study population consisted of 500 residents of age 22-84 years with known tobacco usage who were screened clinically.

Results & Discussion: Nearly 144 patients were diagnosed clinically with OSMF. Thus, a prevalence rate of 28.8%, which was comparatively higher to previous tribal studies in central India. This study is novel to the Andaman Islands and served as a potential tool to educate the natives on the tobacco consumption habits.

Keywords: *Andaman, Habit control, Oral submucous fibrosis, Awareness, Quality of Life*

Introduction

Oral submucous fibrosis is a chronic insidious potentially malignant disorder exclusively affecting the oral cavity and pharyngeal region with initial vesicle formation followed by epithelial atrophy and juxta-epithelial fibroelastic changes leading to fibrosis of oral mucosa and inability to open the mouth. Betel nut alkaloids consumed with or without tobacco, in the form of areca quid is a common practice in the Indian-subcontinent and prevalence of OSMF among them is high enough to be authorizing areca nut as the etiological agent in causation of OSMF. Tobacco in its chewing

and smoking form has been recognized as the major risk factor for oral cancer in India. ⁽¹⁾

The Andaman and Nicobar Islands comprises of a distinct population group of aboriginal tribes and migrants among whom tobacco chewing habit is rampant. Tobacco consumption is as high as 52% according to a study in 2011 among the tribal population in India, especially the lower socio-economic groups. ⁽²⁾ The advent of migrants from northern regions of India introduced commercial tobacco products into the society. Studies on the pattern of tobacco consumption and types of tobacco in this native population are lacking.

Very few community-based studies are centered on the native population of India and to our best knowledge this study is the first of its kind that aims to throw light on the chewing patterns and its effect on patients suffering from OSMF in the indigenous population of Andaman and Nicobar. Quality of life is vital health outcome

measure that is relevant to patients, hence we also recorded the quality of life questionnaire from all the patients to suit the scenario. Apart from this subjective examination using VAS, questionnaires to evaluate the habit control and barriers to quit were also recorded.

Material and Method

Study setting and population: The study was conducted in Port Blair, Andaman in June 2014. The population comprised of Ranchi tribes resettled from Jharkhand region and Bangladeshi settlers resettled by the Government of India and non-settlers or migrants of Tamil, Telugu and Malayalam speaking origin. The study was conducted adhering to strict ethical protocol and written informed consent was obtained from the subjects prior to commencement of study.

Inclusion Criteria: The study population consisted of 500 residents of age 22-84 years with known tobacco usage who were screened clinically and 144 were diagnosed with Oral submucous fibrosis upon visual screening done by medical officers using criteria proposed by Bailoor and Nagesh et al.⁽³⁾ Age and gender

matched controls with no deleterious habits and absence of any clinically diagnosable premalignant disorders was chosen.

Exclusion Criteria: Clinically diagnosed patients with OSMF who were unwilling for incisional biopsy and patients already under treatment for OSMF were excluded from the study.

Subsequently the patient's personal history elicited tobacco consumption habits, frequency and duration of chewing among the OSMF patients. Symptoms such as burning sensation, restricted mouth opening and difficulty in swallowing were also recorded. Complete intra-oral and extra-oral examination was done and mouth-opening, check flexibility and protrusion of tongue was measured in accordance to methods proposed by Ranganathan et al.⁽⁴⁾

Functional staging was done according to Haider et al. Incisional biopsy was done after routine blood investigations, in order to confirm histopathological diagnosis and grading of OSMF was done in accordance to Pindborg et al.⁽⁵⁾⁽⁶⁾

6.	Worst possible, unbearable,excrtiating pain	5

Discussion

In our study of 500 patients with tobacco habits were included after initial screening and 144 were diagnosed clinically with OSMF. Thus, a prevalence rate of 28.8% was comparatively higher to previous tribal studies in central India by Kanna et al who provided prevalence of 6.3% (2004) and 7.2% in tribes of wayanad (2013).⁽⁷⁾⁽⁸⁾ In the previous studies Leukoplakia was the major

oral disorder among tobacco abusers and smoking was more predominant with beedi smoking being the chief habit. Since among our population of native Andaman tribes smokeless tobacco and areca nut chewing was rampant as compared to smoking form of tobacco our study reflects a higher prevalence rate of OSMF.⁽⁹⁾

The patients diagnosed with OSMF were in the mean age of 34.7 years which is consistent with previous

studies by Haider et al (2000).⁽¹⁰⁾ This is much higher compared to studies conducted in 2009 by Ceena et al where they found the average age range was 26 years and majority of cases were in the age range of 21-30 years thereby concluding that the younger age group was more susceptible to both areca chewing habit and occurrence of OSMF.⁽¹¹⁾ Previous tribal studies have shown a high prevalence of 52.07-63% of smokeless tobacco use among the adolescent population with mean age range of 13-49 years with average age of initiation of smokeless tobacco use being at least 13.7 years.⁽¹²⁾⁽¹³⁾ The difference in the distribution among our study population can be attributed to it being majorly migrated population now native to the island for few decades, and indigenous tribes. The mean age of occurrence of OSMF seems to be a decade away from mean age of initiation of smokeless tobacco habit.

Among the OSMF patients 37% were females and 63% were males thus showing a male predominance similar to studies by Ranganathan et al and Pandya et al (2009).⁽¹⁴⁾⁽¹⁵⁾ Nevertheless studies by Jhonson et al (2000) showed female preponderance among OSMF patients. To best of our knowledge no studies have analyzed OSMF prevalence among native population in Andaman and Nicobar Islands.

Among the 500 smokeless tobacco chewers the most prevalent habit was chewing of indigenously made Paan masala with tobacco (36.4%) followed by Supari and Zarda. Areca-nut chewing (15%) was more popular among the female population. Among the 140 OSMF patients 51 patients chewed Paan alone or in combination with other habits. Paan is a combination of areca-nut catechu, lime and flavoring agents and chewed along with betel leaf at homes or available as commercial mixtures along with tobacco. Areca nut alone causing OSMF was previously documented in studies by Van Wyke et al.⁽¹⁶⁾ Since these mixtures are predominantly prepared by self, they tend to consume more dry weight of areca-nut which further induces fibrosis of oral mucosa at an earlier stage and consuming them for longer periods causes addiction and dependency.

The presence of burning sensation was the most prevalent complaint of OSMF patients (72.8%) and most common cause of reporting to a dental check-up following which 46.4% of patients complained of

difficulty in mouth opening while 12.85% presented with no previous symptoms and were unaware of suffering from the disease.

Among the OSMF patients 102 had mouth opening \geq 20mm which is comparable to previous study by Ara et al, 16 patients had mouth opening of 11-19mm and 22 patients suffered from mouth opening less than 10mm.⁽¹⁷⁾

Among the OSMF patients 53.6% had chewing habits for a duration of <15 years and 11.4% from 16-30 years only 4.2% of habits greater than 30 years developed OSMF. The association between duration of tobacco chewing and advent of OSMF in these patients were compared by chi-square was not significant ($p=0.089$). Among them majority of the patients who chewed <10 packets of smokeless tobacco were classified as Stage A of OSMF according to functional staging (60.7%) while the 13.6% of patients with chewing habits between 10-20 packets predominantly developed Stage C OSMF. These results are comparable to previous studies by Ahmed et al who also found that severity of OSMF increased in correlation to the frequency and duration of smokeless tobacco abuse.⁽¹⁸⁾ In other studies by Rajendran et al they deduced that though frequency or no. of packets of smokeless tobacco had direct relationship with the severity of OSMF the duration of chewing was irrelevant to the development of the disease.⁽¹⁹⁾ In our study we noticed that OSMF developed predominantly in younger population with lesser duration of chewing habits hence emphasizing the inherent toxic nature of the Paan and other smokeless tobacco products. Similarly, Shah et al hypothesized that the burden of exposure of toxic products at a period affected the development of OSMF in these models.⁽²⁰⁾ The relationship between chewing habit duration and mouth opening in OSMF patients was studied using chi-square and they gave a significant relationship with increase in duration of chewing showed reduced mouth opening among OSMF patients ($p=0.004$).

On correlating clinical staging and histological grading, analysis with Chi square test was not significant with $p>0.05$ which is like a study by Syeda Arshiya Ara et al who also found no significant relationship between histological grading and functional staging in OSMF. While studies by Kiran et al and Pandya et al, found

significant relation between the staging and grading these differences in results can be attributed to factors such as site of OSMF, fibrosis at the time of staging, duration of disease at time of assessment and the differences in system of assessment used. ⁽²¹⁾

Several “quality of life” questionnaires have been developed over the past, however to our knowledge there are no questionnaire to suit the Andaman population. Keeping this in mind we aimed at developing a standardized QOL questionnaire to fulfill all the domains of life. The KMO score was 0.86 which shows that the sample was adequate for factor analysis. Hence can be concluded that the present QOL is a multidimensional construct with many factors within it.

Apart from the QOL questionnaire even Habit control, Barriers to quit habit etc were taken into consideration (Table 5). Around 69% of the study population were willing to quit the habit, Major barrier for quitting the habit was stress (39%) and dependence (23%). The study results would be a valuable piece of information for public health personnel to enlighten the population about the ill effects of the deleterious habit and about the dreadful disease that they would encounter.

Conclusion

The duration of tobacco chewing significantly affects the severity of mouth opening and in turn the levels of fibrosis in OSMF patients. However, the comparison of functional and histopathological lesions was of little use in our study and clinical indicators are a more reliable marker of the disease when compared to functional staging. This study is novel to the Andaman Islands and served as a potential tool to educate the natives on the tobacco consumption habits. Since our study concentrated on a smaller sample in one region of the Andaman Islands it needs to be expanded to cover more geographical and ethnic population to provide promising results in addressing the tobacco challenge in these regions.

Status of Oxidative Stress in Patients of Chronic Obstructive Pulmonary Disease

Authors: Rashmi Bathri¹, Ruchira Chaudhary², Ragini Gothwal³

¹ Research Scholar, Department of Biotechnology, Barkatullah University, Bhopal, ² Professor, Department of Zoology Sarojini Naidu Govt. Girls PG College, ³ Dean Life Sciences and Head, Department of Biotechnology, Barkatullah University, Bhopal

Abstract

Chronic Obstructive Pulmonary Disease (COPD) is the major cause of death worldwide. It is projected to be third leading cause of death globally by 2030. Reactive oxygen species plays important role in pathophysiology of COPD. High ROS generation resulted in increased lipid peroxidation. MDA which is a biomarker to evaluate the level of lipid peroxidation is used to evaluate the oxidant antioxidant level in COPD patients. Significant difference between COPD patients and healthy subjects is found in our study. It is concluded therefore, that a biomarker-based (preferably MDA) study can be utilized to assess the efficacy of novel antioxidant or other agents in modifying the course of this disease.

Key Words: COPD, Oxidative stress, MDA, Free radicals, Lipid Peroxidation

Introduction

Chronic obstructive pulmonary disease (COPD) is one of the big reason of morbidity and mortality worldwide. It is a major public health problem and is projected to rank third leading cause of deaths globally by the year 2030¹. An imbalance between oxidant antioxidant play an important role in pathophysiology of COPD²⁻⁴. One of the results of increased ROS generation is increased lipid peroxidation. It involves free radical chain reactions leading to the decomposition of polyunsaturated fatty acids, constituting, for example, the components of cell membranes⁵. In this process, once a hydrogen atom is detached from a polyunsaturated fatty acid molecule, a reconfiguration of double bonds occurs and leads to the generation of conjugated dienes (CDs)^{6,7}. Among the secondary products of lipid peroxidation, generated as a result of further reactions, (e.g., β -elimination and decomposition of polyunsaturated fatty acid derivatives), are aldehydes,

mainly malondialdehyde (MDA)⁸. The present study was undertaken to evaluate the oxidant anti oxidant levels in COPD patients.

Materials and Method

Study subjects

20 Stable cases of COPD are recruited in the study. 10 healthy subjects with no pulmonary, cardiovascular, or oncological disease, inflammation, infection, and neurological dysfunction that could influence the oxidative status were enrolled as controls.

COPD was defined according to the Global initiative for Chronic Obstructive Lung Disease (GOLD) criteria⁹. Subjects with history of tuberculosis, bronchial asthma, diabetes mellitus, hypertension, lung cancer, cardiovascular, renal diseases, chronic hepatic failure, and prior antioxidant intake were excluded from the study. The study was approved by institutional ethical committee and is in accordance with ethical standards outlined in the Declaration of Helsinki. Detailed written and informed consent was taken from all subjects.

Marker of Oxidative stress

The levels of serum lipid peroxidation products i.e., thiobarbituric acid (TBA-MDA) was measured spectrophotometrically at 630 nm by the modified Birgül method (2005) The concentrations of lipid peroxidation products was calculated as MDA concentration, using the extinction coefficient for the MDA-thiobarbituric acid complex of $1.56 \times 10^5 \text{ M}^{-1}$ for calculation¹⁰.

Statistical Analysis

The results were presented in mean \pm standard deviation and percentages. The Chi-square test was used to compare the categorical variables. The unpaired *t*-test was used to compare two discrete variables. The $P < 0.05$ was considered statistically significant. All the analyses were carried out using SPSS 16.0 version (SPSS Inc., Chicago, IL, USA).

Results and Discussion

The mean age of the study population was 45 ± 10 Baseline demographic and Clinical characteristics are shown in [Table 1]. Majority of the subjects in our study population were male. Almost all the COPD patients (90%) were smokers. , out of the controls 50% were smokers and 50% were non-smokers. Majority of the patients were in GOLD Class 2 (60%). Cough and breathlessness were predominant symptoms in study patients.

Results of biomarker analysis of the study are presented in [Table 2]. MDA levels, which is a marker of oxidative stress, were significantly higher in COPD patients than controls (7.21 ± 1.9 vs. $0.51 \pm 0.29 \text{ nmol MDA ml}^{-1}$, $P = 0.0001$) . Also when compared the plasma level of MDA was found significantly higher in males compared to females [$P = 0.001$]

All these data point toward a greater oxidative and anti-oxidative imbalance in males when compared to their female COPD counterparts.

Among patients with COPD, the mean level biomarker of oxidative stress ;MDA were higher in smokers compared to nonsmokers [$P = 0.001$], All these data corroborate with a greater oxidative and anti-oxidative pathway imbalance in smokers. However, nonsmoking COPD patients still have significantly

higher values of oxidative markers compared to their non-COPD counterparts.

There was no difference in oxidative stress marker according to site of enrolment – outpatient, inpatient, or intensive care setting. This implies that oxidative stress is prevalent at all stages of COPD.

Of the various symptoms, the presence of cough significantly correlated with higher levels of MDA ($P = 0.001$). Cough also more frequent in high COPD severity grades than lower grades ($P = 0.04$). This could explain the relationship of cough and higher levels of oxidative stress in the study.

Our study results support the oxidant and antioxidant imbalance theory of COPD. Lungs are exposed to large amount free radicals. Reactive oxygen species that are produced has the direct correlation with oxidation of proteins, DNA, and lipids. Membrane lipids are highly vulnerable to free radical damage which is very much harmful for the cell function. MDA is a product of lipid peroxidation and an indirect measure of free radical activity in body. As free radical injury increases lung function decreases. Oxidative stress is reported to play an important role in the pathophysiology of COPD. The aim of the present study was to evaluate the oxidant-antioxidant imbalance in healthy controls and COPD group. The levels of oxidative marker such as MDA were significantly higher in COPD patients when compared with controls. Various studies have similarly found significantly raised levels of MDA in patients of COPD when compared to healthy controls^{11,12} . Gender and smoking had judicious effects on oxidative stress. In our study, males had higher plasma level of MDA compared to females. The more frequency of smoking and high environmental exposure might be the reason for this difference. Smokers COPD patients in our study had higher level MDA marker when compared to non smokers. It is because cigarette smoke is the main generator of oxidative free radicals¹³. Although, COPD non-smoker patients do continue to have oxidative stress from other sources such as respiratory infections, inflammation, dust, and air pollution. With increasing grades of GOLD class for COPD severity, the levels of MDA were progressively increased. The presence of cough indicated high-oxidative stress and diminished antioxidants. Our study and various studies^{14,15}

mentioned clearly prove the point that MDA is the marker which has consistently shown correlation with disease severity.

The understanding of COPD has undergone a paradigm shift in recent years. It is thought to be a systemic disease associated with extrapulmonary manifestations such as cardiovascular disease, diabetes, obstructive sleep apnea, and metabolic syndrome¹⁶. Even subclinical atherosclerosis is common in COPD patients contributing to overall COPD morbidity¹⁷. Oxidative stress can be the only plausible common pathogenetic

link between COPD and other systemic manifestations.

COPD is a chronic disease without any disease modifying therapy till date. Oxidative stress is potential mechanism which can be altered to halt its progression. A biomarker-based (preferably MDA) study can be utilized to assess the efficacy of novel antioxidant or other agents in modifying the course of this disease.

The primary limitations of the study include smaller sample size and lesser number of healthy volunteers compared to diseased subjects.

Table 1: Baseline demographic and clinical parameters of the study subjects

Age (in years)	Cases (20)	Control (10)	P value

Anatomical study of Variations of Median Nerve and Musculocutaneous Nerve in the Arm

Rashmi C Goshi

Assistant Professor, JSS Medical College, Mysuru

Abstract

Background: The variations related to the median nerve and musculocutaneous nerve are relatively less common. The variations may have potential clinical implications especially during surgeries and nerve blocks.

Materials and Method: The routine dissection of 50 adult cadavers including 42 males and 8 females in the Department of Anatomy during undergraduate training was carried out to detect the variations in the structure, formation and relation of Median nerve and musculocutaneous nerve.

Results and Findings: There was a variation observed in the formation of median nerve in three adult cadavers. In three male cadaver, there was unilateral variation in the formation of the median nerve by more than two roots. However, in each of these cadavers the distribution of the median nerve was normal in arm, forearm and palm. There was normal pattern of formation, relation and course of Median nerve in rest of the cadavers. Absence of musculocutaneous nerve, and nerve not piercing coracobrachialis, and communication between median and musculocutaneous nerve was found. Photographs of abnormalities were taken for proper documentation of the variations.

Conclusion: These variations have been explained by some embryological facts available. These variations of formation of median nerve are clinically important for physicians, surgeons and anesthetists because symptoms of median nerve compression due to these variations are often confused with radiculopathy and carpal tunnel syndrome. The knowledge of variations of musculocutaneous nerve is important to the surgeons and anesthetists' for carrying out surgical procedures and nerve blocks in axilla and arm.

Key Words: *Median nerve, Musculocutaneous nerve, Brachial plexus variations.*

Introduction

The median nerve is formed by the union of medial root from medial cord (C8, T1) and lateral root from lateral cord (C5-C7) of brachial plexus anterior or lateral to the third part of Axillary artery.

In the arm the nerve passes at first lateral to brachial artery crosses to the medial side from front of

it descending down to the cubital fossa. No branches of median nerve are found in the arm.¹¹

Similarly Musculocutaneous nerve is a branch of lateral cord pierce the coracobrachialis and gives branches which supplies all the muscles of arm.

In close to the cubital fossa, it lies lateral to the biceps tendon and anteriorly to the brachialis muscle that becomes known as the lateral antebrachial cutaneous nerve (or the lateral cutaneous nerve of forearm) which supplies common sense of the skin in anterolateral region of the forearms as far distally as the base of the thenar eminence¹.

The MCN entrapment is rare. It can occur due to an inadequate positioning of the arm during sleep because the CbM and BM act as anchor point for MCN. If this situation coexists with a communicating branch where a part of MN passes through CbM, the clinical signs could be similar to those found in MN neuropathy in the hand. The diagnosis of MCN-MN communication in this clinical presentation by electromyographic methods could prevent unnecessary releases of the carpal tunnel.

The knowledge of anatomical variations of these nerves is important as these nerves could be injured during surgical procedures and because variation may explain unusual clinical symptoms.⁷

The present study is aimed at assessing the variations of median and musculocutaneous nerves in the arm and their clinical correlations.

Materials and Method

The present study was conducted on 50 limb (42 male and 8 female) specimen during routine dissection

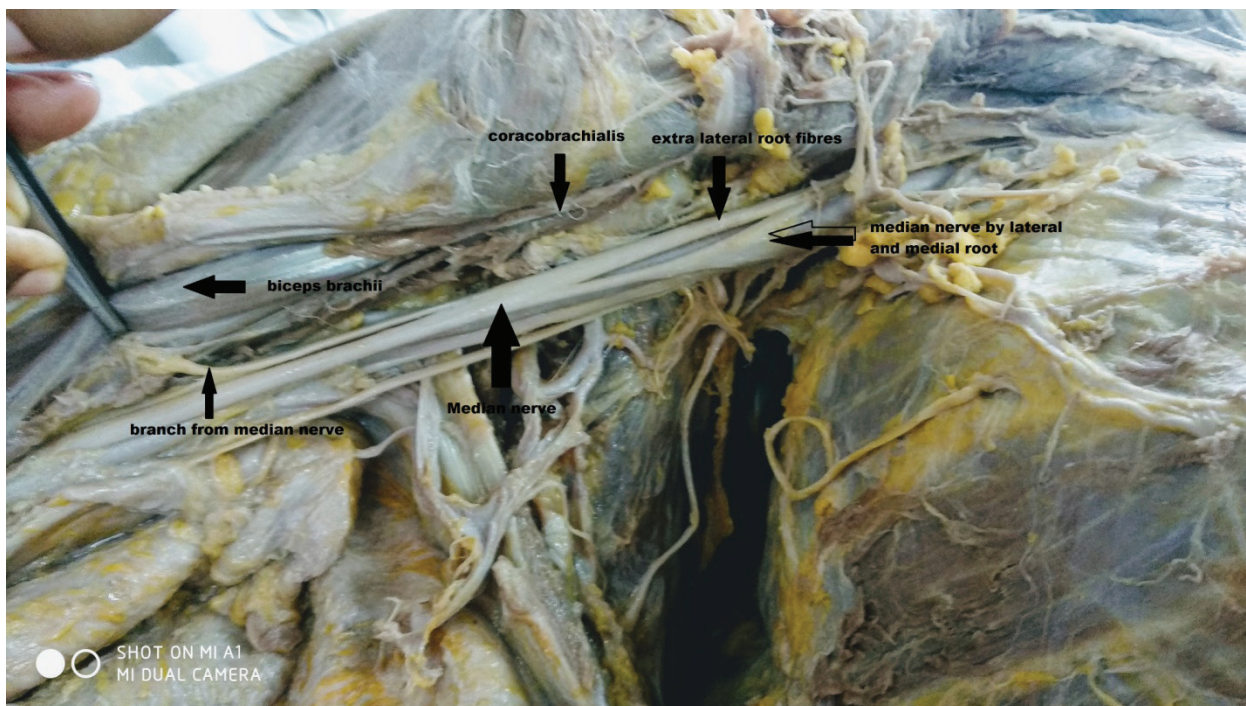

for MBBS students. The Axilla and Arm were dissected in the anatomy department of the JSS Medical College, Mysuru, India, over a period of 2 years. The cadavers were embalmed and preserved in a weak formalin solution. The infraclavicular part of the brachial plexus was dissected according to the guidelines of the Cunningham's manual of Practical Anatomy. During the dissection, The variations of Median nerve, Musculocutaneous nerve in the arm were noted, the normal pattern, as well as variations from the normal pattern, were noted and photographed. The number of the variations was noted and the result was tabulated using a regular statistics method. Any variations from normal was noted and tabulated (► Table 1).

Results

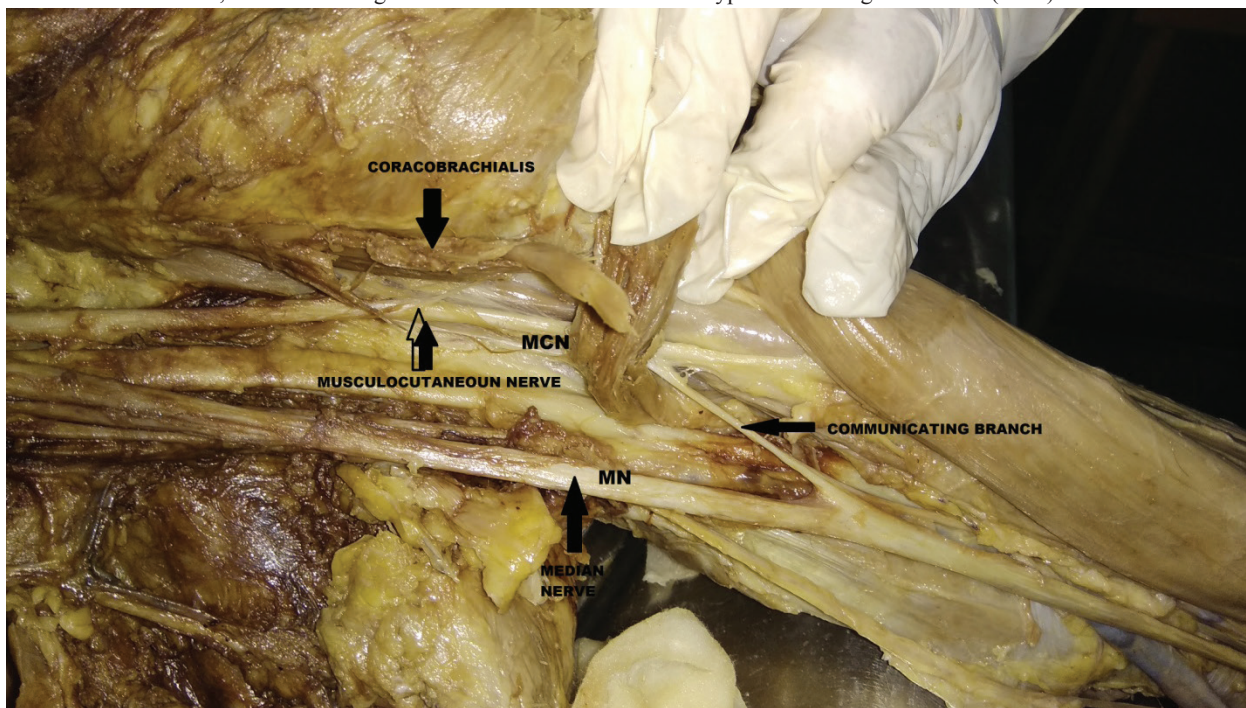

1) Formation of the median nerve by three roots was seen in 1 out of 50 specimen. Out of the three roots of median nerve, two roots was given by the lateral cord of the brachial plexus and one root was given by the medial cord of brachial plexus as seen in ► Figure 1.

2) Absence of the musculocutaneous nerve was seen in 1 out of 50 specimen. In the absence of the musculocutaneous nerve, the muscles of the anterior compartment of the arm were innervated by the branch coming from median nerve as seen in ► Figure 2. This variation comes under type v as described by Li Minor(1990).

3) Communication between the median and the musculocutaneous nerves was seen in 2 specimens out of 50. The communication was in the middle of the arm, as seen in ► Figure 3 This variation comes under type II according to Li Minor(1990).

4) Musculocutaneous nerve was arising normally from the lateral cord traversing between coracobrachialis and biceps brachii, then between biceps brachii and brachialis supplying all three muscles. Here the variation noted was musculocutaneous nerve not piercing coracobrachialis seen in 1 out of 50 specimen. It is one of the very rare variation found. ► Figure 4(MCN- musculocutaneous nerve, MN- median nerve, Br- brachialis muscle)

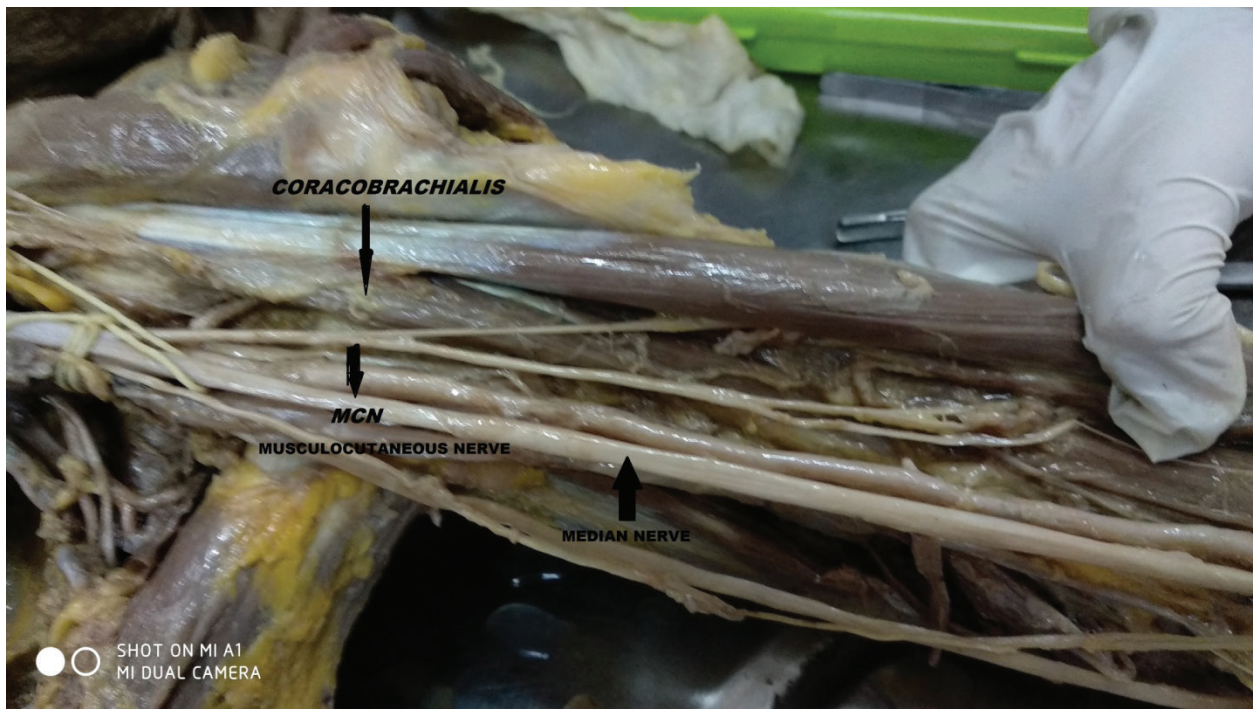

TABLE NO 1: Showing all the variations observed

Discussion

Variations of the lateral cord are not rare and have been reported by many authors in the past as seen in table 2. On the basis of embryological development, anomalous pattern of the median nerve and musculocutaneous nerve can be explained. The upper limb buds lie opposite the lower five cervical and upper two thoracic segments. As soon as the buds form, the ventral primary rami of the spinal nerve penetrate into the mesenchyme of limb bud. Immediately, the nerves enter the limb bud and they establish intimate contact with the differentiating mesodermal condensations. The early contact between nerve and muscle cells is a pre-requisite for their complete functional differentiation. The growth as well as the path finding of nerve fibres towards the target is dependent on concentration gradient of a group of cell surface receptors in the environment. Several signaling molecules and transcription factors have been identified, which induce the differentiation of the dorsal and ventral motor horn cells. Misexpressions of any of these signaling molecules can lead to abnormalities in the formation and distribution of particular nerve fibres^{1,2,11,12}.

At the infraclavicular level, the lateral fascicle of the brachial plexus usually bifurcates giving origin to the musculocutaneous nerve (MCN) and the lateral root of the median nerve (MN). However, during the embryological development process it is possible that bundles of fibers corresponding to the MN initially

run together with bundles of fibers of the MCN. The MN recovers the fibers required to perform its motor and sensorial functions in the upper extremity, only when the bundles of fibers were connected with their nerve of origin (MN) at the proximal or mid-thirds of the arm. Although with low frequency, fibers of the MCN have also been seen to initially run along of the MN and later reestablish their configuration through a communicating branch.¹⁻⁵ The incidence of the MCN-MN communication has been reported in diverse population groups with a wide variability between 2.1 and 63.5%.⁵⁻⁸ The majority of the studies only report the MCN-MN communication. Maeda et al.³ and Chiarapattanakom et al.⁶ have reported an occurrence of 3-6.8% for the communication from the MN to the MCN. Information about the prevalence of side of MCN-MN communication is low. Few studies report predominance of the left side and of the unilateral expression of this communicating branch.^{4,9,10} Several ways to classify this communicating branch have been proposed by the wide variability in its expression.^{3,7,8,10,11} Knowledge of the existence of the MCN-MN communication in the arm is clinically important.¹⁴

Communications between MN and MCN have been described to the five types^{8,1,2}

- ▶ Type I-There is no communication between median nerve and musculocutaneous nerve.
- ▶ Type II- Some fibres of lateral root of median

nerve pass through musculocutaneous nerve and join median nerve in the middle of the arm.

▶ Type III- All the fibres of lateral root of median nerve pass along musculocutaneous nerve and after some distance leave it to form the lateral root of the median nerve

▶ Type IV- Musculocutaneous nerve joins the lateral root of median nerve and after some distance the musculocutaneous nerve arises from the median nerve.

▶ Type V- Musculocutaneous nerve is absent and entire fibres of musculocutaneous nerve pass through lateral root of median nerve to median nerve. The fibres to the muscles supplied by musculocutaneous nerve branch out directly from the median nerve.

Classification of variations of the median nerve and the musculocutaneous nerve according to Le Minor (1990). CBM: Position of the coracobrachialis muscle; CB: coracobrachialis ramus (nerve); BB: Biceps brachii ramus; B: Brachialis ramus; LR: Lateral root forming the median nerve; MR: medial root forming the median nerve; LC: lateral cord; MR: medial cord; MCN: Musculocutaneous nerve; MN: median nerve; UN: ulnar nerve.

In the present study, formation of the median nerve by three roots was noted in 3 out of 50 cases (6%). In all of these cases, two roots were coming from the lateral cord, and one root from the medial cord. In one case, there was also communication between the median and the musculocutaneous nerves. A similar case of formation of the median nerve by three roots was described by Anju Bala¹², K Lakshmi Kumari¹¹ in 26.41% and Amrita Bharti¹⁵ in 2% cases. K Lakshmi Kumari¹¹ has reported median nerve which is formed by 4 roots in 1.88%.

Dr Shashank M J³, Abhilasha Priya⁴, Virendra Budhiraja⁷, Parminder Kaur², Charushila D Shinde⁶ have observed absence of Musculocutaneous nerve in

5%, 5%, 11.2%, 13.2% cases respectively. Whereas in our study it was found to be 2%.

Arian Azimi⁵ found a variation in which lateral cord was giving off MCN which was small and thin and needed to be looked carefully to find it in the macroscopic dissection, then the lateral root continued as the lateral root of median nerve innervating the muscles of arm.

Communication between Median and Musculocutaneous nerve after piercing or without piercing coracobrachialis muscle is quite common compared to other variations as per the results of previous studies (by Virendra Budhiraja⁷, Abhilasha Priya⁴, Hamid Tayefi Nasrabadi¹). The same is been tabulated in Table No 2.

Musculocutaneous nerve not piercing Coracobrachialis without communication with median nerve is one of the rare variation, which we found in our present study.

The MCN injury proximal to the MCN-MN communication can lead to an unexpected weakness of the forearm flexor muscles and thenar muscles with clinical signs like seen in a MN injury at the level of the

arm. Furthermore, the MN injury proximal to the MN-MCN communication can lead to a clinical presentation characterized by functional preservation of forearm and hand muscles innervated by MN. In the peripheral nerve surgery, especially in nerve transfers techniques, a good knowledge of the MCN-MN communications is required.

Conclusion

The MCN has been successfully used as a receiver nerve to the recovery of elbow flexion. Furthermore, the MCN motor branch to BrM has been used as donor to anterior interosseous nerve and posterior interosseous nerve for the treatment of lower brachial plexus injuries as well as in the treatment of tetraplegic patients.

The high median nerve entrapment symptoms may be used in differential diagnosis of unexplained clinical symptoms like sensory loss, pain, wakefulness and paresis. The knowledge of such rare median nerve variations is thus important for anatomists, anesthetists, radiologists and surgeons.

The knowledge of such variations is of much interest to Anatomists and Surgeons. Anatomical variations are significant during exploration of axilla and arm surgeries involving neoplasms and other vascular masses.

Conflict of Interest: No

Abstract

Background: World Health Organization (WHO) estimates that, globally more than three million of acute poisoning cases with 2,20,000 deaths occur annually. Of these, 90% of fatal poisoning occurs in developing countries particularly among agricultural workers. It has been reported that acute poisoning approximately constitutes 10% of admission in medical emergency departments in India. **Objectives:** 1. To assess the patterns of socio-demographic variables of patients admitted with acute poisoning in a rural tertiary care hospital 2. To determine the various poison related factors in relation to the outcome of patients admitted with acute poisoning in a rural tertiary care hospital of Nalgonda district. **Methodology:** This was a retrospective record based study conducted using patient's discharge summaries comprising of the patients admitted to the emergency medicine department for acute poisoning from July 2019 to January 2020. Data was entered and analyzed using Microsoft Excel 2010. **Results:** During the study period, a total of 77 acute poisoning cases were admitted, with 5 deaths, resulting in a mortality rate of 6.5%. Acute poisoning was most seen in males (58.4%) and in the 14 to 30 years (62.3%) age group. Majority of the patients were admitted for ingestion of poison (89.6%) and the most commonly consumed poison was insecticides (40.3%). **Conclusion:** Insecticide poisoning is the most common form of poisoning with high mortality among males. There is a need for appropriate training and counselling sessions of preventive strategies for individuals who are at risk of acute poisoning especially the younger age groups.

Keywords: Acute poisoning, Rural, Insecticide, Suicide, Pattern

Background

Acute poisoning forms one of the most common causes of emergency hospital admissions. It has been reported that acute poisoning approximately constitutes 10% of admission in medical emergency departments in India.¹ Cases of poisoning depend on availability of poisons, socio economic status, religious and cultural influences, occupation prevalent in the region and likewise. It is estimated that upto half a million population die every year as a result of poisoning, particularly due to pesticide poisoning.² Poisoning is the fourth common cause of mortality in rural India.³ World Health Organization (WHO) estimates that, globally

more than three million of acute poisoning cases with 2,20,000 deaths occur annually.⁴ Of these, 90% of fatal poisoning occurs in developing countries particularly among agricultural workers.⁵

The pattern of poisoning in our country differs from that in the Western countries. In our country, Organophosphorus insecticides take the lead by great majority, in the west it is the tranquilizers, hypnotics and sedatives which are most frequently used in self poisoning.⁶ Easy availability of numerous poisonous substances due to rapid development in science and technology, vast growth in industrial and agricultural set up has tremendously increased the incidence of

poisoning cases. A number of chemical substances, which were developed to save the agricultural products from rodents and pests so as to protect the human from starvation, are in fact themselves becoming man eaters.⁷ Reducing deaths due to poisoning requires effective medical management of acute poisoning. Knowledge about poisoning cases pattern in region is important for early diagnosis and prompt treatment. This is essential for introducing the new and evaluating the old preventive measures at regular intervals.⁸

Objectives

1. To assess the patterns of socio-demographic variables among patients admitted with acute poisoning in a rural tertiary care hospital of Nalgonda district
2. To determine the various poison related factors in relation to the outcome of patients admitted with acute poisoning in a rural tertiary care hospital of Nalgonda district

Materials and Method

A retrospective record based study was conducted using data from patient's records such as patient's discharge summaries comprising of the patients admitted with acute poisoning to the emergency medicine

department in Kamineni Institute of Medical Sciences, Narketpally of Nalgonda district in Telangana state for a period of 7 months, i.e., from July 2019 to January 2020. So a total sample of 77 patients were included in the study. The study comprised of patients who were admitted for acute exposure to drugs and chemicals. The data includes demographic details such as age and sex, the type of poison consumed, the route of exposure, the method of exposure, time interval between exposure of poison and admission to hospital, factors effecting morbidity like duration of hospital stay, the need of ventilator support and the outcome of the patient. A study approval was obtained from Institutional Ethical Committee before the initiation of study. Data was entered and analyzed using Microsoft Excel 2010. Results were expressed in terms of frequency and percentages. Necessary statistical tests like simple proportions and Chi-square test were applied and $p < 0.05$ was considered as statistically significant.

RESULTS:

During the study period, 77 cases were admitted to the emergency medicine department with the diagnosis of acute poisoning of which, 5 cases faced mortality (6.5%) which was depicted in Figure 1.

Figure 1: Outcome of the admitted acute poisoning patients

There is a higher frequency of males brought with exposure to poisoning (58.4%), compared to females (41.6%). The mortality rate in males was found to be 11.1% while there was no mortality in females. Majority of the cases were seen in the age group of 14 to 30 years (62.3%) i.e., 48 out of 77 cases. Of the 77 admitted cases of poisoning, 69 (89.6%) of them were brought with ingestion of poison, while only 8 (10.4%) were brought with inhalation of poison which was shown in Table 1.

Inhalation	8 (10.4)	0	0.0
Method of Exposure			
Accidental	10 (13)	0	0.0
Suicidal	67 (87)	5	7.5
Duration of Hospital Stay			
< 5 Days	58 (75.3)	1	1.7
5-15 Days	17 (22.1)	3	17.6
15-30 Days	2 (2.6)	1	50.0
Ventilator Support			
Yes	12 (15.6)	5	41.7
No	65 (84.4)	0	0.0
Time between exposure and admission			
<30 minutes	3 (3.9)	0	0.0
30-60 minutes	9 (11.7)	0	0.0
1-2 hours	15 (19.5)	1	6.7
>2 hours	50 (64.9)	4	8.0

Most patients (75.3%) had a duration of stay in the hospital for less than 5 days, which had a mortality rate of 1.7%, while those who had a stay of 5 to 15 days had a mortality rate of 17.6%. Only 2 patients had a hospital stay of

15 to 30 days, of which there was one mortality, giving the mortality rate of 50%. It was observed that, of the 5 cases of mortality, 4 of them were brought to the hospital with time interval of more than 2 hours. The mortality rate for those brought to the hospital with an interval of more than 2 hours is 8%. Those brought in less than 1 hour had zero mortality. Of the admitted patients, 12 patients were kept on ventilator support of which 5 died, with a mortality rate of 41.7%. 67 patients consumed poison with the intention of suicide, with a mortality rate of 7.5% which was shown in Table 1.

The Chi-square test for sex distribution has a value of 3.80, with a p value of 0.05, this result was statistically significant. The Chi-square test for ventilator support is 28.96, with a p value of <0.0001, this result was highly significant. The Chi-square value for duration of hospital stay was 11.89, with a p value of 0.002, which is significant. The Chi-square value for mortality among various poisoning was 15.30, with a p value of 0.004, significant. The p values for age group, method of exposure, and time interval between consumption of poison and admission to hospital are all statistically not-significant ($p > 0.05$).

Discussion

In the present study, majority of the cases were males and belonging to the age group of 14 to 30 years. Acute poisoning was most seen in males (58.4%) which was similar with other studies like Awasthi PM et al.⁹ (63.1%); Gupta P et al.⁸ (57.58%); Somasundaram K.V et al.¹⁰ (64.7%); Joshi M et al.⁵ (54.4%); Chakrabarty P et al.¹¹ (64.2%); Ahmad M et al.¹² (58%); Gupta BD et al.¹³ (62.1%); and Dash SK et al.¹⁴ (53%). This may be due to the family burden, society pressures and work tension. However in a study done by Jamil H⁶, there was a greater percentage of females i.e., 52.8% which is 1003 cases out of 1900. In this study, poisoning was common among younger age group 14 to 30 years, which is the productive age group leading to burden on society i.e 62.3%. This was in similar to the study done by Jamal H⁶ in which 77% of their patients fall under the age group of 11 to 30 years.

The present study showed that the maximum number of cases were of poisoning cases with insecticide consumption (40.3%) which is expected in an agriculture based setting. This correlates with other studies like

Gupta P et al.⁸ showing 57.2% of poisonings to be organophosphorous poisoning; Joshi M et al.⁵ showing 25.8%, which was the leading cause of poisoning in their study. This was against a study done by Patil A et al.¹⁵ in which majority were of consumption of household products (44.6%) followed by pesticides (14.9%). In our study 87% of patients consumed poison with an intention of suicide, which was similar to the study done by Jamal H⁶ (70%). These results may be due to the easy availability of the insecticides in rural areas for agricultural use. An increased time interval between exposure to poisoning and admission to the hospital shows increased mortality rate in our study which was similar to a study done by Somasundaram K.V et al.¹⁰ Mortality rate observed in the present study was 6.5%. This mortality was lesser when compared to other studies like Somasundaram K.V et al.¹⁰ (12.1%) and Joshi M et al.⁵ (15.8%). Efforts should be made to educate the population regarding the importance of early admission and how that will decrease the mortality. Other reasons for delayed admission could be the lack of health care centres nearby or lack of proper transportation to health care centres.

Conclusion

The present study provided pattern of various acute poisoning cases and their outcome in a rural tertiary care hospital of Nalgonda district from July 2019 to January 2020. Our results showed that insecticide poisoning is the most common form of poisoning with high mortality among males. Poisoning was common among younger age groups and the poisoning with the intention of suicide was much greater than poisoning by accident. Factors like sex, type of poisoning, duration of hospital stay and ventilator support were significant factors determining the outcome. There is a need for appropriate training and counselling sessions of preventive strategies for individuals who are at risk of acute poisoning especially the younger age groups.

Cognitive Behaviour Therapy for ‘Internet Gaming Disorder’ A Systematic Review

Rekha B. Raveendran¹, S. Vinod Kumar²

¹KSCSTE Post-Doctoral Fellow, ²Head of the Department, School of Behavioural Sciences, Kannur University, Kannur, Kerala

Abstract

Internet gaming disorder (IGD) is a new disorder added in the 11th Revision of the International Classification of Diseases (ICD-11) by WHO. The DSM-5 states that Internet Gaming Disorder is most common among adolescents. Over the last epoch, there has been an increase in, problematic use of online videogames. Consequently, providing effective treatment is also disapprovingly crucial. The aim of this review is to assess the efficacy of Cognitive behaviour interventions for Internet gaming disorders. A computer database search PubMed, ScienceDirect, Springer Link, SciELO, Researchgate, SciHub and Google Scholar were conducted to identify all available research evidence on interventions for Internet gaming disorders. All searches have been limited to full text papers published from 2009 to 2019. The findings show that different interventions are applicable in reducing Internet gaming disorder signs and the period paid for gaming. When analysed the findings of previous studies, Cognitive Behaviour Therapy was found to be more prevalent for effective dealing of internet gaming disorders.

Key Words: *Internet gaming disorders, Cognitive Behaviour Therapy, Systematic Review*

Introduction

Currently, the whole World is discussing about the game and gaming. The entertainment business market is more concentrating on games and promoting the dependency toward gaming. Introducing new sequence of games with the release of new movies and television serials are examples for such addiction motivations. Internet Gaming Compulsion is more on gamers who have an unhealthy preoccupation with online video games, regardless of whether they are played on computers, consoles, or mobile devices³.

Internet Gaming Disorder is a “Condition for Further Study” in the DSM-5. The DSM-5 states that Internet Gaming Disorder is most common in male adolescents 12 to 20 years of age². ICD-11 categorized it under disorders due to addictive behaviours as Gaming disorder, predominantly online. Internet gaming disorder may lead to school failure, job loss, or marriage failure. Other diagnoses that may be associated with Internet gaming disorder include major depressive disorder, attention deficit hyper activity disorder, and obsessive-compulsive disorder⁸.

The prevalence of Internet gaming disorder is unclear because of the varying questionnaires, criteria and thresholds employed, but it seems to be highest in Asian countries and in male adolescents 12-20 years of age. There is an abundance of reports from Asian countries, especially China and South Korea, but fewer from Europe and North America, from which prevalence estimates are highly variable.^{14, 10}

So, in such a life-threatening condition, it is vital to review available, pertinent literature effective for gaming disorders. These findings can lead to the directions toward appropriate interventions for Internet gaming disorders.

Method

An organized systematic review has been conducted in computer database by the search terms: Psychological/ Treatment/ Intervention for Internet gaming disorders/ internet gaming addiction. The search databases were PubMed, ScienceDirect, Springer Link, SciELO, Researchgate, Sci Hub and Google Scholar and selected full text papers published from 2009 to 2019.

The following results were contained within in each database: ScienceDirect-7, PubMed-5, Springer Link-2, Sci Hub-2, SciELO-3, Research gate-3 and Google Scholar-8. There were a total of 30 studies discussing about the treatments for internet gaming disorders but screening of the studies in PRISMA criteria excluded 20 numbers of studies and selected only 10 studies for the meta-analysis. The initial exclusion was based on the duplication of studies and 7 studies excluded based on the duplication criteria. Then, the number of studies identified was 23 and again screened for full papers, five of the studies omitted. There were total 18 numbers of studies with full papers. Then, according to the eligibility criteria, 8 additional studies were eliminated since they reported lack of treatments, 4 studies were deleted since not mentioned about effectiveness of the treatments, 3 other studies rejected as not mentioned name of the interventions, 3 other study also excluded because of inclusion of psychiatric medication along with psychological treatments. Consequently, there were only 10 studies to proceed with the systematic analysis.

Results

Thirty studies were evaluated in terms of sample characteristics, aim of the study, treatment, and results. Although the searched for studies from 2009, in the current systematic-analysis, the first study obtained from year 2012. Two studies in 2014, one studies each in 2015 and 2016. Two studies published in 2017, 2 studies in 2018 and one study in 2019.

There were a total of 30 studies discussing about the treatments for internet gaming disorders, but screening of the studies excluded 20 numbers of studies and selected only 10 studies for the systematic analysis. The initial exclusion was based on the duplication of studies and 7 studies excluded based on the duplication criteria. Then, the number of studies identified was 23 and again screened for full papers, five of the studies omitted. There were total 18 numbers of studies with full papers. Then, according to the eligibility criteria, 8 additional studies were eliminated since they reported lack of treatments, 4 studies were deleted since not mentioned about effectiveness of the treatments, 3 other studies rejected as not mentioned name of the interventions, 3 other study also excluded because of inclusion of psychiatric medication along with psychological treatments.

Consequently, there were only 10 studies to proceed with the systematic analysis and for the discussion of the psychological interventions.

Discussions

When analysing the treatment methods in all these 10 studies, Cognitive Behaviour therapy was found to be more popular for treatment of internet gaming disorders.

King et al.⁹ conducted a study on 'Clinical Interventions for Technology-Based Problems: Excessive Internet and Video Game Use'. The study presented an overview of the prevalence of technology-based problems and the known cognitive behavioural dimensions of problematic technology use. The paper also gone through issues related to the assessment of technology-based problems, and critically reviewed clinical treatments for technology-based problems and find out that multimodal approach to treatment, including psychoeducation and CBT-based therapies are more effective in management of Internet Gaming Disorders. The paper came to these conclusions through analysing of recent prevalence studies conducted in Western and Eastern countries. All the studies were with more than 1,000 participants and being published in the recent 5 years.

Karapetsas et al.⁷ illustrated the underlying factors for game addiction are poor interpersonal relationships, aggressiveness, isolation, introversion, low self-esteem, low self- control, tediousness, and communication problems. The researchers recommended motivational interviewing and social skill training as interventions for internet gaming addiction.

Internet and video game addictions: a cognitive behavioural approach was explored by Lemos et al.¹¹. The study described cognitive behaviour therapy as the best psychotherapy for Internet and video game addiction. Diagnosis and Management of Video Game Addiction was a study by Griffiths⁵. The study suggested that, family therapy, couple therapy, social skill training, mental health counselling, interpersonal therapy, motivational interviewing, subliminal therapy and behaviour therapy are effective treatments for gaming disorder.

Zhang et al.¹⁶ recognized that craving behavioural intervention is effective in reducing craving and severity in Internet gaming disorder. Young et al.¹⁵ investigated the available theoretical foundations and practical evidences and the application of the Interaction of Person-Affect-Cognition-Execution (I-PACE) model, for the development of new intervention patterns based on Cognitive-Behavioural Therapy for Internet gaming disorder and concluded that the cognitive restructuring is useful for changing the expectancies of gamers and to manage addiction towards gaming.

Torres-Rodríguez et al.¹³ conducted a study on the treatment of internet gaming disorder: a brief overview of the PIPATIC program. The model put together different aspects of interventions which include: psychoeducation, common management techniques, intrapersonal, interpersonal, family intervention, and development of

a new lifestyle. The efficacy of the treatment program reported hopeful, based on the participant observation.

González-Bueso, et.al.⁴ evaluated the effectiveness of a cognitive behavioural treatment on reducing symptomatology, and the results indicated the effectiveness of psychoeducation programme.

Nazlıgül et al.¹² carried out a study on internet gaming disorder and its treatment approaches to determine the results of psychoeducation for the parents and cognitive behaviour therapy for gamers. The analysis concluded that psychoeducation and cognitive behaviour therapy are effective interventions.

Costa et al.¹ conducted a systematic review is to create an idea of the interventions used for gaming disorders in clinical practice and taken together, verified that clinical studies primarily use CBT interventions.

Table 1: Psychological Interventions for Internet Gaming Disorders

INTERVENTION	S1	S2	S3	S4	S5	S6	S7	S8	S9	S10
Psychoeducation	*						*	*	*	
Cognitive Behaviour therapy	*		*			*		*		*
Craving behavioural intervention					*					
Family therapy				*			*	*		
Couple therapy				*						
Social skill training		*		*						
Counselling				*						
Motivational interviewing		*		*						
Subliminal therapy				*						
Behaviour therapy				*						

S= study

Cognitive behavioural therapy suggested by 5 studies, Psychoeducation recommended by 4 studies, family therapy proposed by 3 studies, motivational interviewing recommended by 2 studies, social skill training proposed by 2 studies, craving behavioural intervention, couple therapy, counselling, subliminal therapy and behaviour therapy were recommended by one studies each.

Thus, the evidences from the studies suggested that, cognitive behaviour therapy, the psycho-social intervention that aims to improve mental health is found to be more effective treatments for internet gaming disorder.

Although there are a very a smaller number of studies were conducted in this field and still scientific world is not much involved in the problems related to Internet gaming disorders, a small evidence base suggests that cognitive behaviour therapy has good preliminary support in treating gaming addicted adolescents.

Conclusion

The internet gaming disorder apparently generating disturbances in individual's psychological and social wellbeing. When analysing the previous studies in internet gaming disorder intervention, both individual and family therapies were found to be essential for removal of the addiction and management of associated behaviours.

In the present review, Cognitive behaviour therapy was recommended by most of the researches and shown more efficacy to attain self-discipline and self- control.

Effects of Stretch Pole Exercises on Pulmonary Functions among Smartphone Users

Rekha K¹, Rubi Kankariya², Roshini Nivetha M²

¹Assistant Professor, Saveetha College of Physiotherapy, Chennai, India,

²BPT Intern, Saveetha College of Physiotherapy, Chennai, India

Abstract

Aim: To determine the effects of stretch pole exercises on pulmonary functions among smartphone users.

Objective: To evaluate the effects of stretch pole exercises on FEV₁, FVC, and FEV1/FVC.

Method: A total of 10 patients were selected based on the inclusion and exclusion criteria. Detailed procedure was explained to the patient in colloquial terms, and informed consent was obtained. They were allocated in a single group and were treated with stretch pole exercises. After four weeks forced vital capacity, forced expiratory volume in one second and the ratio of forced expiratory volume in one second to forced vital capacity was measured as a post test.

Result: Based on the obtained statistics, there was significant improvement in FVC, FEV1 and FEV1/FVC ratio at the end of four weeks within the group when compared to the pre-test values (p<0.05).

Conclusion: The study concluded that the stretch pole exercises both clinically and statistically have significant effect in improving forced vital capacity, forced expiratory volume in one second and their ratio among smartphone users. Therefore, the implementation of these exercises is recommended in clinical practice.

Keywords: Smart phone users, Pulmonary functions, stretch pole exercise.

Introduction

In today's society, a smartphone is one of life's essential goods and its usage has been increased progressively. The magnitude of smartphone addiction among Indian teens is from 39% to 44%, in UK it was found to be 60%, in South Korea it is 18%, double the addiction rate of 9.1% for adults [1]. "Smartphone's addiction/abuse/misuse" is now challenging the health policy makers globally to think on this rapidly emerging issue. In 2013, there were around "51 million"

Smartphone users in Urban India and rate of rise from year 2012 was 90%. The age group of 16-18 years using Smartphone's have shown a rapid rise from 5% in 2012-25% in early 2014. Prolonged smart phone usage causes faulty posture such as forward neck posture, slouched posture, or rounded shoulders which can cause injury to the structure of the cervical and lumbar spine, as well as ligaments [2].

The head represents 6% of total body weight; therefore it can significantly affect the biomechanics of human posture control, movements and activities. When set out of vertical body axis, head position interferes with the work of the other links in the kinematic chain. Changing the position of the head causes disturbances in the three-dimensional shape of the chest and its respiratory movements [3]. When forward head posture (FHP) is maintained for prolonged periods the neck

Corresponding author:

Rekha K, MPT, PhD

Assistant Professor, Department of Cardio-respiratory Physiotherapy, Saveetha college of Physiotherapy, Saveetha Institute of Medical and Technical Sciences, Chennai, Tamil Nadu, India

flexors and the erector spinae muscles in the upper thoracic region are weakened due to their lengthening, and the scapula is elevated due to tension in the levator scapula, sternocleidomastoid, splenius muscles, and the suboccipitalis, which also causes tension in the upper trapezius. Therefore, because of an imbalance in the muscles, such as the shortening or lengthening, or straining or loosening of the muscles around the neck, a rounded shoulder posture is exhibited. This causes imbalance in stretching and shortening of antagonist and agonist muscles which further aggravates pain and damage [4]. Some studies have reported that the forward head posture causes nasal breathing or mouth breathing which is a mechanically incorrect form of respiration.

Body position can influence respiratory function by altering the Diaphragm, thereby influencing its ability to generate tension. Several studies have reported that a slumped, poor posture significantly reduces lung capacity, expiratory flow, and lumbar lordosis compared with a normal upright posture [5]. The shortening of respiratory muscles such as the serratus anterior, pectoralis minor and intercostalis may increase energy expenditure and reduce lung volumes and capacities [6]. The non-neutral position of neck may affect lung functions; a distinct decrease was seen in lung volumes and capacities [7]. When used for many years with postural and respiratory compromise it can further lead to decrease in functional capacity of the individual [8].

The placing of the head and neck in proper alignment can reduce airway obstruction, helping to increase pulmonary function [9]. The cervical curve interacts with thoracic vertebrae and lumbar vertebrae [10]. Increased kyphosis of lumbar vertebrae correlates with forward head posture; flexion of lumbar vertebrae leads to increased cervical extension [11].

The exercises like chin tuck ins, push ups and cervical sustained natural apophyseal glide are proven to be effective in improving respiratory functions like forced vital capacity, forced expiratory volume in one second and ratio of forced expiratory volume in one second to forced vital capacity in altered posture.

Thoracic Conditioning training on stretch pole involves exercises that are given for trunk muscles, postural control and respiratory muscles may thus have the potential to induce benefits in muscle strength, spinal

mobility and balance performance [12]. The respiratory muscles are directly involved during common core stability exercises [13]. Hence, this study is proposed to determine the effects of thoracic conditioning with stretch pole on pulmonary function among smart phone users.

Materials and Method

A Quasi Experimental Study was conducted at Saveetha College of Physiotherapy, Thandalam, Chennai. Following the Institutional Scientific Review Board and ethical committee approval the study was initiated. The study procedure was explained to all the participants with an information sheet and written informed consent was obtained.

The inclusion criteria of the study was both male and female, age 17-20 years, Smartphone Addiction Scale of Shorter Version (SAS-SV) score more than 33 in males and more than 31 in females, FVC<80%, Pectoralis minor tightness, BMI ranging from 22-25kg/m² and the exclusion criteria was Cardio Vascular diseases, Obstructive and restrictive lung diseases, Relevant Orthopaedic conditions, Trauma to chest wall and spine, thoracic and abdominal surgery.

A Smartphone Addiction Scale of Shorter Version (SAS-SV) was given to 50 subjects randomly in a population and the participants were asked to answer those questions. Based on the scores, 26 participants were recruited for next level of screening. The assessment of the individuals was done. Four subjects were excluded as they met the exclusion criteria. Also, the pectoralis minor muscle length was measured using inch tape by measuring the distance between coracoid process and 4th rib of the same side. 14 subjects exhibited muscle tightness. These participants with pectoralis minor tightness were tested for pulmonary function parameters like forced vital capacity, forced expiratory volume in one second and the ratio of forced expiratory volume in one second to forced vital capacity using spirometer. Among which 10 subjects had FVC<80% and were included in the study. They were allocated in a single group and were treated with stretch pole exercises. After four weeks forced vital capacity, forced expiratory volume in one second and the ratio of forced expiratory volume in one second to forced vital capacity was measured as a post test.

Treatment procedure:**Shoulder abduction and adduction:**

Position: The subjects were asked to lay supine on stretch pole vertically placed with knees maintained in flexed position. Subjects were instructed to repeatedly abduct and adduct both shoulders with both forearms sliding on the floor.

Latissimus foam rolling:

Position: The subjects were asked to lie on side with the stretch pole under one armpit. Subjects were instructed to rotate chest slightly open so the pole is hitting the side of the back. Extend that bottom arm up overhead. Then rotate chest toward the ground and then up toward the ceiling.

Thoracic extension:

Position: The subjects were asked to lie supine on stretch pole horizontally placed at mid back region. Knee is maintained in flexed position and the hands crossed over the chest. The subjects were instructed extend

back over the stretch pole and simultaneously take arms overhead.

Floor polishing:

Position: The subjects were asked to lie supine on stretch pole vertically placed with knees maintained in flexed position. Subjects were instructed to round hands to draw circles on the floor.

Parameters:

12 repetitions each exercise per session for 3 sets

1 session per day for 20-30mins

5 days / week for 4 weeks

Results

The collected data was tabulated and analysed using descriptive & inferential statistics. To all parameters mean and standard deviation (SD) was used. Paired t-test was used to analyse significant changes between pre-test and post-test measurements.

Table-1: Comparison of Pre-test and Post-test values of FVC, FEV₁ and FEV₁/FVC

Pulmonary function	Pre-test		post-test		SEM
	mean (in%)	SD	mean (in%)	SD	
FVC	73.7	3.45	77.1	2.5	0.562
FEV1	72.1	4.08	74.7	11.4	0.221
FEV1/FVC	99.5	6.67	102.7	16.7	0.727

Discussion

In this study, we investigated whether thoracic core conditioning exercises on stretch pole could change the respiratory function among smart phone users. Recently, the number of smart phone users has been increasing worldwide. Accordingly, the negative aspects of smart phone overuse have been emerging as a major topic of interest in young adults.

Previous studies have investigated that the people who used smart phones for prolonged duration had

partly impaired respiratory function. Legrand et al concluded that forward head posture causes shortening and weakening of the accessory respiratory muscles, thereby decreasing the respiratory function. Shortening of accessory respiratory muscles such as the pectoralis minor, serratus anterior and intercostalis may increase energy expenditure and reduce respiratory capacities^[14].

Baghery H et al reported that respiratory function in slumped sitting is significantly lower than in other posture such as normal sitting or standing & similarly,

kyphotic posture caused by using a smart phone for a long time can impair respiratory function^[15]. Measuring Pectoralis minor muscle length with an electromagnetic motion capture system using the coracoid process and the fourth rib as origin-insertion landmarks has shown excellent validity and is considered the “gold standard” method. However, the electromagnetic system is time-consuming, expensive, not typically available to clinicians, and mainly used for research purposes. A tape measure and calliper both demonstrated good reliability with the electromagnetic system. Although both tools have good reliability, a tape measure is more readily available and easily manipulated in clinical practice. Pulmonary function tests are valuable investigations in the management of patients with suspected or previously diagnosed respiratory disease. They aid diagnosis, help monitor response to treatment and can guide decisions regarding further treatment and intervention. A sitting position is typically used at the time of pulmonary function testing to prevent the risk of falling and injury in the event of a syncopal episode.

Previous studies found that subjects with head, neck, and shoulder discomfort are more likely to have a smaller cervical angle. Costa R et al stated that postural changes influences the diameter of rib cage and in long run affects the expansion of it and thereby reducing the FVC and FEV₁ equally^[16]. Gibson GJ et al concluded that overweight and obese individuals are more likely to have respiratory symptoms than individuals with a normal BMI, even in the absence of demonstrable lung disease^[17].

In this study the obese patients were excluded as obesity increases the work of breathing because of the reductions in both chest wall compliance and respiratory muscle strength. This reduction creates an imbalance between the demand on the respiratory muscles and their capacity to generate tension, which leads to the perception of increased breathing effort. Berolo S et al found the prevalence of musculoskeletal symptoms among mobile hand-held device users and their relationship to device use. They reported that prolonged smart phone usage causes faulty posture such as forward head posture, slouched posture or rounded posture^[18].

There are a number of studies about the adverse effects of smart phone overuse. However, there are

no studies about the effect of exercises in solving the abnormalities mainly respiration and its effect on pulmonary capacity among prolonged smart phone users. Hence, for these reasons we have proposed this study to investigate the effects of thoracic core conditioning exercises with stretch pole on pulmonary function among smart phone users.

This study included both male and female participants between 17-20 years of age. These exercises are subjected to be more comfortable in supine on the stretch pole which reduces strain and gives a better feeling of relaxation of the whole body. The stretch poles used were selected according to the built and comfort of the subjects. It is found from the analysis that the subjects who received four weeks of thoracic core conditioning exercises with stretch pole have shown significant improvement on the FVC, FEV₁, FEV₁/FVC ratio.

Although the exercises were short and simple, the facilitated muscles would influence the improvement of respiratory function. The core conditioning exercises help to stretch the respiratory muscles which reduce the muscle tension resulting in relaxation of the muscles of the respiration. While performing these exercises thorax is observed to stretch on the pole. The findings of the study showed that proper exercise could be a good method of improving the pulmonary function in smart phone users. Hence, we reject the null hypothesis.

Conclusion

Since the prolonged usage of smartphones adversely affects the human health, it is the need of the hour to teach young adults to be structured; to become the master of technology instead of its slave. It is concluded that the stretch pole exercises both clinically and statistically have significant effect in improving forced vital capacity, forced expiratory volume in one second and their ratio among smartphone users. Therefore, the implementation of these exercises is recommended in clinical practice.

A Study on Employee Health and Safety of Weaving Cooperative Society with Reference to Kannur District

Reshmi Jk Babu¹, Ambily AS²

¹M.Phil Research Scholar, ²Assistant Professor, Department of Commerce and Management, Amrita School of Arts and Science Kochi, Amrita Vishwa Vidyapeetham, India

Abstract

The study on employee health and safety in weaving cooperative society examines the health and safety adopted by the management for the employees and also the level of satisfaction of the employees. Through this study it gives an overall idea about the health and safety measures taken in the weaving cooperative society and also it can improve the strategy if needed. And it's also a kind of information which can be adopted by many. The study is mainly targeted at the employees in the weaving cooperative society and the study is conducted in cooperative weaving society in Kannur district. The type of research used in the study is descriptive in nature.

Keywords: *Employee health and safety, weaving cooperative society, Kannur district, Kerala handloom industry, employee awareness, role of management in employee health and safety, measures taken by society, training of employees.*

Introduction

In the economy of Kerala handloom occupies a prominent place as a traditional industry. Handloom industry is the major traditional industry in Kerala. The handloom industry includes the cooperative societies both industrial, primary, kadhi units and the unorganized individual units. Handloom industry has its presences in all the 14 districts of Kerala. The directorate of handlooms, government of Kerala has identified Kasargod, Kannur, Palakkad, Kuthampully in Thrissur district, Chandamangalam in Ernakulam district, Balaramapuram in Thiruvananthapuram district as places of regional importance in handloom production. Handloom industry in Kerala is dominated by the cooperative society. Among these Kannur is one of the handloom cooperative societies.

Kannur the Northern district of Kerala⁵, is properly known as the 'city of loom and lore's', town of export excellence". Due to its unending relation with handloom industry. Industry is spread in 37 panchayat and 5 municipalities'. Because of the quality and frame of kannur handlooms, kannur is commonly known as the Manchester of Kerala. The total number of handlooms

societies in Kannur are nearly 52 and among them working are only 37 and rest are 5 are liquidated and 10 are not working. The first weaving society introduced in kannur was at chirakkal, in 1936.

⁵In the present study titled 'employee health and safety in weaving cooperative society of Kannur district' the researcher mainly focuses on the importance of health and safety of employees of cooperative society, the study also analyze the health and safety measures provided by the society for the employees. Since health is an important part in the life of human being the organization gives keen interest in the same. In weaving society there are many measures that are taken by the management in the health and safety of the employees. The training and other procedures are done in order to make the employee familiar about the safety measures and regular medical checkups are also conducted for the employees. So this study helps to know about the procedures taken by the weaving society for the health and safety betterment of the employees.

Statement of the Problem:

Human resource of an organization is considered to be the wealthier assets. But the organization in order to

satisfy the consumers need provide more focus on quality and quantity of products produced. Management gives more focus on the customer satisfaction by ignoring the employee health and safety that effect in future on their work. And this leads to their poor performance and low quality of products. It is important that management has to give attention on both employee health and safety and on production. So, management can take appropriate strategy to improve the employee health and safety to have a better future.

Literature Review

1. K. Logasakthi, K.Rajagopal,¹ in the year 2013, made a “study on employee health, safety, and welfare measures of chemical industry in the view of Salem region. And study focused on the health and safety measures taken by the management for their employees. And the study found that management provides all the facility and also all the health and safety to the employees that will help to produce high performance in there working.

2. Samuel howardquaterny and Bill buenarpiplampu,³ in 2012, made a study focused on “employee health and safety practices: An exploratory and comparative study of the shipping and manufacturing industries in Ghana”. The purpose of the study is to examine the employee health and safety practices in shipping and manufacturing industries. The study resultsthat shipping industry has more health and safety measures than the manufacturing industry. Since the shipping industry consider health and safety as a part of social responsibility.

3. Susana garicahemero, Javiergarrica and Dale ritzel,⁴ in the year 2011, made a study on “the impact of occupational hazard information on employee health and safety an analysis by professional sector in Spain”. The aim of the study was to analyses the influence in which preventives information has on certain variables relating to workers. The results indicated the importance of information in companies. The given information for workers has the most positive impact.

4. Muhtesembaran, PelinKantenmurat², in the year 2009, conducted the study on “An empirical research on the relationship between job insecurity and employee health and safety”, the study is to investigate

the relationship among the insecurity perception of employees, health symptoms and unsafe behavior of employees. The study results that both mental and physical health symptoms are related with job insecurity perception.

Objective of The Study

1. To study the employee health and safety in weaving cooperative society.
2. To study the awareness of workers about health and safety in the workplace.
3. To study the role of management in communicating the health and safety measures.
4. To know the satisfaction level of employees towards health and safety measures.
5. To study employee satisfaction with respect to working environment.

Hypothesis:

The hypothesis governing the study is given below:

1. H0: There is no association between awareness of workers and the effective communication of health and safety measures.

H1: There is an association between awareness of workers and effective communication of health and safety measures.

2. H0: There is no significant relationship between the work environment and the level of satisfaction of employees.

H1: There is a significant relationship between the work environment and the level of satisfaction of employees.

Research Methodology\

The study is purely descriptive in nature. Both primary and secondary data is used for the study.

Primary data was collected through questionnaire among 40 respondents from weaving cooperative society. Secondary data are collected through books, magazines, journals, paper publications, reports. The sampling method used for the study is simple random

sampling.

Sample design

Sample size cooperative societies	Total number of respondents
weaving cooperative society	20
weaving cooperative society	20
Total	40

For the purpose of getting analysis output the statistical tool used for the study are chi-square, ANOVA and regression.

Scope of the Study:

The study is limited towards the 2 cooperative society of Kannur district. The study is mainly focused on the health and safety of the employees in the weaving cooperative society in Kannur district. Since the study is focused to the health and safety of employees it does not have the scope for questions from whole of cooperative society and their other operations. So, the study is useful for assessing the regulations of management in employee health and safety.

Analysis And Interpretation:

For the purpose of knowing the reliability of the questions which consisted of 26 items the Cronbach

alpha was conducted, and by testing the reliability, the Cronbach's alpha value obtained is 0.966, which indicates a high level of consistency i.e., the extent to which a scale produces consistent result.

Reliability Statistics	
Cronbach's Alpha	No of Items
.966	26

In the present study titled 'a study on employee health and safety of weaving cooperative society with reference to Kannur district 'mainly focus on health and safety of the employees. Majority of the employees are with age group of 36-45 with the qualification pre-degree and with the experience of 15 years. Study helps to know about the employee awareness about health and safety and also there satisfaction level in the working environment.

For analysis the chi-square test is being used as statistical tool. A sum of revision has been directed to discover the association among awareness of workers and the effective communication of health and safety measures is yet to be obtain its owing in the exploration.

Chi- square

Table: 1 Awareness of the respondents on health and safety measures.

Chi square	Value	Df	Asymptotic Significance (2-sided)
Pearson Chi-Square	52.923a	9	.000
Likelihood Ratio	60.109	9	.000
Linear-by-Linear Association	34.430	1	.000
N of Valid Cases	40		

a. 13 cells (81.3%) have expected count less than 5. The minimum expected count is .05.

Source: primary data

Table no 1.1 shows a significant impact of awareness of respondents on health and safety measures adopted and effective arrangements for communicating health and safety matters. Since p value <0.05, df=9, since reject the null hypothesis and alternative hypothesis is accepted.

The statistical tool used for the analysis is regression. A sum of revision has been directed to discover the association among awareness of workers and the effective communication of health and safety measures is yet to be obtain its owing in the exploration.

Regression Model 1

Table : 2 The safety of working environment and the satisfaction level of employees

Table 1.2: Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.859a	.738	.732	.508
a. Predictors: (Constant), satisfactory level of health and safety measures taken				
b. Dependent Variable: safety of working environment				

Source: primary data

The regression analysis in table 1.2 with the fore mentioned dependent and independent variables supported an R² of 0.738 and adjusted R² value of 0.732.

Table : 3 ANOVA						
Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	27.690	1	27.690	107.255	.000b
	Residual	9.810	38	.258		
	Total	37.500	39			
a. Dependent Variable: safety of working environment						
b. Predictors: (Constant), satisfactory level of health and safety measures taken						

As shown in Table 1.3, the examination of the model also indicated that all these variables together work as a significant predictor of the effect of testing on employee satisfaction (F=107.255, P< 0.01).

Table : 4 Coefficients						
Model		Unstandardized Coefficients		Standardized Coefficients	T	Sig.
		B	Std. Error	Beta		
1	(Constant)	.488	.146		3.343	.002
	Satisfactory level of health and safety measures taken	.753	.073	.859	10.356	.000

a. Dependent Variable: safety of working environment

The study postulated in hypothesis that there is significant relation between satisfactory level of health and safety measures taken. In support with this, the study significant result (beta=0.488, P<0.01) Thus, the study found support for the significance of hypothesis.

Findings

- The majority of the employees are in the age group of 36-45 in weaving cooperative society.
- Majority of the employees in weaving cooperative society are female.
- Majority of the employee in cooperative society are with the qualification pre-degree.
- Majority of the employees are provided with well developed training facilities.
- Also majority of the employees are with above 15 years of experience.
- Employees are provided with the health and safety measures and also the basic needs are being satisfied.
- The majority of the employees are registered in the trade unions.
- Employees are provided with well furnished work space.

- Safety inspections are being conducted in regular intervals to ensure the safety of the employees at work.
- Study resulted that employee are well satisfied with the health and safety measures taken by the society.

Suggestion:

- The management should provide the health insurance to the employees working in the cooperative society.
- The employees should be provided face masks free of cost so that respiratory issues may not occur to the employees.
- The employees should be given adequate training in handling the equipments so that they reduce the cost of employing other equipped people.

Conclusion

Health is quite significant for every human capital. Human capital here means the employees. By giving the proper health and safety for the employees the management can achieve higher productivity. The management communicates the health and safety measures taken to the employees, and for this purpose they should have a proper superior subordinate relationship. This study establish the significant relationship between the awareness of workers and the effective communication of health and safety measures and also the working environment and level of satisfaction of the employees and the study conclude that it has a positive relationship between the awareness

of workers and the communicating the health and safety measures and also it has a significant relation among the work environment and the level of satisfaction of employees. Hence, the study of employee health and safety in weaving cooperative society in Kannur District.

A comparative study of Venous and Capillary blood glucose in a Tertiary Care Hospital

Richa Sirohi¹, Ravi Pratap Singh¹, Kalpana Chauhan²

¹Assistant Professor, Department of Biochemistry, ²Associate Professor, Department of Microbiology, Subharti Medical College and Associated Chhatrapati Shivaji Subharti Hospital, Meerut, UP, India.

Abstract

Introduction: The cornerstone of providing optimum diabetic care in a tertiary care hospital is monitoring of glycemic status of the patient by the health care provider. Bed-side monitoring helps in achieving the glycemic goals in admitted patients. But it is important that the glucometer being used is accurate, calibrated and the values obtained from glucometer are as near as to the plasma glucose values obtained in the laboratory. Above factors can lead to unnecessary change in treatment which might result in hyper or hypoglycemia, which is a life-threatening situation and most common complication of diabetes. Therefore correlation in capillary and venous blood glucose will definitely help in better management of patients, especially in Intensive Care Units (ICUs). **Aims and Objectives:** The present study was done to determine the mean difference and correlation between capillary and laboratory venous plasma glucose estimation. **Material and Methods:** The study was carried out in a tertiary care hospital in Meerut. Total 373 subjects (176 males and 197 females) including 149 cases with altered glucose levels and 224 control subjects were studied. After overnight fasting, capillary blood glucose by glucometer and venous plasma glucose by Siemens autoanalyzer were estimated from all subjects, aged above 18 years. Both samples were taken at the same time. Mean difference and correlation coefficient were determined. **Results:** It was observed that there was a significant difference between capillary and venous blood glucose values. The capillary blood glucose value on an average was 10.19% higher than venous blood glucose values. **Conclusion:** According to the results obtained, it was concluded that glucometer, as a sole measuring device in a hospital setup, is not satisfactory. The venous blood glucose is a better indicator and is of utmost importance for confirmatory results. This is also of utmost importance in deciding the dose of insulin in diabetic patients who are on insulin infusion.

Keywords : Continuous glucose monitoring, Venous blood glucose, Capillary blood glucose

Introduction

Monitoring of blood glucose concentrations is very important, especially in diabetics. The blood glucose may fluctuate from time to time. There are various factors which may lead to this fluctuation in daily healthy life including diet component, level of activities, mental status and change in environment. This fluctuation

further increases in diseased state, especially in type 2 Diabetes Mellitus (T2DM). Blood glucose monitoring is the basis of the treatment of diabetes. It helps to formulate therapeutic measures, determines the level of carbohydrate metabolism, evaluate effects and optimal control of blood glucose^[1]. Blood glucose estimation can be done by capillary blood (finger-prick method) using a glucometer at the bedside of the patient and by venous blood (plasma) sampling tested in the laboratories.

Corresponding Author

Dr Ravi Pratap Singh

Subharti Medical College and Associated
Chhatrapati Shivaji Subharti Hospital, Meerut, UP, India
e-mail: dr Raviochem@gmail.com

Continuous glucose monitoring (CGM) has an immense potential in revolutionization of diabetic care. The data that is provided is both complex and voluminous^[2]. CGM device is used to measure blood glucose in the interstitial compartments. This interstitial

blood glucose level is related to blood glucose through a diffusion process^[3]. Few studies have been done to estimate the accuracy of CGM by glucometers. Rabiee *et al.* reported that CGM missed around 50% of the 30 episodes of hypoglycemia as estimated by Accu-Check glucometer, and therefore the authors concluded that it is unsafe to use glucometers especially in Intensive Care Unit (ICU) settings^[4].

Glucometers work predominantly on two principles: Electrochemical(amperometry) and reflectance photometry. The enzyme used in glucometers is glucose oxidase. This induces an electric current through the strip, which is in proportion to the amount of glucose present. In reflectance glucometers, the colour of the strip changes colour according to the amount of glucose present in the sample. The quantification of colour change in these glucometers is done by reflectance photometry. Glucometers can give a false low value if the drop of blood does not cover the entire testing area of reflectance. Also, they are either manual (wiping) or automatic (non-wiping). Another factor which has shown to affect the glucose values in reflectance meters is the ambient temperature. It has been demonstrated in one study, that the manual reflectance glucometer overestimated the glucose concentrations by 14% at 44°C and underestimated by 12.7% at 25°C^[2].

The American Diabetes Association (ADA) recommends that glucometers should produce measurements within 5% of reference values. They can be used as an alternative to reference glucose analyzers if the measurement error of these glucometers is less than 5%^[5]. The purpose of this study was to compare Venous and Capillary blood glucose in a Tertiary Care Hospital.

Material and Method

Study design and setting

This is a cross-sectional study carried out in Clinical Biochemistry Laboratory, Subharti Medical College and associated Chhatrapati Shivaji Subharti Hospital, Meerut, for a period of 6 months(August 2019 to January 2020).Chhatrapati Shivaji Subharti Hospital, Meerut. A total of 373 subjects were included in the study .Out of which 167 were males and 206 were females.

Sample Collection:After pre-informed overnight fasting (atleast 8 hrs.) venous blood samples were collected by professional nurses from the right antecubital vein in fluoride vial and capillary blood was collected by finger-prick from right ring finger were taken simultaneously from all the subjects.

Sample Processing

The capillary blood glucose was estimated by CareSens N Glucometer using strips by Glucose Oxidase Method. The venous blood samples were centrifuged for 10 minutes at 3500 rpm to obtain plasma in Clinical Biochemistry Laboratory. The blood glucose levels were estimated by a fully automated analyzer (Dimension RXL) by hexokinase method.

All subjects were divided into two groups according to the glucose values obtained in the laboratory. Control group included non-diabetic values (fasting <100 mg/dL) and Diabetic group (fasting \geq 100 mg/dL). Diabetic group included a total of 149 subjects (67males and 82 females) and the control group included 224 subjects (109 males and 115 females).

Statistical Analysis

The statistical significance was assessed by a Pearson correlation. A value <0.0001 was considered as statistically significant.

Ethics

The approval from the Institutional Ethical and Research Committee was obtained before conducting the study.

Results

A total of 373 subjects were enrolled in the study, out of which 176/373 (47.2%) were males and 197/373 (52.8%) were females with a mean age of 38.7 \pm 13.2 and 40.6 \pm 12.2 respectively. The mean venous and capillary blood glucose were 115.4 \pm 55.6 and 126.2 \pm 62.4 respectively, giving a statistically significant difference (p<0.001) between the mean values for the laboratory and capillary glucose samples (10.8 mg/dL; 95% confidence interval (CI) 5.8 to 22.8).

The authors observed a good correlation between capillary and venous plasma glucose level in all the

subjects (Fig 1) , control group (Fig 2) and Diabetic group (Fig 3) and on statistical analysis , significant p value (<0.0001) was obtained in all the groups. Appreciable differences were observed despite good correlation in capillary and venous plasma glucose level (Bland and Altman plot- Fig 4) .

Fig 1:The correlation between venous and capillary blood glucose in all subjects . (n=373)

Fig 2:The correlation between venous and capillary blood glucose in control group . (n=224)

Fig 3:The correlation between venous and capillary blood glucose in Diabetic group. (n=149)

Fig 4: Bland and Altman plot: capillary and venous plasma glucose. (n=373)

Discussion

Blood glucose monitoring should be done on regular basis for preventing hypoglycemia and titrating medications [6]. However, it is important that blood glucose measurement is accurate. The evidence provided in literatures is not established as to whether capillary or venous blood glucose measurements are more accurate. In addition to this, there is an increased concern about the accuracy of capillary blood glucose estimation in systemic illness, and in such patients, it has been suggested that venous sampling tested in laboratories may be more accurate [7].

The aim of the present study was to test the accuracy of capillary derived blood glucometer results versus venous plasma glucose levels tested in the laboratory. A statistically significant difference ($p < 0.0001$) was seen between capillary versus venous blood glucose estimations. In our study, capillary values were higher than the venous values. In control group (< 100 mg/dL), the capillary values were higher by 8.5%, while in patients with high blood glucose levels (≥ 100 mg/dL), the capillary values were higher by 10.4%. The capillary blood glucose was higher by 9.4% combining both control and high glucose value groups.

Similarly, Mitra S *et al* reported that the capillary values were higher than the venous values and it was

within 10-11% of the venous values [8]. A study by Patel N *et al* compared capillary and venous blood glucose levels taken from patients on outpatient department basis irrespective of their diabetic and non-diabetic status. The values were compared at less than 100 mg/dl, between 100-200 mg/dl and more than 200 mg/dl. The capillary blood glucose levels measured by glucometer were 7% to 15% higher than venous blood glucose levels by laboratory and also agreed more than 95% times [9]. Yang C *et al* reported in their study that the mean capillary blood glucose concentration was higher than the mean venous blood glucose concentration by 35% [10]. The phenomenon of capillary blood glucose concentrations higher than venous blood glucose concentrations was common at all time points

In the present study, it was also observed that the variation between capillary and venous blood glucose values increased with an increase in the blood glucose values. Similarly Patel N *et al* also reported in their study that the variation percentage between capillary and venous values increases as blood glucose level increases [9].

Capillary blood glucose measurement can be done for glucose charting in all patients, but it should be compared with plasma glucose values on a daily basis. Boyd R *et al* reported, a degree of caution should

be taken in the interpretation of bedside glucometer measurements as they may not be accurate to replace laboratory blood glucose results.^[7]

Conclusion

To conclude, capillary blood glucose estimation by glucometer is not as reproducible as venous blood glucose estimation. The variation becomes wider as the glucose value increases without any specific trend. It is recommended that venous blood glucose should always be estimated as it is very important to test an accurate blood glucose value and find out symptoms of hypo or hyperglycemia immediately without further deterioration. So, it is advisable that where the blood glucometer result is borderline or likely to alter clinical management, a laboratory plasma glucose measurement is essential.

Abstract

Background & Objective: Violence is a global issue and domestic violence is no exception. In the world about 35% women are the victims of domestic violence. Domestic violence has its serious effects on women's overall health, which can be seen in the form of short and long-term physical, mental and reproductive health problems. In some setting, it may increase the risk of acquiring HIV. Women residing in slum are at more risk of it. Hence, this study was conducted to know the prevalence of domestic violence among married women residing in an urban slum.

Method: A cross-sectional study was carried out among married women in the year 2015 which included 385 married women, who were selected by systematic sampling method. Information on socio-demographic factors and domestic violence was collected through face-to-face interview using a pretested semi-structured questionnaire after obtaining written informed consent. Data was analyzed in SPSS software version 20. Frequency and percentage were used to calculate the prevalence of domestic violence.

Results: In our study prevalence domestic violence was 42.1%, among them verbal abuse was found to be 88.8% followed by psychological (81.5%), financial (63.6%), physical (53.7%) and sexual (14.8%).

Interpretation & Conclusions: Verbal and Psychological abuse seems to be more and sexual abuse was less among married women residing in a slum.

Key Words: Domestic violence; Married women; Prevalence; Slum area

Introduction

Domestic violence is defined as "Any incident of threatening behaviour, violence or abuse (psychological, physical, sexual, financial or emotional) between adults who are or have been intimate partners or family members, regardless of gender or sexuality"¹. Both men and women can be the victim or perpetrator, most commonly women. Physical violence has serious consequences for woman's overall health^{2,3}.
