It was also pointed out that obesity, diabetes, hypertension and coronary heart disease have been directly related with children's eating habits and their food consumption. The study also marked that a desire is being created in children to purchase goods that is been shown in various advertisements. (9)

Some of the studies even concluded that childhood obesity is increasing worldwide due to the overconsumption of unhealthy food. This increase has been labelled as an epidemic by the canters for disease control and prevention and the world health organisation. (12)

It was noted that food advertisement and children's food preferences are of critical interest. In those study it was commented that exposure to more advertisements resulted in increased intake of unhealthy food. Exposure to food advertisements lead to increased consumption. (13)

ANALYSIS AND INTERPRETATION

Table 1.Chi-Square Tests

	Value	**df**	**Asymp. Sig. (2-sided)**
Pearson Chi-Square	38.788a	4	.000
Likelihood Ratio	36.648	4	.000
Linear-by-Linear Association	5.721	1	.017
N of Valid Cases	120		

a. 4 cells (44.4%) have expected count less than 5. The minimum expected count is .53.

From the above table1, the obtained chi square value 38.788 is significant at 95% confidence interval, it means that the obtained significance value (0.000) is less than the cut off value (0.05).

Table 2 Chi-Square Tests

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	82.500a	4	.000
Likelihood Ratio	84.107	4	.000
Linear-by-Linear Association	46.401	1	.000
N of Valid Cases	120		

a. 4 cells (44.4%) have expected count less than 5. The minimum expected count is .53.

The above table 2 indicates that the obtained significance value 0.00 which is less than cut off value of 0.05.

Therefore to sum up from both the chi- square tables above: the null hypothesis is rejected and alternative hypothesis is accepted. There is a positive relation between time children spend watching television and making demands.

Table 3 Correlations

		Time watching television	**frequency of making demands**
Time watching television	Pearson Correlation	1	.219*
	Sig. (2-tailed)		.016
	N	120	120
frequency of making demands	Pearson Correlation	.219*	1
	Sig. (2-tailed)	.016	
	N	120	120

*. Correlation is significant at the 0.05 level (2-tailed).

From the above table 3, the Pearson correlation value 0.219 is significant at 95% confidence interval, this indicates that frequency of making demands is positively correlated with time of watching television.

Table 4 : One way analysis of Variance

		Sum of Squares	**df**	**Mean Square**	**F**	**Sig.**
Unhealthy eating habits	Between Groups	.009	3	.003	.018	.997
	Within Groups	19.191	116	.165		
	Total	19.200	119			
Ads are too persuasive for children	Between Groups	.090	3	.030	.109	.955
	Within Groups	31.910	116	.275		
	Total	32.000	119			
identify products	Between Groups	.052	3	.017	.035	.991
	Within Groups	57.415	116	.495		
	Total	57.467	119			
pressurize parents to purchase	Between Groups	.056	3	.019	.092	.965
	Within Groups	23.411	116	.202		
	Total	23.467	119			

From, the above analysis we find that the significance value obtained for unhealthy eating habits is 0.997, ads

persuasive for children is 0.955, children identifying products is 0.991, pressurising parents to purchase is 0.965. All of these are above p value 0.05 and therefore, there is no statistically significant difference in the age of pre-schoolers and the above variables which shows the influence of food advertisements.

Hence the null hypothesis is accepted and alternative hypothesis is rejected, there is no significant relationship between age of preschoolers and influence of food advertisement.

Societial Implications of The Study

The study pinpoints to a solid statement that all of the preschoolers who were examined in the study watched television on a daily basis. The alarming fact is that parents consider television as a means to keep their kids engaged without causing any disturbance to them. But what really happens is that they watch a lot more than what is actually necessary for their age. The first thing is the very appealing food advertisements that they watch amidst their television programs, 90% of the children enjoy food advertisements and they make demands for these food items which are least important for their health.

Children at this tender age is very vulnerable and they are not aware of the genuineness and health implications of the products advertised, it is the parents and the care takers who should guide on them in this regard

When enquired about whether their children discuss with their classmates, about 60% disagreed and 40% of the parents had a neutral stand. Surprisingly 100% of the parents agreed that their children demand products based on food advertisements. Majority of the children demand food products when they are taken out for shopping.

Parents have a neutral response regarding advertisements being too persuasive for children. All parents unanimously agreed that food advertisements lead to unhealthy food preferences among children. 60% of the parents strongly agree and 40% of the parents agreed that their children pressurize them to purchase according to their demand. Children are very smart in identifying products shown in advertisements. Majority of the parents said that their children do not interfere in the products that parents buy. Some of the parents commented that there should be strict government regulations on advertising unhealthy food products.

Suggestions

- Proper awareness and education should be given to parents regarding the effects of unhealthy eating habits.
- Children should be encouraged to eat healthy food in pre-schools.
- No unhealthy food should be encouraged during meal time whether at school or at home.
- Children should be educated that all products advertised are not good ones.
- Healthy food habits should be inculcated right at home itself.
- Children should spent very limited time of their childhood unproductively in front of television.

Conclusion

As parents all of us are conscious about the health of our children, but sometimes parents tend to forget that it is very small things that contribute to this health factor. One thing that every parent disclosed during the study was that every child right from the age of three years watch television, even if not daily but watch them frequently, it is a mode of keeping their tiny tots sit at one place without roaming around. Everything else follows this first step of watching television.

But fortunately certain parents though their children watch television and make demand for unhealthy food products, they can win their child and divert their child to the right path. So to conclude on this study it is not only watching television and food advertisements cause unhealthy eating habits among pre-schoolers, but there are certain other things that parents should follow. They should always be vigilant on what is going around your child, what is he observing, what is he talking in his groups and whether the demands that these children make are right or wrong. Parents and teachers should train children in such a way that he or she is in a position to say no to what is not good for them.

Luciferase Enzyme and its Application

Poojashree. B[1], Geetha R.V[2], G. Karthikeyan[3],

[1]Graduate Student, BDS IV year, [2]Reader, Department of microbiology, [3]Professor, Department of Periodontics, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Aim: The aim of this review is to know about luciferase enzyme and its application

Background : Luciferase is a generic term for the class of oxidsative enzymes that produce bioluminescence and is distinct from a photoprotein. "Firefly luciferase" as a laboratory reagent often refers to P. pyralis luciferase although recombinant luciferases from several other species of fireflies are also commercially available. Firefly luciferase is a euglobulin protein that catalyses the oxygenation of luciferin using ATP and molecular oxygen to yield oxyluciferin, a highly unstable, singlet-excited compound that emits light upon relaxation to its ground state. Luciferase can act as an ATP sensor protein through biotinylation. Bioluminescence assay systems have become increasingly used in biology and medical research laboratories in addition to (or as alternatives to) fluorescence and chemiluminescence detection strategies. Luciferase enzymes isolated from different animal species have inherent variability in light emission, allowing two or more luciferase enzymes to be used in combination for multiplex analyses, including in vivo imaging, cell viability and single and dual-spectral luciferase reporter assays.

Reason: This review is made to know in detail about the Luciferase enzyme uses and its application in diagnosis

Keywords: *Luciferase enzyme, application, structure, bioluminance imaging, Green fluorescent protein*

Introduction

The term for the class of oxidative enzymes that produce bioluminescence, and is distinct from a photoprotein is. The name is derived from Lucifer, the root of which means 'light-bearer'. One example is the firefly luciferase from the firefly Photinus pyralis[1].

One well-studied luciferase is that of the Photinini firefly Photinus pyralis, which has an optimum pH of 7.8. Firefly bioluminescence color can vary between yellow-green [2]. Firefly luciferase are used to study the role of chaperones in protein folding [3] and of bacterial luciferase to study co-translational folding of polypeptides [4] and of the genes encoding luciferases to monitor transcriptional activities [5,6].

Luciferases from different organisms probably evolved independently, rather than from a common ancestral enzyme. Bacterial luciferase, the first luciferase to be cloned and also the first to be structurally characterized, is a flavin monooxygenase that utilizes flavin mononucleotide (FMN) to activate molecular oxygen, yielding a flavin C4a peroxide [7]. Luciferase is a light-producing enzyme naturally found in insect fireflies and in luminous marine and terrestrial microorganisms. the luciferase and other light-emitting photons a visualizing marker/reporter has drastically expanded the versatility of reporter gene technology. luciferase gene fusion product in expression confers on the host the ability to glow in the dark. The transcriptional and

translational expression of the attached foreign gene, and enables one to localize it to particular domains, cells, or organelles of almost any organism. This can be done noninvasively, with inexpensive, nonisotopic, easily available substrates, and at extremely high sensitivity under no significant endogenous background.

Two types of luciferase genes cloned from bacteria and firefly are used as sensitive reporter systems in a wide variety of cells such as bacterial, yeast, insect, animal, and plant cells. Bacterial luciferases are flavoenzymes composed of two subunits each encoded by the *lux A* and *lux B* genes, while the firefly luciferase is a single polypeptide specified by the *lux* gene. The two types of luciferase catalyze different reactions. The bacterial luciferase oxidizes decanal (and some homologous long-chain aldehydes) with the energy transfer from $FMNH_2$ and produces blue-green light with an absorption maximum at 490 nm. The firefly enzyme couples the oxidation of luciferin with the energy transfer from ATP and produces yellow–green light with a pH-dependent absorption maximum. The bacterial and firefly luciferase systems present respective advantages and disadvantages associated with inherent differences in substrate profiles and enzyme structures. Recent developments and improvements on the two luciferase systems have rendered the two systems almost equally amenable to a wide variety of applications. To utilize the reporter systems to their full capacity, however, one has to make a judicious choice based on an understanding of their respective characteristics.

This section describes the bacterial luciferase (Lux) in the first part and the firefly luciferase (Luc) in the second part [8,9].

Structure of Luciferase

The fold assumed by the luciferase polypeptide appears to be unique. The N-terminal domain consists of a β barrel and two β sheets flanked by α helices which form a five-layered αβαβα structure. The C-terminal domain, consisting of five β strands and three α helices, is folded into a compact structure that is connected to the N-terminal domain by a disordered loop (connecting residues 435 and 441). There are three other disordered loops not visible in the electron density, one in the C-terminal domain connecting residues 523 and 529, and two in the N-terminal domain (connecting residues 198–204 and residues 355–359). Conti et al. have taken advantage eof the homology of firefly luciferase with other enzymes that catalyze similar reactions [8,9]. In the large N-terminal domain of the molecule, the central regions of the two -sheet subdomains share a similar structure. These regions can be superposed such that 87 pairs of topologically equivalent -carbon atoms, have a separation ≤2.5 Å, giving an overall rms separation of 1.6 Å. The two 'modules' are approximately related by twofold symmetry with a rotational component of 178.4° and a translational component of 2.0 Å[10].

Reaction catalysed by luciferase

Firefly luciferase catalyzes a multistep reaction [11]. In the first step, luciferin reacts with Mg2+-ATP to form luciferyl adenylate and pyrophosphate. The luciferyl adenylate is oxidized by molecular oxygen, with the intermediate formation of the cyclic peroxide, a dioxetanone and a molecule of AMP. The is decarboxylated as a result of intramolecular conversions to produce an electronically excited state of oxyluciferin in the enol or keto form. Return to the ground state is accompanied by emission of a quantum of visible light with a wavelength of maximum light intensity of 562–570 nm[12] demonstrated that one oxygen atom of the product CO2 arises from the substrate oxygen. Non-enzymatic oxidation of luciferin yields oxyluciferin without luminescence[13]. The appearance of bioluminescent light varies greatly, depending on the habitat and organism in which it is found. Most bioluminescence, for instance, is expressed in the blue-green part of the visible light spectrum. These colors are more easily visible in the deep ocean. Also, most marine organisms are sensitive only to blue-green colors. They are physically unable to process yellow, red, or violet colors. Most land organisms also exhibit blue-green bioluminescence. However, many glow in the yellow spectrum, including fireflies and the only known land to bioluminesce, native to thetropics of Southeast Asia. Few organisms can glow in more than one color. The so-called railroad worm (actually the larva of a beetle) may be the most familiar. The head of the railroad worm glows red, while its body glows green. Different luciferases cause the bioluminescence to be expressed differently[14].

Application of luciferase enzyme

Luciferase can be produced in the lab through for a number of purposes. Luciferase genes can be synthesized and inserted into organisms or transfected into cells. Mice, silkworms, and potatoes are just a few of the

organisms that have already been engineered to produce the protein[15]. All applications of bioluminescence systems are based on the principle of a chemical reaction; that is, the light intensity as the measurable product depends on the amounts of luciferase, luciferin, and cofactor(s). Using beetle bioluminescence as an example, in the presence of excess luciferin and luciferase, the bioluminescence intensity correlates with the amount of ATP, producing a beetle bioluminescence system that can measure the amount of ATP[16]. This system can be applied to detecting bacteria in food, because bacteria contain ATP as an energy source[17].

Bioluminescent organisms are a target for many areas of research. Luciferase systems are widely used in genetic engineering as reporter genes, each producing a different colour by fluorescence, and for biomedical research using bioluminescence imaging. For example, the firefly luciferase gene was used as early as 1986 for research using transgenic acceptor into a single polypeptide can also allow the detection of ligand-induced conformational switches in monomeric proteins in the millisecond time scale. Many of these approaches are amenable to high throughput screening and the drug discovery process. G protein-coupled receptors (GPCRs) represent a key drug target class. Specific applications of energy transfer techniques to the identification of ligands for this class of protein are highlighted to illustrate general principles.

Bioluminescence imaging

has emerged as a powerful new modality for studies of viral infection and therapy in small animal models. BLI technology captures the light emitted from different luciferase enzymes to detect sites of viral infection and quantify viral replication in the context of a living animal [18].

Green fluorescent protein

The technical revolution resulting from the discovery of relates to a miraculous property of the chromophore that is responsible for its fluorescence. This chromophore is formed spontaneously from a tri-peptide motif in the primary structure of , so that its fluores- cence is “automatically” turned on in every organism where it is expressed. In other words, the maturation of the tri-peptide-based chromophore in only requires oxygen and does not depend on the presence of enzymes or other auxiliary factors. and its related variants thereby provide universal genetic tags that can be used to visualize a virtually unlimited number of spatio-temporal processes in virtually all living systems. This revolution in the biological sciences has been greatly accelerated by a rapid parallel development of quantitative light microscopy, electronics, computational power and molecular modelling of intra- and inter-cellular processes with systems-biology approaches[19].

Bioluminescence and fluorescence resonance energy transfer

A limitation of is the requirement for external illumination to initiate the fluorescence transfer, which can lead to background noise in the results from direct excitation of the acceptor or to photobleaching. To avoid this drawback, Bioluminescence Resonance Energy Transfer has been developed[20,21].

Dental Management of Medically Compromised Patients- A Questionnaire among Dental Practitioner

Poojashree.B[1], Nandhini Subramaniam[2]

[1]Undergraduate Student, [2]Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha University, Chennai, India.

Abstract

Introduction : An increase in the number of medically compromised patients in dental clinics may cause serious problems for practicing dentists all over the world. When a dentist does not understand well the relationship between oral and systemic diseases, dental care may become a quite complicated issue. Management of the medically compromised patients require acquisition of complete health history as well as dental history of the patient. This should include documentation via questionnaire as well as a verbal history. Preferably an oral history should also be obtained as a review of systems. The dental history should also include questions related to current oral conditions such as periodontal disease or oral ulceration and past dental treatment and potential complications from prior intervention including treatment failure and the delivery of anesthesia or post-treatment medication. The first step in managing the patients with medical problems is acquiring thorough health history of the patients.

Aim: The aim of this study is to analyse the knowledge about dental management of medically compromised patients among dental practitioners.

Materials and Method: A cross sectional survey was initiated from a randomly chosen population of 100 dental practitioners. Informed consent was obtained from the participants. the survey was conducted online using online survey planet online survey tool. the survey instrument used was a pretested questionnaire comprising of 10 questions eliciting responses pertaining to the dental management of medically compromised patients among dental practitioners.

Results: Among 100 dental practitioners 100% of them enquire medical history including medication and allergy, 68% of them obtain vital signs of the patient commencing dental treatment, 50% of them are confident in handling emergency conditions. 82% of them have emergency kit in dental office, 98% of them get consent from the physician before treating medically compromised patients, 62% of them have knowledge about prescribing AHA guidelines of antibiotics for cardiovascular patients, 42% of them said they can efficiently manage patients on 1st, 2nd and 3rd trimester and 88% of them are aware of diagnosing oral signs of anemia and management.

Conclusion: Dental practitioners have adequate knowledge about managing medically compromised patients in a dental unit. The handling of a medical emergency in a dental office is a skill. One must have hands on experience to gain the level of confidence necessary to manage life threatening situations. This can be done by regularly attending hands-on workshop which will subsequently assess the skills acquired.

Introduction

An increase in the number of medically compromised patients in dental clinics may cause serious problems for practicing dentists all over the world. When a dentist does not understand well the relationship between oral and systemic diseases, dental care may become a quite complicated issue. Management of the medically compromised patients require acquisition of complete health history as well as dental history of the patient. This should include documentation via questionnaire as well as a verbal history. Preferably an oral history should also be obtained as a review of systems. The dental history should also include questions related to current oral conditions such as periodontal disease or oral ulceration and past dental treatment and potential complications from prior intervention including treatment failure and the delivery of anesthesia or post-treatment medication. The first step in managing the patients with medical problems is acquiring thorough health history of the patients.

Effective management of medical emergencies in the dental office is ultimately the dentist's responsibility. Lack of training and inability to cope with medical emergencies can lead to tragic consequences and sometimes legal action. Therefore, dental practitioners must be able to recognize and communicate adequately about relevant medical problems as well as have appropriate knowledge of oral health care and potential interactions with medical conditions. The purpose of this study was to assess the dental management of medically compromised patients among dental practitioners[1].

Materials and Method

A cross sectional survey was initiated from a randomly chosen population of 100 dental practitioners. informed consent was obtained from the participants. the survey was conducted online using online survey planet online survey tool. the survey instrument used was a pretested questionnaire comprising of 10 questions eliciting responses pertaining to the dental management of medically compromised patients among dental practitioners.

The questions include:

1. Do you enquire about medical history including medication and allergy?

2. Do you obtain vital signs of the patients before commencing any treatment?

3. Do you think you can handle emergency condition on your dental office very confidently?

4. Availability of emergency kits in your dental office?

5. Do you get consult from the physician before treating medically compromised patients?

6. Are you aware of prescribing AHA guidelines (2007) of prescribing antibiotic prophylaxis for cardiovascular disease?

7. Are you aware of managing patients experiencing epilepsy attack on dental chair?

8. Do you monitor INR for the patients on combination of blood thinners?

9. Are you aware of managing patients during 1st, 2nd, 3rd trimester?

10. Are you aware of diagnosing oral signs of anemia and dental management of same patients?

Results

1. Do you enquire medical history including medication and allergy?

Responses To Question Number 1

Among the 100 dental practitioners 22 were male participants and 78 were female participants. 100%of the participants said that they will enquire medical history including medications and allergies.(Fig 1

2. Do you obtain vital signs of the patient before commencing dental treatment?

Responses To Question Number 2

Among the 100 dental practitioners 22 were male and 78 were female participants. Overall awareness about obtaining vital signs of the patients before commencing dental treatment is 68%. Among them 52 were females and 16 were males. In this survey 32% of the participants are not aware.(Fig 2)

3. Do you think you can handle any emergency in your dental office confidently?

Responses To Question Number 3

When we ask 'Do you think you can handle any emergency conditions in your dental office very

confidently', only 50% of the participants said yes. Among them 28 were female and 22 were male participants. In this survey 50% of the participants said No to this question.(Fig 3)

4. Availability of emergency kit in your dental office?

Responses To Question Number 4

When we ask about availability of emergency kit in dental office, 82% of them said yes. Among them 60 were female and 22 were male participants. In this survey 18% of the participants said no for this question. (Fig 4)

5. Do you get consent from the physician before dental treatment?

Responses To Question Number 5

When we ask ' Do you get consent from the physician before treating medically compromised Patients' 98% of them said yes. Among them 77 were female and 21 were male participants. In this survey 2% of the participants said no for this question.(Fig 5)

6. Are you aware of prescribing AHA guidelines of antibiotics for cardiovascular patients?

Responses To Question Number 6

Among 100 dental practitioners 22 were male and 78 were female participants. Overall awareness about prescribing AHA guidelines (2007) of prescribing antibiotic prophylaxis for cardiovascular patients is 62%. Among them 44 were female and 11 were male participants. In this survey 38% of the participants said no for this question.(Fig 6)

7. Are you aware of managing epileptic patient in dental chair?

Responses To Question Number 7

When we ask ' Will you able to manage patients experiencing epileptic attack on dental chair', 72% of them said yes. Among them 52 were female and 20 were male participants. In this survey 28% of the participants said no for this question.(Fig 7)

8. Do you monitor INR for patients on anticoagulants?

Responses To Question Number 8

When we ask 'Do you monitor INR for patients on anticoagulants?' 72% of them said yes. Among them 27% were male and 50% were female. In this survey 28% of the participants said that they are not aware about monitoring INR.(Fig 8)

9. Are you aware of managing patients under 1st, 2nd, 3rd trimester?

Responses To Question Number 9

When we ask 'Can you efficiently manage patients on 1st, 2nd, 3rd trimester of pregnancy?' only 42% said yes. Among them 13% were male and 29% were female. In this survey 58% of the participants said they can't manage pregnant patients efficiently.

10. Are you aware of diagnosing and management of anemia?

Responses To Question Number 10

When we ask about 'overall awareness about diagnosing oral signs of anemia and management of same patients', Majority of 88% of them are aware. Among them 11% were male and 77% were female. In this survey 12% of the participants are not aware of diagnosing and managing anemia.(Fig 10)

Discussion

Life-threatening emergencies are common in dental practice. Invasive procedures in the dental Office might result in medical emergencies. Dental surgeons must have good knowledge and awareness of medical emergencies, and they should be prepared to manage such situations. The extent of treatment by dentists requires preparation for and prevention and management of medical emergencies. To alter the treatment plan, a complete medical history is required[2].

Vital signs traditionally consist of blood pressure, temperature, pulse rate and respiratory rate[3]. Vital signs are an important component of monitoring the patient's progress during hospitalisation as they allow for the prompt detection of delayed recovery or adverse events[4]. Dysregulated organ system function as a result of age or age-associated pathophysiology, coupled with age-related loss of protective homeostatic mechanisms, suggests that among older patients vital sign response may not only deviate from normal ranges, but also

remain confined to a range of values, unable to respond appropriately to stressors. Thus, healthcare professionals should pay special attention to vital signs in the elderly[5].

Dentists must be prepared to manage medical emergencies that may arise in practice. Therefore, dentists should be ready to manage these events. Preparation focuses primarily on prevention but should also include the presence of specific equipment and emergency drugs[6]. Some of the emergency drugs that has to be mandatorily present are oxygen for almost any medical emergency. Epinephrine for anaphylaxis, asthma, cardiac arrest. Nitroglycerin for pain of angina. Antihistamine got allergic reactions. Salbutamol for asthmatic bronchospasm. Aspirin for myocardial infarction. Some of the other emergency drugs are glucagon for hypoglycaemia, atropine for bradycardia, ephedrine for hypotension. Hydrocortisone for adrenal insufficiency. Morphine for angina like pain. Naloxone for reversal of opioid overdose. Midazolam for status epilepticus. Flumazenil for benzodiazepine overdose[7].

Informed consent is a widely accepted part of medical practice. All clinicians recognise a duty to obtain the informed consent of patients before surgery, invasive procedures, and participation in biomedical research. Hospital accreditation standards require documentation of informed consent prior to designated procedure and treatments. Despite the wide acceptance of the general need for informed consent, clinicians have little guidance as to which clinical decisions need informed consent[8].

Following publication of the 2007 AHA recommendations, there was a significant reduction in AP prescribing. Consistent with the new recommendations, the greatest reduction was among those at moderate risk of IE[9]. Highest risk of adverse outcomes of AHA 2007 guidelines of endocarditis are previous infective endocarditis, prosthetic valve, unrepaired cyanotic congenital heart disease, 6 month period post prosthetic repair of chronic heart disease, repaired chronic heart disease with residual defects, cardiac transplant with valvulopathy. Antibiotic prophylaxis of AHA 2007 guidelines of endocarditis- All dental procedures involving gingival tissue manipulation or periapical region of teeth or oral mucosa perforation, procedures on respiratory tract or infected skin/musculoskeletal tissue.

Epilepsy is a disease that involves seizures, which are characterized by an alteration of perception, behavior, and mental activities, as well as by involuntary muscle contractions, temporary loss of consciousness, and chronic changes in neurological functions that result from abnormal electrical activity in the brain.Dental treatment of patients with epilepsy and seizures should be carried out by dentists who are knowledgeable about these disorders. patients who have poorly controlled epilepsy and experience frequent generalized tonic–clonic seizures exhibit worse oral health in comparison with patients who are better controlled or only have seizures that do not involve the masticatory apparatus[10]. If a seizure occurs while a patient is in the dental chair, a dentist should be able to manage the situation by knowing the primary steps including discontinuing the procedure immediately and placing the patient on his/her side to decrease the chance of aspiration of secretions or dental materials in the patient's mouth[11].

Efficacy of Oral anticoagulant depends on maintenance of the international normalized ratio within the designated therapeutic range. control of INR is beset by a large number of problems inherent to vitamin K antagonists that are heavily influenced by drug-drug and food-drug interactions, alcohol consumption, hepatic dysfunction, genetic variation in enzyme activity, and dietary intake of vitamin K. Maintenance of this narrow therapeutic INR range is important because there is an increased risk of hemorrhagic stroke with INR > 3.0 and thromboembolic complications at INRs < 2.0[12].

In general, pregnant females tend to over estimate the risk of teratogenicity in the foetus resulting from medical and dental procedures and/or drugs. This may cause them to avoid necessary treatment, leading to detrimental health effects for both the foetus and themselves[13]. Coronal scaling, polishing and root planing may be performed at any time as required to maintain oral health. However, routine general dentistry should usually only be done in the second and third trimester of pregnancy. Organogenesis is completed by the end of the first trimester, and uterine size has not increased to the extent that sitting in the dental chair is uncomfortable. Moreover, nausea has generally ceased by the end of the first trimester. Extensive elective procedures should be postponed until after delivery[14].

The diagnostic criteria for anaemia in IDA vary Hb <10–11.5 g/dl for women and <12.5–13.8 g/dl for men[15]. Pallor of the conjunctiva, tongue, palm or nail beds was 66% sensitive and 68% specific in distinguishing children with moderate a anaemia (haemoglobin concentration 5-8 g/dl) and 93% sensitive

and 57% specific in distinguishing those with severe anaemia (haemoglobin concentration < 5 g/dl)[16]. There are several ways to manage anemia including, following a healthy diet, exercising regularly, avoiding exposure to chemicals that set off anemia, washing your hands often to avoid infection, talking to your doctor about any changing symptoms. Patients with moderate to severe can improved by hospitalization and blood transfusion [17].

Conclusion

Dental practitioners have adequate knowledge about managing medically compromised patients in a dental unit. The handling of a medical emergency in a dental office is a skill. One must have hands on experience to gain the level of confidence necessary to manage life threatening situations. This can be done by regularly attending hands-on workshop which will subsequently assess the skills acquired.

Biomarkers in Orthodontics: An Overview

Poonam Agrawal[1], Dhirja Goel[2]

[1]Professor, Dept of Orthodontics and Dentofacial Orthopaedics, [2]Reader, Dept of Pediatric and Preventive Dentistry, School of Dental Sciences, Sharda University. Greater Noida (UP)

Abstract

A biomarker is a substance that is measured and evaluated objectively as an indicator of normal biologic processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention. Tooth movement by orthodontic treatment is characterized by remodelling changes in the periodontal ligament, alveolar bone, and gingiva. A reflection of these phenomenons can be found in the gingival crevicular fluid (GCF) of moving teeth, with significant elevations in the concentrations of its components like, cytokines, neurotransmitters, growth factors, and arachidonic acid metabolites. Knowledge of biomarkers present in the GCF may be of clinical use leading to proper choice of mechanical stress for better orthodontic treatment and lesser side effects.

***Key words**: Biomarkers, orthodontic tooth movement, gingival crevicular fluid*

Introduction

Orthodontic treatment aims at the correction of dental irregularities and disharmony in jaw relations. Tooth movement induced by orthodontic force application is characterized by remodelling in the dental and periodontal tissues.[1] Orthodontic tooth movement (OTM) is characterized by abrupt creation of compression and tension in periodontal ligament (PDL) (Goutoudi, Diza et al. 2004). These force-induced strains alter the PDL vascularity and blood flow, resulting in local synthesis and release of various key molecules, such as neurotransmitters, cytokines, growth factors, colony-stimulating factors, and arachidonic acid metabolites. These molecules can evoke many cellular responses by various cell types in and around teeth, providing a favourable micro-environment for tissue deposition or resorption (Simonet, Lacey et al. 1997; Cetin, Buduneli et al 2004). Gingival crevicular fluid (GCF) contains inflammatory products, bacterial products, and products of tissue break down. Noninvasive procedures to determine the changes in salivary constituents are used to diagnose several diseases in clinical medicine. Thus, examination of GCF is an ideal method of evaluating the tissue destruction during orthodontic treatment. GCF arises at the gingival margin and can be described as a transudate or an exudate. Clinically GCF can be easily collected using platinum loops, filter paper strips, gingival washings, and micropipettes. A number of GCF biomarkers are involved in bone remodeling during OTM. The data suggest that knowledge of the biomarkers present in the GCF may be of clinical use leading to proper choice of mechanical stress to improve and to shorten treatment time and avoid side effects.

Gingival crevicular fluid

Gingival crevicular fluid (GCF) is an exudate that can be harvested from the gingival sulcus, which offers a great potential as a source of factors associated with changes sand destruction in the underlying periodontium due to orthodontic force application. The early phase of orthodontic tooth movement involves an acute inflammatory response, characterized by periodontal vasodilation and migration of leukocytes out of periodontal ligament capillaries. The mechanism of bone resorption might also be related to the release of inflammatory mediators that can be detected in gingival crevicular fluid.

Biomechanism of orthodontic tooth movement

Two interrelated processes involved in OTM are bone bending and remodelling of the periodontal tissues, including the dental pulp, periodontal ligament, alveolar bone, and gingiva. The applied force causes the compression of the alveolar bone and the PDL on one side (pressure), while on the opposite side the PDL is stretched (tension). [2]Orthodontic forces change

periodontal tissue vascularity leading to the synthesis of various signalling molecules and metabolites. The released molecules generate cellular responses around the teeth, providing a favourable microbiological environment for tissue deposition or resorption.

The pressure-tension theory proposed by Schwartz in 1932 is the simplest theory describing tooth movement on mechanical loading. On the pressure side, the biological events are as follows: disturbance of blood flow in the compressed PDL, cell death in the compressed area of the PDL (hyalinization), resorption of the hyalinized tissue by macrophages, and undermining bone resorption by osteoclasts beside the hyalinized tissue, which ultimately results in tooth movement.[2]On the tension side, blood flow is activated where the PDL is stretched, which promote osteoblastic activity and osteoid deposition, which later mineralizes. The fluid flow hypothesis, describing a mechanism by which osteocytes respond to mechanical forces, states that locally evoked strain derived from the displacement of fluid in the canaliculi is very important. When loading occurs, interstitial fluid is squeezed through the thin layer of the non-mineralized matrix surrounding the cell bodies and cell processes, resulting in local strain at the cell membrane and activation of the affected osteocytes.

The sequence of events following orthodontic tooth movement can be characterized using suitable biomarkers. Proinflammatory cytokines: Interleukin-1 (IL-1), Interleukin- 6 (IL-6), Interleukin-8 (IL-8), tumor necrosis factor-α (TNF-α), and prostaglandin E (PGE). The analysis of the association between alkaline phosphatase (ALP) and bone metabolism, under healthy gingival conditions, is a suggestive indicator of histological and biochemical changes in bone turnover and therefore of the amount of tooth movement. Finally, specific properties of GCF ALP activity render this enzyme an interesting diagnostic tool in orthodontics.

Biomarkers of orthodontic tooth movement

A biomarker is a substance that is measured and evaluated objectively as an indicator of normal biologic processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention.[3] A good biomarker should be specific and sensitive and have the ability to inform about the biological condition in terms of periodontal tissue changes and their relationships with the particular phase of OTM.

Table Showing Biomarkers of Orthodontic Tooth Movement

Metabolic products of paradental remodeling	Inflammatory mediators	Enzymes and enzyme inhibitors
Glycosaminoglycans	Prostaglandin E	Cathepsin B
Pyridinium derivatives	Neuropeptides (Calcitonin related gene peptide and substance P)	Acid phosphatase and alkaline phosphatase
Pantraxin 3	Transforming growth factorα1	Glucuronidase
N-telopeptide type 1 andosteocalcin	Epidermal growth factor	Aspartate aminotransferase
Matrix metalloproteins 1 & 8	α2 microglobulin and insulin like growth factor 1	Lactate dehydrogenase
	IL1 receptor antagonist 1α,2,6,8	
	Tumor necrosis factor	
	Macrophage-CSF	
	RANK/RANKL/ osteoprotegerin system	
	Myeloperoxidase	
	Markers of root resorption	

Metabolic products of paradental remodeling

Glycosaminoglycans (GAG) were investigated in the flow of GCF at three stages of orthodontic treatment viz. before orthodontic treatment, during canine retraction, and in retention, to relate them to tooth movement. Studies concluded that the increase in GCF volume during OTM and the decrease during retention were only partly due to changes in the severity of gingival inflammation (Pender et al). The pyridinium derivatives, pyridinoline (Pyr), and deoxypyridinoline (dPyr), are structural elements that bind together collagen chains. Pyr is abundant in skeletal tissues, whereas dPyr is a minor component found predominantly in bone and dentin.These two molecules are used as markers to evaluate bone resorption in such cases as Paget's disease and primary hyperparathyroidism.[5] Pentraxin3 (PTX3), also known as tumor necrosis factor (TNF) stimulated gene 14 (TSG14), is a 45kDa glycoprotein with a 202 amino acids Surlin *et al.*[12] measured the levels of PTX3 in GCF in orthodontic young and adult patients in the first 2 weeks after the orthodontic appliance showing an increased GCF levels of PTX3 suggesting PTX3 involvement in periodontal orthodontic remodeling and the aseptic inflammation induced by the orthodontic forces. N-telopeptide (NTx) is a specific marker of bone resorption because of its crosslinked a2 (I) NTx. When multiple biochemical markers of bone turnover were compared, NTx was found to be a more sensitive measure of bone resorption. Hence, NTx might be an important marker of active periodontal bone loss and could be useful for analyzing site specific responses to periodontal therapy. Osteocalcin is a noncollagenous matrix protein of calcifying and calcified tissue. It is produced by osteoblasts and has been described as the most specific marker of osteoblast function. Matrix metalloproteins (MMPs) are chemokines may contribute to differential bone remodeling in response to orthodontic forces through the establishment of distinct microenvironments in the sites of both compression and tension.[6] MMPs are enzymes that play a central role in PDL remodeling, both in physiological and in pathological conditions.

Inflammatory mediators

Prostaglandin E (PGE2), specially, is able to mediate inflammatory responses and induce bone resorption by activating osteoclastic cells.[7] Prostaglandins (PGs) are a group of chemical messengers and are derivatives of arachidonic acid. It has been found that PGs have an important role in promoting bone resorption. Although the exact role of PGs in bone resorption is not clear, it is thought to do so by stimulating cells to produce cyclic adenosine monophosphate, which is an important chemical messenger for bone resorption. Research proved that the application of orthodontic force increased the synthesis of PGs, which in turn stimulated osteoclastic bone resorption. The peripheral sensory nervous system contributes to the development of acute and chronic inflammatory processes through the local release of neuropeptides. [20,21,22] With the application of physiologic orthodontic force, SP increases production of proinflammatory cytokines and formation of osteoclasts in dental pulp fibroblasts in patients with severe orthodontic root resorption.[8] Transforming growth factor is a family of polypeptides produced by cells within the periodontium involved in many biologic activities, including cell growth, differentiation, and apoptosis, as well as in developmental processes and bone remodeling.[9] Epidermal growth factor (EGF) is another cytokine possibly associated with bone remodeling. Fibroblasts and stromal cells produce it. [10] Uematsu *et al.* in a study reported a transient elevation of EGF levels in GCF after application of mechanical stress of an experimental tooth. Alfa-2 microglobulin (α2MG) enhances the biologic action of insulinlike growth factor I (lGF). [11] They are a family of peptides that promote cell proliferation and differentiation and have insulin like metabolic effects. They have been associated with stimulation of the osteoblasts and its functions. [12]

Interleukin1 (IL1) are cytokines that affect bone metabolism and OTM, has 2 forms – á and â– that code different genes have similar actions. It was recently found that the concentration of leptin in GCF is decreased by orthodontic orthodontic tooth movement and this conclusively proved that leptin may have been one of the mediators responsible for orthodontic tooth movement. IL-17 has been found to be increased in patients with periodontitis, while it was barely detectable in sera from periodontally healthy individuals. Tumor necrosis factor-α, another proinflammatory cytokine, was shown to elicit acute or chronic inflammation and stimulate bone resorption. TNF-α is a pro-inflammatory cytokine that is often overexpressed in periodontitis and is responsible for alveolar bone resorption during periodontal breakdown. TNF-α plays a pivotal role in the bone resorption process, thus helping in orthodontic tooth movement. Colony stimulating factors are specific glycoproteins, which interact to regulate production,

maturation, and function of monocyte macrophages CSF (MCSF) as well as granulocytes CSF (GCSF). They might have implications in bone remodeling and thereby during tooth movement.[13] An important implication in tooth movement is played by the MCSF through an increased early osteoclastic recruitment and differentiation.[14] In the future, optimal dosages of MCSF already correlated with measurable changes in tooth movement and gene expression will provide a great potential in accelerating clinically the rate of tooth movement. The TNF related ligand receptor activator of nuclear factor kappa ligand (RANKL) and its two receptors, receptor activator of nuclear factor kappa (RANK), and osteoprotegerin (OPG), are known for involvement in bone remodeling process. In the bone system, RANKL is expressed on osteoblast cell lineage and exerts its effect by binding the RANK receptor on osteoclast lineage cells. This binding leads to rapid differentiation of hematopoietic osteoclast precursors to mature osteoclasts. Osteoprotegerin is a decoy receptor produced by osteoblastic cells, which compete with RANK for RANKL binding. The biologic effects of OPG on bone cells include inhibition of terminal stages of osteoclast differentiation, suppression of the activation of matrix osteoclasts, and induction of apoptosis. Myeloperoxidase (MPO) is an enzyme found in polymorphonuclear neutrophil (PMN) granules and can be used to estimate the number of PMN granules in the tissues. Mean MPO activity increased in both the GCF and saliva of orthodontic patients 2 h after appliance activation and they might be a good biomarker to assess inflammation in orthodontic movement.

Enzymes and enzyme inhibitors

Cathepsin B, an intracellular lysosomal enzyme is known to play an important role in the initiation and perpetuation of inflammatory processes. The accumulation of cathepsin B in GCF has been shown to increase with OTM. They were increased around osteoclasts and played a role in the decomposition of exposed collagen fibers and collagen degradation byproducts.[15,16] Alkaline phosphatase and acid phosphatase have been examined as bone turn over markers in orthodontic tooth movement.[17] Bone metabolism is associated with alkaline phosphatase (ALP) and acid phosphatase (ACP), expressed, respectively, by osteoblasts and osteoclasts. Alkaline phosphatase is a ubiquitous tetrameric enzyme, localized outside the cell membrane. [18] A biomarker of primary granule release from polymorphonuclear leukocytes is the lysosomal enzyme β glucuronidase (β G). Increased levels of this enzyme have been found in the GCF of adolescents treated with the rapid maxillary expander. Moreover, β G, as other biochemical mediators like IL1β, responds to direct and indirect application of mechanical force to teeth, with an increased level that is higher than following stronger forces. [19,20] Aspartate aminotransferase (AST) is a soluble enzyme that is normally confined to the cytoplasm of cells, but is released to the extra-cellular environment upon cell death. The activity levels of AST in the GCF are considered to be important in regulating alveolar bone resorption during orthodontic tooth movement. Aspartate aminotransferase (AST) and lactate dehydrogenase activities in GCF have been measured to confirm the biological activity, which occurs in the periodontium during orthodontic treatment. They are soluble enzymes normally confined to the cytoplasm of cells then released to the extracellular environment after cell necrosis.[21] Lactate dehydrogenase, an enzyme normally limited to the cytoplasm of cells, signals an increase in LDH during orthodontic tooth movement due to changes in the periodontal ligament.[22] Lactate dehydrogenase (LDH), an enzyme normally limited to the cytoplasm of cells, is only released extracellularly after cell death.

Conclusion

The orthodontic displacement of a tooth is the result of a mechanical stimulus, generated by a force applied to the crown of a tooth, which results in an acute inflammatory response in periodontal tissues, which in turn may trigger the cascade of biological events associated with bone remodeling. Orthodontic force application could be based on individual tissue responses. The problem of relapse can be solved upto some extent by considering bone turnover rates around each experimental tooth, however a simple noninvasive method is required for achieving these possibilities. The gingival crevicular fluid alkaline phosphatase levels in can be used as a diagnostic biomarker to assess the health and pathology of the periodontium during orthodontic treatment. It can be used in early detection of changes in the periodontium and can assess the efficacy and prognosis of orthodontic treatment.

Effect of Kinesiotaping on Diastasis Recti in Post-Partum Women

Pournima A. Pawar[1], Ujwal L. Yeole[2], Manasi Navale[3], Komal Patil[3]

[1]Assistant Professor, [2]Principal, [3]Student, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune 37.

Abstract

Background: Diastasis recti is a separation of rectus abdominis muscles in the midline at the linea alba. Diastasis recti may occur in pregnancy as a result of hormonal effects on the connective tissue and the biomechanical changes of pregnancy.The kinesio taping results shows increased fluid flow through an injured area, better control over muscle contractions, reduced pain, and ultimately faster healing. **Methodology:** Permission was taken from institutional ethical committee. Subjects were selected by convenient sampling method. Patients were evaluated pre and post for diastasis recti using finger-width test and for disability assessed by using modified oswestry disability index. **Result:** The analyzed data showed that it was not a normal distribution using shapro -Wilk test hence Non parametric test-Wilcoxon sign rank test was performed to analyze the data within the groups. Diastasis recti of group A above umbilicus level pre-intervention mean was 3.040±0.4643 and post-intervention mean was 0.2350±0.3986. At umbilicus level pre-intervention mean was 3.100±0.3482 and post-intervention mean was 0.2950±0.4026and below umbilicus level pre-intervention mean was 2.435±0.4802 and post-intervention mean was 0.035±0.1466. In group B above umbilicus level pre-intervention mean was 2.965±0.5088 and post-intervention mean was 0.365±0.4542. At umbilicus level pre-intervention mean was 3.215±0.4988 and post-intervention mean was 0.4100±0.4626 and below umbilicus level pre-intervention mean was 2.115±0.5461 and post-intervention mean was 0.1350±0.3397. Comparison between the groups was done using Mann-Whitney U Test above umbilicus p value is 0.0059 which is very significant, at umbilicus p value is 0.9072 which is not significant, below umbilicus p value is 0.1124 which is not significant.

Conclusion: Our study shows that kinesio taping with exercise shows greater effect on diastasis recti than only exercises in post-partum women.

Keywords: *diastasis recti, kinesio taping, finger-width test, modified oswestry disability index*

Introduction

Post-partum is period following the childbirth or period after pregnancy. Women after childbirth there is physiology and structural changes in their appearance and shape that may require repair in order to restore their physical and psychological well- being. There is increase in abdominal girth during pregnancy that causes stretching and thinning of the midline abdominal fascia, thus aggravating preexisting diastasis of the rectus muscle that can result muscle that can result in herniation or protrusion of abdominal contents.[1]

The condition of diastasis recti may produce musculoskeletal complaints, such as low back pain, it result of decreased ability of the abdominal musculature and thoracolumbar fascia to stabilize the pelvis and lumbar spine.[2]

It has been claimed that Diastasis recti abdominis may changes posture and give more back strain due to reduced strength and function, leading to low backpain.[3]

Kinesio tapeis acomparatively new technique used in rehabilitation programs. It is increasingly become an adjunct treatment option for the other musculoskeletal impairments, correcting muscle function by strengthening weakened muscles and improving circulation of blood and lymph by eliminating tissue fluid and skin by moving the muscle, decreasing pain through neurological suppression and repositioning sublaxed joints by relieving abnormal muscle tension, helping to return the function of fascia and muscle.

There are total five different corrective applications of KT which include the following : mechanical correction fascia correction; space correction; ligament / tendon correction; functional correction, that provide several potential effects of KT, depending which technique is used and degree of tape stretch, providing the sensory stimulation, aligning fascia tissues, reposition of sublaxed joints, minimizing pain/inflammation, assisting in the reduction of edema in the addition to inhibit muscle function.[5]

The elastic quality and proprioceptive input as well as subtle biomechanical factors of kinesio taping may account for the functional changes observed. When the application procedure is correct, the taped area can be used to facilitate a weakened muscle or to relax an overused muscle. The method for applying the tape varies depending on the specific goals such as improve active range of motion, relive pain, adjust misalignment, or improve lymphatic circulation.[4]

Method

Permission was taken from institutional ethical committee. Different hospitals were approached and permission was obtained prior to the study. 200 subjects were selected by convenient sampling method. Post-partum women were selected who had normal delivery, after 1 month of women who had caesarian section. Women who were having sensitivity of taping, open wounds, any recent abdominal surgery and abdominal hernia were excluded for the study. The study was explained to the patient. The pre and post intervention assessment were done for diastasis recti with finger-width test. The abdominal strength were assessed by sphygmomanometer anddisability were assessed by modified oswestry disability index. The exercise program was given 45 minute of session 3days/week for 4 weeks. In group A kinesio taping was applied for 6days/4week with exercises. The exercises includes the corrective exercise for diastasis recti, stabilization exercises with progressive limb loading for abdomen and trunk.

Exercise program:

Week 1: In conventional therapy

1. Corrective exercise of diastasis recti:

- Head lift: Patient position and procedure: Hook-lying with her hands crossed over midline at the level of the diastasis for support. Have the woman exhale and lift only her head off the floor or until the point just before a bulge appears. At the same time, her hands should gently approximate the rectus muscles toward midline. Then have the woman lower her head slowly and relax. 5 repetition without hold.

- Head lift with pelvic tilt-Patient position and procedure: Hook-lying. The arms are crossed over the diastasis for support as above. Have the patient slowly lift her head off the floor while approximating the rectus muscles and performing a posterior pelvic tilt, then slowly lower her head and relax. All abdominal contractions should be performed with an exhalation so that intra-abdominal pressure is minimized. 5 repetition without hold

- Week 2: Correction exercise for diastasis recti-Head lift and head lift with pelvic tilt : 5 reps with 5sec hold

- Week 3: Correction exercise for diastasis recti-Head lift and head lift with pelvic tilt. Stabilization exercise for trunk and abdomen: Basic lumbar stabilization with progressive limb-loading exercise for abdominals. Procedure: Patient position hook lying. Begin exercise with drawing in maneuver for 5sec hold to activate core muscles. Determine level at which patient can maintain pressure constant (stable pelvis) while performing either A, B, or C limb load activity. A- Lift bend leg 90 hip flexion. B- Slide heel to extend knee. C- lift straight leg to 45. 5 repetitions. Basic lumbar stabilization with progressive limb-loading exercise for trunk extensors: Procedure: Patient position quadruped. Patient assumes neutral spine in lumbar and cervical regions (keeping eyes focused toward floor or exercise mat), performs drawing-in maneuver for 5 sec, and moves extremities. Motions are repeated for 5 times. A- flexion of one upper extremity. B- Extend one lower extremity by sliding along the exercise mat.

• Week 4: Correction exercise for diastasis recti- Head lift and head lift with pelvic tilt: 10 reps with 10sec hold. Stabilization exercise- For abdominals: 10 reps, For trunk: A, B, C, D: 10 reps, C- extend one lower extremity by lifting it off the mat, D- flexing one upper extremity while extending contralateral lower extremity and alternate to opposite extremities. 5 repetitions.

Statistics

The analyzed data showed that it was not a normal distribution using Shapro -Wilk test hence Non parametric test-Wilcoxon sign rank test was performed to analyze the data within the groups. Unpaired T-test was used to analyze the data between the groups.

Result

Table no.1: Comparison of Diastasis recti between groups

Diastasis recti	Above umbilicus pre	Above umbilicus post	At umbilicus pre	At umbilicus post	Below umbilicus pre	Below umbilicus post
Group A	3.04+0.4643	0.235+0.3986	3.1+0.3482	0.295+0.4026	2.965+0.5088	0.035+0.1466
Group B	2.965+0.5088	0.365+0.4542	3.215+0.4988	0.41+0.4626	2.115+0.5461	0.1350+0.3397
P value	0.0059		0.9072		0.1124	

Interpretation: Comparison between the groups was done using Mann-Whitney U Test above umbilicus p value is 0.0059 which is very significant, at umbilicus p value is 0.9072 which is not significant, below umbilicus p value is 0.1124 which is not significant.

Table no.2: Abdominal Strength

Abdominal Strength	Pre-intervention	Post-intervention	P value
Group A	59.220+15.167	129.44+20.303	0.1670
Group B	61.860+19.314	129.02+21.457	

Interpretation: The abdominal strength of group A pre intervention mean is 59.220±15.167 and post intervention mean is 129.44±20.303 and group B pre intervention mean is 61.860±19.314 and post intervention mean is 129.02±21.457 with p value 0.1670 which is not significant.

Table No.3: MODI score

MODI score	Pre-intervention	Post-intervention	P value
Group A	57.160+7.723	16.400+3.929	0.0977
Group B	57.500+9.300	15.600+3.856	

Interpretation: MODI score of group A pre intervention mean is 57.160±7.723 and post intervention mean is 16.400±3.929 and group B pre intervention mean is 67.500±9.300 and post intervention mean is 15.600±3.856 with p value 0.0977 is not quite significant

Discussion

Post-partum is period following the childbirth or period after pregnancy.[1] Diastasis recti is a separation of rectus abdominis muscles in the midline at the linea alba. The condition of diastasis recti may produce musculoskeletal complaints, such as low back pain, it result of decreased ability of the abdominal musculature and thoracolumbar fascia to stabilize the pelvis and lumbar spine.[2]

This study was conducted to investigate the effect of kinesio taping for diastasis recti. In our study, women were divided into two equal group- Group A treated by kinesio taping on abdomen and exercise for diastasis recti and Group B treated by exercises for diastasis recti for 4 weeks.

In our study, the diastasis recti was assessed pre and post values with finger-width test. In finger-width test, we measured diastasis recti at three levels above umbilicus, at umbilicus and below umbilicus. The abdominal strength pre and post values was assessed with sphygmomanometer. The disability was assessed by Modified Oswestry Disability Index (MODI) score.

In our study, group A mean of age group is 24.22$\pm$3.338 and in group B mean of age group is 24.2$\pm$3.62. The mean of BMI in group A is 25.09$\pm$3.069 and in group B is 24.65$\pm$2.884 as shown in table no.1.

In group A the diastasis recti results shows that (Graph no.1) there is significant difference between pre and post treatment on all three levels. Kinesio taping techniques focused on improving circulation, muscle activation, proprioception, function and decrease pain. The pressure directed away from the belly of a muscle and towards the Golgi tendon organs which produces relaxation of the muscle, while pressure toward the muscle belly, from the region of the Golgi tendon organs strengthens it; pressure directed near the belly of the muscle, towards the muscle spindle weakens it and while pressure away from the spindle near the belly strengthens it.Our study also support with the study conducted by Mohamed A. Awad et.al. concluded that Kinesio taping was effective in reducing diastasis recti in postpartum women.[4] Kinesio taping can increase the effect of exercise by stimulating muscle facilitation. Acute and chronic effects of Kinesio taping on neuromuscular performance and muscle activation and function, taping should be planned for patients as part of a rehabilitation program or in combination with exercise programs. This is also support with the study done by Ceren Gursen et.al. stated that addiction of kinesio taping with exercises in the postpartum physiotherapy program provides greater benefit for abdominal recovery in women.[6] In group B the diastasis recti results shows that , there is significant difference in pre and post treatment on all three levels. Exercise helps to maintain tone, strength and control of the abdominal muscles, consequently reducing stress on the linea alba. The transversus abdominis muscle is the deepest abdominal muscle. It has strong fascia links with the rectus abdominis muscle and the linea alba. Exercise of the muscle draws the bellies of the rectus abdominis muscle together, also improves the integrity of the linea alba and increases fascial tension which allowing efficient load transference and torque production. Our study also support with the study conducted by D.R.Benjamin done on theeffects of exercise on diastasis of the rectus abdominis muscle in the antenatal and postnatal periods.[8]

All corrective exercises had been in form of pulling in an abdominal muscles. Abdominal exercises can help to bring the left and right sides of rectus abdominis muscle, it will not cause extra stress on stomach or back. Abdominal muscle strengthening exercises continue to recommended during the postpartum period, particularly to reduce inter recti distance.

To obtain improvement of muscle strength following abdominal exercises via adoptive changes in the muscle caused by exercises as metabolic capabilities of the muscle are progressively overloaded. The muscle which is contractile tissue become stronger which is result of hypertrophy of muscle fibers and it increased recruitment of its motor unit. According to strengthening core control muscle of the abdominal region in postnatal period is very important as it help in creating a muscular corset to support the spine. This is also support the previous study done by Sanjeevani Khandale and Deepali Hande concluded that abdominal exercises are very effective in reducing diastasis recti in early postpartum women and inter recti distance.[9]

The result of abdominal muscle strength shows that, there is significant difference in values of pre and post treatment in group A and B. There is more improvement of abdominal muscle strength in group A women. The kinesio tape helps to correcting muscle function by strengthening weakened muscles and improving circulation of blood and lymph by eliminating tissue fluid beneath the skin by moving the muscle, decreasing pain through neurological suppression and helping to return

the function of fascia and muscle.This is also support to the previous study done by Mohamed A. Awad et.al. concluded that Kinesio taping was effective in reducing diastasis recti in postpartum women.[4]

Bycontracting the abdominal muscles makes it possible to reduce intra-abdominal pressure while exercising. It causes improvement of muscle strength and decreased rectus and increased intra-abdominal pressure which contributes to mechanical spine stability through the co activation of trunk flexors and extensors musculature. As abdominal muscle contract increased pressure and it converts the abdomen into rigid cylinder that increased stability of spine, improves abdominal strength. This is also support the previous study done by Sanjeevani Khandale and Deepali Hande concluded that abdominal exercises are very effective in reducing diastasis recti in early postpartum women and inter recti distance.[9]

The results of Modified Oswestry Disability Index (MODI) score shows the significant difference between the pre and post treatment in both group A and B. But there is more reduction of score in group A than B. The trunk stabilization exercises are aimed at improving the neuromuscular control, strength, and endurance of the muscles that are central to maintaining the dynamic spinal and trunk stability. It includes several groups of muscles particularly targeted the transversus abdominis and lumbar multifidi, but also other paraspinal, abdominal muscles. Thestabilization exercises may be useful in reducing pain and disability for all patients with nonspecific low back pain. Our study also support with the previous study done by Hye Jin Moon et.al. concluded that lumbar stabilization and dynamic strengthening exercise strengthened the lumbar extensors and reduced low back pain.[10]

Our study shows that the kinesio taping and exercise combine therapy is more effective than only exercise therapy in post-partum women. According to the Mann-Whitney test the difference between the pre and post values of group A and B above umbilicus level p value is 0.0059 which is very significant so the study shows that kinesio taping and exercises are effective for improving diastasis recti above umbilicus level. At umbilicus level p value is 0.9072 which is not significant and below umbilicus p value is 0.1124 which is not significant. The difference between the pre and post values of group A and B of abdominal strength p value is 0.1670 which is not significant.So study shows that for diastasis recti at umbilicus level, below umbilicus level the duration of intervention may be more. The difference between the pre and post values of group A and B of MODI score p value is 0.0977 which is not quite significant this signifies the exercises are effective for improving disability in post-partum women.

Conclusion

Study concluded that effect of kinesio taping and exercise on diastasis recti are more effective than only exercises in post-partum women.

Systematic Review in Dentistry: Awareness and Perception among the Faculty of Four Indian Dental Institutions

Pradnya Kakodkar[1], Revati Deshmukh[2], Shishir Singh[3], Alka Kale[4], Priya Joshi[5]

[1]Deputy Director, Dr D Y Patil Vidyapeeth,Pimpri, Pune, [2]Prof and HOD, Department of Oral Pathology, Bhartiya Vidyapeeth Dental College and Hospital, Pune, [3]Dean, Professor and Head, Department of Conservative Dentistry and Endodontics., Terna Dental College, Mumbai, [4]Principal, KLEVK Institue of Dental Sciences, Belgaum, [5]Prof and HOD, Department of Oral Pathology, Vasantdada Patil Dental College and Hospital, Sangli

Abstract

Context (Background): Systematic review (SR) is the key element of evidence based practice (EBP) and is especially important in today's dental practice.

Aim: To assess the awareness and perception about systematic review in dentistry among the dental faculty.

Method and Material: A cross-sectional survey was conducted among 122 dental faculty of the four dental colleges in India. A self-administered, structured, self-designed, validated and pilot tested 14 item questionnaire was used for data collection. Q1-2 assessed awareness and Q3-5 assessed the perception. The collected data was analyzed descriptively (number and percentages)

Result: Only 110 (90.16%) completed the questionnaire entirely. There were 72 females and 38 males aged between 27 years to 58 years. The knowledge about EBP terminologies was very low. Only 13.63% participants were able to complete the evidence based pyramid correctly, 60% reported that it is hard to relate SR findings to patient care, 72.72% agree that SR can be undertaken as library dissertation for postgraduate studies and 100% have preferred past clinical experience as first preference in clinical decision making. Lack of access to full text articles was reported as a major barrier by 81.81% participants followed by lack of skill to appraise scientific articles (78.18%).

Conclusion: The awareness about Systematic review among the dental faculty is low and there is a positive perception towards learning, undertaking training and practicing EBP.

Key words*: systematic review, EBP, dental, evidence pyramid.*

Introduction

Dentistry is the science and art of providing oral health services to the patient. A dentist's 'toolkit' is created during the five years of their professional training and in addition during the three years of post-graduation. Further, it may not be updated regularly[1]. "The current method of dental and medical training is dependent on Professors, obsolete text books and opinion of the seniors who are often dogmatic and unresponsive to new ideas"[2]. Today, the world is changing because of digitalization, leading to information explosion on the internet and consumer participation. The extra-ordinary advancement in internet has fortified the change of relationship between the patient and the dentist; patients are now partners in the decision-making process [3].

Evidence based dentistry (EBD) can be said to be the current best approach to provide interventions as it improves dentist's skills and knowledge as well as quality of treatment provided to the patients[1]. David Sackett laid the foundation of evidence-based practice by defining it as "integrating individual clinical expertise with the

Deputy Director Research, Dr D Y Patil Vidyapeeth, Pimpri, Pune. Email:pradnya.kakodkar@gmail.com
Mobile: 9881409089

best available external clinical evidence from systematic research"[4]. Although, this concept of Evidence based practice (EBP) was born two decades ago its arrival is new in India and is in its developmental stages especially in dentistry[5] . Systematic review (SR) is a key element of EBP. It is defined as "a review of the evidence on a clearly formulated question that uses systematic and explicit methods to identify, select and critically appraise relevant primary research, and to extract and analyse data from the studies that are included in the review."

As per the Dental Council of India, the three year post-graduation curriculum do not include any training in EBP in general and SR in particular[6]. Further, the perceived road blocks for India, whenever the idea of evidence base education is mooted are that " our teachers are not trained for this, we just don't have the time, or our universities will not allow it" [2] .

EBP is especially important in today's world of great scientific breakthroughs and achievement because it is directed at reversing an unsystematic clinical practice that is often based on intuition and pathophysiologic basis and replacing it with one that is evidence based and scientifically proven[5]. Owing to the background and the importance of EBP, post-graduation curriculum can be reinforced by including training in EBP and undertaking SR as Library Dissertation. Thus, the aim of this study was to assess the awareness and perception among the dental faculty about systematic review in dentistry.

Method

A cross-sectional survey was conducted among the dental faculty of the four dental colleges in India. Scientific and ethical approval was obtained before the start of the study . Those faculty who have completed their post-graduation (MDS) and were willing to fill the questionnaire were recruited for the study. A pool of questions was framed based on the review of the previous literature. The questions were shortlisted and distributed in 2 domains (awareness and perception). The questionnaire used for data collection was self designed, validated (face validity, content validity and reliability) and pilot tested. The self-administered, structured questionnaire had 14 items and was a combination of open and closed ended questions (Q1-2 assessed awareness and Q3-5 assessed the perception). Overall, 122 faculty participated in the study. The collected data was entered in Microsoft excel and descriptive statistics (number and percentages) were calculated.

Results

Out of the 122 participants, only 110 completed the questionnaire entirely. The response rate was 90.16%. There were 72 females and 38 males aged between 27 years to 58 years.

The awareness regarding the EBP terminologies is presented in Table 1. Out of the 15 terminologies, 100% participants were aware about 5 of them, while there were 8 other terminologies like Hierarchy of evidence, evidence based dentistry, evidenced based pyramid , systematic review, meta-analysis, Cochrane database, PRISMA guidelines and PICO whose awareness was very low among the participants (12.72% to 24.54%).

Fig 1 depicts the percentage distribution of the participants according to the correct knowledge of the appropriate study design in the evidence based pyramid. Overall, only 15 (13.63%) participants were able to complete the evidence based pyramid correctly.

Table 2 shows the perception of the faculty towards SR in dentistry. Majority participants have responded in agreement for the use SR in patient management(63.63%), improve clinical skills (89.09%), quality care (83.63%) and clinical decision making (54.54%) . 60% have reported that it is hard to relate SR findings to patient care. 72.72% agree that SR can be undertaken as library dissertation for postgraduate studies, 88.18% also agree that SR can be taken for Journal club discussion by the postgraduate students. 60.90% believe that the students should be trained in EBP.

Table 3 shows the faculty preference in clinical decision making. The participants have ranked their past clinical experience as first preference, followed by books, evidence from journal articles and lastly from SR.

Table 4 presents data of the perceived barrier for undertaking SR. Lack of access to full text articles was reported as a major barrier by 81.81% participants followed by lack of skill to appraise scientific articles (78.18%). A small number of participants also reported that SR is not useful for clinical practice (12.72%). Meager percentage of participants also reported Internet issues to be a barrier (5.45%).

Discussion

There are no studies reporting the awareness and perception of SR among the dental faculty in India, however a few studies [5,7-13] exist which have assessed the knowledge, perception and barriers regarding EBP. Further, majority of these studies have been carried out among clinical practitioners and also, there is variation in the assessment tool. Following is the summary of the studies undertaken in different parts of India.

In Bhopal[7], a study was conducted among 250 private dentists. It was evident that the participants have low knowledge about evidence based dental practices (EBDP) but they showed positive attitude towards adopting it in their future practice. The most commonly reported barrier was lack of time (79.5%) followed by lack of skill to appraise scientific journals (73.1%). Out of 141, who heard of EBDP, almost 50% of dentists favored evidence from scientific literature and 50% preferred "Past clinical experience". For guidance during treatment planning, they took help from dental practices expert, Textbooks, other professionals and 60.3% never checked electronic database like Pubmed.

In Jharkhand[8] , 94 private practitioners of Hazaribag participated in the study of which only, 44 of them had knowledge about EBP and 25 knew the EBP pyramid completely. 9.09% practiced EBD. 46.81 % used books and among the electronic source, most of the dentists preferred any website (39.36%) followed by PubMed (30.85%) to obtain information, while 10.64% knew about Cochrane database. All the dentists (n = 94) acknowledged that they never critically evaluated the evidence obtained but majority of them had positive attitude towards learning the concepts of EBP.

In Vadodara[9], 87 practicing dentist reported that the barrier for practicing EBP was lack of time (59.29%), difficulty in evaluation (37.04%) and lack of knowledge (33.3%).

In Jodhpur[10] , a study was conducted among 138 academician. Lack of personal time was reported as one of the major perceived barriers for EBP (72.4%), the academician believed that learning skills of evidence-based dentistry helped them to utilize evidence-based dentistry in daily practice (50.7%), 14.49% understood systematic review and were able to explain it to others, 36.23% felt they did not have the skill for critical appraisal and 31.88% did not feel the importance of SR .

In Davangere[11], a study among 117 private practitioners, reported that only 6.8% and 12.9% correctly knew that expert opinion and case report formed the base and systematic review formed the apex of evidence-based pyramid. Ninety percent of the dentist felt the need to be trained in EBP. When faced with clinical uncertainty, 37% preferred electronic source and 23.8% preferred asking a friend. Seventy-six percent practiced EBP in decision-making; however, only 56.4% felt that without EBP, their practice was inefficient. 78.6% critically analyzed the evidence. 38.5% were aware of the evidence based pyramid. Practitioner who were attached to institution and were also practicing had more correct knowledge regarding EBP.

In Bangalore[5], a study among 300 academician and practitioners revealed that EBP is possible only when there is access to information sources. Most of the respondents reported lack of time, training and access as barriers to practice EBD. Most of the participants chose to rely on their own judgment (92%) followed by referring textbooks (29.4%), dental journals (26.4%), and consulting colleagues (23.1%) to guide their primary care practice and support their clinical decisions. Very less number of dentists relied on Cochrane library as a reliable source for EBP.

In Pune[12], among the 150 dental academician, it was reported that lack of access to full text articles (60.6%), lack of time (58%), lack of application of evidence in patients(39.3%) , lack of interest(32%), lack of skill to appraise scientific journals (30.6%), lack of computer literacy (27.3%) and lack of internet connection (27.3%) are among the perceived barriers for EBP.

In Nagpur[13], a study was conducted in three teaching dental hospitals among the postgraduate students and the faculty regarding EBD. Positive attitude toward EBD was significantly lower among post graduate students than in the staff. The staff believed that patient care can be improved by EBD, whereas the post graduate trainees thought that EBD is of limited value in general practice and places an extra demand on the over loaded practitioners. The participants perceived that personal barriers and lack of training was the reasons for not practicising EBD.

Based on the present study results and literature reports [5,7-13], it is clear that the dental faculty need to update their tool kit in EBP and SR. The dentists (private clinician or academician) in different parts of India have

reported common barriers towards EBP. Lack of time appears to be a major barrier and every dentist must be informed and motivated to spend some time for EBP. Collectively all the dental colleges at the DCI level, must initiate steps for getting access to full text articles, because major crux of EBP lies on literature. They also have demonstrated a positive attitude towards learning, undertaking training and practicing EBP.

Recommendation

Including evidence based dental practice teaching in dental curriculum may prove to be a significant step in effective and efficient dental care delivery to the patients[7] . Therefore, strategies for enhancing EBD training and implementation should be delivered at the basic level for the growth and development of dental profession[13] . As recommended earlier[1] it is reinforced that post-graduate students need to be prepared on evidence based dentistry not only for the benefit of their patients but also to improve the quality of research work carried out by them. The DCI curriculum should make provision for mandatory training in EBD and voluntary provision for undertaking SR as Library dissertation.

Ethical Clearance: Clearance obtained from Institutional Ethics Committee (BVDU/128/2019-20).

Abstract

Background of the study: In the contemporary epoch, In India there is a rapid health transition with major and increasing burden of chronic non communicable diseases, supremely hypertension, cancer, diabetes mellitus, chronic lung disease and stroke and increased age was one the cardinal cause of elevated blood pressure. **Objectives:** 1) to assess breathing pattern of children suffering with lower respiratory tract infection after nebulization therapy with hypertonic saline (3%Nacl). 2) To assess breathing pattern of children suffering with lower respiratory tract infection after nebulization therapy with salbutamol. 3) To compare the effect of hypertonic saline (3%Nacl) and Salbutamol nebulization therapy on breathing pattern of children suffering with lower respiratory tract infection.4) To find out the association between selected demographic variables and breathing pattern of children suffering with lower respiratory tract infection after nebulization therapy with hypertonic saline (3%Nacl) and salbutamol. **Methodology:** A comparative study was carried out by selecting 86 children which were suffering with LRTI through non probability purposive sampling technique. Demographic data was collected by questionnaire as well as breathing pattern was assessed by modified clinical severity score. **Result:** The study finding shows that the mean clinical severity score 1.4283 with hypertonic saline nebulization therapy was lesser than the mean clinical severity score 1.8469 with salbutamol nebulization therapy with the mean difference of was 0.4186. ANOVA calculated; P value is 0.000which less than 2.91 (df 2, level of significant 0.05).so, that H_0 is rejected. This indicates that the hypertonic saline (3% Nacl) is effective to improve breathing pattern compare to salbutamol nebulization therapy.

Conclusion: The research study concluded that hypertonic saline(3% Nacl) nebulization therapy is more effective compare to salbutamol nebulization therapy.

Introduction

Young children are precious in their own right and they are the future of the nation. Illnesses of the child engulf the whole family in a vicious cycle of apprehension, anxiety, helplessness and disturbed lifestyle. Lower Respiratory Tract Infection place a considerable strain on the health budget and are generally more serious than Upper respiratory infections.[1]

Lower respiratory tract infection is most commonly present in infancy period characterized by cough, wheezing, tachypnea and fever. Lower respiratory tract infection is the major reason of infant hospitalization in both developed and developing countries. Although it is common there is no current standard treatment. Supportive care is the only evidence based treatment option. Many studies focused on testing the effects of bronchodilators such as β2-agonsits, epinephrine,

glucocorticoids and magnesium sulphate with controversial results.[2]

The lower respiratory tract begins from the trachea and ends in the lungs. The tract enters into the lungs and divides in the bronchi. Then each bronchus divides further into smaller air pipes that are bronchioles. The bronchioles appear from the secondary and tertiary bronchi. These bronchioles end in small air sacs which known as alveoli. Many alveoli bunch up together and form the alveolar sac. From these alveoli the blood capillaries go out. The exchange of air occurs in every alveolus and the capillaries which go out of these alveolar sacs and spread throughout the body carry the blood which came in from veins spread in the body. The infection which occurs in the lower respiratory tract of human body is usually termed by the doctors as lower respiratory tract infection. The infections begin from the lower larynx and can also attack the bronchi and even the whole lungs. The common illnesses are bronchitis, pneumonia, bronchitis and flu.[1]

The primary cause of lower respiratory tract infection is various kinds of viruses that attack our system. The viruses that enter our body often take the shape of structural proteins and hence pass through unrecognized by the human immune system. Also viruses secrete some toxins which are stronger due to this immunity drops down and further humans are infected with the respective virus. After completion of incubation period the victim's body represents the clinical signs and symptoms.[5]

Bronchitis is a common lower respiratory tract infection. There are two kinds of Bronchitis; acute and chronic. The virus swells the bronchial tubes which causes difficulty in breathing, thus the infection affects the airways. About 4% of the people in a population of 1000 are affected by this virus. Acute or chronic disease is decided by the stage of the virus infection and the presentation of its structure.[3]

Pneumonia is another lower respiratory tract infection. It is caused by streptococcus pneumonia. The virus causes a great damage to the lung and the mortality rate is 25% of the patients affected by the virus. If a child below the age of 5 is affected, then he or she might not survive at all. Flu is caused by the influenza viruses and affects both the upper and the lower respiratory tracts. Bacterial meningitis caused by the virus Neisseria meningitides can cause lower respiratory tract infection. Scarlet fever causes by Group-A streptococcus. Tuberculosis caused by the bacteria mycobacterium tuberculosis which causes a consistent damage to the lungs. Bronchiolitis is also a lower respiratory tract infection. It is caused by RSV or respiratory syncytial virus. It mainly affects the respiratory tracts and the airways of little children. [3]

Lower respiratory tract infection (LRTI) are the third most important cause of mortality globally and are responsible for more than 4 million deaths annually.[4]

A nebulizer is a medical device which converts liquid medicine into vapor, mist or aerosol so that it can be inhaled directly into the air tubes or lungs. It uses electricity to generate compressed air which converts liquid form of medicine into vapors; much in the same way as an old style "Flit" sprayer does.[4]

Methodology

The study was executed by using quantitative research approach with comparative descriptive study design. The elected population for the study was children who are suffering with Lower Respiratory Tract Infection in selected hospitals of central Gujarat. Participants were selected by calculating power analysis with using the formula $n = 2(\sigma/\Delta)^2 (Z_\alpha + Z_{1-\beta})^2$. In that n = Sample size, σ = Standard deviation = 1, Δ = critical difference = 0.5, Z_α = Error (5%) = 1.96, $Z_{1-\beta}$ = Power (80%) = 0.84. So, 86 samples were selected and assigned in to two groups by using non-probability purposive sampling technique, the participants who elected in hypertonic saline group (3% Nacl) and salbutamol group were observed once a day for three days. Independent variable was hypertonic saline (3%Nacl) and Salbutamol nebulization therapy. as well as dependent variable was breathing pattern and demographic variables were age in month, gender, Is the baby on any medications for LRTI? Symptoms at admission, Duration of hospital stay, Oxygen requirement. All the data was collected by utilizing Demographic data was collected by questionnaire as well as breathing pattern was assessed by modified clinical severity score. Pilot study was conducted from 7th April to 20th April 2019 among 10 patients Hypertonic nebulization therapy (3%nacl) (5) &Salbutamol nebulization therapy (5) in baby children hospital, Ahmedabad to identify feasibility of the samples and reliability of the tool. The main study was conducted in different children hospitals .Moreover, the data was analysed and interpreted by using descriptive

and inferential statistics.

Results

1. **Breathing pattern of children suffering with lower respiratory tract infection after nebulization therapy with hypertonic saline (3%Nacl).**

Clinical severity score	f	%	Mean	SD	Median	T value	P-Value
Mild	06	13.95					
Moderate	31	72.09	1.4283	0.4737	1.500	18.94	0.000
Severe	06	13.95					

2. Breathing pattern of children suffering with lower respiratory tract infection after nebulization therapy with salbutamol. N=43

Clinical severity score	f	%	Mean	SD	Median	T Value	P-Value
Mild	01	2.33					
Moderate	17	29.53	1.8469	0.3387	1.9167	15.64	0.000
Severe	21	48.84					

3. **Effect of Hypertonic saline (3% Nacl) nebulization therapy (ANOVA)**

Source	DF	Adj SS	Adj MS	F-Value	P-Value	Mean of 3 days
Factor	2	281.2	140.583	158.44	0.000	2.2674
Error	513	455.2	0.887			1.5465
Total	515	736.3				0.4709

Table value p= 2.91(df 2, level of significant 0.05)

4. **Effect of salbutamol nebulization therapy (ANOVA)**

Source	DF	Adj SS	Adj MS	F-Value	P-Value	Mean of 3 days
Factor	2	179.5	89.7684	112.83	0.000	2.5407
Error	512	407.3	0.7956			1.9006
Total	514	586.9				1.0988

Table value p= 2.91(df 2, level of significant 0.05)

There is a no significant association between selected demographic variables and breathing pattern of children suffering with lower respiratory tract infection after hypertonic saline(3% Nacl) and salbutamol nebulization therapy except symptoms at admission.

Disscussion

In this study it is found that majority of the participants 31(72.09%) were having moderate clinical severity score 6 (13.95%) were having mild and severe clinical severity score among the children suffering with lower respiratory tract infection after nebulization therapy with hypertonic saline.

In this study, majority of the participants 21(48.84%) were having severe clinical severity score, only 1 (2.33%) were having mild clinical severity score and 17(29.53%) were having moderate clinical severity score among the children suffering with lower respiratory tract infection after nebulization therapy with salbutamol.

During assessment it is noted that the mean clinical severity score 1.4283 with hypertonic saline (3% Nacl) nebulization therapy was lesser than the mean clinical severity score 1.8469 with salbutamol nebulization therapy with the mean difference of was (0.4186). ANOVA calculated P value is less than 0.05, it is 0.000. So, we can strongly reject our H_0. This indicates that the hypertonic saline (3% Nacl) is effective to improve breathing pattern compare to salbutamol nebulization therapy.

There is a no significant association between selected demographic variables and breathing pattern of children suffering with lower respiratory tract infection after hypertonic saline (3% Nacl) and salbutamol nebulization therapy except symptoms at admission.

Conclusion

The research study concluded that hypertonic saline (3% Nacl) nebulization therapy is more effective compare to salbutamol nebulization therapy. The common side effects of salbutamol nebulization therapy are fine tremor, anxiety, headache, muscle cramps, dry mouth, and palpitation. Other symptoms may include tachycardia, arrhythmia, flushing of the skin, myocardial ischemia (rare), and disturbances of sleep and behaviour.

Ethical Clearence : The study was approved by the research committee, IEC – 10/05/2019- ARIP/IEC/19/19 and a formal written permission was gathered from the authority of.

Pattern and Convergence in Access to Individual Household Latrine Facility in Indian States and the Impact of Swachh Bharat Intervention

Prasant Kumar Panda[1], Pavithra. S[2], Anjali Elsa Skariah[3]

[1]Associate Professor and Head, [2]Integrated Master Scholar,Department of Economics, Central University of Tamil Nadu, Thiruvarur, [3]Research Assistant, ICSSR funded Research Project, Department of Economics, Central University of Tamil Nadu

Abstract

Backgorund: Access to improved sanitation facility for all is an essential to maintain good health and well-being. However in India, millions of people suffer from diseases and infections due to lack of adequate sanitation. Realising the importance of sanitation and hygiene, Government of India announced the flagship programme Swachh Bharat Mission (SBM) in 2014. One of the important features of SBM is to provide financial assistance to construct individual household latrine facility. It is important to understand the impact of SBM on pattern and access of households to latrine facility in Indian states.

Objective: This paper tries to examine the pattern and trends in access to individual household latrine facility from an inter-state perspective and convergence in access to latrine facility among the states after the implementation of SBM.

Methods: Data have been obtained from Census, reports from Ministry of Drinking Water and Sanitation, GOI and Swachh Bharat Mission Gramin website for the period 2011 to 2018. Sigma and beta convergence techniques have been employed to analyse the convergence in access to toilet facility and percent and ratios are employed to analyse the pattern.

Results: The findings of the study confirmed the positive impact of SBM in increasing the access to toilet facility in rural India and convergence in access to toilet facility among Indian states in post SBM implementation. During the period 2014-2018, ie, after implementation of SBM, the increase in sanitation coverage at national level is four times higher than the progress made during the decade of 2001 to 2011. Many of the States have reported 100 percent open defection free Villages in the year 2018. So Implementation of SBM not only improves the share of households having latrine facility, but it has widely reduced the gap between high and low income states in access to the sanitation facility.

***Key Words**: Rural sanitation, Swachh Bharat Mission, SBM, Access to Toilet facility, Convergence, Rural House hold Infrastructure, Impact of SBM.*

Introduction

Access to safe water, improved sanitation along with good hygiene is of paramount importance because of their implication on people's health and socio-economic development. Lack of access to improved sanitation is one of the main reasons for the existing disease burden in the form of diarrhoeal diseases, undernourishment, other infections and tropical diseases. The cost of poor sanitation is often measured in economic terms as the direct cost associated with the treatment of diseases related with poor sanitation, but loss of income , productivity and loss of work hours due

to distant and inadequate sanitation facility also have severe implications. Considerable improvement in all of these factors can reduce mortality rates, morbidity and improve quality of life of people, especially infants and children in developing countries. Hence, water and sanitation remain the fundamental requirement of human beings.

Open defecation is the main challenge for healthy hygiene and sanitation. One of the main reasons for open defection is lack of adequate and proper sanitation infrastructure like individual household toilet facility. Globally, 2.3 billion people lack basic sanitation facilities, 892 million practice open defecation; and nearly 80% of the people residing in rural India lack improved sanitation facilities [1]. Over the past few years, countries have made commendable progress in sanitation facilities but the benefits are not evenly spread. It is observed in several studies that, there exists inequality between rural- urban, rich- poor, educated-uneducated, and men-women [2-3]. Most developing countries, including India, have excessive pressure on infrastructure facilities that is required to meet the "healthy living needs" of growing population. The challenge to provide sanitation facilities to people in the rural areas, as well as, urban areas are aggravated by rapid urbanisation and dwindling social sector investments [4], with millions of people falling in short of basic facilities.

Despite the staggering figures, continuous efforts are being made by the Government of India (GOI) to effectively address the problem of sanitation and water. In 1980's, GOI introduced Central Rural Sanitation Programme (CRSP), with focus on rural sanitation. The survey on drinking water, sanitation and hygiene carried out by National Sample Survey Organisation in 1998 and a similar report by Central Bureau of Health Intelligence in 1998-99, revealed shocking disparities across people living in rural and urban areas. Total Sanitation campaign (TSC) was introduced in 1999 as a restructure to existing programme, i.e, CRSP, to curtail the widening gap and worsening situation of sanitation, water and hygiene in rural India. Later in 2012, TSC was renamed as Nirmal Bharat Abhiyan and subsequently, in 2014, it was relaunched as Swachh Bharat Mission. The mission is aimed to fulfil universal coverage and to bring about a change in perception and attitude towards use of latrines, thereby, translating into use of the facilities.

In Indian context in spite of many initiatives by the government, people lack basic facilities like toilet at home. This is the basic requirement and first step towards checking open defecation and improved sanitation, though change in behaviour in adopting the use of toilet is also important. Findings from different studies show that unavailability and lack of facilities are the reasons for open defecation in India.[5] Also, functioning toilets[6], electricity facility, proximity and in- house water connections [7] can affect the effective and persistent use of latrine among members of household. Therefore, creation of toilet facility is definitely the first step coupled with complementary facilities (like electricity, availability of water, proper drainage etc.) will reduce open defecation.

Studies pertaining to analysis of sanitation facilities are usually at household levels. In literature many studies have tried to identify the important determinants that affect sanitation facilities of households. A study conducted in Ghana revealed that, economically active people are more likely to afford the facility.[8] There is prevalence of deplorable sanitation conditions of labourers in textile firms.[9] A study highlights uneven progress of sanitation in India.[10] Studies acknowledge a positive relation with the sanitary facility and wealth. [8] It is suggested to increase share of health spending as per cent of state GDP in the states for better health indicators.[11] Similarly a study observes that health is not luxury in Indian context as income elasticity of public health expenditure is less than unit.[12]

Even with access to latrine facility open defecation is still rampant in different parts of the country.[2] It is observe from a study that latrine access doesn't not always result in use of the facility.[13] Poor governance and lack of appropriate spending and on other side traditional practices and cultural factors influence health outcomes in India.[14]

There have been very limited studies in regard to analysis of the pattern of sanitation coverage, and convergence at state level in India. Besides it is important to observe the influence of Swachh Bharat Mission on increasing pattern of access to sanitation and convergence across states. In this paper we have confined our analysis to access to individual household toilets in Indian states from a macro perspective. The main objectives of the paper are (i) to analyse the level of infrastructure facility like households having individual toilets from an interstate perspective; (ii) to examine the convergence or divergence in access to household toilet in Indian states and (iii) to verify the impact of

SBM on increasing access to household toilets and on convergence across states. Rest of the paper is structured with the following sections: data and methodology, empirical results and discussion and conclusion.

Data And Methodology

2.1 Data

The data pertaining to sanitation coverage have been obtained from Census 2001 and 2011. Sanitation coverage data for 2014-2018 have been obtained from Ministry of drinking water and sanitation, Government of India. The criteria used in Census for sanitation coverage is "Availability of latrine facility within household premises". The data for the same have been taken from Swachh Survekshan conducted by Ministry of Drinking Water and Sanitation (GOI) under SBM. As the nature and pattern of resource generating financial development activities are different for special category states (SCS) than the same in general category states (GCS), we have separately analysed SCS and GCS.

Our findings reported in this paper are observed on the basis of data provided by SBM through Swachh Sarvekshan. So findings are subject to the limitation of data reported in these Swachh Sarvekshan.

2.2 Methodology

The data has been analysed using percentage – ratio methods. Sigma and beta convergence tools have been employed to understand the convergence or divergence among states. For convergence, log linear trend growth rate of households having latrine has been computed by using the following regression equation:-

$$\ln(Y) = \alpha + \beta t + e$$

Where Y is the share of households having individual latrine;

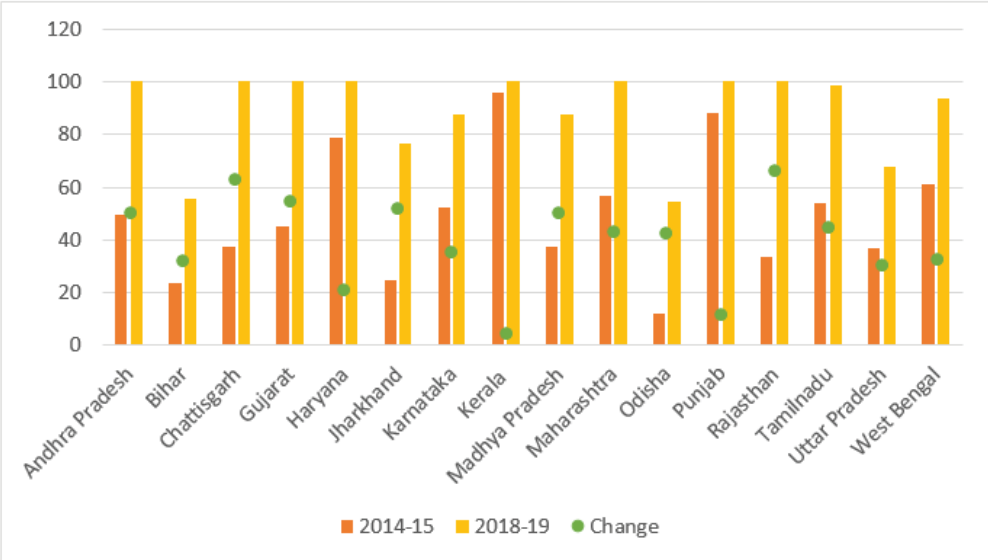
The estimated value of β is regressed on initial level of share of households having latrine facility to find the convergence.

Empirical Results And Discussion

This section provides findings of the study.

3.1 Patterns and trends of sanitation coverage

The figure -1 shows the change in sanitation coverage, i.e, share of households having latrines for 2014 and 2018 for the major states of India. Overall, there has been an improvement in the coverage for all major states over the span of four years. States like Andhra Pradesh, Chhattisgarh, Gujarat, Haryana, Kerala, Maharashtra, Punjab, Rajasthan, and Tamil Nadu, have reported 100 % coverage in 2018. Rajasthan, Gujarat, Andhra Pradesh and Chhattisgarh have shown significant progress with an increase in coverage of more than a half, while Bihar, Odisha and Uttar Pradesh are still lagging behind.



Source: Authors compilation from SBM data

Figure .1: Sanitation coverage for major states in India

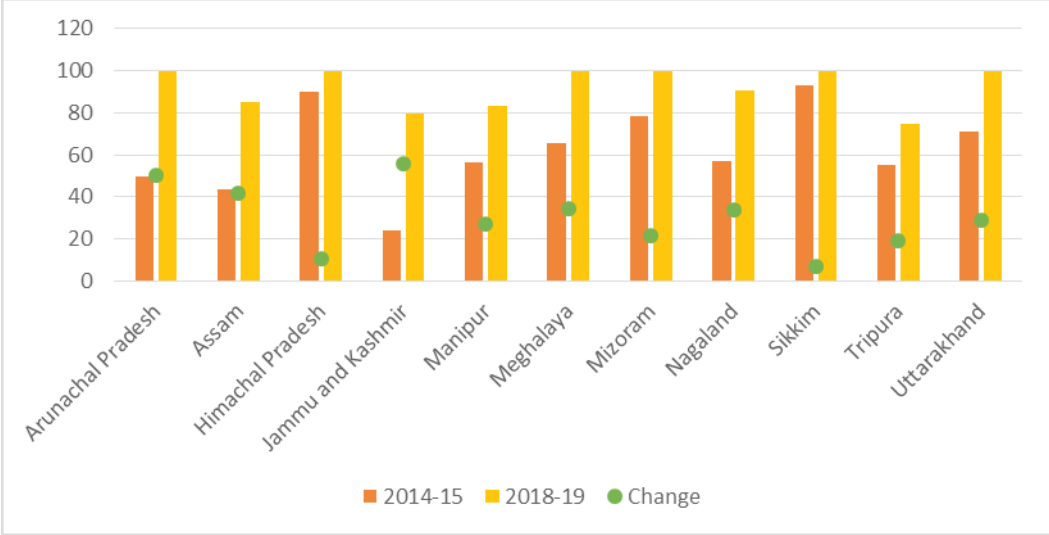


Figure 2: Sanitation coverage among the Special Category states in India

Source: Authors Compilation from SBM data.

The figure 2 shows the sanitation coverage among the special category states for 2014-15 and 2018-19. Six out of the 11 states have attained 100% sanitation coverage in 2018-19. A similar trend of improved sanitation coverage can be observed for the special category states. States of Jammu Kashmir, Assam, and Arunachal Pradesh have made marking difference in sanitation coverage. Tripura is the only state which is has coverage share less than 80% in 2018.

Table .1: Percentage Change in Sanitation Coverage

	2014	2018	% Change	2001	2011	% Change
India	42.56	83.71	41.15	36.40	46.90	10.50
Major States	49.71	88.82	39.11	35.43	47.05	11.63
Special category states	62.55	92.16	29.61	62.75	73.35	10.60

Source: Authors compilation from Census and SBM data

The table 1 shows the percentage of change in share of households having latrine facility in 2018 over 2014, and between 2001 and 2011. It is quite interesting to note the progress made in the past 4 years compared to past 10 years. During the period 2014-2018, the increase in sanitation coverage at national level is 4 times the progress made in previous decade. A striking similar trend can observed for major states and special category states. The whopping increase could be attributed to the implementation of Swachh Bharat Mission.

3.2 Convergence of sanitation facilities in Major States

Individual household latrine facility and its coverage are important for states irrespective of their income status. If the growth in the share in access to toilet facility among the deficient states can grow at faster rate than the states where majority of households have access to toilet, then convergence in access to toilet facility across Indian states will be achieved. So a larger intervention is required through policy for low income states or sanitation deficient states in order to improve

their sanitation facility to converge them with high income states. So it is important to analyse how SBM has helped in converging the access to toilet facility in Indian states.

The figure-3 shows the pattern of convergence or divergence of states in coverage of individual household latrine facilities. It has been observed that the in the initial years, there is divergence among states until 2014. But after 2014, there is steady decline in standard deviation of states of sanitation coverage across states, indicating convergence of major states. The figure 4 below also depicts a similar trend and establishes that the states converge with the high performance states in due course of time.

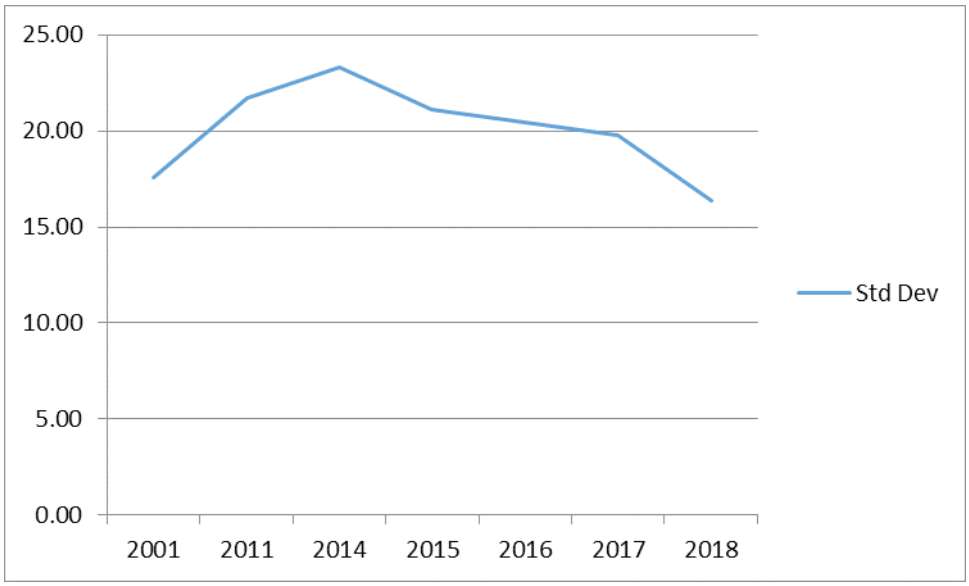

Figure 3: Pattern of convergence across states.

Source: Authors calculations based on Census and SBM data

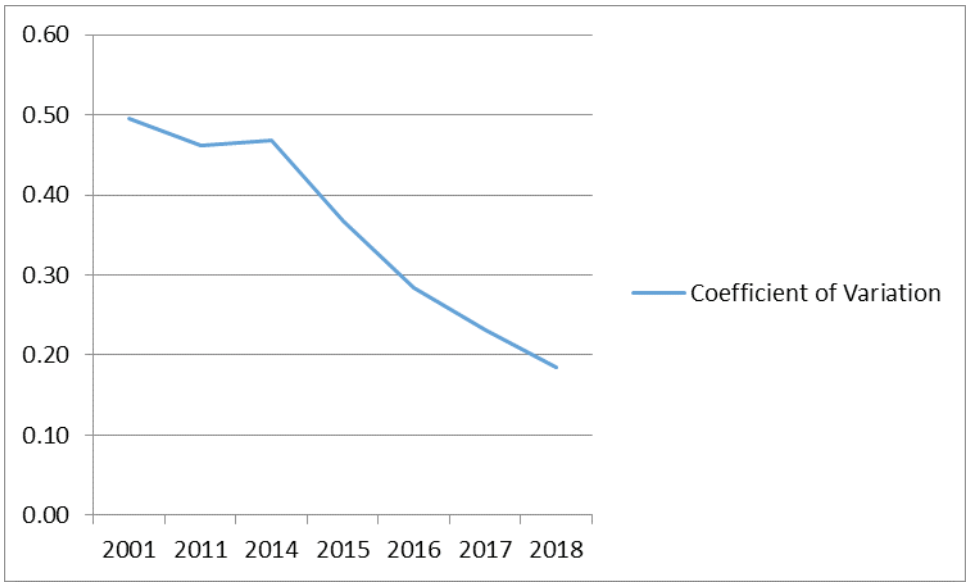

Figure 4: Coefficient of variation in Access to toilet facility among Indian states during 2001 to 2018

Source: Authors calculation based on data from Census and SBM

From the table-2, it's observed that the beta convergence coefficient is significant and negative for all three cases, i.e, major states, special states category and the all states taken together. Comparing years of implementation of SBM, i.e, 2014 to the current year 2018, there is convergence to access to individual household latrine facility. This suggests that the implementation of SBM not only help to improve percentage of people having toilets but it has widely reduced the gap between low and high income states. Low income states have constructed the toilets at a faster rate to achieve the convergence with the higher income states.

Table 2: β- Convergence coefficient for Indian States

	Major states	**Special category States**	**Combined**
b	-3.25**	-4.20*	-0.83*
	(-2.95)	(-4.79)	(-5.80)
constant	83.49	95.48	59.24
	(-6.7)	(12.33)	(10.02)
R2	0.42	0.72	0.59
F	8.71	22.95	33.63
	(0.01)	(0.00)	(0.00)
N	14	11	25

Note: ** indicates significant at 5% and * indicate significant at 1%.

Source: Authors calculations based on data from Census and SBM

Conclusion

The paper is an attempt to look into the pattern and trends of sanitation facilities at state level, to understand the convergence or divergence over the years after the implementation of SBM. Indeed, the country has made striding progress in the years after the implementation of SBM. Our findings also suggest that the poor performing states in terms of facilities, are catching up with the well-off states, as well as, this progress is taking place at a faster pace. There is convergence in access to individual household latrine facility across India states after implementation of SBM. So implementation of SBM helps in improving the share of households having toilet facility in Indian states and it also widely reduces the gap in the same between high and low income sates.

Awareness about Role of Physiotherapy Management During Labour among Obstetricians and Gynacologists

Pratik Goyekar[1], Ruchita Shah[2]

[1]Final Year Physiotherapy, [2]Assistant Professor, Department of Community Health Sciences, Faculty of Physiotherapy, Krishna College of Physiotherapy, Krishna institute of Medical Sciences, Karad

Abstract

Background- Pregnancy is the period where a woman goes through many physiological changes, this changes are physical and also emotional. To make this phase comfortable during pregnancy and at labour is important concern. Various measures are available for this purpose one of this is physiotherapy. Breathing Exercises, relaxation, swiss ball etc. This study is conducted to find if this is been practised and till what extend and find the awareness about role of physiotherapy management during labour pain among obstetricians and gynaecologists. This will also help us to overcome the problems**. Objectives**- To assess the knowledge of obstetricians about physiotherapy management in labour pain. To determine the awareness about role of physiotherapy in managing labour among obstetricians and gynaecologists**. Method**- total 144 obstetricians and gynaecologist was taken in this study, they were explained about the purpose of the study. Each of them was given a self-made questionnaire. Data was recorded. Later statistical analysis was done in accordance to awareness about physiotherapy management during labour**. Result**- The present study showed that the awareness among obstetricians in less regarding role of physiotherapy in managing labour due to lack of knowledge and also due to unavailability of a qualified physiotherapist in that particular area. **Conclusion**- On the basis of result it can be concluded that there is need for better interaction and communication between physiotherapist and obstetricians and gynaecologists, which can done through journals, seminars, UG/PG curriculum, social media, workshops.

Key Words- *Physiotherapy, labour, awareness, obstetricians, gynaecologist.*

Introduction

Apart from allopathy, India is blessed with different indigenous system of medicine. Where each system aims at encouraging good health; out of it Physiotherapy is one.

Physiotherapy offers service that maintain, repair, and expands people's maximum functional ability. It can be beneficial to people at any stage of life.

Pregnancy is a period when a women undergoes many physical and psychological changes in the body. These all changes are normal and because of growing foetus mainly changes are noticed in abdominal and thoracic regions. (1)

Labour: Labour is defined as series of events that take place in the genital organs in an efforts to expel the viable product of conception (foetus, placenta and membranes) out of the womb through the vagina into the outer world. (2)

There are 3 stages of labour:-

· **First Stage-** It begins with the onset of contractions and ends when the cervix is fully dilated.

Duration: In Primigravida = 8-12hrs.

In Multigravida = 6-8hrs

· **Second Stage-** It begins after the cervix has fully dilated and baby's head has moved down in to the birth canal. It ends when the baby is born.

Duration: In Primigravida = 1-2hrs

In Multigravida = ½ hrs

· **Third Stage-** It involves the expulsion of the placenta from the body.

Duration: Up to 30 minutes, however the average length of the third stage of labour is 10 minutes. (2)

The control of labour pain and prevention of suffering are major concerns of clinician and pregnant lady. So management of labour pain is the most important goals of maternity care. (3) This management includes pharmacological as well as non-pharmacological approach. In non-pharmacological ways "PHYSIOTHERAPY TREATMENT" is one of them.

Obstetric physiotherapy is subspecialty in physical therapy which deals with the promotion of health throughout the child bearing phase. Utilization of physical therapy depends upon knowledge of obstetrician and their attitude towards physiotherapy. (1)

Early bird classes are conducted for reducing the discomfort during child bearing phase. This antenatal classes are conducted by the team consisting of obstetricians, gynaecologists and physiotherapists.

In this classes women's are encouraged to bring their partners or some other person of their choice.

In early bird classes physiotherapist helps patient with following things:-

Pregnancy back care

Pelvic floor and pelvic tilting exercises

Exercises for circulation and cramps

Fatigue

Effects of stress on body and mind

Emotional reactions

Advice of lifestyle

At the end of 'Early bird classes', the mothers have sufficient knowledge about relaxation techniques, ergonomically correct positions etc. which will help her for preparation of labour without discomfort. (4)

Role of physiotherapy in obstetric conditions like pregnancy, labour, puerperium, pre-operative period is important. (5) Postural re-education, strengthening of pelvic floor muscles helps during pregnancy. While TENS (Trans cutaneous nerve stimulation), positioning, relaxation techniques, heat and cold, ball exercise, massage and breathing techniques help during labour pain.

For the management of the labour there are several techniques and approaches are used by physiotherapists according to the stage of labour.

Physiotherapy management includes:-

1. TENS (Trans cutaneous nerve stimulations)
2. Positioning
3. Massage
4. Relaxation techniques
5. Breathing techniques
6. Hot water bath
7. Swiss ball exercises. (3)

Generally in first stage we start with breathing exercises which help to maintain ventilation and helps mother to push. TENS is used for back pain management, then patient is made to sit, stand or lying in different positions for pain relief. Relaxation techniques are given to relax mother and prevent fatigue. Massage can also be given for relaxation. Hot water bath is given for relaxing the pelvic floor muscles. Swiss ball exercises are also included in first stage of labour.

In second stage of labour relaxation techniques are given along with breathing exercises to keep mother calm and relaxed which also helps in easy vaginal delivery.

In third stage breathing exercises are given. (6)

Child bearing is the most important and crucial time for any women; physiotherapy helps for the betterment of the mothers health. As there are various methods for managing the labour pain, so the present study intended to find the awareness about the management by physiotherapy for labour pain among Obstetrician and gynaecologists.

Material and Methodology

This study was to find the awareness about role of physiotherapy management during labour among obstetricians and gynaecologists. The study was carried out in Dhule district. An approval for the study was obtained from the protocol committee and ethical committee of KIMSDU. Individual were approach and those fulfilling the inclusive criteria were selected. The purpose was explained and written inform consent was taken prepared in accordance with the Helsinki Declaration from those who are willingly to participate. The total 144 participants were taken from different hospitals in and around Dhule. The Inclusion criteria was Obstetrician and gynaecologists male and female, Rural and sub-urban practitioners, New and old practitioners, Government and Private doctors of Dhule. The Exclusion criteria was Obstetrician and gynaecologist residents and Metro city practitioners. Demographic information of the subjects was taken. The individuals were explained about the purpose of the study. Each of them was given a self-made questionnaire. Data was recorded. Later statistical analysis was done in accordance to awareness about physiotherapy management during labour.

Statistical Analysis

Statistical analysis of the recorded data was done by using the software SPSS version 20. The p value is less than 0.001 which is significant.

Result

The present study showed that the awareness among OBG in less regarding role of physiotherapy in managing labour due to lack of knowledge and also due to unavailability of a qualified physiotherapist in that particular area.

Table No 1- Gender Distribution:

Gender	No. of Participants	Percentage %
Male	64	47
Female	71	53
Total	135	100

INTERPRETATION- The table shows the gender wise distribution of the participants of this survey; there are 47% of males and 53% of females participated in the study.

Table No 2- Distribution of Question Wise Percentage of Awareness:

QUESTIONS	ANSWERS				
ARE YOU AWARE THAT PHYSIOTHERAPY CARE IS REQUIRED DURING LABOUR?	YES (68%)	NO (32%)			
WHAT DIFFERENT TREATMENT OPTIONS OF LABOUR MANAGEMENT FROM PHYSIOTHERAPY YOU AWARE OF?	relaxation techniques (10%)	Breathing exercises (8%)	Kegel's exercises (10%)	Yoga (10%)	Don't know (62%)
DO YOU REFER OR CONSULT PHYSIOTHERAPIST DURING LABOUR PAIN MANAGEMENT?	Yes (33%)	No (67%)			
DID YOU EVER CONDUCTED EARLY BIRD CLASSES WITH THE HELP OF PHYSIOTHERAPIST FOR ANC PATIENTS?	Yes (13%)	No (87%)			

Cont... **Table No 2- Distribution of Question Wise Percentage of Awareness**:

ACCORDING TO YOU WHY ANC PATIENTS ARE NOT REFERRED TO PHYSIOTHERAPISTS?	Lack of Knowledge/ Poor Awareness /Don't Know (79%)	Unavilability Of physiotherapist (10%)	Lack of Councilling of Patients (5%)	Don't find it Necessary (1%)	Ignorance (5%)
WHAT IS YOUR FEEDBACK FOR PHYSIOTHERAPY SERVICES PROVIDED IN LABOUR PAIN?	Positive Feedback (50%)	Negative Feedback (8%)	Lack of Awareness (12%)	Lack of Availability (5%)	Don't Know (25%)

Interpretation:

The table shows the question wise responses of the participants.

When we ask them if they are aware that physiotherapy care is required during labour 68% Obstetrician and gynaecologist are aware about physiotherapy care is required during labour and 32% says that they are not aware about this practice.

From this participants 67% participants don't know about any treatment options of labour management from physiotherapy remaining 10% knows about relaxation techniques, 10% yoga, 10% Kegels exercises and 8% knows about the breathing exercises.

33% of participants says they refer or consult physiotherapist during labour pain management and 67% participants says they don't refer/consult physiotherapist during labour pain management.

13% participants conducted early bird classes with physiotherapist for ANC patients and 87% never done this for there ANC patients.

When we try to find out the exact reason for not referring ANC patients to physiotherapist we found lack of knowledge/poor awareness is the one of the most important reason for this 79% participants finds this option correct, 10% says unavailability of OBG specialised physiotherapist is the reason, 5% participants find lack of counselling of patient is the correct option and remaining 1% says they don't find physiotherapy necessary during ANC period.

When they share their feedback for physiotherapy services provided in labour pain then 50% participants says positive things, 8% says negative things, 12% says there is need to make patients and doctors aware about physiotherapy during labour management, 5% says unavailability of OBG specialised physiotherapist is the reason and 25% don't know about it.

Discussion

The study was conducted with the primary aim to find awareness about role of physiotherapy management during labour among obstetricians and gynaecologists. Many doctors were approached but only 135 responded and were willing to participate in this study. From that 135 people there are 64 males and 71 females which is 47% of male and 53% females.

In this study maximum doctors were between the age group of 36-45 years, that is 49 which means 36% of all the participants. There were 42 doctors between the age of 46-55 years which makes 31% of all the participants. 38 young doctors participated in this study they were between the age group of 25-35 years which makes 28%. Senior most doctors also participated in this study but the made only 5% of all the participants they were 6 doctors from age group of 56-65 years.

Differentiation by the practice in field like government and private practitioners there were 44% of government practitioners and 56% are private practitioners also in this study.

From this 135 doctor 112 doctor said they had physiotherapist nearby them and 23 of them said there was no physiotherapist nearby them.

81% of participants were aware about post-graduation courses in physiotherapy reimaging 19% says they are not aware about the post-graduation courses.

Doctors who are aware about physiotherapy care during labour are 68% and 32% were not aware about it.

34% of doctors says they came to know about physiotherapy role in management of labour during their under graduation degree and 16% says they came to know about it in post-graduation degree. Were seminars and journals makes awareness in 36% of doctors and remaining 14% says they come to know about it from internet, social media, colleagues, physiotherapists and by experience. In this study 60 participants from government sector and out of them 39 means 65% practitioners are aware about the physiotherapy role during labour pain management and reaming 21 means 35% practitioners are not aware of physiotherapy role during managing labour pain. There are 75 practitioners are from private sector and out of 75 53 are aware about the physiotherapy role during labour pain management and remaining 22 participants means 29% are not aware about the physiotherapy role during labour pain management. In this study out of 135 participants 38 were know at least one exercise for labour pain management which means 97 participants were less aware about physiotherapy during labour pain management. Which makes 38% participants are aware about at least single exercise in labour pain management reaming 62% participants don't know about it. This study shows that there are 33% participants which refer or consult physiotherapist during labour pain management and 67% participants are not aware about it or they are not working with physiotherapists. 45 participants says that they were working with physiotherapist for labour pain management from that 45 participants 43 says they are satisfied with the post physiotherapy outcomes of labour pain management were 2 people says they are not satisfied with the outcomes which means 96% are satisfied with outcomes and 4% are not satisfied with it. From this 135 participants 121 participants which makes it 90% of study population says they will now suggest physiotherapy for labour management to their colleagues and patients remaining 14 participants 10% of study population says they don't want to suggest physiotherapy to colleagues and patients. Which shows that maximum participants are welcoming the physiotherapy services for the betterment of the patient and they want it to help them during labour pain management. Which means they are willing to promote and utilize physiotherapy for better results.

In this study we ask them to tell us about why they are not referring ANC patients to the physiotherapists and all of them responded. They share their valuable opinions. Maximum participants which means 79% of them says it's because of lack of knowledge and poor awareness; 10% of them says that there is unavailability of the OBG specialised physiotherapist. 5% of them says there is lack of counselling to the patient is a reason; were 5% says ignorance towards the non-pharmacological approach. 1% participants don't find it necessary for their patients. During this study lots of suggestions are taken from them. Most of participants are willing to improve their services by utilizing physiotherapy and make it better for their patients. They also says there is lack of knowledge about it in their filed and lack of awareness about physiotherapy during management of labour pain. As previous literature also says that there is lack of awareness about the OBG physiotherapy in comparison to Musculoskeletal physiotherapy, Neuro physiotherapy, Cardio respiratory and sports physiotherapy.

Conclusion

This study also shows that maximum participants are come to know about physiotherapy management during labour pain from journals and seminars so it may be the best and easy way to communicate with them and make them aware about this. As well as we can aware them during their UG/PG degree curriculum. There is need for better interaction and communication between physiotherapist and obstetricians and gynaecologists, which can done through journals, seminars, UG/PG curriculum, social media, workshops. Which needs to be done properly.

Study of Awareness of Ergonomic Principles in Small Scale Industrial Workers

Pratik Patil[1], Radhika Chintamani[2]

[1]Final Year Student, [2]Assistant Professor of Department of Musculoskeletal Sciences, Faculty of Physiotherapy, KIMS " Deemed To Be University" Karad, Maharashtra, India

Abstract

Background : Industrial workers due to their long working hours which exposes them to various musculoskeletal and cardiopulmonary disorders. Long working hours and lack of proper health related guidelines to be followed during work they often overuse themselves which hampers their body mechanics and quality of life. studies have proved that ergonomic advice for low back pain and neck pain have improved satisfactorily the work capacity of the individuals. As far as authors knowledge, there is paucity in the literature targeting the awareness of ergonomic advice for industrial workers in rural areas, hence this study is been undertaken.

Objectives : To identify ergonomic awareness of musculoskeletal disorders in small scale industrial workers and To identify ergonomic awareness towards respiratory disorders during work in small scale industrial workers.

Results : 42% of people are aware about the necessary workplace health and safety training when starting job and there is a regular communication between employees and management about safety issue, 50% people are clear about their rights and responsibilities in relation to workplace health and safety and 47% people fell free to voice their concerns or make suggestions about workplace health and safety

Conclusion : After carrying out a study of awareness of ergonomic principles in small scale industrial workers, we found out that industrial workers in small scale industries in india lack awareness about the occupational hazards and various safety regulations that are enacted in the betterment of employees.

***Key words** : Awareness, Ergonomics, Industry, Workers*

Introduction

The 'ergon' means work and 'nomos' means law. [1] Ergonomics means right person at right place for maximum output of person. Ergonomics, a relatively new science, looks at the application of physiological, psychological and engineering principles to interactions between people and machines. Ergonomics attempts to define working conditions that enhance individual health, safety, comfort and productivity. This can be done by recognizing three things: the physiological, anatomical and psychological capabilities and limitations of people, the tools they use and the environments in which they function.

Ergonomics has gained attention and take into consideration by the workers in the different fields of works recently. It has given a huge impact on the workers comfort which directly affects the work efficiency and productivity. The workers have claimed to suffer from the painful postures and injuries in their workplace.

MALE	68

Interpretation : 32 female and 68 male participated in the study.

Distribution of awareness of ergonomic principles in small scale industrial workers

Table no. - 2 : Occupational Health and Safety awareness

Question Occupational Health and Safety awareness	Strongly Agree	Agree	Disagree	Strongly Disagree	DK/NA
I am clear about my rights and responsibilities in relation to workplace health and safety	10	50	30	5	5
I am clear about my employers' rights and responsibilities in relation to workplace health and safety	0	55	40	5	0
I know how to perform my job in a safe manner	14	66	20	0	0
If I became aware of a health or safety hazard at my workplace, I know who (at my workplace) I would report it to	10	55	20	10	5
I have the knowledge to assist in responding to any health and safety concerns at my workplace	0	60	30	0	10
I know what the necessary precautions are that I should take while doing my job	15	41	19	0	25

Table no. - 3 : Participation in occupational health and safety

Question Participation in occupational health and safety	Strongly Agree	Agree	Disagree	Strongly Disagree	DK/NA
I feel free to voice concerns or make suggestions about workplace health and safety at my job	15	55	30	0	0
If I notice a workplace hazard, I would point it out to management	10	50	40	0	0
I know that I can stop work if I think something is unsafe and management will not give me a hard time	10	50	35	0	5
If my work environment was unsafe I would not say anything, and hope that the situation eventually improves (reverse scored)	10	56	24	5	5
I have enough time to complete my work tasks safely	10	49	31	0	5

Disscussion

Occupational health is essentially preventive medicine. Occupational health should aim at the promotion and maintenance of the highest degree of physical, mental and social well being of workers in occupations. Preventive medicine and occupational health have same aim. Occupational health, therefore, is the application of preventive medicine in all phases of employment.

In the past it was customary to think of occupational health entirely in relation to factories and mines hence the term 'industrial health' or 'industrial hygiene' were in vogue. Modern concept of occupational health now embrace all types of employment including small scale industries and includes the subjects of industrial hygiene, industrial disease, industrial accidents, toxicology in relation to industrial hazards, industrial rehabilitation and occupational psychology. Occupational environment is the sum of external conditions and influences which prevail at the place of work and which have a bearing on the health of the working population.[1]

Ergonomics is now a well recognized discipline and constitutes an integral part of any advanced occupational health service. It simply means 'fitting the job to the worker'. The objective of ergonomics is 'to achieve the best mutual adjustment of man and his work, for the improvement of human efficiency and well being'. The application of ergonomics had made a significant contribution to reducing industrial accidents and to the overall health and efficiency of the workers.

42% of people are aware about the necessary workplace health and safety training when starting job and there is a regular communication between employees and management about safety issue. Workplace health and safety is considered as importantas production and quality. Also there is an active and effective health and safety committee which communicates about workplace healthand safety procedures.[1]

50% people are clear about their rights and responsibilities in relation to workplace health and safety. They know how to perform their job in a safe manner and are also aware of health or safety hazards at their workplace. They are also enlightening how to

assist in responding to any health and safety concerns at their workplace. They also have initial brefining about necessary precautions that need to be taken while doing their job.[2]

47% people feel free to voice their concerns or make suggestions about workplace health and safety. They would point a workplace hazard to the management if they notice any. They feel free to stop work if they feel something is unsafe.

Conlusion

After carrying out a study of awareness of ergonomic principles in small scale industrial workers, we found out that industrial workers in small scale industries in India lack awareness about the occupational hazards and various safety regulations that are enacted in the betterment of employees.

Conflict of Interest: Do not have any conflicts ofinterest to declare.

Effectiveness of ANATOMY QUIZ for Improvement of Academic Performance in First MBBS Students

Priya P. Roy[1], Swapna A Shedge[2], M.A.Doshi[3]

[1]Associate Prof, [2]Assist. Professor, [3]Professor & HOD, Department of Anatomy, KIMS, Karad, Maharashtra

Abstract

Teaching and learning are the two important components of education.Quiz as an additional method of teaching will definitely improve the knowledge about the subject. It will serve as a method of self directed learning which is added in new curriculum. It will make the subject interesting and adds to critical thinking by the students. The present study was undertaken to observe the effectiveness of anatomy quiz for improvement of academic performance in first MBBS students. A total of 400 willing male and female first MBBS students of 2016-17 and2017-18 batchesatKrishna Institute of Medical sciences, Karad were included in the study. Three quizzes are taken in one academic session. Questions areof MCQ with negative marking,one line answers and two marks questions and image based questions, At the end feedback of students was also taken.Results of quizzes were correlated with the final university results. It was seen that results were improved compare to previous year . 80 % of the students selected in quiz scored distinction marks in university exam.The study results support the importance of quiz in the medical education. Most of the students recommended in feedback that the anatomy quiz should be held routinely in coming years

Key words: *Quiz, MCQ, Academic performance, Medical students, Medical education*

Introduction

The medical council of India published the policies andstrategies of medical education every year with the objectiveto improve quality and standards of medical educationand training. It is also to make an Indian graduate medicaldoctor skilled to maintain the standards in graduationcomplied according to strategies mentioned in vision 2015.[1]Teaching and learning are the two important componentsof education. So, there were considerable changes in theeducation system at the medical workplace because ofstrong correlation between the methods used in deliveringthe information by the lecturers and the assimilation of thatknowledge by the students. So we can change the way forteaching and learning the process in a better way to bothhow and what is taught. "Deep learning"[2]requires higherorder cognitive skills such as analysis and synthesis, while"surface learning" consists primarily of comprehension andreproducing knowledge." This requires the acquisition offour main domains of competencies defined by the MedicalCouncil[3] as: (1) Knowledge, skills, and performance;(2) safety and quality; (3) communication, partnership, andteamwork; and (4) maintaining trust.

The MCI Vision 2015 states that lectures are not adequateas a method of teaching and training also a poor methodof transferring or acquiring information.[4]The lectureshave less impact at skill development and attitudes andcompetence-based education, and we encountered largeclasses, for example, 120 approximate per class. So, there isneed of innovation in the form of active learning opposeto passive learning.[5]The didactic lectures have certain drawbacks such as lossof interest or limited attention span, less retention ofsubject, passive learning. There is lack of development ofany logical or analytical skills because the students are onlylistening and not actively participating during lecture. Thereis no active interaction or feedback from the students.[6,7]The purpose of interactive teaching methods aregeneration of interest in the subject and acquirementof more knowledge in general, active and participatorylearning, development of life-long learning habits andattitudes, acquire, retain and apply the knowledge, activeinvolvement of students, thorough understanding of thesubject, use of internet and other options at disposal forbetter understanding of matter, promote group learning,heightened motivation, and enthusiasm.[8] Active listeningof opinions of others and asking questions.

In the medical professional course, Anatomy is one of the basic sciences of medical school. Anatomical knowledge is traditionally tested by means of summative examination, providing information for pass/fail decisions.[9]A quiz is a form of game or mind sport, in which the players (as individuals or in teams) attempt to answer questions correctly. In some countries, a quiz is also a rief assessment used in education and similar fields to measure growth in knowledge, abilities, and/or skills. The results of a well designed quiz often provide valuable insight on how effectively the course material is being presented based on previous university question paper. In addition to keep finger on the pulse about students' learning progress, quiz results help you assess your own teaching accomplishments as well. Earlier studies by Leonieke N. Palmen et al., reported that Participation of students in formative quizzes in an anatomy course is correlated to the scores on the final summative exam. [10]Hence the present study was conducted To observe the effectiveness of anatomy quiz for improvement of academic performance in first MBBS students.

Materials and Method

Study Participants: A total of 400 willing male and female first MBBS students of 2016-17 and 2017-18 batches were included in the study after obtaining voluntary informed consent.

Study setting: The present study was conducted at Krishna Institute of Medical sciences, Karad, Maharashtra.

Method: After completion of each region for the academic years, students were trained regarding quiz and three quiz was conducted for students. Each quiz comprises of MCQ questions with negative markings , one line answers and two mark questions. Maximum marks was 50. Quiz questions were prepared by senior faculty in the department under the supervision of HOD. Quiz questions were projected by using LCD and each student was provided answer sheet to fill the answers for projected questions. At the end of the quiz answer sheets were collected for evaluation. At the end of third quiz feedback was taken from the students by using a questionnaire. Participants were requested to give their opinion about the 10 statements pertaining to the Quiz which were conducted in the department of Anatomy. Each statement should be ranked on five point scale

Data analysis: The data was collected using standard proforma. The data was entered using Microsoft Excel spreadsheets. The collected data was presented in the form of tables and graphs for frequerncy analysis and it was further analyzed by SPSS 20.0. The overall performance between the students who performed well in anatomy quiz and those who did not performed well in quiz were compared with the help of Chi-square test. P-value less than 0.05 was considered to be significant.

Results

The present study was conducted among first year medical students of KIMS Karad among students of 2016-17 and 2017-18 batches. The students were evaluated using quiz method in the present study and the results were compared with their final university examination marks. Quiz questions were projected by using LCD and each student was provided answer sheet to fill the answers for projected questions. At the end of the quiz answer sheets were collected for evaluation. At the end of third quiz feedback was taken from the students by using a questionnaire.

In this study, various responses regarding importance of quiz in academic curriculum and overall understanding of the subject were noted and are mentioned in figures 1 to 10.

In this study we compared the quiz results with the final results of the university examination during the undergraduate course for the same year (first year MBBS). We observed that in the present batch of students total 10 students participated in third round of anatomy quiz competition. Out of them total 8 students passed the final university examination with distinction marks. We tested the observations using chi-square test and observed that the difference was found statistically significant (Chi-square statistic: 74.1419, p-value: <0.0005). (Table 2)

We conducted a post test to evaluate effectiveness of anatomy quiz in overall improvement of the students in their knowledge and attitude, at the end of anatomy quiz. We observed that majority of the students found the anatomy quiz effective. Majority of the students responded that the quiz is better for enhancing ability to work as a teamwork, it is helpful for self learning. Most of the students recommended that the anatomy quiz should be held routinely in forthcoming years.(Table 3).

Table 1: Overall statistics of the first year students appeared for university examination in June / july2018

Total students appeared for the university exam	**200**
Total students passed in the exam	198 (99%)
Passed with first class	119
Passed with distinction	12

Table 2: Comparison between academic performance and quiz performance

		Distinction		**Total**
Quiz selection		Yes	No	
	Yes	8	2	10
	No	8	182	190
Total		16	184	200

Table 3: Students responses over effectiveness of quiz

Sr No	**Questions**	**Strongly disagree**	**Somewhat disagree**	**Neither agree nor disagree**	**Somewhat agree**	**Strongly agree**
1	Quiz are an effective way to study Anatomy	4	6	23	64	94
2	Quiz have motivated you towards self study	4	6	23	64	94
3	Participating in Quiz improves self learning	2	10	13	71	115

9	Quiz should be continued in the forthcoming years	6	2	19	62	122
10	Quiz should be incorporated in the university curriculum	14	9	37	65	86

Discussion

The undergraduate medical curriculum is vast and spread over several years. A major part of the teaching and learning takes place though the traditional lectures format. Creating innovative educational methods that enhance and supplement the lectures has been a challenge for medical educators. While students are taught material focused upon the functional aspects of the subject, there are many peripheral bits of information that lend colour and sparks interest in the subject. Medical quiz has been used as a method of teaching and learning. Studies have shown that medical Quizzes improve students comprehension and enhance interest levels in the subject Quizzes have been mostly on single subject, delimited by the curriculum and are really a traditional assessment in a new format. [11]

In India, a quiz approach ensured greater participation of students in the learning process. The students found the method very useful and interesting.[12] Active learning strategies have been shown to be helpful in improving retention of information and improving students conceptualization of systems and their functioning.[13]Goud el al in a comparative cross sectional study of 96 medical students to evaluate quiz competitions as teaching learning methodology found a statistically significant improvement in their performance.[14]Beylefild et al used a quiz type board game successfully to impact positively on students attitude and interest towards microbiology. They fell that the positive experience during learning enhanced team effort and communication in addition to enhancing recall of factual knowledge. [15] Also in their study, Vasan et al showed that student performance improved and students perceived it as motivational collective team learning that was self directed and fostered pear respect.[16]

The development of innovative methods is important toimprove student performance. The aim of this preliminarystudy was to ascertain the effectiveness of quiz as aninteractive teaching technique in lectures and implementvarious quizzing activities and evaluate their impact onlearning. This study highlights about teaching theorieswhich proved useful in the development of interest ofstudents in contrast to the traditional lecture method. Thedemographic data was collected in the two study groups tocontrol for confounding factors.

We conducted a post test to evaluate effectiveness of anatomy quiz in overall improvement of the students in their knowledge and attitude, at the end of anatomy quiz. We observed that majority of the students found the anatomy quiz effective. The study covered all competences regarding the topic,and the quiz was arranged to include all aspect. We had also obtained the summary of feedback from thestudents and faculties regarding the quiz method.The students responsewere encouraging, and they asked for the more quiz duringdifferent years.Majority of the students responded that the quiz is better for enhancing ability to work as a teamwork, it is helpful for self learning. Most of the students recommended that the anatomy quiz should be held routinely in forthcoming years.

The new innovative method of learning hadensured active participation of the students, interesting, interactive, informative, strong mode of teaching, more effective, helped to build healthy competition among groups, friendly and playful method of education.

Conclusion

Most of the students agreed and supported conduction of quiz in anatomy for better retrival skills. We recommend further studies in this area to recommend adoption of the quiz in the curriculum. The present study proved that quiz can be another method to improve the academic performance of the students.

Isolation and Identification of Pathogenic Bacteria from Soil Mixed with Hospital Wastes

Purna C. Mahapatra[1], Rabindra N. Padhy[2]

[1]Research Associate, Forest and Environment Department, Kharavel Bhawan (Secretariat Building), Government of Odisha, Bhubaneswar, Odisha, India, [2]Professor, Central Research Laboratory, Institute of Medical Sciences & Sum Hospital, Siksha 'O' Anusandhan University, K-8, Kalinga Nagar, Bhubaneswar, Odisha, India

Abstract

Objective: Hospital solid wastes when not incinerated (nor waste-waters are scientifically treated) remain as sources of a myriad of pathogenic microorganisms.

Methods: A total of 960 waste samples (soil mixed with waste) were collected from waste disposal site of the hospital. After successful growth, bacteria were sub-cultured in nutrient agar slants for preservation. Biochemical characteristics of isolated bacteria were done for identification of bacteria.

Results: A total of 150 collected waste soil samples yielded 103 bacterial colonies, as 65 single and 38 mixed colonies, while 47 samples had no microbial growth. Methicillin resistant *S. aureus* (MRSA), vancomycin resistant *enterococci* (VRE) and *Pseudomonas aeruginosa* isolates were in numbers, 28, 19 and 18, respectively. Of 103 colonies, 63 and 40 were from wastes of wards and ICUs. Invariably, MRSA strains were isolated, as single or mixed colonies. The average minimum inhibitory concentration (MIC) range against oxacillin was recorded as 16 µg/mL for MRSA, and Vancomycin 16 µg/mL for VRE and 8 µg/mL gentamicin for *P. aeruginosa*.

Conclusions: Site specific variation and seasonal variations underplay prevalence of different types of nosocomial spread of opportunistic pathogenic bacteria.

Keywords: *Hospital wastes, MRSA, VRE, Pseudomonas aeruginosa*

Introduction

Wastes are basically the source of pathogenic viruses, bacteria and fungi; especially, hospital solid wastes when not incinerated and waste-waters that are not scientifically treated, remain as sources of a myriad of pathogenic microorganisms. Overall soil-lots, leachates and hospital drains are the overwhelming sources of pathogens, since soil and flowing water are the immediate sink to wastes in dumpsites. Serious health problems of workers linked to places of waste generation and the collection till disposal at dumping sites are vulnerable to direct infections. In most developing countries, the concerned personnel hardly use protective devices for getting exposures. Particularly the indiscriminate waste disposal habits land at release mixed lots of ions, chemicals microbes detrimental to health from pollutes.[1] Due to faulty management of wastes, microbial pathogens from decomposing wastes get transmitted and cause emergence of community-acquired infections, contributing to the burden of morbidity and mortality from communicable diseases.[2] Moreover, pathogens resisting the typical climatic conditions of a place would be transmitted by direct contact with the skin or mucous membranes, through inhalation/ ingestion or by any suitable vector.[3] Often, soil-water interface provides niche that help survival of pathogens that cause infections in the next suitable season depending upon the types composition of hospital waste.[4] Indeed, about 5.3 million people die each year from waste related diseases.[5]

Commonly identified bacterial pathogens such as, *Pseudomonas* sp., *Corynebacterium diphtheriae, Escherichia coli,* and *Staphylococcus* sp. as methicillin resistant *S. aureus* (MRSA) or methicillin sensitive *S. aureus* (MSSA) and a few more have been reported to be part of the hospital wastes and community wastewaters.[6, 7] MRSA-colonized humans shed bacteria/spores to aerosol from nose, skin and faeces as body-wastes.[8] Furthermore, *Enterococcus faecalis* and *E. faecium* inhabit the gastrointestinal tracts of humans and animals and are the major causes of nosocomial infections worldwide. Vancomycin being the antibiotic of choice for enterococci, the prevalence of vancomycin resistant enterococci (VRE) has increased in the recent decades, presumably due to the high antimicrobial pressure in hospitals from wastewaters.[9] Antimicrobial resistance is one of the most serious public health concerns of the twenty-first century.[10] Hospitals are the main environment for multidrug resistant (MDR) bacteria and play a major role in the emergence and spread of these bacteria that thrive in wastewaters.[11] Moreover, large amounts of antimicrobials are discharged into wastewaters and exert a continuous selective pressure upon the survival of MDR bacterial strains. Heavy metals and disinfectants may also favor the persistence of MDR in the wastewater microbiome, by eliminating sensitive strains.[12] As known, antimicrobial selective pressure favours the intraspecific and interspecific transfer of resistance genes.[4] Particularly, hospital waste-dumping effluent could increase the prevalence of resistant bacteria in the recipient sewage/soil by mechanisms of introduction of resistant bacteria from biomedical waste dumping-site soil.[13] Similar surveillance work being in dearth in literature, this work was initiated, locally. The objective of this study is surveillance by isolation, identification and antibiotic profiling of bacteria from hospital-waste contaminated soil. Herein, quantitative and qualitative data of MRSA are summarized; MIC data of the commonly isolated bacteria isolated from waste-soil samples against representative antibiotics of the day were recorded, which is an extension of previous work on MRSA.[14] This work is expected to help to revision of the present antibiotic stewardship program of the hospital.

Materials and Method

Collection of waste soil samples and isolation of bacteria

A total of 960 waste samples (soil mixed with waste) were collected from waste disposal site of the hospital. Samples were collected in sterile zip-lock plastic maintaining aseptic conditions. The collected samples were used for isolation of pathogenic bacteria; if necessary, samples were stored at 4° C after marking resources or specific location. Serial dilution of soil samples were done for the isolation of bacteria. In this technique sample suspension was prepared by adding soil mixed with 1 gm waste, each. From each dilution tube 0.1ml of dilution fluid was transferred into nutrient agar (NA) culture media and incubated at 37^0C for 24 hours. After successful growth of bacteria, those were sub- cultured in NA slants; for vigorous growth and were preserved. Biochemical characteristics of isolated bacteria were done, as previously performed.[15]

Results

From 150 collected samples, 103 bacterial colonies grew as 65 single and 38 mixed colonies on agar plates and no microbial growth was seen with 47 samples. MRSA, VRE and *P.aeruginosa* isolates were 28, 19 and 18, respectively (Figure 1). Of 103 bacterial colonies, 63 and 40 were from wards and ICU. Of course, there were only 65 single- bacteria were isolated, as a single colony; while the remaining 38 bacteria were isolated as mixed colonies (Table 1). Furthermore, MRSA strains, as both single and mixed colonies were isolated. The minimum inhibitory concentration (MIC) range against Oxacillin was 16 µg/mL, the MIC range, for MRSA, Vancomycin 16 µg/mL for VRE and 8 µg/mL gentamicin for *P.aeruginosa* . These MIC values confirmed the presence of all strains, as the break point for being resistant (Table 2).

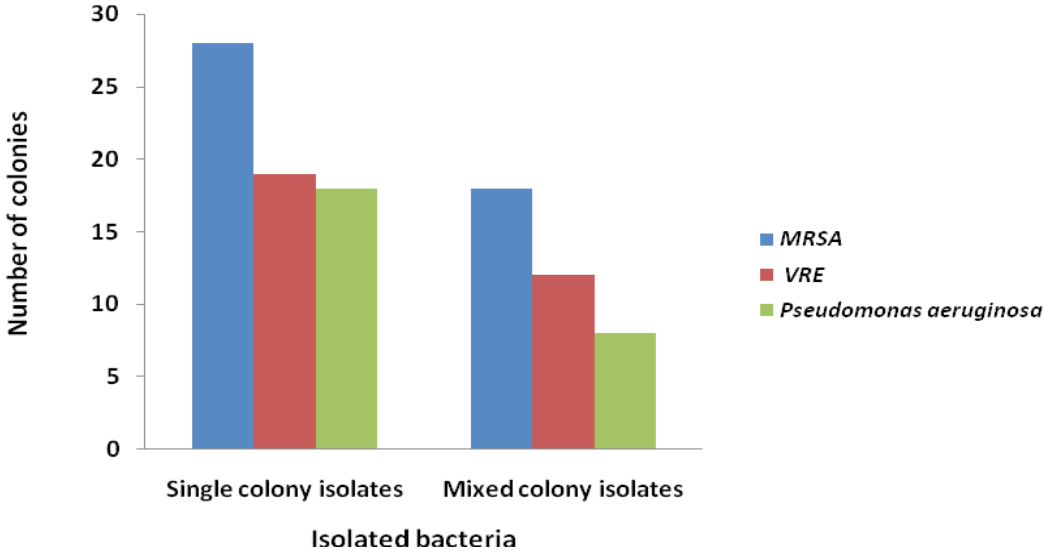

Figure 1 Growth of bacteria in cultures of waste water samples of hospital as single colony and mixed colonies. MRSA: Methicillin resistant *Staphylococcus aureus*, VRE: Vancomycin resistant *Enterococci.*

Table 1 Numbers of growing bacteria from cultures of hospital soil samples with waste.

Colonies	Wards	ICU	Total
Single colony	42	23	65
Mixed colonies	21	17	38
Total	63	40	103

Table 2 Detection of MRSA isolates based on MIC values due to oxacillin in a 12x8 micro-titre plate.

Well	Oxacillin (µg/ml)	Number of isolates MRSA = 28	Vancomycin (µg/ml)	VRE= 19	Gyntamycin (µg/ml)	P. aeruginosa = 18
1	0	28	0	19	0	18
2	≤0.25	–	≤0.25	11	≤0.25	09

12	≥ 256	07	≥ 256	17	≥ 256	–

Note: The oxacillin stock solution of 512 µg/ml was serially diluted at each successive well, from the 12th well for final concentration of 0.25 µg/ml oxacillin at the 2nd well; –, no growth; total *Staphylococcus* sp. = MRSA with123. Results of the second repeated experiment are presented.

Discussions

Since pathogenic bacteria can cause serious public health problems, which demands more research for creating public awareness. Due to irrational uses of antibiotics in last few decades, the numbers of antibiotic resistant bacteria are increasing day by day, and the condition is becoming worse in developing countries.[16] In addition, animal faecal wastes and particulate soil matter at polluted sites provide niches for pathogenic human viruses in addition to bacteria for dissemination and survival directly or as environmental vectors for the horizontal transfer pathogens and their genomes. Indeed, antibiotic resistance genes spread among bacterial consortia, which may be phylogenetically distant even.[17] The occurrence of Methicillin sensitive *S. aureus* (MSSA) and MRSA is on the rise, resulting in increased incidences of hospital-acquired and community-acquired infections worldwide, posing a major public health concern.[18] Basically, *S. aureus* is one of the most successful and adaptable human commensal-turned-pathogen, due to its proficiency in acquiring antibiotic-resistant mechanisms and pathogenic determinants, invading to nosocomial and community settings.[19] Nosocomial colonization of MSSA and MRSA can go undetected, and signs of infection may only appear months after a patient is exposed to the extent of some detectable traits of illness. In USA, MRSA and VRE were identified from a wastewater.[20] *P. aeruginosa* is ubiquitous within wastewaters, with higher concentrations in hospital than in urban wastewater. *P. aeruginosa* isolates resistant to ciprofloxacin or producing VIM-type metallo-β-lactamase, or ESBLs have been obtained from wastewater and hospital discharge sites.[21] Thus, hospital waste dumping effluent could increase the number of resistant bacteria in the recipient sewages by both mechanisms of introduction and selection of MDR bacteria isolated from biomedical waste dumping site soil. [22] Hospital wastewater, which receives high loads of antimicrobial agents and human pathogens, is considered a reservoir for antibiotic resistance and other genetic factors which promote the potential spread of AMR to the environment.

Conclusion

In this present study confirmed the presence of pathogenic bacteria in the hospital solid waste, in the different department/units of the hospital. It contains various types of nosocomial with opportunistic pathogenic bacteria were appeared in the hospitals sites variation and seasonal variation, confirmed that the prevalence types of bacteria vary based on seasonal and spatial variables.

Plastic Waste, Health & Climate Change: Issues & Challenges of Odisha

Purna C. Mahapatra[1], Basanta K. Sahu[1], Amit K. Mohanty[2]

[1]Research Associate, [1]Sr. Scientist, [2]Sr. Research Fellow, Climate Change Cell, Forest and Environment Department, Kharavela Bhawan (Secretariat Building), Government of Odisha, Bhubaneswar, Odisha

Abstract

The population of Odisha is near about 41 million according to the 2011 census. The total area is 155.707 square kilometer which is the 4.8% of total area of India. Various activities such as construction, packaging, infrastructure, communication, mines, entertainment, agriculture and textiles uses plastics because for its low cost, best choices for packaging, durability and easy availability. Last few years, the consumption pattern and life style of people of Odisha has gone up due to change in socio-economic conditions. This, in return generates huge quantities of plastic waste. This quantum of plastic wastes become dangerous to environment (have adverse effects on health and climate) and need to be handled properly for its disposal.

Key words: *Plastic, Waste, Health, Climate,Environment*

Introduction

Plastic is the great creation of human being which changed the whole world and made the life smooth. Because of its high strength, lightweight and lesser cost, this man made material became a part in every sphere of human existence. Variety of the sectors (Industry) such as construction, infrastructure, automotive, communication, entertainment, agriculture, packaging and textiles uses it because for its better benefits. Generally, plastics are the polymers produced by the conversion process of natural products or by chemical reactions of the monomeric unit primarily synthesized from oil, natural gas or coal joined together by chemical bond to form a long chain of polymer of plastic [13]. Due to rapid growth of urbanization, population & industrialization, the consumption of Plastic increased day by day tremendously [9] and this plastic products now becomes very popular both in rural and urban areas globally.

Plastic Production and Trends

The rapid rate of development has led to increase in consumption of plastic products. Much of the growth in plastic production is driven by single use or disposable applications. Nearly 50 % of plastic used are single used products. The use of plastic in packaging both as rigid and flexible forms has been increasing. In India, the average per capita consumption of Plastic is about 11 kg, which are considerably one tenth uses of USA and one sixth of Europe [1]. Whereas average consumption is 28 Kg Globally (Fig 1). Having an estimation by the Ministry (Petroleum and Natural Gas), Government of India suggests that the per capita consumption of plastic in India would be doubled annually by 2022. Further World Economic Forum suggest that the consumption and production of plastic would increase drastically which leads generation of large amount of plastic waste and Green house gases which effects directly or indirectly to climate change.

Clasiffication Of Plastic

Basing upon the physical nature of plastic, it may be thermoplastic or thermosetting materials. Thermoplastic material can be softened or remolded by the application of heat where as thermosetting materials cannot be changed after their formation [6]. These are PET (Polyethylene terephthalate), HDPE (High-density polyethylene), PE (polyethylene), PVC (Polyvinyl Chloride), LDPE (Low Density Polyethylene), LLDPE (Linear Low Density Polyethylene), PP (Polypropylene), PS (Polystyrene) and PC (Polycarbonate).

Plastic and Environment

In spite of heavy demand, plastics are non-biodegradable and cause threat to the ecological system as they reduce the fertility of soil and thereby hamper the growth of plants, choke drains and sewer resulting in overflowing gutters and if swallowed by cattle, they may cause death by obstructing their intestine. The color pigments contaminate food products wrapped in them and cause health hazards and some of it are even carcinogenic. The plastic bags when discarded can get filled with rainwater offering ideal breeding ground for vector borne diseases like malaria and burning of plastics also releases most carcinogenic and toxic substances like dioxins, furans and hydrogen cyanide, which pollute air as well as cause severe and chronic health problems. Plastic products take hundreds of years for degradation [14], as they are not biodegradable like paper bags, they also block the rainwater infiltrating into the soil hindering recharge of ground water. In last decade, due to the widespread littering of plastics, which badly affects the quality of the environment by generating huge amount of waste on the land, has attracted attention of whole world [2].

Plastic and Its Adverse Effects on Human Health

It is estimated that, about 54 % of the world plastic production is Polyethylene and polypropylene [11], which is not only widely used for packaging but also for protecting, serving and disposing all kinds of consumers goods due to its non-biodegradable nature. There are several toxic materials are being secreted by the plastics and their additives. Among them, Bisphenol A (BPA) is most important. BPA has been associated with a number of health problems such as ovarian chromosomal damage, decreased sperm production, rapid puberty, rapid changes in immune system, type-2 diabetes, cardiovascular disorder, obesity etc. Some studies have also claimed that BPA increases the risk of breast cancer, prostate cancer, pains, metabolic disorders, etc. BPA in women and impaired health, including obesity, endometrial hyperplasia, recur-rent miscarriages, sterility, and polycystic ovarian syndrome [12 & 15]. Similarly PVC Causes Cancer, Birth Defects, Chronic Bronchitis, Ulcers, Skin diseases, Vision failure, Liver dysfunction. Polystyrene causes Eye, Nose and Throat

irritation, Lymphatic & Hematopoietic cancer for workers. Polyurethane Foam causes Bronchitis, Coughing, Skin & Eye Problem. Polyester causes acute Skin rashes, Eye & Respiratory tract infection and many more. The adverse effects of Plastics are enumerated in Fig (2).

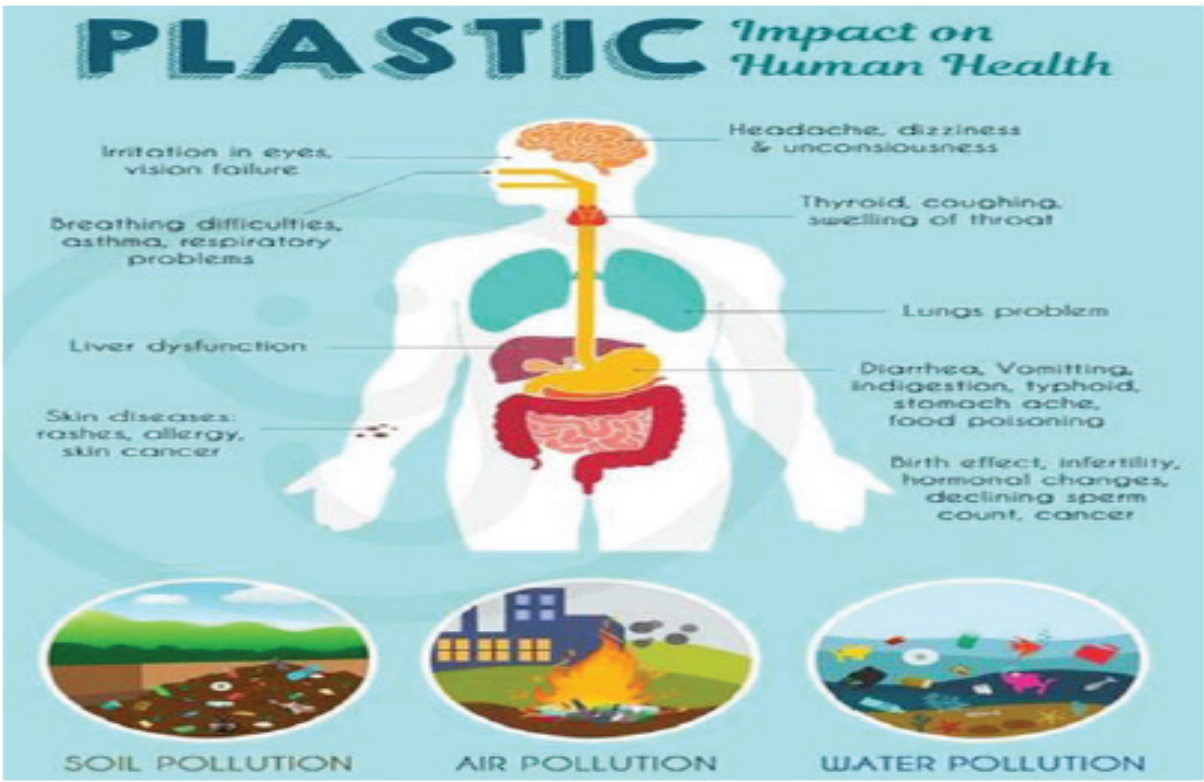

Fig 2: Impact of Plastics on Human Health

Plastic and Climate Change

Plastic when exposed directly to sunlight produces Green House Gases (GHGs) in to the atmosphere. Large volumes of plastic accumulating in Environment contribute to Change in Climate. In every stage of Plastic Life Cycle i.e. from manufacturing to decompose/ its management, emitting GHGs. Potential sources of GHGs from plastic to the environment are sludge of sewage treatment plants, waste water, leakage from plastic landfills, incineration fumes and global transport of chemicals from plastic. In addition to this, Methane is also emitted from waste dump and landfills, contributes largely for global warming [3]. Gradually the earth's and oceans atmosphere are getting warmer day by day. This warming makes worsen the climate variability. A report by the Tear Fund (2019) states that global plastic production emits 400Mt of greenhouse gases each year – more than the UK's entire carbon footprint. If the growth of plastic production continues at its current rate, by 2050 the plastic industry could account for 20% of the world's total oil consumptions which will indirectly/ directly contributes on Climate Change.

Climate Change Adaptation and Mitigation

Complete ban on plastic and its product is not going to solve the problem; efforts are required to get rid of the load already created in our environment. For this purpose, we can use the plastic waste in such a way which not only reduce the plastic waste load but also improve in quality of our environment. In this context, the plastic waste can be used for road construction, waste to oil, co- processing in cement kilns. The concept of 5'R principle i.e. Reduce, Reuse, Recover, Recycle and Refuse for plastic must have to be adopted in every sphere of our life- whether in home or in work place.

Management of Plastic Waste

Earth being the Home of thousands of living Organism, large amount of Plastic waste has increased the toxicity of the Environment which in turn leads to the death of Organisms. It is felt necessary that certain stringent steps are needed not only with regard to

regulating the use of polythene but also prohibiting the use of thermocol and similar plastic products in order to save the planet. Ministry of Environment, Forest and Climate Change, Government of India have enacted the Plastic Waste Management Rules, 2016 under the Environment (Protection) Act, 1986 (29 of 1986) restricting the use of certain plastic carry bags and containers and its management. The State Government, Odisha also having considered all the pros and cons of the issues have also restricted the indiscriminate use of certain types of plastic products in all municipal limits of the state. All Gram Panchayats in the state have adopted the "Bye Law on solid waste management in Gram Panchayats of Odisha 2019" which also includes management of plastic waste. It is a good sign that the State Government of Odisha has taken a proactive step to prohibit the use of single use plastics such as PET/PETE bottles, water pouch, and other single use disposable items in the premises of all the Departments.

Plastic Waste Management Rule, 2016

Government of India has noticed Plastic waste Management Rules, 2016 for effective management of Plastic waste in the country. The salient features are

i) Plastic waste, which can be recycled, shall be channelized to registered plastic waste recycler.

ii) Local bodies shall encourage the use of plastic waste (which cannot be further recycled) for road construction as per Indian Road Congress guidelines or energy recovery or waste to oil etc.

iii) Thermoset plastic waste shall be processed and disposed off as per guidelines issued from time to time by Central Pollution Control Board, New Delhi.

Role of various stakeholders in management of plastic waste in odisha

i) State Pollution Control Board, Odisha (SPCB, Odisha)

Ø Enforce of provisions of the said rule relating to registration, manufacture of plastic products, processing and disposal of Plastic wastes.

ii) State Government

Ø Creating awareness among all stake holders about their responsibilities.

Ø Discouraging to use of single use plastic among citizen of the state by sensitization / awareness campaigns programmes.

Ø Promoting the use of Plastic alternative materials such as jute & compostable bags.

iii) Associate Government Departments

Ø Ensuring segregation, collection, storage, transportation, processing and disposal of plastic waste.

Ø Ensuring channelization of recyclable plastic waste to registered recycler.

Ø Ensuring processing and disposal of non-recyclable plastic waste.

Ø Ensuring no open burning of plastic waste.

Ø Framing of bye-laws incorporating the provision of rules

Ø Setting up system, oprationalise and coordinate for waste management in the rural areas by ensuring segregation, collection, storage and transportation of plastic waste.

iv) Producer and Brand owner

Ø Ensure collection of used multi layered plastic sachets/ pouches/packaging material either through their own channel or concerned local body.

Ø Phase out manufacture and use of non recyclable plastic.

v) Waste Generators

Ø Minimize generation of plastic waste.

Ø Ensure segregation of plastic waste at source

Ø Hand over segregated waste to appropriate agencies.

vi) Non- Government Organizations

Organizing mass awareness campaigns in electronic media & print media.

Current status of management of plastic waste

The State of Odisha generates approximately 90138.98 (estimated by SPCB, Odisha for the year 2018-19) tons per annum (TPA) of plastic waste. Details, district wise plastic waste generation as for the year 2018-19 are enumerated in the Fig (3).

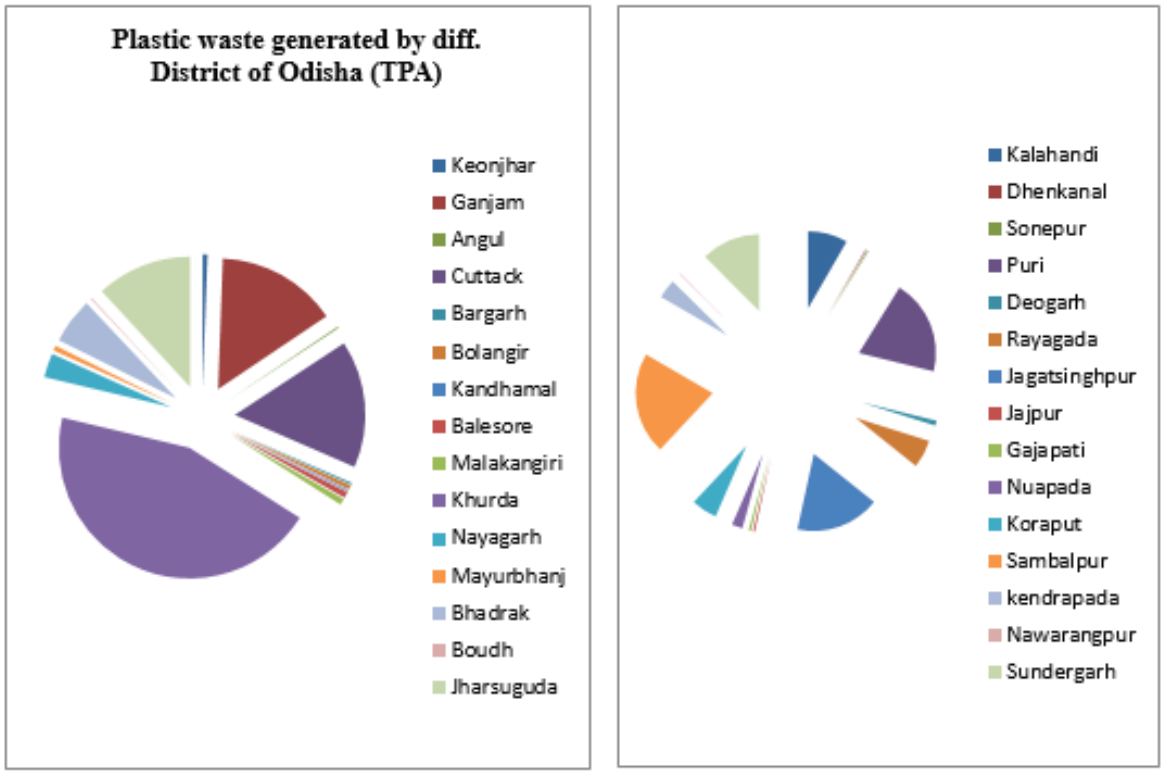

Fig 3 : District wise waste collection of the year 2018-19

Source: SPCB, Odisha

The status of registration of different category of plastic units is as under follows.

i) Recyclers

The SPCB, Odisha has issued registration under the Rule to one (1) number of plastic recycler as on 31st December, 2018.

ii) Producers / Manufacturer

The SPCB, Odisha has issued registration under the Rule to Seven (7) nos. of plastic product manufacturing units.

iii) Brand Owners

The SPCB, Odisha has issued registration under the Rule to Four (4) nos. of brand owners.

Status of utilization of plastic waste in odisha

48 Urban Local Bodies (ULBs), 132 Material recycling facilities (MRFs) have been set up in which plastic wastes are segregated and sent out for recycling.

A) In recycling –Plastic wastes are utilized daily by recycling process.

B) Road Construction-- 4.6 MT of Plastic waste has been used for construction of 9.6 K.M of road in Deogarh & Sambalpur districts of Odisha under Pradhan Mantri Gram Sadak Yojana by Rural Development Dept.

C) Waste to oil-- Consent to establish has been granted to M/s Hindalco Industries for establishment of polycrack converts of 0.5 MT/Day plastic to oil.

D) Co-processing of Plastic Waste in Cement Kilns–

Four cement plants have been identified for the purpose of co-processing and ULBs are advised to send the non-recyclable plastic waste to these cement plants. The quantity of plastics waste used by different cement plants is illustrated in Fig (4) in yearwise manner.

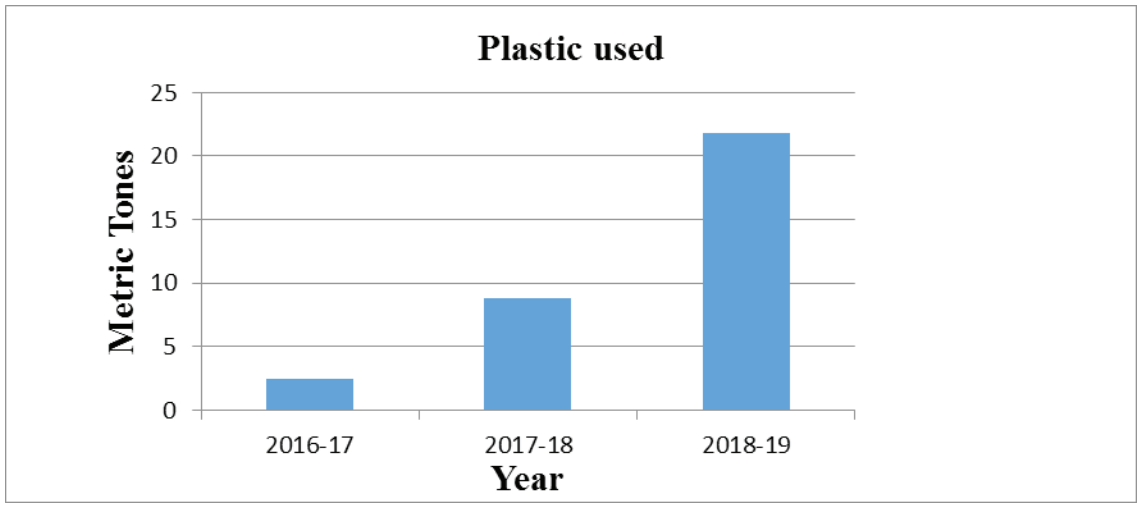

Fig 4: Year wise plastic used in cement plants in Odisha

Source: SPCB, Odisha

Discussion

Single use Plastics also often referred to as disposable plastics (use and throw items), are commonly used for packaging and include items intended to be used only once, before they are thrown away or recycled. Plastic bottles, jars, and container find their way into the reusing and recycling economy through informal chain of rag pickers and kabbadi wallahs or scrap dealers. But single use plastics such as bags, candy wrappers, tobacco and pan masala sachets, soap wrappers and shampoo sachets are either too difficult or not lucrative enough to collect. These plastic items then find their way into landfills, unauthorized garbage dumps or simply remain uncollected on road berms. Eventually, these single use plastic items clog rivers; pollute ground water and other water bodies [8]. They when consumed by animals find their way into our food systems.

It is well appreciated that while plastic is a much used material for a variety of products, it is the littered plastic waste that goes uncollected leading to an environmental hazard [5]. As we aware, these plastic wastes can be segregated and shredded to less than 4mm size and can be used for the construction of road with bitumen [7]. These roads have better resistance towards rain water and making road more durable. While on the other hand this will help to reduce plastic waste and reduce the use of bitumen 8 % resulting in major environmental benefits. Plastic waste can also be used in cement factories for co-processing as alternate fuel. So the option of utilizing plastic waste as alternate fuel may be explored.

Conclusion

The scientific way of management of plastic waste is highly essential to save our mother earth; otherwise its unscientific waste management practices would bring an unwarranted result to the environment. It is important that everyone should follow the mantra of 5 R's i.e. Refuse Reduce, Reuse, Recover and Recycle and in addition to this, should remember 6th R that is responsibility. Without understanding the term responsibility, effective plastic waste management is difficult to achieve.

Conflict of Interest: The authors have no conflict of interest to declare.

Ethical Clearance: In this research no cell-lines/ animals are used. So it's not applicable for ethical clearance.

Various Disinfecting Methods of Orthodontic Pliers in Daily Clinical Practice: A comparative Study

Purva Verma, Arvind Sivkumar

[1]Postgraduate Student, [2]Senior Lecturer, Department of Orthodontics and Dentofacial Orthopaedics, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences, Saveetha University

Abstract

Introduction: Orthodontic pliers are essential armamentarium in every orthodontic office and should be used once for one patient, then autoclaved before next use. Clinical orthodontics with higher volume of patients, requires a quick chair side disinfection method for pliers, also in rural centres with minimum infrastructure it is a challenge to maintain sterilisation protocols. Various disinfecting agents include alcohols , quaternary ammonium salts, formaldehyde, chloramine, sodium hypochlorite, spirit, glutaraldehyde etc. are available. Out of these we compared the commonly available disinfectants including ethyl alcohol, 5% glutaraldehyde, and 6% sodium hypochlorite to assess their disinfection efficacy after clinical use.

Materials and method: 20 orthodontic pliers were inoculated with Coagulase negative streptococci. The pliers were divided in 4 groups with 5 pliers in each group. Each group was subjected to different disinfectant solution with one group aiding as control. The disinfectants used were: spirit (group 1), 5% glutaraldehyde (group 2), 2% sodium hypochlorite (group 3) and distilled water (control group).

Results: spirit and 5% glutaraldehyde have shown to be potent disinfectants.

Conclusions: Based on these results, we concluded that among the tested methods, disinfection of orthodontic pliers with spirit and 5% glutaraldehyde are the efficient methods for chair-side disinfection.

Keywords: *Orthodontic pliers, Infection, Disinfectants, Disinfection*

Introduction

The practice of General Dentistry, and Orthodontics in particular, is characterized by plethora of patients with variety of infections and contagious diseases transmitted through various modes.(1)

Some orthodontists consider orthodontics as a non-invasive specialty. This thought is an underestimation of risk of contamination that an orthodontist subjects their patients to, the perilous part being most of the orthodontic patients are children and young adults who are easily susceptible to infection. An orthodontist encounters blood in the patient's mouth at an average of ten times a week, which is a significant number to ignore.(2)(3)

The main guide to achieve successful results in infection control is not to disinfect when you can sterilize. Sterilization is the destruction or removal of all forms of life, including spores, while disinfection is the inhibition or destruction of vegetative forms, not destroying spores and some resistant pathogenic microorganisms.(4)(5)

Orthodontic pliers are essential armamentarium in every orthodontic office. Ideally, each set should be used once for one patient and then autoclaved before next use. In order to follow this protocol of sterilisation we require multiple sets of pliers, repeated cycles of autoclaving and huge manpower to handle these procedures.

These protocols can be followed in most private clinical set-up but following these protocols in centres with heavy patient flow and rural setups will be difficult. Clinical orthodontics with higher volume of patients requires a quick chair side disinfection method for pliers.

Inadequate methods of infection control have been adopted in few orthodontic offices, especially the rural set-ups .The main reason for the lag of infection

control in orthodontic is that this procedure takes time and considerable amount of investment. Moreover, the heat or chemical substances damage most of the orthodontic pliers permanently, which are fundamental and invaluable inventory in an orthodontic office.[6]

There is a need to recuperate infection control practice in orthodontic practice, especially when it comes to pliers. Hence, in this study we aimed to evaluate the effectiveness of the commonly available disinfectants including 95% ethyl alcohol, 5% glutaraldehyde, and 6% sodium hypochlorite to assess their disinfection efficacy after clinical use by orthodontists for disinfection of pliers in their daily practice.

Material and Method

The efficacy of disinfection methods on orthodontic pliers used in everyday practice by orthodontists were evaluated, total 20 pliers were selected for the study with 5 pliers in each group. Each group had:

- Pin and ligature cutter

-Distal end cutter

-Weingart plier

-Posterior Band removing Plier

-Bracket positioning plier.

All the twenty pliers were subjected to Dry Heat Sterilisation in Hot Air Oven at a temperature of 250 C for 1 hour.

After the sterilisation was complete, the pliers were contaminated *in vitro* with coagulase negative staphylococci bacteria as this micro-organism is a part of normal flora of oral mucous membrane, is associated with various nosocomial and opportunistic infections, and also is resistant to many antibiotic. Suspension of coagulase negative streptococci was used for contamination of pliers. All pliers were immersed in the suspension for coating it with bacteria. The pliers were then set to dry.

Contaminated pliers were then segregated into their respective groups. Each group was subjected to treatment with one disinfectant as follows:

Group 1: 95 % Ethyl Alcohol

Group 2: 5% Glutaraldehyde

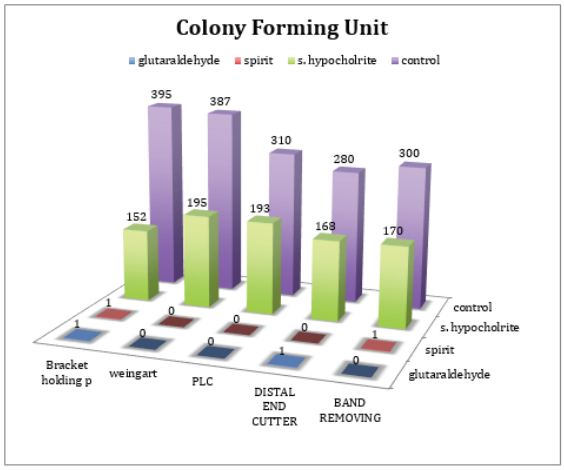
Group 3: 6% Sodium Hypochlorite

Group 4: Distilled water washing (control group)

Each plier was subjected to disinfectant for a treatment time of 2 minutes. Swab was taken from the beak/working end of the plier. The swab was rubbed and cultured on Nutrient Agar and evaluated for the colonies of coagulase negative staphylococcus, incubated at 37degree Celsius for 24 hours.

The effectiveness of disinfection was evaluated by number of Colony Forming Unit on the agar. The colony count was done using a colony counting software named EZEE COUNT. The picture of the incubated agar dish was taken through the app and count was generated.

Result and Statistics



GRAPH 1: The graph here indicates that CFU count is least following treatment with 5% Glutaraldehyde and 95% Ethyl Alcohol (Spirit). 6% Sodium Hypochlorite has shown a high CFU count which indicates its low efficacy as disinfectant.

Discussion

The disinfection methods tested in this study were 2% glutaraldehyde, spirit, 6% sodium hypochlorite and distilled water, which acted as control. Graph-1 shows that 6% sodium hypochlorite couldn't eliminate bacteria completely showing it is a low level disinfectant. It is contradicted by a study done by E. Steve Senia et al. [7] in 1975 who use 5.25% sodium hypochlorite for disinfection of gutta percha cones to eliminate Staphylococcus faecalis, E.coli, Corneybacterium Xerosis and Bacillus subtilis. With 30-seconds exposure all organism except B.subitilis were killed. However, in our study Sodium Choloride failed to eliminate CoNS from the surface of orthodontic pliers. [8] [9] [10] [11]

Spirit proved to be a high –level disinfectant by completely eliminating the CoNS bacteria from the orthodontic plier surfaces. This is in accordance with a study done by Carvalho et al [12], who achieved complete disinfection of rubber toys using spirit. Also, In a study by Klein and Deforest [13] , they concluded that viruses whose coat consists of both protein and lipid were susceptible to a variety of commonly used disinfectants, including spirit, among these lipid-free viruses are such important human pathogens as the polio, Coxsackie and ECHO groups (all enteroviruses) this suggests anti-viral activity of spirit. Similarly, in a study by Earle H. Spaulding [14] , they concluded spirit as effective germicidal, tuberculocidal, and fungicidal and virucidal agent. They also stated that spirit evaporates without leaving a residual chemical on the surface of instrument. This can be advantageous for longevity of orthodontic pliers. [15] [16]

The glutaraldehyde solution is an efficient disinfectant. Graph-1 shows that after the disinfection treatment with 2% glutaraldehyde, the bacteria were completely eliminated from the surfaces of orthodontic pliers. Results of this study showed the efficiency of 2% glutaraldehyde as a disinfectant agent when the objects are immersed for 2 minutes. This result is in agreement with Chapman et al [16], who disinfected rubber toys with the use of glutaraldehyde and Freitas et al [17] who, reported that glutaraldehyde at room temperature is effective in destroying vegetative forms of pathogenic microorganisms, influenza viruses, enteroviruses and tuberculosis bacilli when immersed for 10 to 30 minutes. The authors went further by claiming that glutaraldehyde is effective against highly resistant spores for a period of 6 to 10 hours. The 2% glutaraldehyde solution is chosen for disinfecting instruments. It is the only one who acts in the presence of organic matter.

It is fungicidal, virucidal and bactericidal in 30 minutes and sporicidal at 10 hours. However, it is believed that the 2% glutaraldehyde can destroy vegetative bacteria in less than two minutes and sporulated bacteria in three hours. Myers[19] disagrees, and says that glutaraldehyde is not recommended because the process takes ten hours of exposure, the efficiency is difficult to monitor, and it causes skin irritation, is toxic, discolors and has a corrosive effect on metals.

The need to improve control of infection in orthodontic practice, especially in relation to pliers, is indispensable. It is known that currently, the percentage of adult patients in orthodontic clinics is high, which drops the argument used by orthodontists that patients are very young and therefore have a low risk of inoculation of diseases. Besides, Orthodontics is an invasive specialty, differently from what some orthodontists say.

Conclusion

According to the results obtained from this study, it can be concluded that

a) Treatment with 5% glutaraldehyde and 95% ethyl alcohol is the most efficient of the methods used in this study.

b) 6% Sodium Hypocholrite is a low-level disinfectant and must not be considered as a disinfecting agent for orthodontic pliers.

In day-to-day clinical practice for quick chair side disinfection 5% glutaraldehyde and 95% ethyl alcohol can be used for disinfection of orthodontic pliers in case of unavailability or inaccessibility of sterilizing units.

A Cost-Effective and Innovative Screening Approach, for Idiopathic Scoliosis in Girls, Before their Skeletal Maturity

Mudasir Rashid Baba[1], Ravindra Mohan Shenoy[2], Ajith Soman[3]

[1]Assistant professor, Yenepoya Physiotherapy College, Yenepoya (deemed to be) University, [2]Professor & Head Department of Orthopaedics, Yenepoya Medical College & Hospital Yenepoya (deemed to be) University, [3]Assistant Prof, College of Applied Medical Sciences, Dept of Health Rehabilitation Sciences, Shaqra University, Saudi Arabia

Abstract

Background: Adolescent idiopathic scoliosis is a three dimensional deformity of the spine with no identifiable causes. Early detection of scoliosis prevents progress into severe scoliosis in a growing child before the skeletal maturity**.** There are two critical stages in the development of body posture during the school years. These are the age when a child goes to school and the attainment of puberty. The growing children may show accelerated or retarded periods of growth at certain stages giving rise to a rapid or slow progression curve. In girls the pre-pubertal growth spurt falls in the age range of 10-13 years.

Objective: To identify high risk idiopathic scoliotic curve in pre pubertal school girls using non-invasive technique**,** Adams forward bending test (FBT), Scoliometer and I phone app.

Method: The present descriptive cross sectional study was conducted in pre pubertal girls aged 10-13 years enrolled in both the aided and unaided schools of Dakshana Kannada (Karnataka-India). All the willing students (n=600) were screened using physical examination (Adams forward bend test), Scoliometer device and Scoliometer application.

Results: A total of 24/600 of the pre pubertal girls were found to have asymmetrical back when physically examined in standing position with FBT, resulting in right thoracic level curve 3^0 , 5^0,7^0 . All 4% of the high risk identifiable participants had a reading $>5^0$ when screened using the Scoliometer device and I phone App i.e. similar results were obtained. Body mass index (BMI) was increased in some of the positive cases.

Conclusion: The study found that the inclination degree of 5° or greater is more acceptable in early detection of scoliotic curve before the skeletal maturity of the spine. This predictive value was satisfactory to advocate the school screening programme in early detection of scoliosis**.**

Key words: *idiopathic scoliosis, skeletal maturity, scoliometer, scolioguage, BMI*

Introduction

Adolescent idiopathic scoliosis (AIS) is defined as a three dimensional (3D) deformity of spine [1-3], with no recognizable causes,[4] in an otherwise healthy growing child. The children with AIS on inspection have a trunk asymmetry, which accentuates when bending forward. The accentuation results due to the prominence of the costal or lumbar hump in a forward bending position.[5] The reported prevalence of Idiopathic scoliosis is about 0.4 to 7% among adolescents in Asian countries.[6] Scoliosis can affect a child's appearance, may lead to symptoms of pain, and can lower a child's self-esteem due to a feeling of social isolation.[7] There has never been a universal agreement about scoliosis screening due to its controversial nature, therefore, the screening efforts vary considerably around the world.[8] Many countries

including USA, UK and Japan have legislated scoliosis screening programmes and have included screening in the health curriculum of their schools.[9] It is important that scoliosis be diagnosed between the ages of 10 and 15 years. The early identification of potentially progressive curves allows conservative management in the form of physiotherapy and bracing allowing the patient to avoid surgery for the correction of developing curve.[10] The human skeleton comprises of two periods of rapid growth, the first one between the birth to 5 years and the second one at the onset of puberty.[11] The body posture is influenced by two critical stages of development during the school years, when a child starts school, and at the attainment of puberty. The rapid or slow rate of progression in curve may result due to certain faster or slower periods of growth at certain stages during growth. The pre-pubertal growth spurt in girls falls in the age range of 10-13 years. The pre-pubertal girls have Risser 0 at standard, and are 0 before the onset of menarche with a progression factor at 2, which represents a risk for being progressive of 90%. The risk of progression can be calculated using Lonstein and Carlson (1984) formula.[12] They carry risks to the quality of the body posture, in the age range of 6-7 and 12-16 years old, i.e., during the puberty stage. The child is exposed to the vulnerability of various external features during this stage and the development of the muscular system does not follow the rapid growth of the bones.[13] The bone density and its metabolism have been correlated with the serum levels of tartrate-resistant acid phosphatase serum band, 5(TRAP5b). Lower bone density in AIS patients show higher rate of bone resorption.[14] High peak bone mass is directly related to high physical activity.[15-17] As a higher gain than the loss in the density of bone occurs during the pre-pubertal period, it is the perfect period for physical training compared to the rest of the lifetime.[18,19] The reported incidence of scoliosis was 0.2%, favouring girls more than the boys in the ratio of 2.2:1.[7] The scoliosis research society (SRS) considers scoliometer, used alone with Adams forward bending test (FBT) as a reliable and valid measure for trunk asymmetry.[20] The scoliometer identifies any rotational deformity, associated with scoliosis in a very dependable and a simple fashion. Although, scoliometer shows low correlation with the lateral curvature of the spine, yet it shows a good reproducibility.[21] Advanced technology like, iPhones have been used for the measurement of asymmetry in the trunk and results indicate that such advanced tools are equally efficient to measure trunk asymmetry similar to conventional tools like manual protector. Furthermore, the use of iPhones consumes 15% less time for measurements than the conventional tools. The Mobile phones (with inclinometer application) can store measurement data in updated versions of the software for measurement of angle, and thus make these modern tools useful for clinical measurement applications.[22] The evaluations of the Scoligauge, iPhone application, show outstanding intra and inter observer dependability and validity comparable to that of Scoliometer. This application renders itself as an effective means for assessing clinical measurements and does not require a special adapter.[23]

This study was carried out for a cost-effective approach of screening 10 to 13-year old girls and to identify pre-pubertal girls with a potential progressive scoliotic curve.

Materials and Method

A descriptive cross-sectional study involving a total of 600 school-going girls, aged 10-13 years, enrolled in both aided and unaided schools. The permission was taken from the regional block education officers. Ethical clearance was obtained from the University ethics committee before recruitment of the participants. Informed consent and accent was obtained from the students and their parents, prior to the screening. Based on the student population data provided by the block education officers in 2018, participants were recruited by cluster sampling technique from 6 randomly selected clusters out of the 15 clusters from Dakshina Kannada, Mangalore, India. The screening was conducted in the school premises with permissions from the concerned management. Each student was accompanied by her mother and class teacher during screening. Physical examination was carried and students with altered gait pattern and other deformities were excluded from the screening. The girls had light clothing and without footwear during the examination. The physical attributes (height, weight, and age) were recorded using stadiometer to calculate the Body Mass Index (BMI). The Adam's forward bending test (FBT) was applied for the scoliosis screening. The test considered positive when back asymmetry in the form of a hump was detected. Further measurement of inclination degree using scoliometer and scolioguage was conducted when FBT was positive. The girls with positive FBT and scoliometer/ scolioguage angle of 3 degree or more were considered to pose some risks to the quality of the body posture, occurring during the puberty stage. The parents

of these girls were notified of the potential for progressive curves and referred to the orthopedic and physical therapy departments of the University hospital for further evaluation and treatment recommendations.

Results

Six hundred school girls in the age range of 10-13 years were screened for potential curves for scoliosis. (Table I). Twenty four pre-pubertal girls were found to have an asymmetrical back (hump detected, resulting in a positive Adam's forward bending test and scoliometer test. Body mass index (BMI) was increased in some of the positive cases (Figure 2).

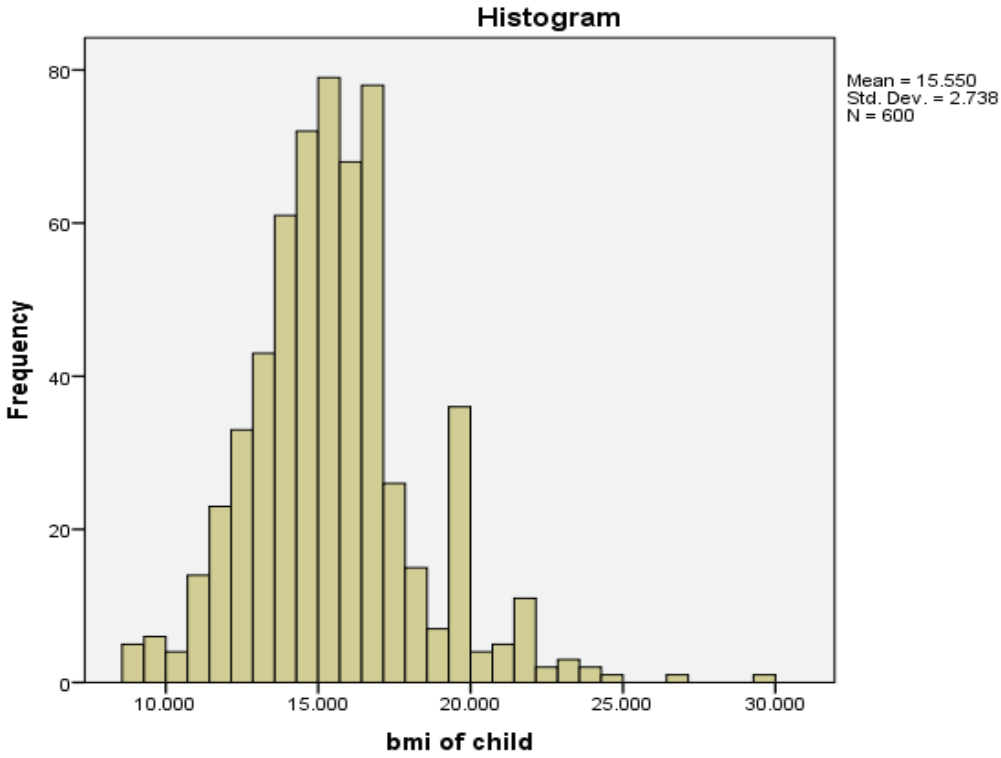

Figure 1: Body Mass Index (BMI) of 600 girls.

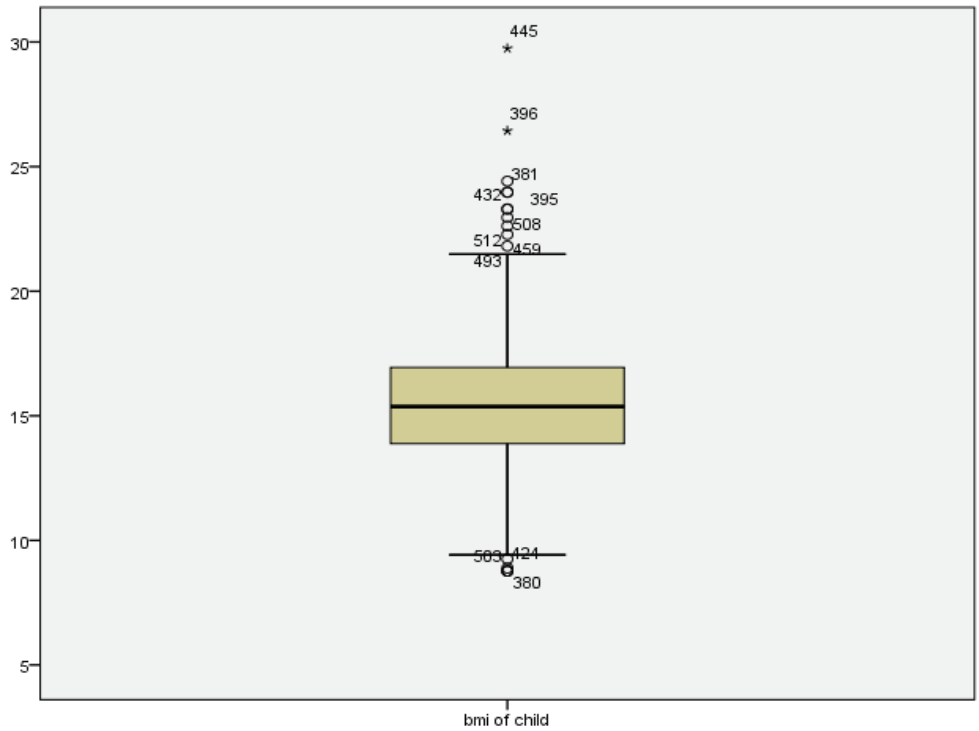

Figure 2: Body Mass Index (BMI) was increased in few of the positive cases.

Discussion

The overall prevalence of positive scoliosis cases among pre-menarche girls in the current study was 4%. The curvatures of 5°, 10° & 12° were witnessed at the thoracic level, inclined towards the right side when viewed from the backside. These findings are consistent with the epidemiological study from chongming island (china), which showed thoracic curves towards the right 60.3 %.[24] Another epidemiological study from Greece found that 75.5 % of thoracic curves were to the right side.[25] The current study showed increased BMI in some of the positive cases, in contradiction with a study by Chen JCY et al., (1999), which showed a significant relationship between severity of scoliosis and the BMI [26], while another study found no relationship between scoliosis and BMI.[27] American Academy of Orthopaedic Surgeons released a position statement that screening for spinal deformity should be part of the medical home preventive services visit. The screening is considered valuable in these domains: technical efficacy, clinical program, and treatment effectiveness. In order to identify high risk cases, scoliosis screening should be carried out and potential cases referred for further evaluation .[21] Screening is defined as 'the presumptive identification of unrecognised disease or defect by application of tests, examination or procedures, in a rapid manner.[28] The use of Scoliometer for the measurement of ATR is non-invasive, with no radiations and a cheap method of screening. It can be easily implemented and it has been proven to have a good correlation with radiological analysis ($r=0.7$, $p<0.05$) and a very good intra-rater reliability.[29,30] In this study a $>7^0$ scoliometer reading was taken as cut off which is in accordance with a study done by Raphael et al., in Norway.[31] The present study showed ATR $>7^0$ in the thoracic scoliotic curves. Similar findings >7 ^{0}application reading for thoracic scoliotic curves. The readings of the Sociometer device and Scoliometer HD application which are therefore similar. This is in agreement with a study done by Franko et al wherein the findings of the smart phone application were compared to those of the scoliometer device and thereby the application was validated as an efficient and cost effective tool for screening of scoliosis.[32] Therefore, the application was found to be more convenient due to its greater availability and cost effectiveness. We therefore suggest making the combination of FBT, scoliometer and scolioguage app as a screening tool.

Limitations of the study: The sample size was small and did not include both the genders. To obtain national prevalence rate, the authors suggest a regular nationwide screening of AIS. The data collected from a large population based screening could be used to

perform longitudinal study with minimum bias.

Conclusion

The prevalence rate of AIS in school going girls of age group10-13 years was evaluated in Dakshina Kannada region of India. The study also found that the inclination of 5° or greater is more acceptable in early detection ATR before the skeletal maturity of the spine. This predictive value was satisfactory to advocate the school screening programme for early detection of scoliosis.

Conflict of Interest: The authors declare no conflict of interest.

Household Health Care Expenditure and Utilization of Health Care Services: A Study in Dibrugarh District of Assam

Nilutpal Neog[1], Pranjal Protim Buragohain[2]

[1]Research Scholar, Department of Economics, Dibrugarh University, Dibrugarh, [2]Associate Professor, Department of Economics, Dibrugarh University, Dibrugarh

Abstract

Indian health care system is a complex one with the existence of high out of pocket health expenditure, low spending on health sector and also high cost of medical services etc. Increasing cost of medical services has become a serious concern over the years, heavy amounts of medical expenses creates financial pressure on households and the situation become more worse when they do not have any kind of financial protection and an even source of income. The aim of the present study was to investigate the utilisation and expenditure on health care services at household level. This study was conducted among 225 households of Dibrugarh district of Assam. There were 719 reported illness cases during the reference period, out of which 85.2% cases were treated at medical institutions, 9.3% cases were not treated due to financial constraints. The coverage of health insurance was found to be very low, only 12.45% households had any kind of health insurance. In the absence of any kind of financial support from any sources, some households had to borrow for medical expenditure. Expenditure per illness cases was highest in private hospital; sample households incurred average monthly expenditure of 11.35% of their income on health care. Regression analysis revealed that income, place of residence and educational qualification of the head of the household were the significant determinants of household health care expenditure. It is necessary for the government to improve health infrastructure, spending on health sector must be increase along with. Expansion of health insurance coverage particularly in rural and remote areas is much needed so that people can understand the benefits of being enrolled in health insurance.

Keywords*: Utilization, Expenditure, Health insurance, Health care services*

Introduction

For Economic growth, a wealthy workforce is recognized as an essential element. A healthy working population both physically and mentally can lead a nation to the path of sustainable development. Human capital formation can keep a country on a pillar of economic progress. Our country is featuring low spending on health care, unbalanced patient-doctor relation, problem of proper health infrastructure and all these lead to the popularization of the private health care sector. Providing proper health facilities has not been on the list of prime goal for the government. The country at present spending only 1.15-2% of its GDP towards medical sector. To be in a healthy state of mind with a sound body, government should take care of its people[1]. Development of private health care sector has made the cost of health care services expensive. Therefore it is difficult for the people to go for proper health care services or treatment who even find it difficult to fulfill basic needs. Due to some existing financial constraints govt. is not able to finance health services for the betterment of all and this compels the households to spend out of their pocket. High out of pocket expenditure put financial burden on households. MHFW, India figures out 70 % of total expenditure on health is out of pocket expenditure by households.

People can survive well in life when they are in a good health and to be in a good health, we should have access to health care services which is a fundamental right of every human being. The state should set the

Research Scholar**,** Department of Economics
Dibrugarh University, Dibrugarh, Assam- 786001
Email: nilutpal900@gmail.com

prime objectives to ensure proper and productive health care facilities for its people. A large section of population from remote and rural areas still find it difficult to access medical services. Inadequacies of medical personals and poor infrastructure are the main drawbacks of public health system in India. According to the Rural Health Statistics 2017, almost 37% of health workers posts in India remain vacant, only 11% sub-centres and 13% primary health centres are functioning. Private health care services are such expensive today that households from lower income groups and even middle class often find it difficult to bear high cost of medical services, even it seen that some prefers treatment at home rather visiting a health institution.

Though government has taken initiatives in providing health services yet it is not able to succeed in it and huge out of pocket expenditure is also observed. It is evident that both expenditure on health care services and utilisation of health services have impact on health status.

In India utilisation of health care services has not good and this can be attributed to insufficient provision of health care services, ignorance, low level of household income. The problem of under utilisation of health care services is very severe in rural areas. The rural area doesn't have sufficient number of health institution and those that have also lack adequate equipments and infrastructure. In India more than 70 percent of its population still lives in rural areas and has limited access to health care services[2]. There exist wide gap between rural and urban population in terms of access and utilization of health care services. In case of health related issues high health care expenditure becomes a serious reason for poverty in poor households [3]. The performance of health system of a nation can be improved by properly delivering basic and quality health care services to its people.

Aim of the Study

In the phase of increasing health care cost and utilization of health care services, this study investigated the utilization and expenditure towards health care services. The study also examined the factors that have influence on determining health care expenditure at household level.

Method

The study investigated the choice and extent of utilisation of health care services. Along with this, expenditure towards health care services and the factors affecting the same have been analyzed. The study was conducted in Dibrugarh district of Assam. The district covers a wide network of health care institutions both private and public along with the only medical college in upper Assam division. A structured validated questionnaire covering information regarding socio-economic, demographic details, health care services utilisation and expenditure related information etc. was prepared to collect required information from 225 households. A multistage sampling method was used to select sample households. The reference period for the study was one year. The study was carried out during July 2016 to November 2016.Household information was collected considering one respondents from each households. The data were analyzed using Excel and SPSS Software.

Results

Utilization and expenditure on health care services depends upon socio economic condition of households. For socio economic information of households, types of house, religion, family type, religion, literacy, income and occupation were considered and analysed

Table 1 : Socio Economic Information

Household Characteristics	Variables	Frequency	Percentage

Source : *Primary Survey*

There were 719 morbidity cases in the sample during the reference period. Majority of the illness cases, 613 (85.2%) were treated at medical institutions. Among the other cases, for 67 (9.3%) illness cases no medical treatment was sought, 21 (2.5%) illness cases were self treated. The most significant reasons that stand out for not seeking medical care was the lack of money, 29 (43.3%) cases remained untreated primarily due to financial constraints. Utilization of health care services involves preferences towards health care providers for medical services. As both public and private health care services exist and differs primarily in cost and quality of services, households can make choices for treating diseases. Majority 136 (60.4%) households preferred public health care services followed by 71 (31.6%) households towards private health care services and 18 (8.0%) households preferred indigenous or traditional system of health care services.

Health related expenditure is generally unpredictable. Expenditure involves in accessing and utilizing health care services made from direct income without any kind of financial assistance sometimes hampers household's day to day activities along with financial repercussions on households.

Table 3: information Relating Households health care expenditure	
Source of finance for health care expenditure (n=household)	
Income	115
Savings	68
Selling Assets	14
Borrowing	21
Insurance	7
Household covered under health insurance (n=household)	
Households with health insurance	28
Households without health insurance	197
Reasons for not having health insurance (n=household)	
No awareness	116
No illness	18
Financial constraints	23
Not necessary	31
No return for investment	9
Health expenditure and debt	
Number of households who borrowed	21
Total debt incurred (INR)	174000
Average amount borrowed (INR)	8285

Source : *Primary Survey*

It was observed that most of the households (51.11%) carried on their expenditure on health through disposable income only, 30.22% from savings, 6.22% households even sell their assets to meet their medical expenditure. Though health expenditure can help households to lower the financial burden, yet it was observed that only 12.44% households had any kind of health insurance. It was reported that 51.56% households were unaware of the benefits of health insurance, 13.78% households thought that they were not in the need of health insurance. 9.33 % households compelled to borrow for medical treatment.

Table 4 : Out of pocket expenditure per illness cases

Health Care Institution	No of treated illness	Mean expenditure per illness cases SD (INR)
Public	475	683.3±549.6
Private	138	1563.8±1290.2

Mean out of pocket health care expenditure per illness cases was highest in private health care institute, (1563.8±1290.2. INR). Majority of the reported illness cases (77.48 %) were treated at public health institute, 22.52% cases were treated at private health institute.

Table 5 : Descriptive statistics regarding health care expenditure

Variables	Mean	SD	Mini.	Max.
Monthly income	8864	9326.4	5500	40000
Food Expenditure	1954	2361.3	1000	3000
Non Food expenditure	3628	4137.2	2500	8000
Expenditure on Health care	11.3	16.2	7.0	22.0

Mean monthly income of the households was 8884 with a minimum of ₹ 5500 and a maximum of ₹ 40000, mean monthly food expenditure was ₹ 1954 with a minimum of ₹ 1000 and a maximum of ₹ 3000, mean non food expenditure was ₹3628 and it ranges from and it ranges from ₹2500 to ₹8000. The mean monthly expenditure on health care incurred by the households was 11.3% with a minimum of 7% to a maximum of 22%.

To identify the factors that may have significant association with household's health care expenditure, a multiple regression was conducted. Regression analysis of the influence of socio economic and demographic variables on household's health care expenditure is presented in table 6.

Table 6 : Multiple Regression showing variables influencing health care expenditure				
Variables	**Unstandardized Coeffiients B**	**Std. error**	**t**	**Sig.**
Income	.095*	0.26	4.278	0.03
Age	27.188	11.797	2.305	1.161
Occupation of the head of the household	-98.005	112.468	-.238	.812
Nature of disease	784.812	363.088	-1.057	.730
Place of Residence	618.047*	412.468	4.997	.001
Household Size	-29.630	373.708	-.153	.411
Educational qualification of the head of the household	538.246***	221.34	2.813	0.07
Choice of health care providers	168.706	93.29	1.008	0.95

R^2= .549

Variables income, place of residence, educational qualification of the head of the household was statistically significant determinants of household health care expenditure. Income, place of residence (dummy, 1= rural, 0= Urban), education level of the household head had positive impact on household health care expenditure.

Discussion

The study considered 225 sample households among which 129 households (57.33%) were from rural areas and 96 households (42.67%) were from rural areas. Majority 46.7% households had semi pucca houses, 61.8% households belonged to nuclear family. 30.2% households had monthly income in between ₹5001-10000 and 37.8% households were engaged in agriculture activities.

As fount in the study there were 719 reported illness cases during the reference period among which 67 illness cases were not treated, and the most reported reason that came out for the same was lack of money. Majority (60.45%) households preferred public health care services, 40.45% households gave importance on quality of medical services, 26.22% households on cost of health care services while choosing medical institute for health services. Out of 475 illness cases which were treated at public health institute, in 60.85% cases people were not satisfied with the services. The poor quality of services in public health institute were mainly attributed to non availability of medicines, laboratories insufficient medical personals [4]. In a study in Tamilnadu, Kumar and Sobajasmin found that 67.7% respondents were not satisfied with the services provided by the government hospitals, 53.7% reported that private hospitals were efficient for them and these findings were similar to this study [5].

The study also investigated the health care expenditure pattern of households towards medical services. Health care related expenditure is generally unpredictable and expenditure made on health services directly from income without getting any financial support from any party (termed as out-of-pocket expenditure) may sometime put financial pressure on households. There were 713 illness cases during the recall period. 51.11% households used current income, 9.33% households borrowed money to financed health care services payments. The coverage of health insurance was found to be very low among the sample households, only 12.45% households had at least one family member covered under any kind of health insurance. The most important reason for non enrollment of health insurance was no awareness (54.56%). In the study area people were not aware of the benefits of having health insurance and they were also unaware about various health insurance schemes and policies. A study carried out in Sikkim on 2018 found that 38% were unaware of health insurance [6]. A total of 21 households had incurred a debt of ₹17400 for health care services, 5 households borrowed from

financial institutions, 16 households borrowed from other sources. 77.48% illness cases were treated at government hospitals, 21.52% treated at private hospitals. Most of the government health care services are almost free, yet cost of private health care services is increasing day by day. This study found that expenditure per illness case was highest in private hospitals, (1563.8±1290.2, INR). The sample households incurred mean monthly expenditure of 11.3% of their income.

Though all variables namely income, age, education, nature of disease, place of residence and educational qualification of the head of the households have some effect on health care expenditure of households, only income, place of residence, educational qualification of the head of the household were statistically significant determinants of household health care expenditure. These findings were similar to study done in 2014 by Olowolabi which revealed that education and settlement were the significant determinants of household health care expenditure [7].

Conclusion

In this study an attempt has been made to study the utilisation and expenditure on health care services and related issues at household level in the study area. Lack of quality services, insufficient medical staffs and the lack of modern medical equipments in government health institutions forced households to go for private health care services by paying higher charges. This situation can improve when the households can get proper medical services by spending less from their own pocket, high out of pocket health care expenditure can never be good for households. It is upmost importance that investment in public health sector designed in such a way that people can get the quality health services without paying much. It is equally important for households to understand the role of health insurance that can play vital role in reducing financial burden associated with medical services.

Effect of Specific Skill and Drill Training Combined with Pranayama Practices on Physiological Variable among Women Hockey Players

R. Ramya[1], D. Rajalakshmi[2], K. Alaguraja[1], K. Selvakumar[1], K. Kaviyarasan[1]

[1]Research Scholar, [2]Associate Professor, Alagappa University College of Physical Education, Alagappa University, Karaikudi, Tamilnadu, India

Abstract

The purpose of the present study was to investigate the Effect of Specific Skill & Drill Training combined with Pranayama Practices on Physiological variable among Women Hockey Players. To achieve the purpose of the study thirty women hockey players were selected from Karaikudi, Tamilnadu, India during the year 2019. The subject's age ranges from 18 to 25 years. The selected subjects were divided into two equal groups consists of 15 women players each namely experimental group and control group. The experimental group underwent combined concurrent strength training and yogasana practices programme for six weeks. The control group was not taking part in any training during the course of the study. Cardio respiratory endurance was taken as criterion variable in this study. The selected subjects were tested on cardio respiratory endurance was measured through coopers 12 min run/walk test. Pre-test was taken before the training period and post-test was measured immediately after the six week training period. Statistical technique't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference is found due to Specific Skill & Drill Training combined with Pranayama Practices given to the experimental group on cardio respiratory endurance when compared to control group.

Keywords: *Specific Skill & Drill Training, Pranayama practices, cardio respiratory endurance and 't' ratio.*

Introduction

Cardiac endurance is essential factor that can be determined the performance of the hockey players during the particular actives. Concurrent strength training made a unique method for promote the strength of an individual. Yoga is a great soul of the Universe. It can promote the social well being through limps of yoga (Asanas, Pranayama, Kriyas, Mudras and Meditations). To practising yoga regularly it can make you into sound body and sound mind. Yoga is the costless permanents treatment for more diseases[1]. It is a practical holistic philosophy designed to bring about profound state as well is an integral subject, which takes into Consideration man as a whole[2].

One can start practicing Yoga at any given moment of time and you may start with meditation or directly with pranayama without even doing the asanas (postures)[3]. The science of Yoga Nidra is based on the receptivity of consciousness. When consciousness is operating with the intellect and with all the senses, by making an individual think that he or she is awake and aware, but the mind is actually less receptive and more critical[4]. Training is a chain process that can be able to attain certain needs of the person's goal[5]. In the sports world, physical education is the most essential aspect due to the fact physical schooling increases the performance and the effectiveness of the sports[6]. Today, sports have become a part and parcel of our culture. It is being influenced and does influence all our social institutions including education, economics, arts, politics, law, mass communication and even international diplomacy[7]. The sports training can produce some physical fitness, Physiological and psychological benefits to the person and attain performance related task. It's also promoting the individual overall wealth to the sports person[8]. Yoga is a methodical effort towards self-perfection by the development of the potentialities latent in the individual[9]. Today's there is an escalating emphasis on

appearing smarter, feeling etter and living longer. In order to achieve these ideals as, scientific evidence tells us that one of the keys is high fitness and exercises[10]. Asanas is a limp of Yoga practice it can make some health related gains to the individual who involved in yogasana practice regularly. Asanas can be used upon the needs of the person. It's a scientific process the person must be follow the basic principles yogasana practice[11]. Yoga is a practical aid, not a religion and its techniques may be practiced by Buddhist, Jews, Christians, Muslims, Hindus and Atheist alike. Yoga is union for all[12]. Yogic action, or inner technique, such as breath control, parthasarathy., S[13].

Research Methodology

Selection of subjects

The purpose of the study was to find out the Effect of Specific Skill & Drill Training combined with Pranayama Practices on Physiological variable among Women Hockey Players. To achieve this purpose of the study, thirty women hockey players were selected as subjects at random. The age of the subjects were ranged from 18 to 25 years.

Selection of variable

Independent variable

Ø Specific Skill & Drill Training combined with Pranayama Practices

Dependent variable

Ø Cardio respiratory endurance

Experimental Design and Implementation

The selected subjects were divided into two equal groups of fifteen subjects each, such as Specific Skill & Drill Training combined with Pranayama Practices (Experimental Group) and control group. The experimental group underwent Specific Skill & Drill Training combined with Pranayama Practices for five days per week for six weeks. Control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following physiological parameter namely cardio respiratory endurance was selected as criterion variable. All the subjects of two groups were tested on selected criterion variable cardio respiratory endurance was measured through coopers 12 min run/ walk test at prior to and immediately after the training programme.

Statistical technique

The't' test was used to analysis the significant differences, if any, difference between the groups respectively.

Level of significance

The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

Analysis of the Data

The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent 't' test was used with 0.05 levels as confidence.

Table I: Analysis of t-ratio for the pre and post tests of experimental and control group on Cardio respiratory endurance (Scores in meters)

Variables	Group	Mean		SD		Degree of freedom	't' ratio
		Pre	Post				
Cardio respiratory endurance	Control Group	1950.33	1952.66	76.21	71.99	14	1.05
	Experimental Group	1954	2047.33	67.23	58.85	14	17.75*

**Significance at 0.05 level of confidence.*

The Table-I shows that the mean values of pre-test and post-test of the control group on cardio respiratory endurance were 1950.33 and 1952.66 respectively. The obtained 't' ratio was 1.05, since the obtained 't' ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of the experimental group on cardio respiratory endurance were 1954 and 2047.33 respectively. The obtained 't' ratio was 17.75* since the obtained 't' ratio was greater than the required table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant.

Result of the Study

The result of the study showed that there was a significant difference between control group and experimental group in cardio respiratory endurance. It may be concluded from the result of the study that experimental group improved in cardio respiratory endurance due to six weeks of Specific Skill & Drill Training combined with Pranayama Practices.

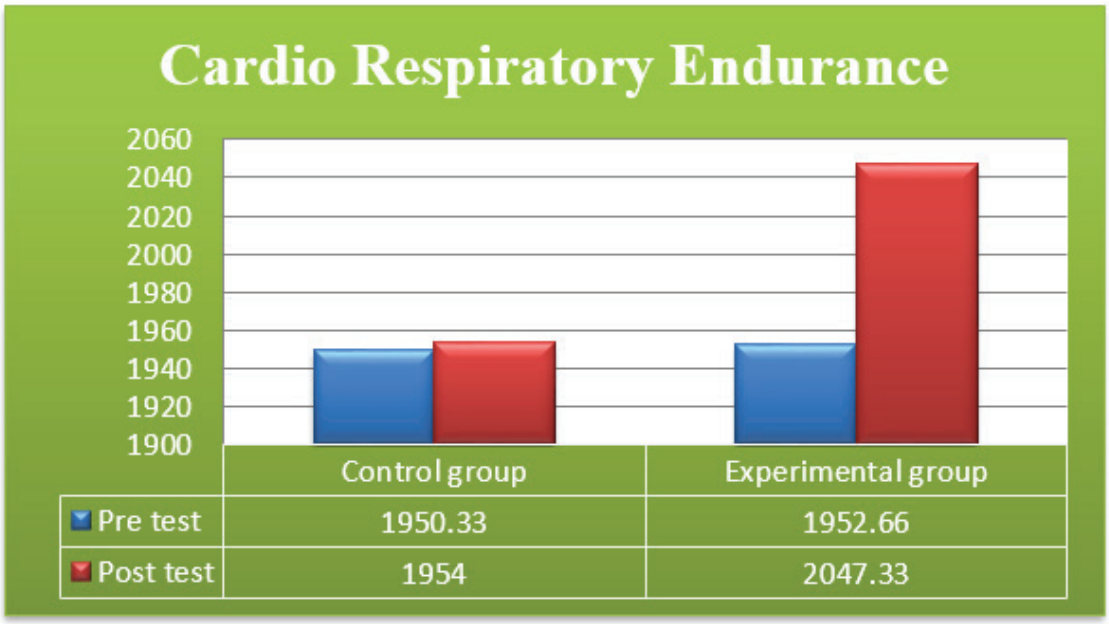

Figure-1: Bar Diagram Showing the Pre and Post Mean Values of Experimental and Control Group on cardio respiratory endurance

Discussions on Findings

The result of the study indicates that the experimental group, namely Specific Skill & Drill Training combined with Pranayama Practices group had significantly improved the selected dependent variable, namely cardio respiratory endurance, when compared to the control group. It is also found that the improvement caused by Specific Skill & Drill Training combined with Pranayama Practices when compared to the control group.

Conclusion

On the basis of the results obtained the following conclusions are drawn,

1. There was a significant difference between experimental and control group on cardio respiratory endurance after the training period.

2. There was a significant improvement in leg explosive power. However the improvement was in favor of experimental group due to six weeks of Specific Skill & Drill Training combined with Pranayama Practices.

Abstract

Background: The development of preterm infants differs widely than term infants and the these infants are at risk of developing neuro sensory, intellectual and behavioural disabilities. The neurodevelopmental growth of preterm infants constitutes 88.8% of cognitive disability and 84.4% of motor disability. Most of the interventions are physical in nature and doesn't seem to concentrate on cognitive aspects and little consideration is given at 1year of age.Cognitive rehabilitation therapies still exists but are not standardized, and left to the clinicians own design to arrive at scientific conclusion.

Aim: This study aims to find out the influence of cognition training on the motor skills of infants born preterm at one year of age.

Methodology: Infants born preterm around one year of age, of both genders who come under inclusion criteria were taken to the study. Prior informed consent was obtained from the parents. Infants were screened using Bayleys scale of infant development for cognition and motor skills. Cognition training was given for a period of one month.

Results: The analysis of this study concludes that cognition training improves motor skills that are affected in infants born preterm.

Conclusion: The analysis of this study concludes that cognition and motor skills are affected in pre term infants. Cognitive training improves motor skills in infants born preterm at one year of age.

Keywords: *Cognition training, preterm infants, gross motor function, fine motor function.*

Background of the Study

Recovery of preterm infants depends on plasticity which refers to good prognosis and vulnerability referring to poor outcomes. The immature brain lacks to do skills resulting in slow recovery.[1]

Corresponding Author :
A. Rajarajeswari

The development of preterm infants differs widely than term infants and the these infants are at risk of developing neuro sensory, intellectual and behavioural disabilities. The neurodevelopmental growth of preterm infants constitutes 88.8% of cognitive disability and 84.4% of motor disability.[2]

Research suggests maximum synaptic density at 1 -2 years of life.[3] Increased production of the above leads to adaptation, leading to better recovery.

Also the first stage of psychosocial development occurs between birth and one year of age, which gets disrupted when infant born preterm.[4]

Cognitive and motor impairments are the major sequelae, in which innate ability of understanding environment constitutes higher order complex skills (cognition) and ability to interact with environment constitutes simple lower order skills (Motor).[5]

Even though the chronological growth of infants are fine, as infant ages ,the demands placed by the environment on them increases resulting in inability to manage the environment leading to deficits.[5]

An infant with deficits is often assessed for motor outcomes predominantly than cognition, that is often ignored.[6]

To understand an infant, motor aspects together with cognition should be considered and emerging trends should focus on these priorities.If not focused the brain will go for "use it or lose it" principle.Also double hazard, the problems with neural processes and environmental factors affecting the infants recovery can be ruled out.[7]

Early interventions refers to prevention focused programs occurring soon after birth when infant is plastic and the interventions are more likely to have maximal impact. Most of the interventions are physical in nature and doesn't seem to concentrate on cognitive aspects and little consideration is given at 1year of age.[7]

Cognitive rehabilitation therapies still exists but are not standardized, and left to the clinicians own design to arrive at scientific conclusion.[8]

Even in adult population, cognitive therapies are yet to meet perfection.

Some of the studies which developed as concepts are,

1.Attention is the foremost component to be projected and trained than advanced skills like memory and problem solving.

2.Presence of an action execution and observation matching system in 6 month old human infants and sensory motor cortex of infants was also activated during observation of a moving object on TV screen.

3 .22 week old fetuses shows an advanced level of motor planning compatible with execution of intentional action.

This study relies on interventions of cognitive aspects to the infants with developmental delay. They are designed, applied and assessed for the outcomes after a certain period of time and tried to exhibit the influence of cognition training on motor skills of infants born preterm at one year of age.[9]

Aim of the Study

To study the influence of cognition training on the motor skills of infants born preterm at one year of age.

Objectives:

To find out

1. Cognitive involvement
2. Motor involvement
3. Influence of cognition training on the motor skills

in infants born preterm at one year of age.

Methodology

Study Setting: Sri Ramachandra Medical center and hospital

Study Design: Interventional Study

Sample Size : 32 infants born preterm at one year of age

Sampling : Random sampling.

Inclusion Criteria:

- Infants born preterm around 1 year of age
- Both Genders

Exclusion Criteria:

- Congenital anomalies
- Un co operative infants.

Procedure:

Data collection was initiated following the approval of Institutional Ethical Committee (CSP/14/OCT/37/206).

Infants born preterm around one year of age of both genders who come under inclusion criteria were taken to the study. Prior informed consent was obtained from the parents. Infants were screened using Bayleys scale[10]

of infant development for cognition and motor skills pre & post cognition training.The techniques used in this study are based on evidences and good results have been obtained.The training programme include:

a. Identifying the reward, when hidden under a wash cloth done by the mother to the infant and the infant observes it and as a progression the infant does it after it adapts to the play.

b. When sat in a cot or holding infant in the hand, a toy is squeezed and put down on the floor and the child searches for the fallen toy towards the floor.

c. Moving an object horizontally and vertically to make the infant follow it.

The first exercise concentrates on executive function, and the other two exercises concentrates on attention. The exercises were taught to the mother and was asked to do it thrice a day for a month. The infants were assessed after a month with BSID.

Results

The collected data was analysed with SPSS 16.0 version.

There is significant association between the gross motor skills and cognition with the p value =.031

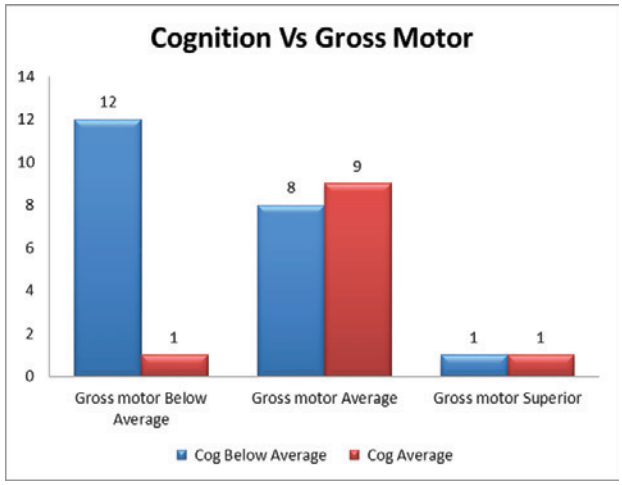

FIGURE : 1 Graphical representation of extensibility of relationship between cognition and gross motor skill

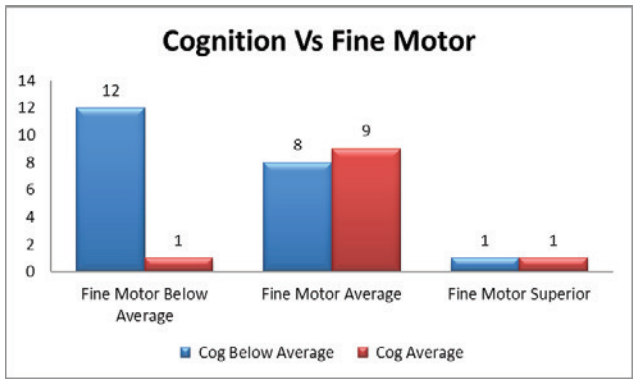

FIGURE: 2 Graphical representation of cognition and Fine motor relationship

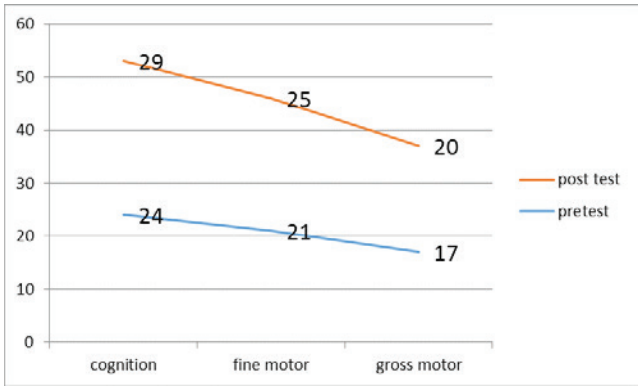

FIGURE : 3 Pre & post scores of cognition, fine motor & gross motor skills

Bayleys scale analysed the skills in infants and it comprised of raw score, scaled score and composite score.[10]

The interventions in this study gave a phenomenal prognosis in the preterm infants in the raw score of BSID which serves as back bone for the study. This result gave a sophisticated authentication that cognitive skills are influencing motor skills. Eventhough there was no change in the final score of BSID, the minute changes were evident from the performance aspect during reassessment.[11]

When trying to find out the relationship between the two, Jan piek discussed that, motor performance influences cognitive performance at later ages which made to think in vice versa which served as a background for this study, which also supports Vander Fels's view that motor skills are improving cognition.[9]

Authors like Roebers and Davis proved that motor and a executive function are highly correlated which supports our study that showed good significant association in both the skills.[12]

This helps to provide a new insight in the field of rehabilitation of infants, which paves the way for better outcomes.

To support strong evidence to support clinical practice and maximize the independence of infants, researches has to be carried out using the cognitive interventional programmes to promote overall skills improvements.

Conclusion

The analysis of this study concludes that cognition and motor skills are affected in pre term infants. Cognitive training improves motor skills in infants born preterm at one year of age.

How Urbanization and Economic Growth affects the Health in East Asian Countries? Evidence from the VECM approach

Ramanpreet KAUR[1], TushinderPreet KAUR[2]

[1]Research Scholar, Lovely Professional University, Phagwara,
[2]Professor, Lovely Professional University, Phagwara

Abstract

The study targets to explore the answer to the question whether there exists any association between urban populations, GDP in East Asian countries and how does it affect the health of public. This research study analyses this concept using panel data of six East Asian countries China, Hong Kong Korea, Japan, Macao and Mongolia. The study has used World Bank indicators to fetch the data for the variables urban population and GDP for the time period 1990-2018. First of all, stationarity of the variables is checked by applying LLC, IP, ADF and PP unit root tests. Further, with the help of JFPC and VECM, the co-integration between these variables is checked. Hence, the results indicate that urban population and GDP in East Asian countries are related to each other in long run. The study could not found any short run co integration between variables. But increasing urbanization in these countries is also developing sustainable challenges in these countries. Thus, urbanization in East Asian countries is acting like a double edged sword. The relationship between urbanization and health varies for different levels of development. Thus the countries with high rate of urbanization need to develop such programs which can spur economic growth as well as environment sustainability in those countries.

Keywords: *Urban Population, GDP, Health, Johanson Fisher Panel Co-Integration, Vector error correction model, Panel Data*

Introduction

Urbanization is defined as the process of rural to urban migration and the concentration of people in urban areas. This process is playing a striking role in the expansion of the countries. Moreover, urbanization and economic development are considered as interdependent variables. Gallup et al (1999) in their study have mentioned that urbanization and economic development are inter-related. Both variables have cause and effect relationship with each other [(7)]. If we have a look at the global scenario of urbanization, in early nineteen's, only 10% population of the world was considered as urban. This percentage has now reached up to 55%. As per projections of UNDP, by the end of 2050, this ratio will be 68% of the total population of the world [(16)]. Asia and Africa are the two continents which are observing rapid urbanization. As per UNDP projections, it is expected that 90% of the total urbanization of the world will take place in these two regions.

In the Asian region, East Asia is the continent with the highest urban population as compared to the other regions of Asia. In 2000, this region was having a total population of 635 million and as per UNDP projections; this number will be 1075 million by 2020. In East Asian region, 80% of the total urban population is covered by China. The association between urban population and GDP varies from country to country. Fay and Opal (2000) in their study have shown a continuously increasing process of urbanization in Kenya without growth [(6)]. Collier (2006) in his study has shown that various low and middle-income countries have observed urbanization without economic growth [(4)]. On the basis of the views of different authors, it can be concluded that there exists doubt regarding the causal association between these variables.

Urbanization is a global phenomenon, but the level of urbanization is different in different continents. Alam et al (2007) mentioned that in the initial stages, urbanization positively influences economic growth. But later on, an inverse association between these two

factors can be seen. In the third stage, rapid urbanization can negatively impact the economy [1]. Turok (2013) argued that infrastructure and institutional settings also have their significant contribution in affecting the GDP of the economy. Thus, it is not always essential that urbanization alone is affecting economic growth [15]. Singh et al (2015) in their study has shown distinctive connection between urban population and growth of the economies in Pacific island economies. According to the results of their study, urban population pushes growth of the economies but there are various negative externalities which can actually undermine the effects of growth [13]. Liddle (2015) in his study has described about ladder effect of urbanization on growth of the economies. According to him, urbanization negatively affects growth of the economies in under developed countries; it has neutral effect on developing countries and positive impact on developed countries [11]. Sun et al (2019) in their study have described the specific association between urbanization and growth of the economies in developed countries. With the use of spatial econometric testing in their research study, they concluded that economic development of the developed countries is accelerating urban population [14]. The association between these two variables has become an extensive inquiry for economists as well as geographers these days. Various researchers have accepted this general consensus of influence of urban population on growth of the economies. But it is required to study urban population with ambivalence to discover the complex association between urban population and growth of the economies. Unplanned urban population in developing countries leads to socio economic challenges which negatively impact the growth of the economies through its negative externalities. Thus the study targets to explore this association between urbanization and GDP of the economies in Asian countries.

Methodology

The study is based on the analyses relationship between urban population and GDP of East Asian countries. Data for Urban population and GDP is fetched from World Bank indicators for the time period of 1991-2018. The variable urban population (% of the total population) is used as a proxy of urbanization and the dependent variable for this study is GDP of the selected countries. The research study has considered all the East Asian countries China, Hong Kong, Japan, Korea, Macao and Mongolia for this research analysis.

Following tables 1 and 2 are related to descriptive statistics of dependent and independent variables. We have used E-Views 10 for the analyses of the data.

Table 1: Descriptive statistics (Urban Population)

	China	Hong Kong	Japan	Korea	Macao	Mongolia
Mean	41.79	99.97	84.46	59.89	99.96	62.09
Median	41.14	100.00	84.64	59.72	100.00	61.44
Max.	59.15	100.00	91.61	61.89	100.00	68.84
Min.	26.44	99.51	77.33	58.38	99.76	56.62

Source: Calculated Using E-Views

Econometric Modeling

In this study, econometric modeling is used to inspect the causal association between urbanization and GDP in East Asian countries. We have assumed a simple panel data models for urban population and GDP with standard auto regressive component as

$$urb_{it} = \phi_i urb_{i,t-1} + \alpha_i d_{i,t} + \varepsilon_{i,t} \quad (1)$$

$$gdp_{it} = \phi_i gdp_{i,t-1} + \alpha_i d_{i,t} + \varepsilon_{i,t} \quad (2)$$

Where i and t represents cross section dimensions and time dimensions respectively, $d_{i,t}$ presents panel specific terms, $\varepsilon_{i,t}$ represents error term.

There are several tests which can be used for the purpose of testing co-integration among the variables, but it is crucial to decide about the use of these tests in case of panel data. JFPC test is considered as the best test for panel data. Pedroni (1999) and Kao (2004) have also proved about the specific results given by their tests in case of panel data but their tests only focus on one way co- integration. JFPC test shows whole panel based co-integration. The study has used the following model for this co-integration analysis.

$$\Delta Y_{it} = \Pi_i y_{it-1} + \sum_{j=1} \Pi_{ij} \Delta y_{it-j} + \varphi_i z_{it} + \varepsilon_{it} \quad (3)$$

Y_{it} in the above model is p x 1 vector of endogenous variable, p represents the number of variables, Π stands for long run p x p matrix and rank of Π remains always between 1 and p. The results of JFPC test are always presented through fisher statistics from the trace test and from max Eigen test. The study has used panel based VECM to check causality between the variables.

$$\Delta Y_t = C_0 + \sum \beta_i \Delta Y_{t-i} + \sum \alpha_i \Delta x_{t-I} + p_i ECT_{t-I} + u_t \quad (4)$$

$$\Delta Y_t = C_0 + \sum y_i \Delta x_{t-i} + \sum \varphi_i \Delta y_{t-I} + n_i ECT_{t-I} + \varepsilon_t \quad (5)$$

Δ in the above equations is a change operator and p_i, β_i and α_i are used as parameters. Error term which is derived from long run co integrating variable is termed as $ECT_{t-i.}$ In this model, disequilibrium level of the previous periods is used to present the change in dependent variable.

Results

For checking the stationarity of the data through panel unit root tests (PURT), we have used LLC, IPS, ADF and PP tests. Table 3 shows the results for variable GDP and Table 4 shows the consequences of the variable urban population.

PURT

Table 3: PURT for variable GDP

Methods	I(0)	I(1)	I(2)
Levin, Lin and Chu t	1.0000	0.4042	0.0000
Im, Pesaran and Shin W-stat	1.0000	0.0181	0.0000
ADF – Fisher Chi Square	0.9999	0.0000	0.0000
PP- Fisher Chi Square	1.0000	0.0000	0.0000

Source: Calculated Using E-Views

Table 3 shows that our independent variable GDP is non stationary at their level for ADF test and it is stationary for other three tests LLC, IPS and PP. Thus, The study has checked it for first order difference. In this case, it was non stationary for PPURT. But at second order difference, it was stationary for all the tests.

Table 4: PURT for variable Urban Population

Methods	I(0)	I(1)	I(2)
Levin, Lin and Chu t*	0.6067	0.0000	0.0000
Im, Pesaran and Shin W-stat	0.6323	0.0000	0.0000
ADF – Fisher Chi Square	0.0033	0.0000	0.0000
PP- Fisher Chi Square	0.0189	0.4728	0.0000

Source: Calculated Using E-Views

Table 4 shows non-stationarity of our dependent variable urban population at level for all PURT i.e. LLC, IPS, ADF-Fisher Chi square and PP- Fisher Chi square. Thus, the study checked it for first order difference. In this case, it was non stationary for Phillips-Perron unit root test. But at second order difference, it was stationary for all the tests.

Results of Johanson Fisher Panel Co integration (JFPC)

Table 5: Johanson Fisher Panel Co integration

Hypothesized	**Fisher Statistics**		**Fisher Statistics**	
No. of CE(s)	(From trace test)	Probability	(From Max-Eigen test)	Probability
None	299.0	0.0000	56.76	0.0000
At most 1	28.63	0.0045	28.63	0.0045

Source: Calculated Using E-Views

Table 5 shows the results of JFPC. According to the results, it can be said that there exists at least one co integration in the variables used in this study. There are only two variables GDP and urban population. JFPC test indicates there exist co-integration between these variables.

Results of Vector Error Correction model

Table 6: Vector Error Correction model

	Coefficient	**Standard Error**	**t- statistic**	**Probability**	**Dependent variable**
Co integration Eq 1	-0.001111	(0.00057)	[-1.95135]	0.0000	Urb
Co integration Eq 2	-6.15E+08	(3.3E+08)	[-1.85749]	0.0642	Gdp

R-Squared	0.938876	Mean dependent var	0.383737
Adjusted R-squared	0.936839	S.D. dependent var	0.521785
S.E of regression	0.131134	Sum squared resid	2.579431
Durbin-Watson stat	2.010848		

Source: Calculated Using E-Views

VECM model is used for further analyses because of same order integration of variables in JFPC test. Table 6 shows the results of VECM. The first co-integration equation shows that value of C1 is negative and the value of probability is significant which is a symbol of long run association of the variables. Value of coefficients shows speed of adjustment of variables. Negative value of coefficient and the significant p value show causal association between urban population and GDP of the countries in the long run. From second variable, the value of coefficient is negative, but p value is not significant. Thus we can say that urban population and GDP have long run relationship.

Results of Wald test

Table 7: Wald Test

Test Statistics	Value	DF	Probability
Chi Square	0.281669	2	0.8686

Source: Calculated Using E-Views

Wald test is used to explore causal association between these variables in the short run. According to this model, no such association exists between these variables because of insignificant probability values.

Discussions

The results of PURT describe that at level and first difference, the variables urbanization and economic growth were not stationary. But these variables showed stationarity, when they were tested at second difference. Results of JPFC proved that there exists only one co integration equation for these variables. Further the results of VECM proved that urban population and GDP have long run relationship in East Asian countries and as per the results of Wald test there is no short run association between these variables. In short, urban population and GDP of East Asian countries are co-integrated in the long run. The study could not explore any short run association among urban population and GDP in same countries. The consequences of the study also show that there is no immediate influence of urban population on GDP in short run. But urban population of these countries significantly influences GDP in the long run. On the other hand, economic growth also influences urbanization in the long run. In East Asia, the countries with high rate of urbanization need to develop such programs which can spur economic growth in those countries. The governments of these economies need to focus on planned urbanization. Various researchers also focused on the influenced of economic development of the countries on urbanization (14). The VECM analyses of this study also shows that economic growth of the countries can accelerate urbanization only in long term. Moreover, in such countries, sustainable development programs are concentrated in cities. Thus, the governments need to develop such policies which can promote equitable benefits sustainable development programs in all the areas.

Conclusions

The research study concludes that in long run urbanization influences growth of economies positively in East Asian countries. In the short run, there exists no such association between these countries. As urbanization in East Asian countries is growing at higher rates, thus the government of the countries needs to design urbanization in such a way that it can spur economic growth of the economies. With the continuous urbanization of the world, concentration of negative effects on health due to increasing sustainable challenges in the countries is also increasing. This challenge becomes crucial in the regions such as East Asia where speed of urbanization is too high. Thus the government of the countries needs to adopt policies for ensuring equitable benefits of urbanization in the countries. To deal with the sustainable challenges in the countries, the governments must explore the forward and backward effects of urbanization. Analyses of forward condition of urbanization can be done on the basis of public services, non-farm activities in the countries and infrastructural facilities. Comprehensive analyses of these forward effects through social, economic and environmental aspects of urbanization can help in better analyses of its effect on the GDP of the countries. Policymakers in the countries should not only focus on acceleration of urbanization, but they should focus on the form of urbanization which can increase employment level, maintain environmental sustainability and can promote overall economic development of the countries.

Comparative Effect of Trunk Balance Exercise over Conventional Back Care Exercise in Patients with Chronic Mechanical Low Back Pain

[1]Ruchi Yogesh Khandhar, [2]Sathya P, [3]Jibi Paul

[1]M.P.T Student, [2]Associate Professor & Guide, HOD of Kinesiotherapy and Physical Diagnosis, School of Physiotherapy, D.Y.Patil Deemed to be University, Neru, Navi Mumbai

Abstract

Background: Mechanical low back pain refers to any type of pain caused due to abnormal stress and strain on muscles of the vertebral column. It can occur due to an acute traumatic event or cumulative trauma. The work place design is one of the major causes for Mechanical low back pain due to cumulative trauma. Mechanical low back pain also occurs due to poor posture, poorly-designed seating and incorrect bending and lifting habits.

Methodology: 40 patients with chronic mechanical low back pain were randomly divided into experimental group (group A, n= 20) that received trunk balance training exercises and hot packs, control group (group B n=20) received conventional back care exercises and hot packs for 3 days a week for 6 weeks. The single leg stance and star excursion balance test for static and dynamic balance assessed before and after treatment.

Results: Data analysis done using paired t- test showed there was a significant difference between pre and post analysis of both the groups. However when post analysis of both the groups were compared, experimental group showed higher difference as compared with control group.

Conclusion: Trunk balance training exercises was effective in improving static and dynamic balance in patients with chronic mechanical low back pain, and can be included in the treatment for patients with chronic mechanical low back pain.

Keywords: *Chronic mechanical low back pain, trunk balance training exercises, conventional back care exercises, single leg stance, star excursion balance test.*

Introduction

Back pain is an extremely common human phenomenon; a price mankind has to pay for their upright posture. Low back pain (LBP) is a most common public health problem, which involves muscles, nerves and bones of the back leads to disability.[1] [2] On the basis of duration low back pain is classified acute, sub-acute and chronic. It can be further classified as either mechanical, non-mechanical or referred pain on the basis of under lying cause.[3]

Mechanical low back pain is the pain in the lumbo-sacral region caused due to abnormal stress and strain on muscles of the vertebral column, where the pain increases due to physical activity with no radiation to foot or toes the common complaint in these.[4] The cause of mechanical low back pain may be an acute trauma or cumulative trauma. The work place design is one of the major causes for Mechanical low back pain due to cumulative trauma. The common clinical presentation shows that pain develops after movements that involve lifting, twisting or forward – bending. Multiple

anatomical structures and elements of the lumbar spine (eg:-bones, ligaments, tendons and discs) are suspected to have a role. Educating patients on prognosis and incorporating psychosocial components of care such as identifying comorbid psychological problems and barriers to treatment are essential components of long-term management.[5]

Balance is a dynamic process by which the body's position is maintained in equilibrium, static or dynamic. Most of the balance intervention programs require a multisystem approaches. Balance exercises are exercises designed to improve balance or postural stability.[6] Postural balance is necessary to maintain normal daily life and physical activity, it involves active interactions of vestibular, visual and somato-sensory information. [7] Several studies have indicated that patients with LBP showed reduced postural control that is commonly manifested in balance problem. Maintenance and control of balance, under static or dynamic conditions, are essential for daily activities. Thus for patients with any musculoskeletal or neuromuscular disorders postural control is evaluated.

Assessment of balance is one of the essential parts in treatment of patients with low back pain as several studies have indicated that such patients have balance affection. Out of all the various methods available single leg stance and star excursion balance test are the test which are patient friendly and can be performed easily, thus these test were used for assessment of static and dynamic balance in this study.

The main purpose of the study was to find effectiveness of trunk balance training exercise in management of patients with chronic mechanical low back pain.

Materials and Method

The study conducted with 40 patients' aged between 18-45 years male and female subjects, diagnosed with chronic mechanical low back pain were recruited from outpatient department of physiotherapy, D.Y. Patil Hospital and Research Centre. Patients with inflammatory arthritis and chronic low back pain having surgical interventions were excluded from the study. Ethical clearance was obtained from institutional ethical committee. Informed consent was taken from the patients prior to evaluation and treatment sessions. The patients were then randomly divided into two groups using lottery method. The experimental group (group A, n=20) receiving trunk balance training exercises and control group (group B, n=20) receiving conventional back care exercises. Static and dynamic balance was assessed for pre and post interventions using single leg stance and star excursion balance test in patients of both the groups. Prior to treatment session the patients in both the groups were given hot packs for 15mins for pain relief. The patients were given exercises 3 sessions per week each lasting for 60 minutes with a total of 18 sessions over 6 weeks of treatment. The objective of this study was to see the effect of trunk balance exercise in patients with chronic mechanical low back pain on static and dynamic balance.

Table 1. Exercise Protocol for Experimental Group (Group A)

Sr.no	Exercise	Progression	Duration
1	Trunk, head & UL rotation from kneeling	Eye closure & head extension	30 secs each side 2 reps/ direction
2	UL flexion and extension with simultaneous head movement from kneeling	Eye closure	3 mins hold performing 6 reps of UL movements.
3	Pelvic bridging followed by raising one lower limb and extending knee.	Eye closure and ball under the foot resisting on couch	30 secs hold 2 reps for each LE.
4	Lifting opposite upper and lower limbs from quadrapued position.	Eye closure & pillows under LL	1 min maintaining for each combination of limbs.
5	Sitting on side of the couch with unilateral support.	Eye closure, crossing upper limbs across chest and pillow under LL.	1 mim hold.
6	Single limb kneeling on the edge of the couch.	Eye closure, head extension, crossing upper arm.	30 secs hold. 2c reps/ each limb.

Table 2. Exercise Protocol for Control Group (Group B)

Sr.no	Exercise	Progression	Duration
1	Supine lying –leg lifts	Unilateral leg lifts & both leg lifts	5 secs hold x 10 reps.
2	Crook lying- abdominal crunches	Crunches with rotation	5 secs hold x 10 reps.
3	Prone lying – leg lifts	Unilateral leg lifts & both leg lifts	5 secs hold x 10 reps.
4	Prone lying – trunk lifts	--------	5 secs hold x 10 reps.

Results and Analysis

The data analysis was done using SPSS software for windows version. Mean and standard deviation of all outcome measures were calculated. The significance level was set at $p<0.05$. The homogenesity of group was maintained. There were non- significant difference between both the groups at baseline measurement.

When pre and post mean values for single leg stance with eyes closed (SLSEC) for group A were compared the average difference was -1.305 secs with SD 0.546. The difference between mean SLSEC at pre and post level was statistically significant since p value=0.000 ($p<0.05$). When pre and post mean values for single leg stance with eyes closed (SLSEC) for group B were compared the average difference was -0.465secs with SD 0.79.The difference between mean SLSEC at pre and post level was statistically significant since p value=0.017. ($p<0.05$).

When pre and post mean values for single leg stance eyes open (SLSEO) for group A were comparison the average difference was -2.130 secs with SD 1.15. The difference between mean SLSEO at pre and post level was statistically significant since p value=0.000 ($p<0.05$). When pre and post mean values for single leg stance eyes open (SLSEO) for group B were comparison the average difference was -0.345 secs with SD 0.613. The difference between mean SLSEO at pre and post level was statistically significant since p value=0.021 ($p<0.05$).

Table 3. Comparison of pre and post mean values for star excursion balance test (Left Leg standing) for group A.

	Paired differences		t	SIG. (2-TAILED)
	Mean	Std. D		
*Presebtltant – postsebtltant	-3.575	1.462	-10.932	.000

Discussion

The main aim of the study was to compare the effect of trunk balance training exercises vs conventional back care exercises in patients with chronic mechanical low back pain. In this study 40 patients with chronic mechanical lowback pain were taken were randomly divided in to experimental group (group A- 20 patients) and control (group B – 20 patients). The subjects in experimental group were treated with trunk balance training exercises and control group were treated with conventional back care exercises. The results obtained in both the groups were statistically analysed.

The patients in experimental group had improvement in single leg stance (eyes closed with mean of 5.205 ± 0.97575 and eyes open with mean of 6.095 ± 2.18812). These patients also showed improvements in SEBT at $p<0.05$ pt in left leg standing at lateral and anterorlateral directions. The results were statistically significant since $p<0.05$.

The patients in control group had improvements in single leg stance (eyes closed with mean of 3.99 and eyes open with mean of 3.975). These patients also showed improvements in SEBT at $p<0.05$ except in left leg standing at anterorlateral, posterorlateral and posterormedial directions. The results were statistically significant since $p<0.05$. The pre and post analysis

of experimental group and control group showed improvements. But when post analysis of experimental and control group was compared, experimental group showed slightly higher difference as compared with control group. This shows that balance training exercises has significant improvement on static and dynamic balance of patients with chronic mechanical low back pain after 6 weeks of interventions.

This findings can be further supported by the study done by Hodges et al, Danneels et al Nourbakhsh et al, Anderson et al, Hides et al where trunk balance and strength training exercises were used in management of pain and disability of the patient and significant improvement was seen.[9],[11],[12],[13] Thus the study shows that there was significant improvement seen on static and dynamic balance in patients with chronic mechanical low back pain following trunk balance training exercises. [14],[15,[16]

Conflict of Interest: There was no conflict of interest to conduct this study.

Funding: This was a self funded study.

Conclusion

The study concludes that there was improvement in static and dynamic balance in patients with chronic mechanical low back pain following 6 weeks of trunk balance training exercises. Thus trunk balance training exercises can be included in the treatment of chronic mechanical low back pain.

Behavioral treatment in autism spectrum disorder children by Repetitive motion control

S. Arun kumar[1], N. Nithyavathy[2], K. Suganeswaran[1]

[1]Assistant Professor, [2]Associate professor, [3]Assistant professor, Department of Mechatronics Engineering, Kongu Engineering College, Perundurai 638060, Erode, Tamilnadu, India

Abstract

Health is a significant concern that focuses on the physical, mental, and social living of humankind. Today keeping individuals as healthy and active with readily available healthcare system is a necessity. Autism is one of the developmental disorders, usually noticed with signs in the first two or three years of child growth which shows symptoms like communication and language inability. Researchers have proved that autism disorders can be overcome by holding therapy or applying deep pressure in children. The treatment involves forced/ tight holding provided by physiotherapist or parents to calm. The improper behaviour of child slowly stops for a fixed time period. The current research suggests a behavioural treatment for repetitive motion in an autistic child. This intervention is achieved due to the control of repetitive or stereotypic motion by sensing the unbalanced signals received from heartbeat and motion sensors placed in the autistic child's body. The irregular sensor signals are communicated to parents and therapist for future data analysis.

Keywords: *Health care system, Autism Spectrum Disorders, Repetitive motion control, Holding therapy.*

Introduction

A modernized patient monitoring system provides individuals with improved healthcare facilities in an economical and patient-friendly way at any instant. The healthcare system is currently experiencing both cultural and modernized transition from a traditional approach to a modernized approach. Healthcare professionals play a vital role in providing knowledge significant part to the patient in the conventional strategy. The basic problem associated is that healthcare professionals must be insight with the patient who is admitted in hospital and they stay bedside to the medical instruments. To overcome this concern, the patients should be equipped with adequate knowledge to play an important role in self-diagnosis and preventive measures. Notification of present state of a patient and its recording for future predictions is of great importance in patient monitoring.

Autism Spectrum Disorders (ASD) is a challenge even to educator those try to plan effective instructional programs for recovery [1]. Autism affected young children are at high risk to face communicational behaviours. Early intervention in autism young children should be done for analyzing their functional and problem behavioural treatment [2]. Because of the ubiquitous nature of autism impacts on the functioning of the individual in college and home, parents need to be included as active partners in the development of the instructional plan of their child. Autism children reported deficits in their ability to generalize their behaviours learned from one person to others [3].

The necessary elements needed for the treatment of autism disorders are support from individuals and families, instructions, well-structured learning environment, approach to their problematic behaviour, and involvement of member of family. Influence of family members is valuable in monitoring a child's environment [4]. A joint partnership with the family and doctors can contribute to the effectiveness of treatments. In their child development, parents are actually the first to recognize delays and difficulties. They are constantly seeking diagnoses and procedures that will enable their kids to gain autonomous abilities and a better quality of life [5]. The present survey has suggested that in order for educational programs that address problematic behaviours of children to be successful, their proactive behaviours must be monitored periodically.

This provides a clear that the problem behaviour of the

Child is not altered, instead,treatments should be focused on replacing the problem conduct with an effective suitable alternative conduct or mechanism resulting in a comparable effect.

A person will not be able to concentrate on a particular work at all means and tend to lose their concentration at certain times that provides a chance for mistakes. Modern patient monitoring should at all times obtain, record, display and communicate physiological information from a patient's body to a distant place by encapsulating the benefits of current bioinstrumentation and telecommunicationtechniques. [6] [7].

A different form of the patient monitoring system should be used to monitor the autistic child. The autistic child behaviour is sent as real-time data by appropriate sensors to their doctor and parents. In case of critical information in the obtained sensor data, the child must be saved by the engineered autistic system and a message of the current state of child should be sent to the doctor as well as parent. The purpose of this work is to engineer a proof of concept system that will inflate an air jacket worn by the child at the desired pressure limit.

Experimental Method

Sensing in the device begins with a motion sensor, and the sensor readings are provided to a microcontroller for processing. Initially, A microcontroller converts the sensor measurements from an analog to a discrete value. This process is achieved before entering the microcontroller bypassing the sensor outputs through an Analog to Digital Converter (ADC). To calculate the necessary elements, the microcontroller must take the digital data from the ADC and apply various formulas and conversion factors. Then microcontroller compares the digital input with threshold limit, initiating triggers when certain preset values or limits get exceeded. In the entire process of sensor readings, the algorithm tries to detect a repetitive motion [8] [9] [10].

Upon detecting this dangerous sensation, the microcontroller initiates a signal which will turn on the driver to inflate an airbag strategically placed at the waist of the patient. Fig 1 shows the process flow for triggering inflation jacket during autism disorders. When the child experiences repetitive problem behaviour s like frequent gestures, unusual postures, teeth grinding, hand flapping, and self-injurious behaviour, causes the change in motion or movement that produces vibration. The sensors acquire the vibration from the child's body and it is provided to the Arduino. The microcontroller receives the signal from the motion sensor and heartbeat sensors located in the child body. The microcontroller actuates the relay if the signal obtained is beyond the threshold limit. In turn, the relay actuates the 24V direction control valve (DCV).

This valve is an integrated electro-mechanical device containing a solenoid coil that actuates a solenoid switch. This opens the pneumatic pressure air to inflate the air jacket worn by the autistic disordered child. This inflation causes a jerk or sudden movement of the person wearing the jacket. This actuation mechanism induces a change in the behaviour of autism children, and finally, the child attains consciousness and tends to stop the repetitive movements. The sensors continuously check for the threshold limit and monitor the behavioural nature of the child.

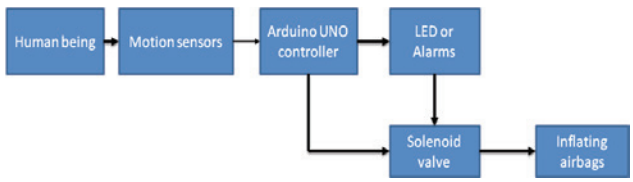

Fig. 1. Process flow for triggering Inflation jacket during Autism Disorders

The present conditions of child behaviour are predicted through simple programs embedded in the controller. The controller contains GSM module and mobile communication modem [11]. Suppose if the child didn't stop the behaviour after the threshold time interval, it sends the data about the problematic state of the child to doctor and parents via a messaging service.

Working of the Project

A child experiences repetitive behaviours, which include frequent gestures, unusual postures, teeth grinding, hand flapping, and self-injurious behaviour. It occurs in the child's body, causing self-injury. Hence these behaviour need to be sensed by a motion sensor like the adxl335 accelerometer. It is a 3-axis accelerometer with low energy, signal voltage conditioning. The sensor measures acceleration with a minimum 3.0 g range and measures static gravitational tilt acceleration to detect dynamic shock or vibration speed. Motion sensors detect the motion after calibrating it to an initial point in the three-dimensional axis. Motion sensors can be placed at

the wrist and neck.

Initially, the motion sensor senses which gives the analog value, and then the analog values are compared to previous analog value when it reaches the higher level the sensor produces output voltage. The output depends on the programming of the Arduino controller. Motion sensors used in this system senses the resonating motion and sends the signal to the Arduino controller that actuates the alarm and sets the LED to glow. Fig 2 shows the Process set-up for triggering inflation jacket. The Arduino board then actuates the solenoid valve and makes the airbags to inflate, and when the readings exceed the saturation value, a signal is sent to the GSM module which sends a message to the patient's parents.

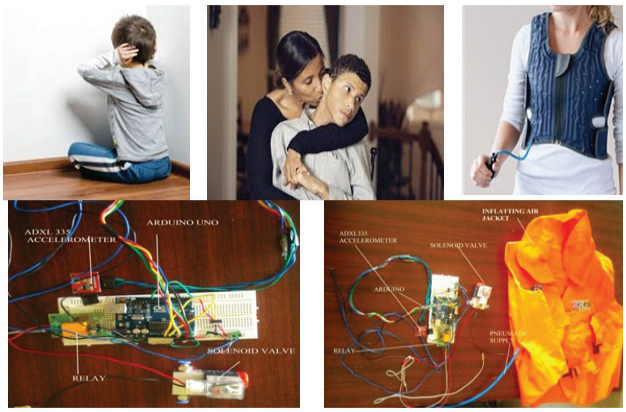

Fig. 2. Wearable air jacket set-up with controller mechanism

Arduino works on the basis of c programming. It is actuated by the signal from the accelerometer sensor. The Arduino controller works on the input of 5volt. The program can be dumped into the Arduino controller based on the requirement. The Arduino controller gives an output voltage of 5v when the accelerometer gives output. A time delay can be added to the program so that we can control the time of output voltage. This output signal from the Arduino is used to actuate the 12V relay. After the actuation of the relay, it remains on position for a particular time based on the Arduino programming. This 12V relay actuates the 24V DC solenoid valve. Thus actuation of solenoid valve opens the pneumatic supply to actuate the inflating airbag.

The solenoid opens according to the timing in the Arduino controller. This quick opening of solenoid valve causes sudden expansion of the inflating air jacket suddenly. The sudden inflation of the pneumatic airbag causes a jerk or sudden movement of the person wearing the inflating airbag. This actuation mechanism of the inflating airbag induces a change in the behaviour of autism children. Thus this sudden expansion causes a change in behaviour, and the child attains consciousness and stops the repetitive movements.

An inflatable air jacket has major components like the chamber to hold air, source for gas (compressed air or CO_2 gas cylinder), and mechanism to discharge gas from the cylinder into the chamber and inflation tube to inflate /deflate air to/from the chamber manually. Usually, inflatable jacket uses compressed air or CO_2 to fill with air. The inflatable air jacket inflates automatically when the jacket is triggered by the sensor signal and inflation of the jacket takes place.

The gas from cylinder fills a nylon or polyamide material jacket such that the gas fills at a velocity of 100 m/s. The entire process that is from the initial sensing to fill the air jacket takes about approx. 500 milliseconds. This set-up weighs approximately 0.9 kg and is fitted inside the standard protective jacket. Timing is crucial in the airbag's ability to save lives in a repetitive mechanism. An air jacket must be able to deployable in a matter of seconds from the initial sensor signal recognition. It must also be prevented from deploying when there is non-occurrence of problematic situation. Hence, the first component of the airbag set-up is a sensor that can detect and immediately trigger the air jacket's deployment.

Thus, as a result, the inflated air jacket is now filled with air from the pressurized cylinders and prevents the impact of repetitive behaviour. This, in turn, reduces their chance of injury. And at the same instant, the GSM module gets activated to send messages to the child's parent and doctor. The doctor can be able to predict the behaviour of child with the help of this GPS system and provides the necessary treatment. The air jacket serves the purpose of protection from the impact of repetitive behaviour by control action.

Conclusion

Children affected with autism should be protected from self-injuring and their problematic behaviour should be overcome. And at the same time parents and doctors will be able to know to monitor the child's health even from the remote location. The significance of extensive behavioural analysis will reduce problems and add aspects to the lives of a child to enhance the richness and efficiency of life, teaching and community activities.

future scope

The sensors can be used to gather and analyze the numbers of biomedical parameters. This scheme may also be coupled with a web-based architecture in which mail is sent to the physicians concerned. The prescribed patient study may also make automated delivery of drugs possible. Miniaturized pneumatic compressors/ cylinders can be used to make the inflating air jackets compact and independent of external pneumatic supply. We predict that the field of system change will be defined and refined in future years, but it is clear that any attempt to implement existing best practices in behaviour al support must recognize that the intervention unit is expanding.

Ethical Clearance- Not required since it is in development phase only.

Role of Tranexamic Acid in Oral Surgery

S. Mounika[1], . Santhosh[2]

[1]Undergraduate Student, [2]Reader, Department of oral surgery Saveetha Dental College, Saveetha University, India

Abstract

Background: Tranexamic acid is a synthetic lysine derivative that exerts its antifibrinolytic effect by reversibly blocking lysine binding sites on plasminogen and thus preventing fibrin degradation. In case of dental surgery, post operative bleeding is a common problem which if uncontrolled can result in increased loss of blood and delayed wound healing. Patients with bleeding and clotting disorders and patients on anti coagulant therapy have tendency for excessive bleeding. In such cases the use of tranexamic acid becomes more significant in dental surgeries. By understanding the pharmacokinetics and pharmacodynamic aspects of the tranexamic acid we can gain a through knowledge about its properties which will aid its use in oral surgery.

Key Words: *Tranexamic acid, surgery, bleeding.*

Introduction

Tranexamic acid is an anticoagulant is used to reduce the blood coagulability to an optimal level to help in providing protection against thromboembolic effects in patient undergoing oral surgeries. This is attained in case of minor risk of spontaneous bleeding. Patients reporting for invasive dental procedures are expected to cause more bleeding.

Consideration regarding whether the anticoagulant treatment as to be continued, modified or discontinued at some point of the the treatment has to be considered. In such situations the dentist has to take into consideration regarding the patient's ability to attain haemostasis in cases of continuation of anticoagulants and in cases of withdrawal of anticoagulants. To avoid these consequences per procedural care.

Tranexamic acid is a synthetic derivative of the amino acid lysin which exhibit its antifibrinolytic effect, through the reversible blocking of lysin binding sites on the plasminogen molecules. Intravenous administration of tranexamic acid has been routinely used for many years to reduce hemorrhage during and after surgical procedures like coronary artery bypass, scoliosis surgery, oral surgery, orthotopic liver transplantation, total hip or knee arthroplasty, and urinary tract surgery[1,2]. A complete drug history is important in patients taking anti coagulants. There is also influence of certain medications which may interfere with haemostasis and prolonged bleeding. Drugs such as alcohol, heroin can result in bleeding[3]

Tranexamic acid is an active trans stereoisomers of amino-methyl cyclohexane carboxylic acid and has been shown to have powerful antifibrinolytic properties. It was first described by Okamoto in 1962[4].

Tranexamic acid is available in both systemic and topical forms. Systemic form of treatment is not advised in patients with oral anticoagulants as it may result in thromboembolism. Concentration of trance amid acid is hardly detectable in plasm after the use in the form of mouth wash and it ha insignificant effect in inhibition of the fibrinolysis [5,6]. Tranexamic acid shows accelerated wound healing [7]. Thus it is significant to know the role of Blood loss and subsequent transfusions are associated with major morbidity and mortality [8,9]. Thus the use of antifibrinolytics can result in reduction of blood loss in cardiac surgery, trauma, liver surgery and solid organ transplantation and non-surgical diseases. The evidence of their efficacy has been mounting for years [10,11]. Synthetic lysine-analogue tranexamic acid (TXA, trans-4-aminomethylcyclohexane-1-carboxylic acid), along with ε-aminocaproic acid (ε-ACA), were first patented by S. Okamotoin 1957 [12]. Okamoto and Okamoto (1962) drew attention to tranexamic acid (AMCA) as a more potent inhibitor of the fibrinolytic enzyme system than aminocaproic acid, first introduced by Okamoto (1959). Further research by Melander et al. (1964) and Okamoto

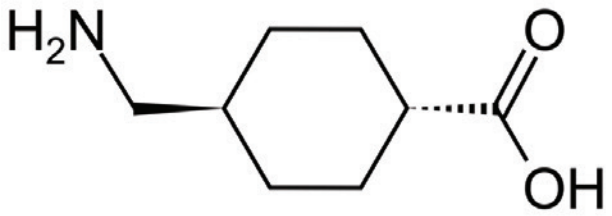
et al. (1964) showed that the cyclohexane derivative consisted of two isomers, the more active being the synthetic amino-acid tranexamic acid.This was found to be at least ten times more potent than amino caproic acid and the effect to last longer, and Anderson et al. (1965) found it to be seven times more potent. The use of amino caproic acid in the control of haemorrhage after the extraction of teeth in haemophilia has been investigated by Melander (1964) (1968).[13]

Several factors , may operate together to cause haemorrhage. For instance, in the presence of defective small vessel constriction or low-grade disseminated intravascular coagulation the action of the normal fibrinolytic response may be sufficient to initiate haemorrhage.[14]

Mechanism of Action:

The main action of the amino caproicacid compounds is to compete with lysine binding sites on plasminogen and plasmin. They inhibit the activation of plasminogen by streptokinase, urokinase and tissue activator. The binding of the heavy chain of plasmin to fibrin in monomerism is achieved by lysin binding sites, the blocking of these sites by amino caproic acid causes yo ichiometric inhibition of plasmin, with the formation of the inactive complex between plasmin and amino caproic acid. It will be no ted from the excellent view by D Colleen that the rate of that the rate of binding of alpha 2 plasmin is dependant on the availability of free ridual plasmin. In the presence of free residual plasmin is rapidly inactivated by alpha 2 to. Antiplasim Conversely, when the lysine residues are blocked, either by fibrin monomer or by amino-caproic acid, inactivation by alpha2-antiplasmin is reduced. This potent action of amino caproic acid as an inhibitor of plasmin in physiological fibrinolysis on a substrate of fibrinogen or fibrin has been recognised only fairly recently much of earlier studies was carried out . Similarly amino caproic acid is relatively inactive against the hydrolytic action of plasmin synthesis . Thus striking action of amino caproic acid Isco block the action of plasmin on fibrin . The interaction between plasminogen, plasmin, activator and fibrin complex. Tissue activators adsorbent to fibrin and in the presence of plasminogen mediate proteolytic cleavage of the terminal part of plasminogen, changing native Glu- plasminogen into Lys- plasminogen. The latter has higher affinity for the fibrin than the native. Plasminogen promote the resolution of fibrin with thrombus rather than causing the digestion of circulating fibrinogen during the fibrinolytic process. Plasmin is change form plasminogen by further cleavage of an internal Arg- Lys peptide bond in plasminogen . Plasmin also has affinity for fibrin. Thus consideration of fibrinolytic inhibitors must include their effective enzymes site but also their ability to interfere with the binding of the various components. The problem is further complicated by the type of activator studied. Tissue has greater affinity for urokinase[15]

Pharmacology of Tranexamic Acid:



Tranexamic acid is a synthetic derivative of the amino acid lysine and it inhibits fibrinolysis by blocking lysine binding site on the plasminogen. It is a competitive inhibitor of activation of plasminogen to plasmin and at higher a concen- trations and a non-competitive inhibitor of plasmin. Topical application of tranexamic acid has the potential to inhibit local fibrinolysis at the site of bleeding but with minimal systemic absorption. In this way, it could reduce bleeding and the need for blood transfusion without systemic side effects such as throm- boembolic events.

TXA is a synthetic lysine-analogue antifibrinolytic [16] that competitively inhibits the activation of plasminogen to plasmin; at high concentrations it non-competitively blocks plasmin, thus TXA inhibits the dissolution and degradation of fibrin clots by plasmin. The binding of TXA to plasminogen is 6 to 10 times more potent that of ε-ACA [17]. TXA has been shown to increase thrombus formation in a dose-dependent fashion in animal models, in contrast to aprotinin, which inhibits thrombus formation [18].

Suppression of fibrinolysis by tranexamic acid is manifested in surgical patients by reductions in blood levels of D-dimer, but the drug has no effect on blood coagulation parameters. Concurrent administration of heparin does not influence the activity of tranexamic acid. A series of cyclic compounds were founding have more potent fibrinolytic activity than EACA. One of the most suitable was AMCHA(4-aminomethyl-cyclohexane carboxylic acid). The potency of this compound, which is a mixture of stereoisomers, is due

to the residues in the trans-isomer, known as tranexamic acid which forms about 20-25% of the parent mixture. Tranexamic acid is some 10times more potent than EACA. It is such that that the potency of the compound depend on critical distance between the essential amino carboxylic acid groups[19].

Pharmacokinetics:

Maximum plasma concentrations of tranexamic acid are attained within 3 hours of an oral dose; the presence of food in the gastrointestinal tract has no effect on the pharmacokinetic parameters of the drug. Elimination after intravenous administration is triexponential, and over 95% of each dose is eliminated as unchanged drug in the urine. The total cumulative excretion after an intravenous dose is approximately 90% after 24 hours.

Of the total amount of circulating tranexamic acid, 3% is bound to plasminogen. The drug crosses the blood-brain barrier and the placenta, but excretion into breast milk is minimal. Tranexamic acid is not detectable in saliva after systemic (oral) administration, and mouth washing with 5% w/v aqueous solutions of the drug results in plasma drug concentrations below 2 mg/L[20]

Indications:

Tranexamic acid can be used in patients with haemophilia for two to eight days ie. Short term use to prevent haemorrhage during replacement therapy following tooth extraction. T XA is the only drug that can be used safely for reducing blood loss. Infusion of IV TXA to trauma patients within three hours of trauma has successfully saved many lives per year 1,000 trauma patients in Tanzania, India and the UK [21]

It can be used in other cases like excessive bleeding, mensuration, trauma and other surgery.

Tranexamic acid in oral surgery and its use in the form of mouth wash:

The treatment is to prevent bleeding after oral/ dental surgery in patients who are taking anticoagulants. It is an effective alternative to reducing patients' anticoagulants before surgery, then increasing them afterwards.

This treatment allows you to keep taking your normal dose of anticoagulant. Any bleeding in the mouth is controlled by tranexamic acid working directly on the bleeding area[22].

It is very important to follow the following methods,

Use the mouth rinses four times a day starting on the day of dental or any oral surgery. Use the first dose of 5-10 minutes prior to the extraction.

Rinse your mouth with 5ml for a period of two minutes each time. Be aware not to swallow any of the mouthwash after dental or other oral surgeries.

By using tranexamic acid in form of mouth rinses showed reduction in plasma levels.[23]

Determination of bleeding disorders prior to dental procedures includes:

Tests associated with the evaluation of bleeding complications for dental patients undergoing surgery include (1) complete blood count (CBC), (2) blood smear (3) bleeding time (BT), (4) prothrombin time (PT) (5) international normalization ratio (INR) (6) partial prothrombin time (PTT) (7) serum fibrinogen which measures the level of fibrinogen in the serum; (8) fibrin degradation products, (9) protamine paracoagulation test, (10) euglobulin clot lysis test [24]

Topical usage of TXA:

The topical use of TXA has been examined by Cochrane[25] Although the authors found reliable evidence that topical TXA reduces bleeding and blood trans-fusion in surgical patients, the risk of thromboembolism is unclear, as many studies do not report this complication or are underpowered. Topical administration results in a ten fold less plasma concentration of TXA when compared to intravenous administration. The surgical extraction of third molars under day case surgery is one of the most frequently performed oral surgical procedures. Bryant *et al*.[26] reported an almost 6-fold increase in the total number of dentoalveolar procedures carried out as day cases under general anaesthesia over the past 20 years with third molar surgery showing a 7-fold increase. Day case surgery patients have unique needs, distinct from those of traditional overnight or long-stay in-patients. The disadvantages of day case surgery are that patients may present for surgery improperly prepared or may be discharged from direct supervision before they have adequately recovered. Their post-operative needs are

central to achieving complete recovery and ensuring there are no unplanned readmissions to hospital. Chye *et al* [27]. reported a readmission rate to hospital of 0.25%,compared with 2.5% and 1.9% was reported.

Side effects of tranexamic acid:

Oral:

Tranexamic acid can cause serious side effects, including:

· Blood clots. The risk of serious blood clots may be increased when tranexamic acid is taken with:

o hormonal contraceptives, especially if you are taking higher than your normal dose of birth control, are overweight, or if you smoke cigarettes

o medicines used to help your blood clot

o some medicines used to treat leukaemia

· problems with your vision (including colour vision);

· sudden numbness or weakness, especially on one side of the body;

· sudden headache, confusion, problems with vision, speech, or balance;

· sudden chest pain or trouble breathing;

· pain or swelling in one or both legs;

· migraine headache;

· pale skin, feeling light-headed or short of breath, rapid heart rate, trouble concentrating; or

· feeling like you might pass out.

Cutaneous Adverse Effects:

Drug eruption, epidermal necrolysis, and bulbous eruption. [28,29]

Conclusion

In the past, the management of patients therapeutically anticoagulated with various anticoagulants requiring dental extractions has posed a dilemma to the attending dental surgeon. The following factors have probably contributed to the favourable evolution of the management of these patients: increased training and experience of dentists; improved dental status of patients, minimizing necessity for multiple extractions and increasing awareness of local fibrinolysis in the oral cavity and the use of local measures. Thus the review about Tranexamic acid would aid to know in use in dentistry and it's method of usage , available forms, indications contra indications and other factors would help in gaining a brief knowledge about TXA.

Effect of Surya Kriya and Shambavi Mahamudra Programme on Selected Psychological Variable among College Men

S. Parthasarathy[1], S. Dhanaraj[2]

[1]Ph.D., Scholar, Alagappa University College of Physical Education, Karaikudi,
[2]Assistant Professor, Centre for Yoga Education, Alagappa University, Karaikudi.

Abstract

The purpose of the present investigation is to find out the effect of surya kriya and shambavi mahamudra programme on selected psychological variable among college men**.** To achieve this purpose of the study 30 students were selected at random from Karaikudi, Tamilnadu, India as subjects. Their age ranged from 18 to 22 years. They were divided into three equal groups of 10 subjects each and assigned to experimental group-I, experimental group-II and control group. The experimental group I underwent surya kriya, experimental group II underwent shambavi mahamudra programme and Control Group was not given any specific training. All the subjects underwent one area of test namely depression. They assessed before and after the training period of 12 weeks. The one way analysis of covariance was used to analyze the collected data. The study revealed that the above said criterion variable was significantly improved due to the effect of surya kriya and shambavi mahamudra programme on selected psychological variable among college men

Key words*: surya kriya and shambavi mahamudra practice**, depression, f- ratio.***

Introduction

Today in our human body there are more common disease can be occurred in day to day life. Blood pressure is the system of circulation of blood cycle. It can be founded two types systolic blood pressure and diastolic blood pressure. Systolic pressure is the response of systole fro, the heart. Diastolic blood pressure is the important function in our circulatory cycle. Shambhavi Mahamudra kriya is a way within the Isha Yoga lineage that having both pranyanama practices and meditation-based techniques[1]. A kriya is a yogic action, or technique, such as breathing control. Yoga is a great soul and wisdom of the Universe. It can promote the social and inner well being through the limps of yoga (Asanas, Pranayama, Kriyas, Mudras and Meditations)[8]. To participating yoga regularly it can made you into sound body and sound mind[2]. Yoga practices are the costless permanents treatment for diseases. It is a practical holistic philosophy structured to bring about profound state as well is an integral matter, which takes into Consideration human as a whole[3]. One can start Yoga practicing at any given moment of time and you can start with meditation practice or directly with pranayama without even doing the asanas, the science of Yoga Nidra is based on the receptivity of consciousness[4]. When it is operating with the intellect and with all the essential senses, by making an individual think that he or she is aware and awake, but the mind is actually less receptive and more critical. Training is a chain process that can be able to attain certain needs of the person's goal[5]. In the sports world, physical education and sports is the most essential aspects due to the facts physical education programme increase the performance and the effectiveness of the sports and games. Today, sports have become the part and parcel of our ethical culture[6]. It is being influenced and does influence our entire social chart including education policy, economics, arts, politics, law and even international diplomacy. The sports training can produce some physical fitness, Motor fitness, Physiological and psychological benefits to the person and attain performance related tasks. It is also promoting the individual overall health and wealth to the sports person[7]. Yoga is a methodical effort towards self-perfection by the development of the potentialities and latent in the individual habits.

Aim of the Study

The purpose of the study was to find out the effect of surya kriya and shambavi mahamudra programme on

selected psychological variable among college men.

Methodology

To achieve this purpose of the study 30 men subjects were selected at random from Karaikudi, Tamilnadu, India as subjects. Their age ranged from 18 to 22 years. They were divided into three equal groups of 10 subjects each and assigned to experimental group-I, experimental group-II and control group. The experimental group I underwent surya kriya experimental group II underwent shambavi mahamudra practice and Control Group was not given any specific training. All the subjects underwent one and Control Group was not given any specific training.

Analysis of the Data

The effects of independent variables on selected psychological variable were determined through the collected data by using appropriate statistical techniques and the results are presented below. Table I presents pre and post test means and the results of the paired sample t-test of surya kriya exercise and shambavi mahamudra practice on depression.

Table- I: The summary of mean and paired sample 't' test for the pre and post test on diastolic blood pressure of experimental groupS

Depression	Surya kriya	Shambavi mahamudra	Control group
Pre test mean ± SD	41.60 ± 0.52	41.80 ± 0.79	41.70 ± 0.82
Post test mean ±SD	36.90 ± 0.99	36.70 ± 0.67	34.00 ± 0.67
't' test	12.82*	13.47*	19.45*

*significant at .05 level. (The table value required for 0.05 level of significance with 2.13 respectively)

The paired sample 't' was computed on selected dependent variables. The results are presented in the above Table I. The 't' value of Surya kriya, Shambavi mahamudra Practice and control group for diastolic blood pressure are 12.82, 13.47 and 19.45 respectively. All the't' values are significantly higher than the required table value of 2.13 with df 9 at 0.05 level of confidence. The result of the study shows that Surya kriya, Shambavi mahamudra Practice and control group has significantly improved the performance of diastolic blood pressure. The analysis of covariance on diastolic blood pressure of Surya kriya, Shambavi mahamudra Practice and control group have been analyzed and are presented in Table II.

Table – II: Values of analysis of covariance for experimental groups and control group on depression

Adjusted post-test means						
SKG	**SMMG**	**CG**	**SS**	**Df**	**MS**	**F-ratio**
36.87	36.73	34.00	52.37	2	26.18	42.91*
			15.87	26	0.61	

Significant at .05 levels. (The table values required for significance at .05 level of confidence with df 2 & 26 is 3.37)

Table-II shows that the adjusted post test mean value of depression for surya kriya, shambavi mahamudra Practice group and control group are 36.87, 36.73 and 34.00 respectively. The obtained F-ratio of 42.91 for the adjusted post test mean is more than the table value of 3.37 for df 2 and 26 required for significance at 0.05 level of confidence. The results of the study indicate that there are significant differences between the experimental groups and control group on diastolic blood pressure.

Table – III: **Scheffe's post hoc paired means comparisons and effect size on depression of experimental groups**

ADJUSTED POST- TEST MEANS				
SKG	**SMMG**	**CG**	**MD**	**CI**
36.87	36.73	-	0.14	0.91
36.87	-	34.00	2.87*	0.91
-	36.73	34.00	2.73*	0.91

(*Significant at 0.05 level of confidence; Scheffe's C.I value of depression 0.91)

Table III shows that the adjusted post- test mean differences on surya kriya and control group, shambavi mahamudra and control group are 2.87, 2.73 respectively and they are greater than the confidence interval value 0.91 which shows significant differences at 0.05 level of confidence. surya kriya and shambavi mahamudra practices are 0.14 respectively and they are lesser than theconfidence interval value 0.91 which shows significant differences at 0.05 level of confidence.

The ordered adjusted means are presented through bar diagram for better understanding of the result of this study in Figure I.

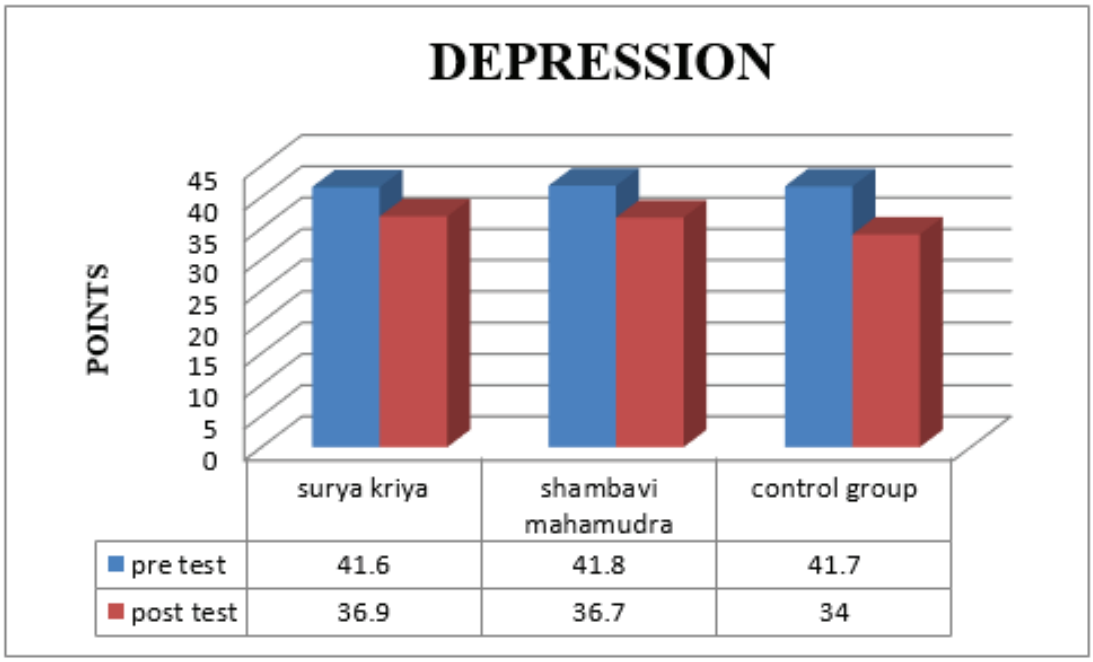

Figure I

Discussion on Findings

The result of the study on depression indicates that all the experimental groups namely Surya Kriya group and Shambavi Mahamudra Practice group brought about significant improvement after the training. The analysis of the data indicates that there was no significant difference on depression between Surya Kriya group and Shambavi Mahamudra group. Based on the mean value, the Shambavi mahamudra practice group was better in controlling the level of depression than the surya kriya group.

Conclusions

1. Finally it was concluded that surya kriya and shambavi mahamudra practice methods helped to increasing the diastolic blood pressure among school Students.

2. There was a little improvement difference between the surya kriya and shambavi mahamudra practice on diastolic blood pressure but not at the significant level. Based on the mean value was concerned, 12 weeks of surya kriya systems diastolic blood pressure more than shambavi mahamudra practices among school Students.

Recommendation:

1. The following recommendation for future research is based on the results of this investigation and the related literature.

2. The results of this research study clearly indicate that the effect of diastolic blood pressure through surya kriya and suryanamaskar programme.

3. Hence, it is recommended that physical education experts should give importance to the physiological exercise and suryanamaskar practice for the school students which will helps to develop, physiological. Hence the students can be very active and alive in the class room and also healthy in their life style.

Effect of Shambhavi Mahamudra and Pranayama Practice on Stress among Middle Aged Men

S. Parthasarathy[1], S. Dhanaraj[2], K. Alaguraja[3], K. Selvakumar[4]

[1]Research Scholar, [2]Professor, [3]Research Scholar, [4]Research Scholar, Alagappa University College of Physical Education, Alagappa University, Karaikudi, Tamilnadu, India.

Abstract

The purpose of the present study was to investigate the effect of shambhavi mahamudra and pranayama practice on stress among middle aged men. To achieve the purpose of the study thirty middle aged men were selected from Karaikudi, Tamilnadu, India during the year 2019. The subject's age ranges from 35 to 45 years. The selected students were divided into two equal groups consists of 15 men each namely experimental group and control group. The experimental group underwent a shambhavi mahamudra and pranayama practices programme for six weeks. The control group was not taking part in any training during the course of the study. Stress was taken as criterion variable in this study. The selected subjects were tested on stress was measured through perceived stress scale. Pre-test was taken before the training period and post- test was measured immediately after the six week training period. Statistical technique 't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference is found due to shambhavi mahamudra and pranayama practices given to the experimental group on stress when compared to control group.

Keywords: *shambhavi mahamudra practice, pranayama practices, stress and't' ratio.*

Introduction

Stress is the major disease that can be affected the human activities. Shambhavi Mahamudra kriya is a protocol within the Isha Yoga lineage that includes both pranyanama and meditation-based techniques[8]. A kriya is a yogic action, or inner technique, such as breath control. Yoga is a great soul of the Universe. It can promote the social well being through limps of yoga (Asanas, Pranayama, Kriyas, Mudras and Meditations)[1]. To practising yoga regularly it can make you into sound body and sound mind[2]. Yoga is the costless permanents treatment for more diseases. It is a practical holistic philosophy designed to bring about profound state as well is an integral subject, which takes into Consideration man as a whole[3]. One can start practicing Yoga at any given moment of time and you may start with meditation or directly with pranayama without even doing the asanas (postures), The science of Yoga Nidra is based on the receptivity of consciousness[4]. When consciousness is operating with the intellect and with all the senses, by making an individual think that he or she is awake and aware, but the mind is actually less receptive and more critical. Training is a chain process that can be able to attain certain needs of the person's goal[5]. In the sports world, physical education is the most essential aspect due to the fact physical schooling increases the performance and the effectiveness of the sports. Today, sports have become a part and parcel of our culture[6]. It is being influenced and does influence all our social institutions including education, economics, arts, politics, law, mass communication and even international diplomacy,. The sports training can produce some physical fitness, Physiological and psychological benefits to the person and attain performance related task. It's also promoting the individual overall wealth to the sports person[7]. Yoga is a methodical effort towards self-perfection by the development of the potentialities latent in the individual. Today's there is an escalating emphasis on appearing smarter, feeling better and living longer. In order to achieve these ideals as, scientific evidence tells us that one of the keys is high fitness and exercises. Asanas is a limp of Yoga practice it can make some health related gains to the individual who involved in yogasana practice regularly. Asanas can be used upon the needs

of the person. It's a scientific process the person must be follow the basic principles yogasana practice. Yoga is a practical aid, not a religion and its techniques may be practiced by Buddhist, Jews, Christians, Muslims, Hindus and Atheist alike. Yoga is union for all. Yogic action, or inner technique, such as breath control.

Research Methodology

Selection of subjects

The purpose of the study was to find out the effect of shambhavi mahamudra and pranayama practice on stress among middle aged men. To achieve this purpose of the study, thirty middle aged men were selected as subjects at random. The age of the subjects were ranged from 35 to 45 years.

Selection of variable

Independent variable

Ø Shambhavi Mahamudra and Pranayama Practice

Dependent variable

Ø Stress

Experimental Design and Implementation

The selected subjects were divided into two equal groups of fifteen subjects each, such as a combined shambhavi mahamudra practice and pranayama practices group (Experimental Group) and control group. The experimental group underwent combined shambhavi mahamudra practice and pranayama practices for five days per week for six weeks. Control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following physiological variable namely stress was selected as criterion variable. All the subjects of two groups were tested on selected criterion variable stress was measured through perceived stress scale at prior to and immediately after the training programme.

Statistical technique

The't' test was used to analysis the significant differences, if any, difference between the groups respectively.

Level of significance

The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

Analysis Of The Data

The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent 't' test was used with 0.05 levels as confidence.

Table I: Analysis of t-ratio for the pre and post tests of experimental and control group on Stress (Scores in points)

Variables	Group	Mean		Degree of freedom	't' ratio
		Pre	Post		
Stress	Control Group	46.33	46.53	14	1.00
	Experimental Group	46.20	52.60	14	17.04*

**Significance at 0.05 level of confidence.*

The Table-I shows that the mean values of pre-test and post-test of the control group on stress were 46.33 and 46.53 respectively. The obtained 't' ratio was 1.00, since the obtained 't' ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of the experimental group on stress were 46.20 and 52.60 respectively. The obtained 't' ratio was 17.04* since the obtained 't' ratio was greater than the required

table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant.

Result of the Study

The result of the study showed that there was a significant difference between control group and experimental group in stress. It may be concluded from the result of the study that experimental group improved in stress due to six weeks of combined shambhavi mahamudra and pranayama practice.

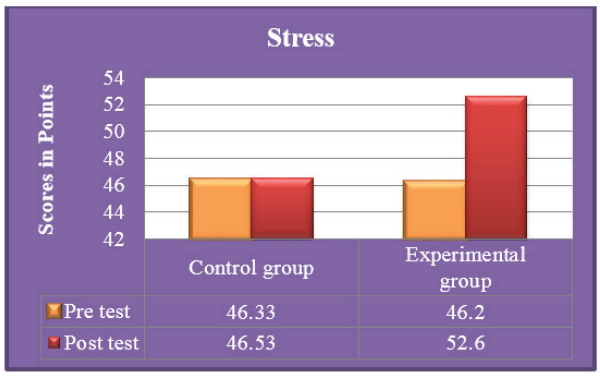

Figure-1: Bar Diagram Showing the Pre and Post Mean Values of Experimental and Control Group on Stress

Discussions on Findings

The result of the study indicates that the experimental group, namely combined shambhavi mahamudra and pranayama practice group had significantly improved the selected dependent variable, namely stress, when compared to the control group. It is also found that the improvement caused by combined shambhavi mahamudra and pranayama practice group when compared to the control group.

Conclusion

On the basis of the results obtained the following conclusions are drawn,

1. There was a significant difference between experimental and control group on stress after the training period.

2. There was a significant improvement in stress. However the improvement was in favor of experimental group due to six weeks of combined shambhavi mahamudra and pranayama practice.

Conflict of Interest : Nil.

Ethical Clearance

With respect to the above said Research Article involving human subjects for which the ethical clearance being sought, I am to state that I have gone through the "NIMHANS Ethical Guidelines…….Human Subjects" and am aware of the Helsinki Declaration of 1975, as revised in 2000 (5) rules governing the studies involving the human subjects. I am also aware that these guidelines are strictly to be followed while carrying out the above said research article involving human subjects.

Knowledge, Attitude, Practice and Perspectives Regarding Tobacco Cessation Program among Students in Private Dental Institution at Chennai –A Cross Sectional Study

S. Shree Lakshmi[1], Pradeep Kumar Rathinavelu[2], I. Meignana Arumugham Indiran[3], D. Srisakthi Doraikannan[2], V. Keerthi Narayan[4]

[1]Post Graduate Student, [2]Reader, [3]Professor, Department of Public Health Dentistry, Saveetha Dental College, Saveetha University, Chennai, India, [4]Senior Lecturer, Department of Oral Pathology and Microbiology, Thai Moogambigai Dental College and Hospital, Chennai, India

Abstract

Aim: Dentists could play an important role in tobacco cessation counseling. This study is conducted to assess dental professionals' understanding of tobacco prevention and control methods. **Material and Method:** A descriptive cross sectional study was conducted in which a close-ended, self-administered 30 item-questionnaire was distributed among 130 interns at private dental institutions in Chennai. Demographic data, tobacco use status, attitudes toward cessation programs, perceived barriers and counseling procedure was filled by the surveyed subjects. **Results:** About 97.7% of the dental interns agreed their role in helping patients to quit smoking. Though 82.3% enquired all their patients regarding their smoking status, 86.9% of them feared improper follow up. Nearly 85.4% of the respondents believed that the counseling done is effective but only 32% anticipated successful intervention and 21% of them were very confident in conducting it. **Conclusion:** It was concluded that although dentists were aware of their obligations towards smoking cessation counseling for patients but certain factors like lack of time, confidence, ,training ,absence of reimbursement and fear of losing patients were the common barriers for the same. Expansion of armamentarium to include tobacco cessation counseling strategies in clinical practice must be adopted by all dental professionals.

Keywords: *Tobacco, Smoking, Dentists, Counseling, Interns, Dental Institutions*

Introduction

Smoking is injurious not only to an individual's health; it is a hazard to the public as well. The World Health Organization reports that tobacco is the sixth risk factor out of eight for death of approximately 6 million people every year [1]and estimates an increase in the annual death toll to more than 8 million by 2030 [2]. Families of smokers on an average spend thrice more than non-smokers for illness episodes [3]. Owing to its causative role in raised mortality and morbidity it is considered a global epidemic [4]. Tobacco related mortality is highest in India with 900,000 annual deaths [5]. The Global Adult Tobacco survey conducted in India between 2009- 2010 concludes that among 275 million tobacco users 164 million use smokeless form of tobacco while 42 million consume both forms of tobacco and discloses that 34.6% of the adult population use tobacco in any form wherein, 47.9% males are habitual to tobacco usage as compared to 20.3% females. It has also to an estimation that 1 million people die in India due to tobacco related diseases [6, 7, 8]. Numerous studies have recognized the adverse effect of tobacco. Chewing tobacco has led to an increase in the number

of cases reported with head and neck cancers. Adults are likely to quit smoking when advised by their dentist [9]. Dental professionals have opportunities to educate and help addicted individuals quit smoking [10] and they are in an ideal position to provide cessation counseling program for achieving an increase in the abstinence rate from tobacco consumption [11, 12]. Unless tobacco users are helped to quit, the proportion of deaths would rise substantially in the nearing future and thus our study is carried out with an aim to assess the demographic data, tobacco use status, attitudes, perceived barriers, counseling procedure, perception and experience of dental interns regarding tobacco cessation program in private institution at Chennai.

Materials and Methodology

Nearly 29 dental institutions are located in Tamil Nadu. Chennai is said to be India's health capital providing health care through various Government and private hospitals is the area selected for conducting this cross sectional study. Among the 13 dental colleges in Chennai city within Tamil Nadu, 3 dental colleges were randomly selected. Nearly 130 interns at different private dental institutions constituted the study population.

Questionnaire:

A self-administered structured questionnaire consisting of 30 item questionnaire designed to obtain dental interns' demographic data, knowledge, attitudes, tobacco use status, practices, perspectives and experience regarding Tobacco Cessation program among dental interns in Private Dental Institution was used. The study participants' willingness to take part in the study by filling the given questionnaire and their agreement for response was considered as obtaining implied consent. One hundred percent response rate was achieved.

Statistical Method: Descriptive statistics using frequency and percentage was used. Inferential statistics using Pearson's Chi-square test was done to check the level of significance and association between variables.

Analysis Report:

A) The present study shows **attitude level** among dental interns regarding tobacco cessation counseling. It shows that among 130 study subjects, 99(76.3%) dental interns felt that they require adequate space with privacy to counsel the patients and 112(86.2 %) of them expect support from other staffs for the smoking cessation program to be effective. About 25(19.2%) of them had undergone training program to handle addicted smokers while 116(89.2%) of the interns were willing for an intensive training course. Nearly 126(96.9%) of them had extended their support for ban of smoking in public places **(FIGURE 1).**

B) The present study shows **perception level** among dental interns regarding tobacco cessation counseling. It shows that 86.9 % dental interns feel that patients might not turn up for the next visit and nearly 76.2% believe that they might not extend co-operation if tobacco cessation counseling is given 92.3 % of them trust that tobacco cessation counseling could be effective when good quality content is used within appropriate time. Only 51.5% of the dental interns are of the opinion that the warning images on tobacco products are effective to discontinue smoking habit. 85.4% of them feel that tobacco cessation counseling is effective **(FIGURE 2).**

C) The present study shows **practice level** among dental interns regarding tobacco cessation counseling. It shows that among 130 study participants, 107(82.3%) of them ask all theirs patients regarding smoking status, 45(34.6%) of them provide pamphlets and books on staying tobacco free, 118(90.8%) explain patients all the health risks due to smoking, only 42(32.3%) make use audio visual aids and 38(29.2 %) make use of electronic gadgets to remind patient enable them quit smoking. It also reveals that 78(60%) of the dental interns are properly document records about tobacco users and 36(27.7%) of them refer smokers to de-addiction centers. Out of the total, only 35(26.9 %) prescribe nicotine substitutes for their patients .About 15 (11.5%) dental interns are smokers currently (**FIGURE 3**).

D) The present study shows the frequency, follow up of tobacco cessation counseling given and financial concerns to it. It shows that 37(28.5%) of the dental interns have given tobacco cessation counseling regularly while 86(66.2%) of them provide only at times whenever time permits and 7(5.4%) do not take up at all. Hardly 48(36.9%) of them had followed up for every case routinely and 64(86.2%) have reported that it is only done sometimes. 18(13.8%) of the dental interns do not follow up at all. About 43(33.1%) of the study population is concerned on financial reimbursement usually when they start the counseling session while 70(53.8%) considers it only occasionally.

Discussion

As health professionals play a vital role in enriching health of the society and dentists are in a better position to spend more time with patients. Around 97.7% participants in this study similar to previous studies feel that it is the moral and ethical responsibility of every dentist to conduct tobacco cessation program with provision of encouragement and motivation for patients to quit use [13, 14]. 82.3% of them routinely ask their patients about tobacco use. The role and responsibility of dental professionals in serving as role model for the community in adaptation of healthy life style is accepted by majority of the interns (86.9%).

Merely 75.4% were found to be confident that they are qualified to counsel smokers. In our study, not all participants reported that they were taught how to counsel smokers and the above findings may be explained by the fact that only 19.2% had undergone training program to conduct counseling. On the other hand 80.9% constituting a massive proportion of our study group have not underwent such training despite the fact that 89.2% show readiness to accept such intense course. About 72.3% revealed awareness regarding behavioral modification while only 50% were familiar with avocation of pharmacological intervention as well. Though 50% were aware of NRT (Nicotine replacement therapy) and 73.1% were not advising at all for patients while 26.9 % prescribed NRT in practice.

As far as knowledge about COTPA (Cigarettes and Other Tobacco Products Act) is concerned only 82 % believed that their campus has legislative policy against use of tobacco while 12% of them have reported that they do not have such regulation and 6 % have no idea in terms of ban for smoking in and around educational institutions **(FIGURE 4).**

Majority of them (90.8%) explained all health risks to smokers but few of them utilized audiovisual aids especially books and pamphlets are offered only by 34.6% intern. Less numbers dentists consisting of 29.2% used their phones to give reminder messages to the patients as well. Nearly 36.9% followed up regularly on their patients to refrain from smoking while 86.2% occasionally tried. Thus the above two factors like knowledge and adequate training contributes as requisites for a successful tobacco intervention which influences the outcome of this study. The role and responsibility of dental professionals in serving as role model for the community in adaptation of healthy life style is accepted by majority of the interns (86.9%). These findings are in consistent with other surveys having the nearly same purpose conducted in the various countries across the world [2, 15, 16, 17].

According to various Indian studies, most doctors did not ask for or suggest methods to quit tobacco [15, 16]. Similarly, in our study also only a minority of the interns actively participated in tobacco intervention services. About 11.5% of the dental interns used tobacco contrary to 22% and 14.2% in other studies, which is high, and a cause for concern [9]. (**FIGURE 5**) About 97.7% participants in this study feel that it is the moral and ethical responsibility of every dentist to conduct tobacco cessation program with encouragement and motivation for patients to quit use, which is in close agreement with the other studies [18, 19]. This is similar to the earlier study on dental students who had also favored a ban on public use and on sale of tobacco products to adolescents [20].

Conclusion

Dental professionals play a significant role in tobacco cessation at clinical and community levels as well. The need of the hour is to train them for successful achievement of the goal of "Tobacco Free Society." Immense efforts are needed to motivate and empower the doctors to actively engage in smoking cessation support. It is high time to fight against tobacco on ground level. Hence active participation of dedicated dentists with sincerity should be encouraged.

Abstract

Oral cancer is of significant public health importance to India owing to its high prevalence. Early detection of oral cancer offers the best chance for long term survival and has the potential to improve treatment outcomes and make healthcare affordable. The objective of this paper is to report a case on similar difficulty faced in public health care scenario and to create awareness among services sector on focusing the incidence of disease in the country highlighting the significance of a community dentist's role in guidance of betterment of life an individual who was ignorant and asymptomatic. Hence an attempt to project this case report with two year follow-up and a quality of life.

Key Words: *Awareness, Diagnosis, Oral Cancer, Oral Public Health, Verrucous Carcinoma.*

Introduction

India is the second most densely populated country with 1,369 million residents. The Government of India has adopted several growth oriented policies witnessing an annual increase of 5.44% public health expenditure. Despite the efforts and achievements, the prevalence of oral diseases in India remains very higher when compared with other countries. Primary Health Centre is the first point contact for an individual towards health care system which serves as an active ground where the presence of a dentist is crucial for early diagnoses, prompt treatments and timely referrals. Around 75% of health infrastructure and resources are concentrated in urban areas where only 27% of the total Indian population resides while 73% of the country's population do not have easy reach to healthcare system. More than half of the community health centres are not functional and there is no dentist in 20% of the rural primary health care centres and one dentist for 2.5 lakh people in rural India [1]. There is an acute shortage of dental auxiliaries, appropriate polices, public and private partnerships leading to poorly equipped dental care setups resulting in lack of prioritization for oral healthcare services for the entire population [2-4].

Oral cancer is of significant public health importance to India owing to its high prevalence. Primarily, it is diagnosed at later stages which result in low treatment outcomes and considerable costs to the patients who typically cannot afford treatments [5]. Secondly, rural areas in middle- and low-income countries also have inadequate access to skilled care providers and limited health services. As a result, delay has also been largely associated with advanced stages of oral cancer. Early detection of oral cancer offers the best chance for long term survival and has the potential to improve treatment outcomes and make healthcare affordable. Oral cancer affects those from the lower socioeconomic strata of society due to a higher exposure to risk factors such as the use of tobacco.

Although clinical diagnosis occurs via examination of the oral cavity, the majority of cases present to a healthcare sector at later stages of cancer subtypes, thereby reducing chances of survival due to delays in diagnosis [6]. Efforts to increase the frame of literature on the knowledge of the disease aetiology and regional distribution of risk factors have begun gaining momentum. Oral cancer will remain a major health problem until efforts towards early detection and prevention are taken which will reduce the burden [6, 7]. In light of this, the objective of this paper is to report a case on similar difficulty faced in public health care scenario and to create awareness among services sector on focusing the incidence of disease in the country highlighting the significance of a community dentist's role in guidance of betterment of life an individual who was ignorant and asymptomatic. Hence an attempt to project this case report with two year follow-up and a quality of life measure was made.

Case Report

About the case: A 62 year old male reported to the community urban health center of our institution with a chief complaint of a non-healing growth of tissue on the right upper back teeth region for a year following an injury that resulted after a stair case fall. He developed pain in the same zones triggered on touch and usage of denture which aggravated on mastication over the course of period. He had undergone an uneventful extraction and replacement in the same region before 4 years and gave a history of consuming hypoglycemic for 12 years.

On intraoral examination:

Following the recording of brief case history intraoral examinations were performed. On inspection an ovoid swelling on the right cheek area was observed extraorally which was tender on palpation (**FIGURE 1**). A solitary, firm, non-scrappable proliferous ulcerative growth measuring 3×2 centimetres was found on the alveolar mucosa of right maxillary vestibule having finger like corrugations which was pinkish with focal areas of white spots (Figure 1).

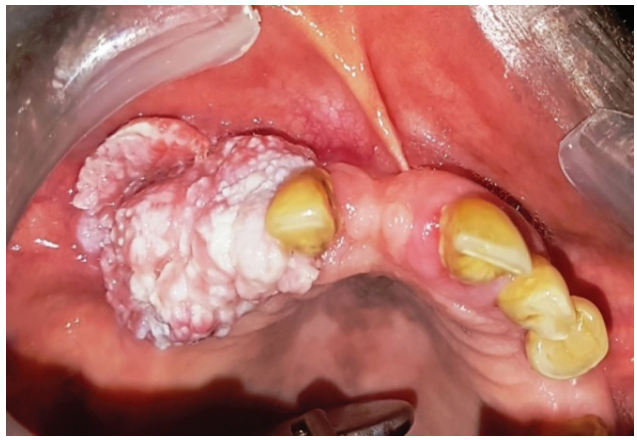

FIGURE: 1: Clinical Photograph showing the non-scrappable proliferous ulcerative growth measuring 3×2 centimeters

Analysis of the past dental and relevant history was done and provisional diagnosis of traumatic fibroma, epulis fissuratum with super added candidal infection, verrucous hyperplasia; proliferative verrucous leukoplakia (PVL), verrucous carcinoma and squamous cell carcinoma were made. He was referred to our college dental speciality wing where he was prescribed topical application of antifungal drugs (1% Cotrimazole) for a week. As the lesion did not show signs of regression, CBC and RBC investigations were carried out and found to be normal and hence CT and incisional biopsy were also conducted.

On special investigations:

Correlating the clinical picture with CT revealing a poorly infiltrating soft tissue dense lesion which was likely to be a mitotic upper gingivo-buccal mucosal CA of stage IV, histopathological examination of the biopsied tissues was done which revealed confirmatory findings [**FIGURE 2**]

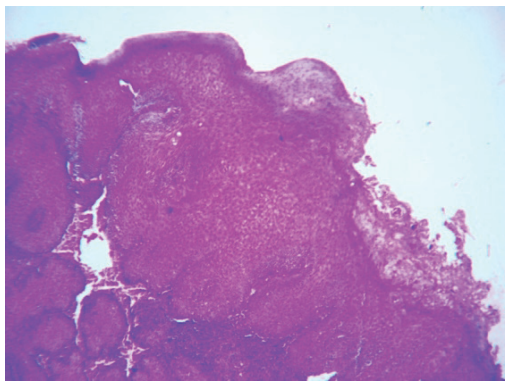

FIGURE 2: Histopathological Image (40x) showing broad bulbous retepegs with mild dysplasia, parakeratin plugging with break in the basement membrane and malignant cells infiltrating in to the subjacent minimal connective tissue stroma.

Points taken into consideration before arriving at a final diagnosis:

Oral fibroma was ruled out since it usually presents as a firm smooth papule in the mouth and it is in the same colour as the rest of the mouth lining which sometimes may be paler or darker if it has bled. The surface may be ulcerated due to trauma, or become rough and scaly. It is usually dome-shaped but may be on a short stalk like a polyp (pedunculated). If it has developed under a denture it may be flat with a leaf-like shape. It should be noted that no histological dysplastic features and other observations were not present and fibromas never develop into oral cancer [8].

Epulis fissuratum is a fibrous overgrowth caused by chronic irritation of the denture flange against the area where the gums meet the alveolar vestibular mucosa. Although it is very uncommon for these lesions to be associated with oral squamous cell carcinoma, as a precautionary measure the removed lesion should be sent for microscopic testing to rule out by histological confirmations [9, 10]. Non response to antifungal drugs was taken note to rule out candida infection as a precipitating or secondary factor.

Final Diagnosis

On complete evaluation of clinical, radiological and histological findings a conclusive diagnosis of verrucous carcinoma (VC) was put forward by ruling out other possible diagnoses.

Discussion

It should be noted that VC of the oral cavity is a different clinicopathologic tumour distinguished from the usual squamous cell carcinoma because of its local invasiveness, non-metastasizing behaviour, and special clinical appearance. Oral verrucous lesions typically presents as slowly enlarging, grey or white overgrowths on the buccal mucosa or gingiva of older men [11]. It is a warty variant of squamous cell carcinoma characterized by a predominantly exophytic overgrowth of well-differentiated keratinizing epithelium. Histologically, it is known to present "elephant feet" like down-growth that seems to compress the underlying connective tissue and typically show minimal or absent cytological atypia [12]. Verrucous hyperplasia (VH) may be a de novo lesion or associated with papillomas. VH and PVL are irreversible clinicopathologic lesions with considerable potential for evolving into verrucous or squamous cell carcinoma. PVL is a disease of the oral cavity in which VH is a part of its developmental spectrum [13].

In a study by Keszler, histologic data showed orthokeratinization more frequently in PVL and VH, while parakeratinization in VC. Although, sharp epithelial projections predominated in all three lesion types, lympho-plasmatic infiltration and Russell bodies were more frequent in VH. Histometrically, connective tissue–epithelial interface, epithelial height and connective tissue–epithelial interface plus verrucous epithelial surface, showed statistical differences between PVL or VH versus VC. Keszler concluded that histometric analysis was able to detect epithelial differences between both premalignant lesions and VC [14]. VC, though uncommon lesion, in its pure form, can be considered a disease of later life, typically occurring in the seventh–eighth decades, with a strong male predominance. VC is strongly associated with the chronic use of tobacco, chewing betel nuts, alcohol and poor oral hygiene [15, 16]

Treatment strategy planned: On complete evaluation of clinical, radiological and histological examination following treatment strategy was planned **(TABLE 1)**

TABLE 1: Table showing the phases of treatment planned for the patient

Emergency Phase	Surgical protocol- Adv. Partial Maxillectomy from 11 to 16 region followed by split thickness graft under General anaesthesia
Phase I	Ø Adv. Health Education, Ø Nutritional Counseling, Ø QOL-OC Measurement
Phase II	Adv. Extraction of 12, 22, 24,43

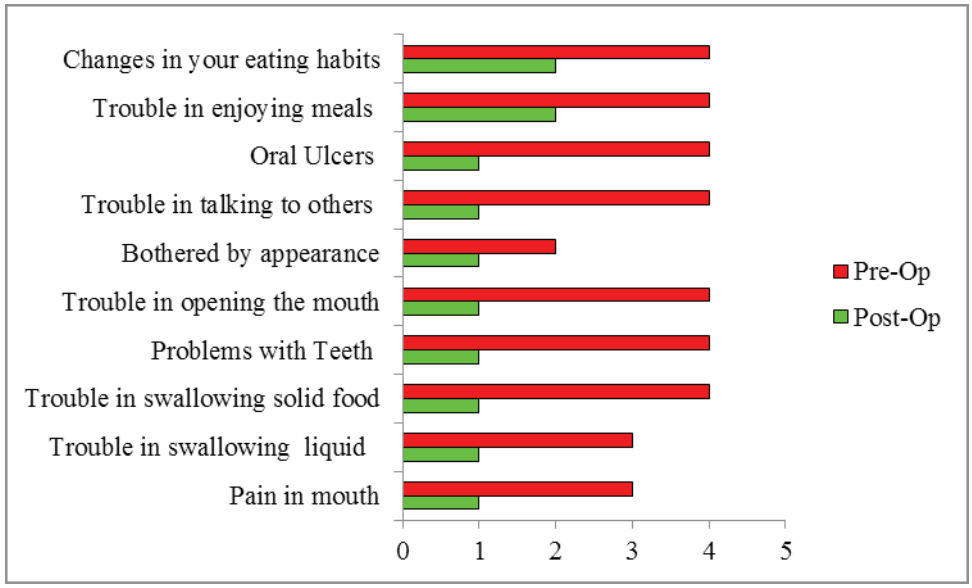
***Cont* .. TABLE 1: Table showing the phases of treatment planned for the patient**

Phase III	Ø Adv. Scaling, Ø Adv. Replacement i.r.t 12,13,14,15,16,17,25, 31,27,41,42, Ø Adv. Class- I restoration in 36, Ø Adv. Class –V restoration in 46, Ø Adv. Class V GIC in 23, and 25
Phase IV	Adv. Recall and Review

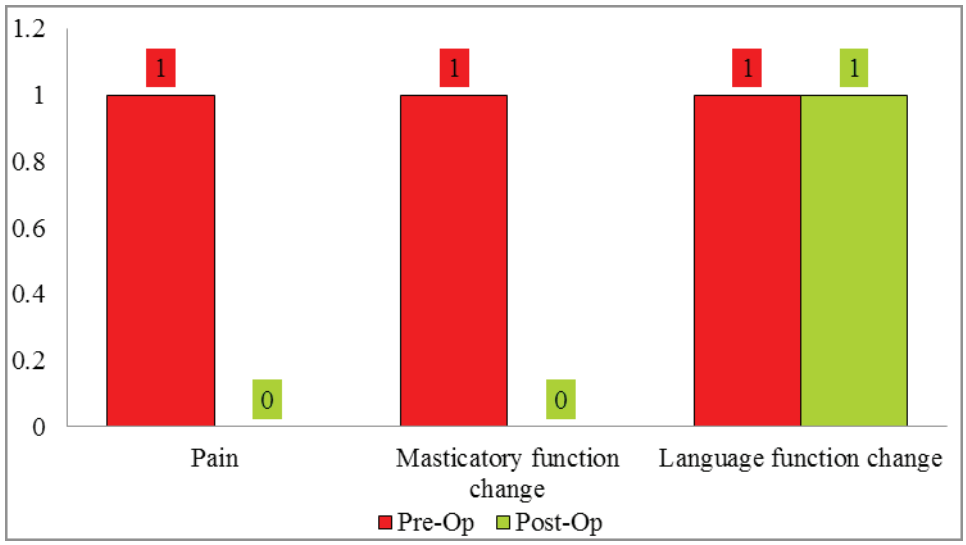
The above treatment plan was explained to the patient. His pre-operative quality of life using Quality of Life-Oral Cancer questionnaire consisting of 29 items was measured and counseling was given prior performing the surgery which ended with placement of an obturator. Deeper sections and complete sampling was required further to rule out frank squamous cell carcinoma. The excised portion was sent for excisional biopsy which revealed adequate clearance. He was prescribed antibiotics and analgesics for three days and instructed to maintain soft diet, good oral hygiene and avoid blowing through nose. His condition progressed with satisfactory healing during the recall visit and subsequent necessary treatment procedures were performed **(FIGURE 3)**

FIGURE 3: Intra-Oral clinical photograph following Phase-III treatment

QOL-OC score of 58 to 32 post surgery denotes an improvement in his quality of living in terms of functional efficiency and esthetics (**GRAPH 1, 2**).



GRAPH 1: Graph showing the range of Perceived Quality of life by the patient before and after Surgery



GRAPH 2: Graph showing the level of Experience of the patient recorded before and after Surgery

The patient reported weight gain post –operatively. Reinforcement of oral hygiene instructions was given with demonstration of brushing technique with teeth model. He was educated with more emphasis on denture hygiene maintenance.

Impact Of The Case Report:

The above report is just a presentation of one case resulting in drastic improvement in the quality of life of an individual following early diagnosis, prompt treatment, regular follow-up and adoption of preventive strategies highlighting the significance of dentists at health centres and conducting health programmes at mass level to focus on the incidence of oral diseases as well. This case emphasizes the need to educate the patient regarding denture care which could have saved him from such a lesion. Though the patient was ignorant initially, appropriate timely professional advice given has enabled him develop a positive dental attitude towards comprehensive treatments as well.

Recommendation:

This case is a classic example highlighting the need for recruitment of dental health professionals in all Government health care centres and urgent fixing of health facilities in rural India along with creation of awareness which can be done by creating attractive opportunities and growth benefits for dentists to migrate from urban to rural areas.

The potential of Public Health Dentists should be well utilized for early identification of oral precancer/cancer, oral health education, tobacco cessation counselling, provision of basic treatments including ART, topical fluoride and sealant applications and most importantly recruiting them to perform the responsibilities of an administrator taking up monitoring roles for the smooth and effective functioning of rural health care centres and ensuring maintenance of updated registers consisting of details regarding regular long-term follow up of special cases [20].

As it was not affordable for the patient to undergo cast partial denture which was a suggested better option, his functional efficiency and aesthetics was regained with removable prosthesis. The Government of India should introduce the free denture scheme for geriatric population like the Government of Karnataka which under the Dantha Bhagya Scheme has benefited 1512 of its senior citizens as of 2019 [18].

Conclusion

Large numbers of outreach programs through mobile dental vans are a solution to spread awareness and disseminate treatment at rural areas. There should be inclusion of dental health programs with family welfare programs by the government like in other developed countries and the barriers in the implementation of National Oral Health Policy should be addressed to achieve universal dental coverage for our country's citizens for which integration of political, social, organizational (both government and nongovernmental), professional dedication and support are the need of the hour making its long term distant goal reachable for a

healthy India.

A Mediation Analysis of the Effect of Perceived Stress on the Relationship between Self Efficacy and Quality of Life in Medical Students

S.GopalJee[1], Ashok Rai[2]

[1]Associate Prof. & Head, Department of Psychology, DAV PG College (B.H.U.) Varanasi,
[2]Pediatrician and State president of Indian medical association, UP

Abstract

Stress in medical students is caused by tenacious medical programs, which may have physical and psychological effects on the quality of life of medical students. The study aimed to examine the relationship between self efficacy and quality of life in medical students. In addition, we examined the mediation role of perceived stress on relationship between self efficacy and quality of life. The study was conducted on hundred medical students (64 male and 36 female) of Institute of medical sciences, Banaras Hindu University, Varanasi in the age range of 19 to 22 years (Mean age= 20.36, SD= 1.26). The data was collected by using the self efficacy scale (Sud et al, 1992), perceived stress scale (Cohen et al 1983) and WHOQOL-26 BRIEF. Results showed that most of the dimensions of QOL as well as the total scores of QOL were correlated positively with self efficacy and negatively with perceived stress. To examine the mediation role of perceived stress in self efficacy-QOL relationship a mediation analysis was carried out. In the total sample, self efficacy predicted QOL in an initial regression model (beta = 0.37, $p < 0.001$). When perceived stress was added to the model, however, self efficacy was attenuated less and insignificant (beta = 0.11, NS). A Sobel test of significance confirmed a mediated effect ($p<0.01$). Self efficacy is associated with QOL in medical students, and this relationship is mediated by perceived stress.

Key words: *perceived stress, Quality of life, Self efficacy*

Introduction

At present, there is increasing interest in the study of self esteem and quality of life. In today's changing and competitive scenario the term stress received a great attention among the medical students. Medical students, who are in a phase of transition from adolescence to adulthood, are in the most challenging phase of life. Most medical students are away from home, trying to adjust in new environment and anxious enough for their future[1]. Self-efficacy is a theoretically and empirically robust motivation belief that has been shown to play an important role in the learning and development of new skills in medical students. Bandura's social cognitive theory suggests that self-efficacy—defined as the confidence to carry out the courses of action necessary to accomplish desired goals and it plays an important role in influencing achievement outcomes through its dynamic interplay with environmental and behaviouraldeterminants[2].Although skills and knowledge provide the raw materials for student success in medical education, beliefs about personal capabilities to use these raw materials can spell the difference between success and failure. Self-efficacy beliefs are goal-oriented, context specific and future-oriented judgments of capabilities that change according to the task involved [3, 4.]

There is growing concern about quality of life of medical students during medical study.The World Health Organization (WHO) defined Quality of Life (QoL) as "an individual's perception of their position in life, in the

context of the culture and value systems in which they live, and in relation to their goals, expectations, standards and concerns"[5] .QoL is comprised of multiple aspects, including psychological health, physical well-being, social relationships, and environmental conditions[6].It is shown by many of the study that decreased QoL scores among medical students during their training years, which is associated with several future adverse effects, including an unhealthy lifestyle, variable psychological problems, academic failure, and other negative impacts on the students' professional development [7,8,9,10,11]. Different types of stress can affect quality of life of medical students such as a stressful clinical visit, continuous attention when interacting with patients, peer competition for academic excellence, the overwhelming load of new and massive information to learn, and of course difficulty[12,13,14].Studies with medical students have found that during the first year of medical school students had a deficit in hours of sleep, physical activity, and social interactions[15,16].

It is evident from the review that self efficacy is associated with enhanced quality of life. Although research on the self efficacy of medical students is of great interest in medical education, no attempts have been made to systematically review the research and examine the role of self efficacy on quality of life of medical students. Previous research did not present the mechanism of perceived stress on relationship between self efficacy and quality of life of medical students. Whereas self efficacy is directly facilitate the quality of life. The observation credits indirect support to our contemplation that the beneficial effect of self efficacy may be mediated by the perceived stress. However, there is lack of literature in this area and most of the previous studies on self efficacy–QOL were conducted on non professional population.

Method

Sample: The present study was conducted on 100 medical students (1st year and 2nd year) from institute of medical sciences, Banaras Hindu University and Heritage institute of medical sciences, Varanasi. They were consists of 64 male and 36 female. Age of participants ranged from 19 to 22 years (Mean age= 20.36, SD= 1.26). Self efficacy, Perceived stress and quality of life scale were administered on these students. None of the participants reported any present or prior history of medical or psychiatric illness in a semi-structured interview conducted before the administration of the tools for the present study.

Tools

1. **Hindi version of General self efficacy scale[17]**: The Hindi adaptation of generalized self-efficacy scale, adopted by SonaliSud[17], was used for measuring self-efficacy, which comprises 10 items. The German scale was developed by Mathias Jerusalam & Ralf Schwarzer[18]. It assesses optimistic self belief used to cope with difficult situation in life. The coefficient of internal consistency, estimated by Cronbach's alpha was determined to be 0.91.

2. WHOQOL-26 BRIEF Hindi version[19]: The 26-item WHO's QoL Instrument-Short Version (WHOQOLBREF) was used to measure QoL. The scale consisted of 2 items about overall QoL and general health perception and 24 items about QoL satisfaction that are divided into four domains, including physical QoL, psychological QoL, social relationships, and environmental QoL. The total score is the sum of the domains and ranges from 20 to 80. Domain scores indicate an individual's perception of QoL in each domain. The Cronbach's coefficients of the total and each domain in a study were from .58 to .90.

3. Perceived stress scale[20]: It is a 14 -item scale which measures the degree to which situations in one's life is appraised as stressful during the past month. There are seven negative and seven positive questions for which the subjects were required to choose from a scale of 5 alternatives 'never' 'almost never' 'sometimes' 'fairly often' 'very often' relating to their feeling of being stressed on a 0-4 scale.

Procedure

The participants were approached after taking permission from the respective hospitals. They were contacted individually and explained the purpose of study.The medical students have signed the informed consent letter which signified their voluntary participation in the research. All participants were requested to ensure that they have responded to each items of all scale. The obtained data were analyzed by using bivariate correlation and mediation analysis.

Results and Discussion

To ascertain the relationship of self efficacy with various domains of Quality of life and perceived stress bivariate correlation coefficients were computed. The obtained results have been displayed in Table 1.

Table 1:Correlations of total quality of life as well as various dimensions of quality of lifewith perceived stress and self efficacy

Measures	**Perceived Stress**	**physical**	**Psychological**	**Social relations**	**Environmental**	Total QOL
Perceived Stress	---	-0.44**	-0.48**	-0.54**	-0.40**	-0.71**
Self efficacy	-0.38**	0.28**	0.21*	0.18	0.26**	0.37**

p<0.05, **p<0.01

Table-1 shows correlations among study variables. The perceived stress is negatively strongly correlated significantly with quality of life as well as all the dimensions of quality of life(r=-0.44, r=- 0.48,r= -0.54,r=-0.40and r=-0.71,p< 0.01). Self efficacy is significantly positively correlated with total quality of life and all dimensions of quality of life except social rations (r=0.28,r=0.21,r=0.18NS,r= 0.26 and r=0.37, p<0.01).Thus, the observed pattern of correlation suggests that This perceived stress may affect both physiological and psychological health negatively and lead to decline in the quality of life of medical students. It means life as medical students is often stressful.This finding is consistent with a previous review; high perceived stress levels of students can have negative effects on QoL and healthy lifestyle, and their experience of depressive episodes could easily lead to decreased QoL[21]. Even burnout, have been documented in pharmacists, physicians, nurses, and dentists[22,23,24,25].

It is evident from Table-1 that opposite pattern of correlations was also obtained between various dimensions of quality of life and self efficacy. All dimensions of QOL (except social relation) positively and significantly correlated with self efficacy (r= 0.28, p<0.01, 0.21, p<0.01, 0.18 NS, 0.26, P<0.01, 0.37, P<0.01). The findings of the present study empirically support the notion that Self-efficacy proposed by Bandura plays an important role in modulating health behaviors and in turn positively affecting life qualities. Many studies have indicated that patients with higher self-efficacy are more effective in the self-management of hypertension[26]. Person with high self-efficacy would be more likely to deal with life stressors with confidence and engage in the necessary behaviors to preserve or restore health[27].

It is also evident from the finding of the present study that higher level of self efficacy is associated with higher level of quality of life and lower perceived stress. This pattern of relationship among self efficacy, perceived stress and quality of life support our assumption that healthy effect of self efficacy is likely to be mediated by the perceived stress. However, we have tried to empirically test this meditational effect on self efficacy-quality of life relationship which is presented in **table-2 and fig-1**

Table-2:Mediation effect of using social media on positive ageing perception–loneliness relationship

Testing step in mediational model	**R**	**R2**	**R2 Change**	**F change**	**B**	**Beta**	**t**
Testing step I Path a							
Predictor to mediator	0.38	0.15	0.15	16.64**	-0.72	-0.38**	4.09**
Testing step II Path B							
Mediator to outcome	0.71	0.51	0.51	101.33**	-1.28	-0.71**	10.06**
Testing step III Path C							
Predictor to outcome	0.37	0.14	0.14	15.30**	1.24	0.37**	3.91**
Testing step IV path C' mediation effect							
Predictor to outcome After mediation ---------- 1. Self efficacy	--	--	--	--	0.37	0.11 NS	1.46NS
2. Perceived stress	0.72	0.52	0.52	52.33**	-1.21	-0.67**	8.79**

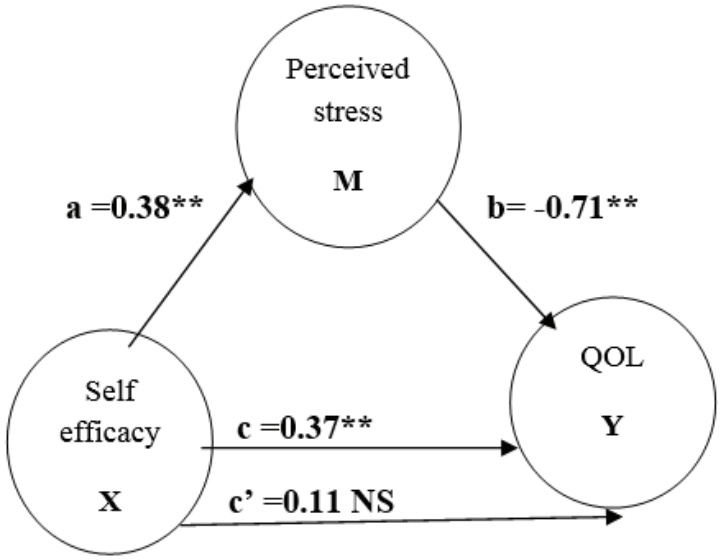

Fig-1 Path diagram of the mediation role of perceived stress

In the hierarchical regression model, the relationships between the self efficacy and QoL contributed significantly to the model, indicating that the self efficacy was a strong predictor of QoL (c = 0.37, $p < .001$). However, after adding perceived stress in the model, the coefficient of self efficacy was diminished (c'= 0.11, NS), suggesting the mediating effect of perceived stress. Additionally, the Sobel test was conducted to examine the significance of the mediator effect by using thefollowing formula

$$\text{Z-value} = ab/\text{SQRT}(b^2X\ s^2_a + a^2Xs^2_b)$$

a = raw (unstandardized) regression coefficient
sa = standard error of a.
b = raw coefficient for the association between the mediator and the DV

sb = standard error of b.

The Sobel test showed highly statistically significant result with Z=3.796, p<0.001. Results indicate that the relationship between self efficacy and quality of life was fully mediated by perceived stress. It suggests that Medical students may experience stressful condition due to their curriculum burden and career responsibilities. Adverse physical and mental health leads to impaired quality of life of medical students which may affect their learning and academic capabilities during medical education.This finding is consistent with a previous review that psychosocial consequences such as depression anxiety as well as stress can reduce the quality of life of medical students[28].Study-related stressors experienced by medical students include high workloads, tight time schedules, dissection of corpses, contact with severely ill, suffering and dying patients, and financial problems, as well as language barriers, communication difficulties and cultural differences especially for south Indian to north Indian[29]. To produce successful doctors, stress needs to be tended to at the early stages of training. Students who enter medical colleges are less likely to be depressed than students in other fields; however, this statistic is reversed by the second year of medical school. Addressing medical student perceived stress right away is essential to stave off depression and anxiety that students often experience.

Conclusion

In sum, the results of this study highlight the negative association between stress and QoLand positive association between self efficacy and quality of life in medical students. Also pointed that factor as perceived stress can maximize this negative association, deteriorating even more the QoL. Self efficacy belief determine our manner of perceiving the work environment in such a way that doctors who believe themselves to be effective face challenging educational demand with efforts. It means self efficacy is powerful personal resource that predicts the quality of life in doctor professionals in positive way but this effect decreases when stress is perceived by doctors. It is pointed out, the reduced number of studies that address the raised issues together i.e., self efficacy, stress and QoLin medical students. Medical studies are perceived to be characterized by competition, lacking time for leisure activities or social contacts and schedules that demand exclusive dedication, all of which can lead to reduced quality of life. Therefore, if we want to improve self efficacy, we must work to reduce stress level.

Effect of Yogicpractice on Resting Pulse Rate among College Men Long Distance Runners

S.Jayasingh Albert Chandersekar[1], N.Ganapathy[2], P.Yokesh[3], R.Manoranjith[4]

[1]Asst. Prof, Dept. of Physical Education & Sports Sciences, SRM IST, Kattankulathur, [2]Director of Physical Education, SRM ValliammaiEngg. College, Kattankulathur, [3]Asst.Prof, Alagappa University College of Physical Education, Karaikudi, [4]PhD Scholar, Alagappa University College of Physical Education, Karaikudi

Abstract

The purpose of the present study was to investigate the effect of yogic practice on resting pulse rate among college men long distance runners. To achieve the purpose of the study thirty men long distance runners were selected from colleges affiliated to Alagappa University, during the year 2015. The subject's age ranges from 18 to 25 years. The selected LDR were divided into two equal groups consists of 15 men LDR each namely experimental group and control group. The experimental group underwent a yogic practice programme for six weeks. The control group was not taking part in any training during the course of the study. Resting Pulse Rate was taken as criterion variable in this study.The selected subjects were tested on resting pulse rate by taking radial pulse. Pre-test was taken before the training period and post- test was measured immediately after the six week training period. Statistical technique't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference is found due toyogic practice given to the experimental group on resting pulse rate when compared to control group.

Keywords: *yogic practice, Resting Pulse Rate and't' ratio.*

Introduction

Yoga is needed and a powerful remedy, not only for the day to day problems but also to overcome niggling health problems. Micro and Macro Yogic Exercises on Vital Capacity.[1] The philosophy of yoga is "Caring, Sharing and empowering". Yogic practices provide an excellent means for returning to normal from Diabetics without any side effect and an inspired life. Regular practice removes obstructions, path to holistic health. [2] Which impede the flow of vital energy. When the cells work in unison, they bring backharmony and health to the system. 20 to 25 minutes (every morning or evening) of callisthenic exercises on resting pulse rate.[3] Pranayama practice increases lung capacity, breathing efficiency, circulation, cardiovascular efficiency, helps to normalize blood pressure, strengthens and tones the nervous system, combats anxiety and depression, improves sleep, digestion and excretory functions, provides massage to the internal organs, stimulates the glands, enhances endocrine functions, normalizes body weight, provides great conditioning for weight loss, the path way to health full living.[4] Improves skin tone and complexion.

Yoga is a most ancient system or education, based on a higher philosophical knowledge and a spiritual concept of man, physiological changes among male athletes.[5] Psychological changes among college women athletes.[6] For the harmonious development of the body and mind. It recognizes thenecessity of developing healthy, vital and well controlled body forthe attainment of a high order of mental life. While, health is a stateof organism in which all organs function uninterruptedly andvigorously and in full co-operation with one another for a longersurvival and the best development of the body. It helps the man toexpress his best through his intellectual, moral, spiritual and physicalactivities. A vital body and dynamic mind are intimately associatedwith vital health. When health is established, the body becomes afitter machine, more enduring, more powerful better developed andbetter controlled, the mind becomes alert, more imaginative betterbalanced and more contemplative and the emotions more normalized and spiritualized.**Gharote.M.L,(1974)**

Resting Pulse Rate

The number of times heart contracts in each minute while the body is at rest.**Robert V. Hockey, Ed.D,(1989).**

The number of beats of a pulse per minute or the number of the beats of the heart and entries per minute. The number of beatsfelt in exactly in one minute is known as pulse rate.**William Goddie, (1964).**

Methodology

The purpose of the study was to find out the effect of yogic practice on resting pulse rate among college men long distance runners. To achieve this purpose of the study, thirty men LDR were selected as subjects at random. The age of the subjects were ranged from 18 to 25 years. The selected subjects were divided into two equal groups of fifteen subjects each, such as a yogic practice group (Experimental Group) and control group. The experimental group underwent yogic practice for three days per week for six weeks. The control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following physiological variable, namely resting pulse rate were selected as criterion variable. All the subjects of two groups were tested on selected criterion variableresting pulse rate by taking radial pulse,at prior to and immediately after the training programme. The‘t’ test was used to analysis the significant differences if any, in between the groups respectively. The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

Analysis of the Data

The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent‘t’ test was used with 0.05 levels as confidence.

Table I: Analysis of t-ratio for the Pre and Post Tests of Experimental and Control Group on Resting Pulse Rate (Scores in beats/minute)

Variables	Group	Mean		SD		Sd Error		df	‘t’ ratio
		Pre	Post	Pre	Post	Pre	Post		
Resting Pulse Rate	Control	68.26	68.53	1.03	1.30	0.35	0.33	14	1.17
	Experimental	68.13	63.13	1.36	1.41	0.26	0.36		14.70*

*****Significance at .05 level of confidence.*

The Table-I shows that the mean values of pre-test and post-test of control group on resting pulse rate were 68.26 and 68.53 respectively. The obtained ‘t’ ratio was 1.17, since the obtained ‘t’ ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of experimental group on resting pulse rate were 68.13 and 63.13 respectively. The obtained ‘t’ ratio was 14.70* since the obtained ‘t’ ratio was greater than the required table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant. The result of the study showed that there was a significant difference between control group and experimental group in resting pulse rate. It may be concluded from the result of the study that the experimental group decreased in resting pulse rate due to six weeks of yogic practice.

Discussions on Findings

The result of the study indicates that the experimental group, namelyyogic practice group had significantly improved the selected dependent variable, namely resting pulse rate, when compared to the control group. It is also found that the improvement caused by yogic

practice when compared to the control group. The result of this study on resting pulse rate has in line with the study conducted by **KewalKrishan and Sudhirkumar Sharma (2009).**

Conclusions

5. There was a significant difference between experimental and control group on resting pulse rate after the training period.

6. There was a significant improvement in resting pulse rate. However the improvement was in favour of experimental group due to six weeks of yogic practice.

Nanoparticles in Wound Healing-A Review

S.Swarna Meenakshi[1], M.Sankari[2],

[1]Post Graduate Student, [2]Professor, Department of Periodontics, Saveetha Dental College, Saveetha University, Saveetha Institute of Medical and Technical Sciences (SIMATS) Chennai, India

Abstract

Impaired Wound Healing is a battle that millions fight every day. Thus, novel and innovative strategies are of utmost need. Nanotechnology has revolutionized the way we treat wounds. This review discusses about the various nanomaterials used for treating wounds, also talks about the development of a novel and potent nanomaterial made of melatonin with special interest as to why it would prove superior to the other materials when it comes to oral tissues.

Key words: *Nanomaterials, wound healing, melatonin, nano particle, silver*

Introduction

The healing of wounds is one of the most complex biological processes that occur during human life. After an injury, there is a synchronized activation of multiple biological pathways. In our everyday life we encounter all kinds of injury from a paper cut to an ulcer to a much severe organ damage. Unlike earthworms that are capable of re-growing lost body parts, we humans are incapable of any such miraculous feats. Hence, it is only natural to possess carefully orchestrated ways to heal our damaged tissues. Wound healing is the process by which the integrity of a damaged tissue is restored. It consists of four phases: Hemostasis, inflammatory phase, proliferative phase and remodeling. These phases involve a series of physiological events that are driven by bioactive mediators that are specific for each phase of healing. [1] Hemostasis phase involves vasoconstriction and activation of the complement cascade; inflammatory phase involves vasodilation and activation of macrophages. In the proliferative phase epithelialization, neo-angiogenesis and granulation tissue formation begins. [2] The principal feature of the remodeling phase is the deposition of Extracellular matrix in an organized manner, formation of myo-fibroblasts and wound contraction.[3] The same holds good when it comes to wounds of the oral cavity. Periodontal tissue destruction is in a sense, a wound as well, since there is ulceration and destruction of tissues within the gingival sulcus leading to further tissue destruction of the periodontium. An alteration or hindrance in any of the phases lead to inadequate or an improper wound healing. Many factors such as lifestyle of the patient, systemic health etc plays a major role in wound healing. [4] When it comes to periodontal tissue destruction, materials that have potent antimicrobial activity in addition to those that are capable of stimulating growth factors and angiogenesis are of utmost need.

Nanomaterials in Wound Healing:

At present wide range of therapy either conventional dressings or modern approaches like usage of biomaterials, synthetic polymers with excellent mechanical properties and biocompatibility are available. Wound healing potentiated by nanomaterials have proved to be promising. The size, biocompatibility, colloidal stability, surface charge, surface functionalization and higher surface area offered by the nanomaterials have an additional advantage and could play a critical role in wound healing. [2]

Polymer Based Nano materials:

The most versatile polymers that are used to manufacture biomaterials specially for wound healing and care are poly (lactide- co-glycolide) (PLGA), polycaprolactone (PCL) and PEG (Polyethylene glycol. PLGA-curcumin nanoparticles showed a tremendous improvement in wound-healing capability compared to that of macromolecules of PLGA or curcumin.[5] Durga Prasad et al[6] , Mau[7] et al in their studies found that PLGA nanoparticles loaded with Curcumin which are known for their anti-inflammatory and antioxidant properties were capable of Quenching Reactive oxygen

species and also had the potential to inhibit the enzyme Myeloperoxidase. A study by Chen Yu et al tested the usage of PLGA nanoparticles to deliver recombinant human EGF (rhEGF) to enhance Full-thickness wound closure in Diabetics rats. [8] The rhECF delivered through PLGA nanoparticles showed sustained release for 24 hours. Park et el in their study proved that Sonic hedgehog intradermal gene therapy using a biodegradable poly (beta-amino esters) nanoparticle facilitated angiogenesis and tissue regeneration by activating angiogenic signaling pathways, thereby enhanced the wound healing.[9] Another study by Archana D et al investigated chitosan nano-dressing to potentiate wound healing and found an excellent antimicrobial and anti inflammatory response.[10]

Carbon Based Nano materials:

Fullerenes and Carbon Nanotubes showed promise in wound healing and angiogenesis. They are powerful Anti-oxidants that are capable of scavenging Reactive Oxygen Species and nitrogen substances. Fullerenes can also be functionalized, thereby reducing their aggregation, altering their solubility as well as reducing their toxicity. [11] Functionalization is done by using hexa-dicarboxyl, tris-dicarboxyl and gamma (γ)-cyclodextrin (CD). Modified Fullerenes are said to have better properties compared to the unmodified ones.[12] Gao et al in their study postulated that tris-C60 significantly reduced the production of proinflammatory cytokines in dermal keratinocytes in a dose/time-dependent manner. [13]

Lipid based Nano materials:

Liposomes loaded with curcumin and quercetin were studied to treat full thickness skin defects in in-vitro and in-vivo models in a study by Castangia et al.[14] They used phytodrugs that possessed antioxidant and anti-inflammatory properties which were able to prevent skin ulceration and enhance early regeneration of wounds. In another study by Fukui et al [15], Liposome-encapsulated hemoglobin accelerated skin wound healing in mice. Study by Plock J et al showed that hemoglobin-loaded phospholipid bilayer vesicles coated with polyethylene glycol (HbVs) improved wound healing and tissue survival in critically ischemic cutaneous wounds in mice. [16]

Metal Based Nano materials:

The most investigated nanoparticle so far is Silver. Silver nanoparticles (AgNPs) have proven to exhibit antimicrobial activity, anti inflammatory as well as anti oxidant potential. [17] Kwan et al, in their study stated that Silver nanoparticles were capable of improving tensile properties of repaired skin by influencing the alignment of collagen. [18] Silver nanoparticles modified with chondroitin sulfate and acharan sulfate were demonstrated to be capable of wound healing and accelerating collagen deposition in the wound area.[19] Dhapte et al in their study found that Green synthesis of silver nanoparticles using Bryonia laciniosa leaf extract improved the cytocompatibility of the particles and had a better effect on wound healing compared to that of a commercially available cream of silver sulfadiazine[20] . A very interesting finding was that, the authors found a scar-less healing which they attributed to the potential of silver to modulate the Pro-inflammatory cytokines (IL-6 and IL-10). Trickler et al [21] and Dykman et al [22] in their studies on Copper and Gold nanoparticles respectively, found that they were capable of enhancing wound healing as well. Potential of Iron oxide in improvement of wound healing was also studied by Ziv-Polat et al, who found that Thrombin-conjugated Iron oxide nanoparticles accelerated the healing of incisional wounds significantly by improving the tensile strength of skin and also reducing scarring.[23]

Ceramic Based Nano materials:

Several materials like Silicates and its derivatives, bioactive glass nanoparticles fall under this category. Krausz AE et al used a Curcumin-TMSO(Tetramethyl orthosilicate) nano material for Wound closure and observed a well organized Granulation tissue,enhanced and organized collagen deposition, improved neovascularization in the wound site.[24] Meddahi-Pelle A et al used Silica nanoparticles for suturing as an alternative to Dermabond (2-octyl cyano-acrylate) and Ethicon sutures in wistar albino rat model and found that they were much more efficient than the compared two. [25]

Melatonin in Wound Healing:

While various nanomaterials such as silver, gold, carbon, zinc oxide, iron oxide, polymers such as PLGA, PCL, chitosan polysaccharides have a successful place as wound healing materials, there is still a need for much effective and potent wound healing stimulators. Once such compound is Melatonin. Melatonin is an indoleamine synthesized and secreted by the pineal

gland, retina, bone marrow and intestines in a circadian rhythm. [26]

Melatonin is of special interest especially in the oral cavity since it is a potent anti oxidant and anti-inflammatory agent. It plays a role in bone remodeling as well. [27] Melatonin is said to promote Osteoblast differentiation, increase the synthesis of type I collagen, Bone matrix proteins such as osteopontin and osteocalcin. [28]-[30] A study by Castrovejo et al showed that melatonin influences bone cell precursors in the bone marrow of rats. [31] Ramirez et al in their animal study proved that melatonin was capable of promoting angiogenesis. [32] Study by Pugazhenthi et al investigated the effect of melatonin on the expression of one of the most potent angiogenic protein, VEGF (Vascular endothelial growth factor) and found a significant increase in VEGF expression. [33] Another study by Soybir et al showed similar results. [34] Several studies have provided evidence that melatonin has significant inhibitory effect on different types of tumors like Breast,Ovary, endometrium, prostrate, intestine, liver and Bone.[35],[36] In addition to this, studies have also shown that melatonin was able to counteract the side effects of chemotherapeutic drugs.[37]

However, melatonin has a short half-life. Thus,encapsulation of melatonin with PLGA particles have had benefits in numerous studies. Zhang et al in their study showed the effectiveness of melatonin encapsulated into PLGA micro and nano particles on osteogenesis of human mesenchymal cells in vitro. [38] Similarly melatonin releasing PLGA nanoparticles seemed to have a good effect on osteosarcoma cells. In addition to these beneficial properties, melatonin loaded on nanohydroxyapatite was capable of regenerating bone in infrabony defects. Thus, formulation and usage of melatonin nanoparticles would have further additional benefits by improving their bioavailability and efficiency. [39]

Conclusion

Beneficial aspects of different nano-materials for wound-healing applications have been reported; however, the underlying molecular mechanisms and signaling pathways are not clearly elucidated or understood. Better understanding of such mechanisms and studies aiming to formulate novel nano-materials such as melatonin will redefine the face of Nanotechnology based wound healing. Further studies involving the development of a nanomaterial using melatonin would have the potential to change the way we look at wounds of the oral cavity.

Evaluation of Etiopathogenesis, Clinical Profile and Lrinec Scoring in Necrotising Soft Tissue Infections

Sahil Mittal[1], Rishab Yadav[2], Kapil Sindhu[3], Parth Patel[1], Pragya Bhagwati[1], Shiva Patel[1]

[1]Junior Resident, Dept. of surgery, [2]Junior Resident, Dept. of Radiology, Dept. of Surgery, [3]Assistant Professor, Dept. of Surgery, MMIMSR, Mullana Ambala

Abstract

Necrotising soft-tissue infections can be defined as infections of any of the layers within the soft tissue compartment that are associated with necrotising changes. NSTI is an uncommon but life-threatening. To resolve this, some authors have developed different diagnostic adjuncts such as finger tests, skin biopsies, bedside ultrasounds and laboratory parameters in distinguishing NSTI from other soft-tissue infections (LRINEC laboratory risk indicator for necrotizing fasciitis score). **Material and Method** : An observational study was conducted in 50 patients (clinically diagnosed necrotising soft tissue infection). clinical observations supported by relevant investigations were documented on the attached proforma and the data so obtained was statistically analysed. **Observation and result** : The results suggested that maximum number of affected individuals are males, middle aged individuals. Majority of patients had normal pulse with mean body temperature of 37.3°C, normal blood pressure,INR, normal serum level of sodium, potassium and bilirubin. High level of RBS (more than 200mg/dl). Tenderness was the most commonly elicited clinical sign of NSTI, crepitus was noted in only 20% patients. Maximum number of patients were found to be infected by streptococcus pyogenes (42%). The mean level was -hemoglobin -10.2+2.3 g/dl, WBC -13,340 + 6116 /mm3, serum creatinine value of s 1.6mg/l. High discrepancy noted in value of CRP. High prevalence of NSTI involving the extremities ranging from 64.39% to 93.The mean value of LRINEC score is 6±2.92 36 % of patients having <6 score and 64% patients having score >6. **Conclusion** : It can be concluded that the local clinical findings are of paramount importance rather than clinical features of systemic toxicity such as fever and tachycardia.

Keywords: *Clinical Profile, Evaluation, LRINEC score,*

Introduction

Necrotizing soft-tissue infections (STIS) can be defined as infections of any of the layers within the soft tissue compartment (dermis subcutaneous tissue, superficial fascia, deep fascia, or muscle) that are associated with necrotizing changes. They are usually caused by the synergistic presence of various aerobic or anaerobic, gas producing or not, bacteria. Their progression is often fulminant and it has been recognised for centuries. NSTI may appear in any anatomical region, multiple layers may be involved at times and, despite the portal of entry being a rupture in the skin continuity, sometimes this cannot be found ([1]) .

The abdomen, perineum and lower limbs are the most common sites of such infections. Practically NSTI may develop after any kind of operation, but more often occurs after incarcerated inguinal hernias, perianal abscesses, urological operations and gynaecological operations [(2,3)] NSTI has been reported after blunt or penetrating trauma, postoperative complications, injection of intravenous drugs or subcutaneous insulin, animal bites, colocutaneous fistula, renal calculi, and idiopathic causes [(4,5)] . A portal of entry as obvious as a tissue injury (iatrogenic or not) or a bite (animal or human) is required for the development of a NSTI. However, these infections may occur without such obvious portal of entry [(6)] . Once susceptible patients are colonised, the causative bacteria produce toxic proteolytic enzymes that allow for tissue invasion [(7)] . Anaerobic environment and vascular thrombosis in the affected area accelerate bacteria proliferation and, through hematogenous spread, a distant infection may occur [(8)].

Predisposing factors of NSTI include advanced age, diabetes mellitus, malnutrition or obesity, drug abuse, corticosteroid use, immunosuppression, AIDS, chronic obstructive lung disease (COPD) together with the chronic use of steroids, serious trauma, and chronic venous or lymph insufficiency with tissue oedema [9,10] . The presence of a foreign body in combination with/or dead tissue formation, urgent and extensive abdominal or perineal operations, as well as tissue ischemia (most often due to tight sutures, haematomas, peripheral angiopathy, irradiation and wide bums), are considered to be local predisposing factors [11, 12].

It is an uncommon but life-threatening disease with a high mortality rate (ranging from 6 to 76%) despite advances in modern medical care [1-3]. Delays in diagnosis and in operations for debridement are associated with increased mortality [1, 6]. Lack of specific clinical features and characteristics in the initial stages of the disease may be the main reason for the failure of early recognition of NSTI [8] . The purpose of this study was to develop a detailed clinical profile of necrotising soft tissue infections as an aid to diagnosis and management.

Material and Method

The study was conducted in the department of General Surgery,Maharishi Markandeshwar Institute Of Medical Sciences And Research (MMIMSR) Mulana, Ambala which is a tertiary care institute situated in Haryana, a northern state of India. All the patients of NSTIs admitted under department of general surgery were included in the study with effect from 1st October 2017- 30 September 2019.

A minimum of 50 patients formed subjects of the study.

Inclusion Criteria :

Patients presenting with infections of any of the layers of soft tissue compartment which includes dermis, subcutaneous tissue, superficial fascia, deep fascia or muscle which are accompanied by necrotising changes.

Exclusion Criteria :

1. Patient not giving their consent.
2. Patients lost in follow-up.
3. Patients not found to have NSTI's.

Study Tools

Following study tools were used for present study :

1. Clinical assessment and observation along with signs and symptoms of patients.

2. Laboratory investigations including The LRINEC score.

Study Protocol

All the patients included in the study were subjected to the following investigations-

Hematological investigations

- completehemogram.
- Fasting blood sugar
- Random blood sugar
- Serum sodium
- Serum potassium
- Serum creatinine
- Blood urea
- Liver function test including serum bilirubin (total and direct) alkaline phosphatase, aspartate transaminase, alanine transaminase and serum albumin.
- Coagulation profile which includes bleeding time, clotting time and PT/INR.
- C-reactive protein.

Radiological investigation wherever needed which includes:

Plain X Ray of the part

Computed tomography (CT scan)

Magnetic Resonance Imaging (MRI)

Histopathological confirmation of diagnosis was done from the biopsy of the involved tissue procured at the time of surgery. Tissue culture and antibiogram were done to identify pathogens and sensitivity.

Observation and Results

Mean age of the study population was 48.1± 17.7 years. Majority of patients were seen to be between 40 to 70 years of age. Tachycardia was reported in overall 28% of patients. Only 10 (20%) of patients NSTI, were

found to be febrile. Hypotension was seen in 6 (12%) of patients of NSTI, with blood pressure <90/60 mm of Hg. Majority of the patients in the present study had normal blood pressure. Tenderness was the most commonly reported clinical presentation of NSTI, with 45 (90%) of patients having tenderness of the involved region. Other commonly reported manifestations included skin discoloration (80) %, edema of overlying skin (68%), swelling (66%), warmth (66%) and exudative discharge (60%). Bleeding was the least common (2%) clinical presentation of NSTI in our study population. 46 patients had low hemoglobin levels of ≤13.5g/dl with 10 (20%) of them having sever anemia, with Hb< 8g/dl. The entire study population had a mean Hb of 10.2±2.3 gm/dl. Very high WBC counts of more than 25000 / cu mm were seen in 4 (8%) of the subjects with mean of 13,340±6116/ cumm. Mean RBS value for the entire study population was 180±117 gm/dl. 15 (30%) of patients had serum creatinine of more than 1.6mg/ dl with a mean of 1.40±0.72 mg/l. In this study there are 36% of cases having the LRINEC score ≤ 5. While 26% cases having score 6-7, only 38% have score 8 or above, suggesting that 36% of cases are expected to have <50% expectancy of having NSTI, while 26% cases are expected to have NSTI to about 50-75% and 38% cases have chance of having NSTI by 75% and above having mean value 6±2.92

Table1:Distribution of patients based on local examination

Clinical presentation	Number of patients (n=50)	Percentage
Skin discolouration	40	80%
Swelling	33	66%
Warmth	33	66%
Tenderness	45	90%
Edema ofoverlyingskin	34	68%
Crepitus	10	20%
Dermalgangrene/necrosis	25	50%
Exudate	30	60%
Foul Odour	15	30%
Bleeding	1	2%
Ulceration	25	50%

LRINEC Score	Number of patients (n=50)	Percentage
≤5	18	36%
6-7	13	26%
≥8	19	38%

Discussion

Taking into account all the values, LRINEC scoring was done.The mean value of LRINEC score is 6±2.92 in our study. Similar findings are seen in the study by D. J. Tilkom et al (88) in which 25 out 30 patients (83.3%) had a LRINEC score > 6. Only in 5 patients (16,7%), the LRINEC score was <6, also it showed the LRINEC mean value of 7.3 against the values in our study showing 12 (27 %) in < 6 score and 32 (73 %) patients.

Similarly in a study done by Chin-Ho Wong et al (71), using the LRINEC score, he stratified the patients into three groups, low (LRINEC score <5), moderate (LRINEC score 6-7), or high (LRINEC score >8) risk categories for NSTI. These risk groups corresponded to a probability developing NSTI of <50%, 50-75%, and >75%, respectively. 89.99% of patients with NSTI had a LRINEC score of > 6 whereas only 10.1% had a score score of <6, comparative to our study having 36 % of patients having <6 score and 64% patients having score > 6. The mean value of our study Was6 ± 2.92, comparable to Wong's value of 7. This finding shows the LRINEC score is capable of detecting early cases of NSTI among patients with severe soft tissue infections. A LRINEC score of >6 should raise the suspicion of NSTI, and a score of is strongly predictive of this disease. The LRINEC score can significantly decrease the time to b diagnosis by stratifying patients into risk categories for NSTI warranting immediate further evaluation. Clinical variables alone are often nonspecific early in the course of the disease and can potentially lead to fatal delay operative treatment. A diagnostic score that includes clinical as well as laboratory variables would inevitably favour advance cases of NSTI where clinical recognition is usually not a problem) and risk missing early cases of NSTI (where early diagnosis would profoundly affect outcome). An objective diagnostic tool based on laboratory variables alone to assess for the possibility of NSTI is therefore advocated.

Conclusion

For the diagnosis of NSTI the local clinical findings viztenderness, skin discolouration are of paramount importance rather than clinical features of systemic toxicity such as fever and tachycardia.

Simple laboratory evaluation using the LRINEC scoring system is useful for diagnosing NSTI. A higher score (>6) is highly predictive of presence of NSTI, however a lower score (<5) does not altogether rule out the possibility of NSTI.

The microbiology of NSTI reveals majority of infections being mono microbial and caused by skin based organisms (staphylococci and streptococci). Therefore tissue culture and gram positive coverage are vital for NSTI patients.

Competing Interests: The authors declare that there is no conflict of interest in this study.

Funding: All funds in this study were covered by the personal fund of the authors.

Conflict of Intrest: Nil

Ethics Committee: Ethical clearance taken from institutional ethical committee.

Prevalence of Knee Joint Dysfunction in Multiparous Pregnant Women

Sakshi Pradeep Shah[1], Pranjali Gosavi[2]

[1]*Final year BPTh Student, Krishna college of physiotherapy, KIMSDU.* [2]*Assistant Professor, Department of Community Health Science*

Abstract

During pregnancy, physiological and hormonal changes lead to increase in ligament laxity and postural changes. Damage to the ligaments of knee joint, and other knee problems which results in increase in the risk of fall in pregnant women. **Objective:** The study was done to determine the prevalence of knee joint dysfunction in multiparous pregnant women. **Method:** The study involved 66 multiparous women at KIMSDU. Each of them was assessed for right and left Q angle and also knee joint proprioception was recorded by using goniometer. Signs and symptoms of knee joint dysfunction were graded based on lysholm knee scoring scale. **Result**: On the basis of this study 29% of women showed signs and symptoms of knee joint dysfunction. 47 subjects had excellent and 19 subjects had poor joint condition. 44 had normal Q angle and 21 had altered Q angle. There are significant changes in knee joint proprioception. **Conclusion:** The study concluded that there is prevalence of knee joint dysfunction in multiparous pregnant women.

Key words: *Multiparous women, knee dysfunction*

Introduction

According to world health organization, pregnancy is nine month or so for which a women carries a developing embryo and fetus in her womb. Pregnant women often experience musculoskeletal problems related to lower extremity due to hormonal, anatomical, and physiologic changes throughout the pregnancy. Symptoms like muscle strain, cramps, pain, fatigue and soreness of knee, hip, ankle are often experienced.[1] Most women do not take medical help until discomforts start interfering their lives. These results in physical changes that occur in pregnancy and results in biomechanical effects upon functional movements.[2]

Physiological changes

Physiological changes during pregnancy are as result of hormonally mediated changes in the collagen and involuntary muscle, increased blood volume, increased blood flow to fetus resulting in consequent enlargement of uterus and increase in body weight and adaptive changes in centre of gravity and posture.[3]

There is increased level of estrogens, progesterone, and relaxin during pregnancy. These increase in levels of hormones are to ease the parturition Especially relaxin has effect on joint laxity. Relaxin hormone is produced by corpus luteum and deciduas .The action of relaxin is to decrease the strength and rigidity of collagen, softening of ligaments that support the joints. So there is a gradual replacement of collagen in the target tissues with remodeled form which has greater extensibility and pliability.[4] So as a result joint becomes more mobile and less stable and hence likelihood of injury to the joints is increased. Pregnancy related ligament laxity may lead to joint instability. There is 50% increase in joint laxity in multipara women compared to primipara women.[1]

Estrogren and progesterone also associated with vestibular affection such as dizziness, vertigo, instability.

Musculoskeletal changes

Musculoskeletal changes during pregnancy have effect on musculoskeletal system.

Weight gain: There is 20% weight gain during pregnancy which can double the force across the hip and knee joint.[1] throughout the pregnancy there is 10 kg to 14 kg weight gain takes place. The average weight gain in primigravidae is 12.5kg and in multigravidae it is probably 0.9 kg less than primigravidae[4] Overloading of the joint due to weight gain and postural realignment causes postural instability.

Postural changes: postural changes in the pregnancy include an increase in lordotic curve in cervical and lumbar region of vertebral column, protraction of shoulder girdle, hyperextension of knee, anterior pelvic tilt, and flat foot. There is forward shifting of centre of gravity.[4,5]

Muscular imbalance: some muscle groups require to work more in order to maintain upright position in order to compensate changes in posture.[1] The muscles that goes into tightness are hip flexors i.e. quadriceps and hamstring and gluteus group of muscles goes into weakness.[4]

Laxity in ligament: laxity in ligament is present due to hormonal changes especially due to increased level of relaxin hormone.[6] knee anterior cruciate ligament laxity is mainly seen. According to the previous study it is seen that laxity had already reached its maximum value during the first half of pregnancy. And found to be constant until the end of pregnancy.

Knee joint dysfunction

Knee joint is modified hinge joint. The ligaments present in the knee are medial collateral ligament, lateral collateral ligament, anterior cruciate ligament and posterior cruciate ligament. These ligaments provide strength and stability to knee joint.[7]

Hyperextension of knee can further cause soft tissue damage, swelling and strain on the ligaments around knee. There is also increase in Q angle (excessive valgus quadriceps angle). [1,2] Any alteration in Q angle increases the lateral force on patella and may lead to subluxation of patella. Q angle is increased by increased femoral anteversion and external tibial torsion.

Static and dynamic stabilizers provide support to the knee. Ligaments, meniscus, and joint capsule play a role of static stabilizer. But there are hormonal changes in pregnancy; especially there is increase in relaxin hormone which causes increase in ligament laxity which further leads to joint instability. Oestrogen receptors are also present in anterior cruciate ligament. Anterior cruciate ligament provides two functions which are mechanical and sensory (proprioceptive). Due to increased level of estrogen, it affects ligament in a such way that it affects tensile properties.[8]

Oedema in the feet which occurs normally in latter part of pregnancy which results from extra blood accumulated during pregnancy and also enlarging uterus puts pressure on the blood vessels of pelvis and legs which causes circulation to slow down and blood to pool in lower extremity. [2,3]

Due to increased laxity in plantar calcaneonavicular ligament (spring ligament), there is also over pronation of feet, also called as flat foot. Flat foot is caused when persons arch flattens on weight bearing, the over pronated foot posture leads to femoral anteversion, external tibial torsion of knee. This produces shear stress on medial tibiofemoral and lateral patellofemoral compartment of knee. This causes pain in the knee. [1,6]

There is onset of pain during the second and third trimester of pregnancy. One of the most commonly seen is cramping pain of gastrocnemius soleus complex which lasts for several minutes. It may due to anterior displacement of center of mass which causes stress on lower extremity.

Proprioception is repetitive neutral input to central nervous system from specialized nerve ending called mechanoreceptors that are located in joints, capsule, ligament muscles, tendons and skin. proprioceptors gives about conscious and unconscious appreciation of joint position, kinaesthesia and perception of force which is essential for anticipation of movement and motor learning. Proprioception helps in carrying out smooth coordinated movements, it also regulate balance and postural control.[8] Proprioception depend mainly upon somatosensory system, visual system and vestibular system.

Increased ligament laxity can also alter joint proprioception. There is interruption of flow of impulses from the mechanoreceptors in a joint capsule into central nervous system, which results in disturbances in joint position and movement.[9] This may affect the balance and postural control in pregnant women which in turn may result in increased rate of falls. Joint pain and changed muscle activity, alteration in ligamentous condition results in narrowing of the joint space and which can

affect joint proprioception. Delayed muscle latencies have been seen due to impairment of proprioceptive activity. Hence assessment of proprioception is valuable for identifying proprioceptive deficit. During pregnancy especially during third trimester due to decrease in balance, a fall rate of 27% has been reported which in turn may cause maternal and fetal complication.[10]

Also it is seen that the changes that takes place during pregnancy may also last in postpartum period and can lead to musculoskeletal dysfunction. Women continue to use their gait pattern which was acquired during pregnancy.[1] There is paucity of literature in ruling out knee joint dysfunction in multiparous pregnant women.

Method

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. Total 66 subjects were approached. Subjects were selected according to inclusion and exclusion criteria. The procedure was explained and written informed consent was taken from those who were willing to participate.

Demographic information of the subjects was taken. The subjects were explained about the purpose of the study. Also, they were informed about the procedure. Each of them was assessed for right and left Q angle and also knee joint proprioception was recorded by using universal goniometer. They were graded according to their signs and symptoms based on lysholm knee scoring scale. Data was recorded. Later statistical analysis was done in accordance to distribution of the age, lysholm knee scoring scale, Q angle measurement and knee proprioception.

Statistical Analysis

· Statistical analysis of the recorded data was done by using the graphpad instat.

· Arithmetic mean & standard deviation was calculated for each outcome measure.

· Arithmetic mean was derived from adding all the values together and dividing the total number of values.

· MS Excel was used for drawing various graphs with given frequencies and the various percentages that were calculated with the software.

· Standard deviation (SD) was calculated according to the following formula.

$$SD = \sqrt{\frac{\sum (X-\bar{X})^2}{N}}$$

Where, √= Square root of all the calculations under this symbol.

X = the individual score.

$\bar{X}$ = the mean score.

∑ = sum of all the calculations to the right.

N = the total number of frequency.

Results

Data Presentation, Analysis and Interpretation

TABLE NO 1: MEAN AND STANDARD DEVIATION OF AGE WISE DISTRIBUTION.

	Excellent joint condition.	Poor joint condition.
Mean+ SD	92.48+5.38	74.26+6.49

According to chi- square test, the difference is considered as not statistically significant (p=0.5722).

Association between Age Group and Knee Joint Condition.

This table shows that, association between age and joint condition by Chi-Square test, it's was found to be (0.3190) with 1 degree of freedom and p-value of (0.5722) which was not significant.

Lysholm Knee Scoring Scale:

Table No 2: Lysholm Knee Score

Excellent / good knee joint condition	Fair / poor joint condition
47	19

Interpretation: According to graph 2, 47(71%) subjects had excellent or good joint condition and 19(29%) subjects had fair or poor joint condition.

RIGHT SIDE Q ANGLE

	POOR	EXCELLENT
NORMAL(13.5-17.5)	14.18+1.34	14.82+1.54
ALTERED(>17.5)	18.93+0.77	18.53+0.55

TABLE NO 3: MEAN AND STANDARD DEVIATION OF RIGHT Q ANGLE

ASSOCIATION BETWEEN RIGHT SIDE Q ANGLE AND KNEE JOINT CONDITION.

Association between right side Q angle and joint condition by Chi-Square test, it's was found to be (0.7208) with 1 degree of freedom and p-value of (0.3959) which was not significant

Left Q Angle:

Table No 4: Mean and standard deviation of left Q angle

	Poor	Excellent
Normal(13.5-17.5)	14.18+1.34	14.82+1.54
Altered(>17.5)	18.93+0.77	18.53+0.55

Association Between Left Side Q Angle and Knee Joint Condition.

Association between age and joint condition by Chi-Square test, it' was found to be (0.7208) with 1 degree of freedom and p-va of (0.3959) which was not significant.

Right and Left Side Knee Proprioception:

Table no 5: Mean and standard deviation of right and left knee proprioception.

Joint Proprioception	Poor	Excellent
Right knee proprioception	13.68+8.75	12.93+7.83
Left knee proprioception	14.63+8.22	11.91+8.21

Disscussion

Knee joint is a important weight bearing joint. Normal functioning of the the knee joint during pregnancy is necessary because any malfunctioning in the knee joint can increase the risk of fall and which is harmful to mother as well as fetus.

Normally the forces transmitted across knee joint ranges between 2 to 3 times of body weight. There is approximately 20% increase in body weight during pregnancy which can place more stress over knee joint. So as a result forces transmitted across knee joint increases. Physiological changes in pregnancy like changes in collagen fibers, involuntary muscle, increase in blood volume, increased blood supply to fetus also contribute in increase in body weight which again can affect knee joint.

The purpose of this study is to find out the prevalence of knee joint dysfunction in multiparous pregnant women.

The objectives of this study were to observe the signs and symptoms of knee joint dysfunction in multiparous pregnant women, to assess their Q angle and to assess the knee joint proprioception.

The study was carried out and the result was drawn by lysholm knee scoring scale, universal goniometery.

Sample size was 66 and age group included were 25-40 years .The subjects were taken from Krishna hospital, karad. The included subjects were multiparous. They all didn't have any recent knee joint surgery, any recent trauma, history of patella subluxation or dislocation, and high risk pregnancy disorder. Then consent form was taken from the subjects.

It is seen during one of the study that there is onset of pain during the second and third trimester of pregnancy. One of the most commonly seen is cramping pain of gastrocnemius soleus complex which lasts for several minutes. It may due to anterior displacement of center of mass which causes stress on lower extremity.

According to table 1, it was found that in the age group between 25-30, 30(45%) subjects had excellent or good joint condition and 10(15%) subjects had fair or poor joint condition. Where in the age group between 31-35,17(26%) had excellent or good joint condition and 9(14%) subjects had fair or poor joint condition. According to chi- square Test, the difference is considered as not statistically significant (p=0.5722).

According to table 2, 47(71%) subjects had excellent or good joint condition and 19(29%) subjects had fair or poor joint condition.

According to table 3, 34(52%) subjects with excellent joint condition and 11(17%) with poor joint condition had normal left Q angle (13.5-17.5). and 13(20%) subjects with excellent joint condition and 8(12%) subjects with poor joint condition had altered left Q angle(>17.5).

Association between right side and left side Q angle and joint condition by Chi-Square test, it's found to be (0.7208) with 1 degree of freedom and p-value of (0.3959) which was not significant.

According to table 4, 34(52%) subjects with excellent joint condition and 11(17%) with poor joint condition had normal left Q angle (13.5-17.5). and 13(20%) subjects with excellent joint condition and 8(12%) subjects with poor joint condition had altered left Q angle(>17.5).

Association between age and joint condition by Chi-Square test, it's was found to be (0.7208) with 1 degree of freedom and p-value of (0.3959) which was not significant.

According to table no.5, the mean and standard deviation of the right side knee proprioception in excellent joint condition were 12.93 and 7.83 respectively. And while in poor joint condition it was 13.68 and 8.75 respectively.

According to table no.6, the mean and standard deviation of the left side knee proprioception in excellent joint condition were 11.91 and 8.21 respectively. And while in poor joint condition it was 14.63 and 8.22 respectively.

The study done by Dr Deepa Abichandani on Comparison of knee proprioception during three trimester of pregnancy was concluded that there is decline in knee joint position sense over three trimester of pregnancy.

According to calguneri et al observation there is 50% increase in joint laxity in multipara women compared to primipara women.

The study done by T. BANYAI, A. HAGA, et al. on knee joint stiffness and proprioception during pregnancy concluded that non pregnant women had better knee joint proprioception than pregnant women. According to this study we got knee proprioception is altered in some patient.

According to this study 21 subjects had altered Q angle (>17.5) out of 66 subjects. Prevalence of 29% of knee joint dysfunction in multiparous pregnant women was present.

Conclusion

According to the present study conducted prevalence of 71% subjects were having excellent or good knee joint condition with no or minimum symptoms of knee joint dysfunction and 29 % subjects were having fair or poor knee joint condition in multiparous pregnant women. 61% subjects had normal Q angle (13.5-14.5) and 31% subjects had altered Q angle (>17.5). According to statistical analysis significant changes were seen in knee joint proprioception in multiparous pregnant women.

Acknowledgement: The authors are very grateful to all the pregnant women who participated in the study.

Conflict of Interest: None.

Ethical Clearance: Ethical clearance was taken from institutional committee of Krishna institute of medical sciences, deemed to be university.

Source of Funding: Self funded.

Effectiveness of Planned Teaching Program On Knowledge Regarding Prevention of Neonatal Hypothermia Among Postnatal Mothers

Sarika Yadav[1], Sonia[1]

[1]Assistant Professor, [2]Assistant Professor, Indian Nursing Council, SGT University, Budhera Gurugram

Abstract

Background:Neonatal hypothermia is increasingly recognized as a risk factor for newborn survival. The World Health Organization recommends maintaining a warm chain and skin-to-skin care for thermo protection of newborn children. **OBJECTIVE** To assess the knowledge of postnatal mothers regarding prevention of neonatal hypothermia.To prepare and conduct planned teaching program for postnatal mothers regarding prevention of neonatal hypothermia. To evaluate the effectiveness of planned teaching program for postnatal mothers regarding prevention of neonatal hypothermia.To find out the association of pretest knowledge score and selected demographic variables. **METHOD** The pre experimental (pretest-post test group) design was adopted . Convenient sample technique was used to select the 30 postnatal mothers as sample. Pretest was conducted using questionnaire after that pretest a planned teaching program was conducted for the post test . **RESULT** The findings of the study revealed that majority (90%) had low knowledge, 10% had average knowledge regarding prevention of neonatal hypothermia in pre test.Similarly, the post test scores depicted that majority (80%) had good knowledge, 20% had average knowledge and none of them had low knowledge regarding prevention of neonatal hypothermia. Most of demographic variables were not significantly associated with level of pre knowledge of postnatal mothers regarding prevention of neonatal hypothermia. Only mother's education status ($x^2 = 8.585$ in the pretest and df=2 and p=0.014) were found to be statistically significant at 0.05 level of significance. **CONCLUSION** This study showed that, the postnatal mother's knowledge regarding prevention of neonatal hypothermia was low and planned teaching program is effective to improve their knowledge.

Key words: *Neonatal Hypothermia, Warm chain, Postnatal Mother, planned teaching program, knowledge)*

Introduction

A neonate is a god's divine precious gift given to a mother. Hence the birth of a neonate is one of the most awe inspiring and marvellous joyful events that occur in every woman's life time. The cry of neonate is the only means of communication and brings a message that "I need care". This also aims at keeping the newborn safe from the environmental and practical harm such as maintaining the normal body temperature.

Corresponding Author:

Assistant Professor, Indian Nursing Council, SGT University, Correspondence Address: SGT University, Budhera Gurugram, Email: sarika@sgtuniversity,.org
Contac No: 9560157710

Newborns are more prone to get hypothermia because of their limited ability to generate and conserve heat. Hypothermia is an essential aspect of neonatal care especially in the immediate neonatal period. So great care is necessary by cloth the baby properly and to maintain the surrounding temperature and humidity, which suits the individual infant.

Neonatal Hypothermia has been defined by WHO as body temperature below the normal range (36.5°C – 37.5°C) and has been sub-classified into three grades: mild (36.0°C – 36 .5°C), moderate (32.0°C – 35.9°C), and severe (<32.0°C) hypothermia.

Each year an estimated 3.6 million neonatal deaths occur, primarily due to infection, complications of preterm birth, and intra-partum related hypoxic events

Infections are estimated to account for approximately one-third of the global burden of neonatal death, with estimates rising to more than half in high mortality settings

Neonatal hypothermia is a major contributor to neonatal illnesses and deaths both in the developed and developing parts of the world of 150 babies aged 0 to 648 hours, 93 had hypothermia with an incidence of 62%. Mild and moderate hypothermia accounted for 47.3% and 52.7% respectively. The incidence of hypothermia was highest (72.4%) among babies aged less than 24 hours. It was also higher among out-born babies compared to in-born babies (64.4%). Preterm babies had significantly higher incidence of hypothermia (82.5%) compared with 54.5% of term babies.[3]

Caring for a newborn is one of life's biggest challenges to care for a newborn child and can be somewhat more difficult than caring for an older infant. a newborn baby's basic need is pretty clear; to be comfortable and to be fed. Hypothermia in neonate is a common problem and is associated with increased morbidity and mortality. Prevention of Hypothermia is therefore an essential aspect of neonatal care especially in the immediate neonatal period.

Objective

· To assess the knowledge of postnatal mothers regarding prevention of neonatal hypothermia.

· To prepare and conduct planned teaching program for postnatal mothers regarding prevention of neonatal hypothermia.

· To evaluate the effectiveness of planned teaching program for postnatal mothers regarding prevention of neonatal hypothermia.

· To find out the association of pretest knowledge score and selected demographic variables.

Hypothesis:

· **Null Hypothesis (H0)**: There will be no statistically significant association between pre-test knowledge scores and selected demographic variables

· **Research Hypothesis (H1):** There will be statistically significant association between pre-test knowledge scores and selected demographic variables

Material and Method

The research design selected for present study was pre-experimental one group pre-test and post-test design to assess knowledge of postnatal mothers regarding prevention of neonatal hypothermia. The present study was conducted at selected OBG Ward, SGT hospital, Gurugram . the population comprised of mothers admitted in OBG ward in SGT hospital, Gurugram.The samples in this study were 30 postnatal mothers. Non probability - convenient sampling technique is used for selecting the samples.

Sampling Criteria

Non probability - convenient sampling technique is used for selecting the samples. Primi and multi gravida mothers admitted in postnatal ward. Who are willing to participate and present during data collection were included. While Mothers who are illiterate. Mothers of neonate those who are severely ill at the time of data collection.

Description of the Tool:

Data collection tools and technique tools are given as under.

Section I: Items on selected baseline data include age, marital status, educational status of mother, religion, area of living, source of information, type of family.

Section II: Items assessing the knowledge of mothers

Part-I : .General questions related to neonatal hypothermia.

Part-II : Questions related to causes and sign &symptoms of neonatal hypothermia.

Part-II : Questions related to prevention & management of neonatal hypothermia.

For the 20 items on knowledge of prevention and management of neonatal hypothermia, a score of '1' was awarded to correct response, which a score of '(o)' was awarded to an incorrect response.

Procedure for Data Collection:

The research investigator obtained ethical clearance and formal permission from the Medical Superintendent, SGT hospital, Gurugram to collect data for the main study. The main study was conducted at Post natal ward

of OBG Ward SGT hospital, Gurugram from 25 April to 9 May 2017.

The steps used for data collection were mentioned below:

1. Written permission was obtained from Dean, Faculty of Nursing SGT University

2. Formal permission was obtained from the Medical Superintendent, SGT hospital, Gurugram.

3. Selected the subjects as per inclusion criteria.

4. On the day of pre-test, at the very beginning, self introduction of investigator to mothers and were explained the purpose of the study.

5. Informed written consent was obtained from each subjects for willingness to participate in the study.

6. The pre-test was conducted on 20 April 2017 Which included items to assess the

knowledge of mothers regarding neonatal hypothermia.

7. Planned teaching programme was administered at the end of pretest.

8. The post-test was taken after 30 minute after administration of PTP using the same

structured knowledge questionnaire used for the pre-test.

9. Data collected was tabulated and analyzed.

Content Validity:

The tool & lesson plan blue print and the lesson plan for planned teaching programme were evaluated by 5 experts in the areas of Child Health Nursing.

Reliability:

Reliability of an instrument is the consistency with which it measures the target attribute. An instrument is reliable to the extent that its measures reflect true reliability of the tool was assessed by administering the tool to 10 postnatal mothers who are admitted in OBG ward in SGT hospital, Gurugram. Reliability of the section of the tool consisting of knowledge questions was tested by Split Half method using Karl Pearson's co-efficient of correlation formula and the reliability computed was r = 0.78. The content validity index [CVI] across the expert's ratings of each item relevance was calculated. A CVI of 0.75 was found for the structured knowledge questionnaire. A CVI of 0.87 was found for planned teaching programme.

Plan For Data Analysis:

The data obtained was analyzed in terms of the objectives of the study using descriptive and inferential statistics. Experts in the field of nursing and statistics directed the development of data analysis plan, which was as follows:

· Organizing data on a master sheet

· Computation of frequency percentage to describe background data and computation of mean, standard deviation and range to describe the data on knowledge scores.

· Classifying knowledge scores using mean, and standard deviation as follows:

X + SD = Good score

X – SD to X+ SD = Average score

X– SD = Poor score

A score of '1' was awarded to a correct response while a score of 'O' was awarded to an incorrect response for the 20 knowledge items

Table 1: **Frequency and percentage distribution according to socio demographic variables.**

Socio-demographic variables		Frequency	Percentage
Age	Less than 20 year	3	10%
	Between 20-30 year	26	86.67%
	More than 30 year	1	3.33%
Marital status	Single	0	0%
	Married	30	100%
	Divorced	0	0%
	Widow	0	0%
Educational status	Illiterate	0	0%
	Under graduate	25	83.33%
	Graduate	5	16.67%
Religion	Hindu	30	100%
	Muslim	0	0%
	Sikh	0	0%
	Christian	0	0%
Area of living	Rural	23	76.67%
	Urban	7	23.33%
	Slum	0	0%
Source of information	Family and friends	15	50%
	Mass media	8	26.67%
	Health personals	4	13.33%
	Any other	3	10%
Type of family	Nuclear family	10	33.33%
	Joint family	20	66.67%
	Extended family	0	0%

Table 2: a. Assessment of level of knowledge of postnatal mothers regarding prevention of neonatal hypothermia in pre and post test.

Level of knowledge	Range of scores	Pre test		Post test	
		No. of respondent	Percentage of score	No. of respondent	Percentage of score
Good	15-20	0	0%	24	80%
Average	10-14	3	10%	6	20%
Low	0-9	27	90%	0	0%

The pretest scores displayed in the table-2 disclosed that majority (90%) had low knowledge, 10% had average knowledge regarding prevention of neonatal hypothermia.

Similarly, the post test scores depicted that majority (80%) had good knowledge, 20% had average knowledge and none of them had low knowledge regarding prevention of neonatal hypothermia.

Table-3: Description of evaluation effectiveness of planned Teaching Programme regarding Prevention of neonatal Hypothermia

	Mean	S.D	Standard error	Calculated t value	df	p value
Pre test-post test knowledge	6.000	2.803	0.511	11.720	29	0.000

The data presented in table-5 presents that the mean value of knowledge scores between pre and post test was 6.000, S.D was 2.803, Standard error was 0.511. The calculated "t" value was 11.720 (in 29 degrees of freedom) and p =0.000 which is significant at the level of 0.05.

So there is the significant difference between the knowledge of post natal mothers before and after the implementation of planned teaching program

Table-4 : Data on association between selected demographic variables of the postnatal mothers and their knowledge (Chi-square test) regarding prevention of neonatal hypothermia.

Demographic variables	Pre test x2 value	Df	P value
Age	5.275	4	0.260
Education status	8.585	2	0.014
Area of living	0.842	2	0.657
Source of information	9.231	6	0.161
Type of family	0.074	2	0.964

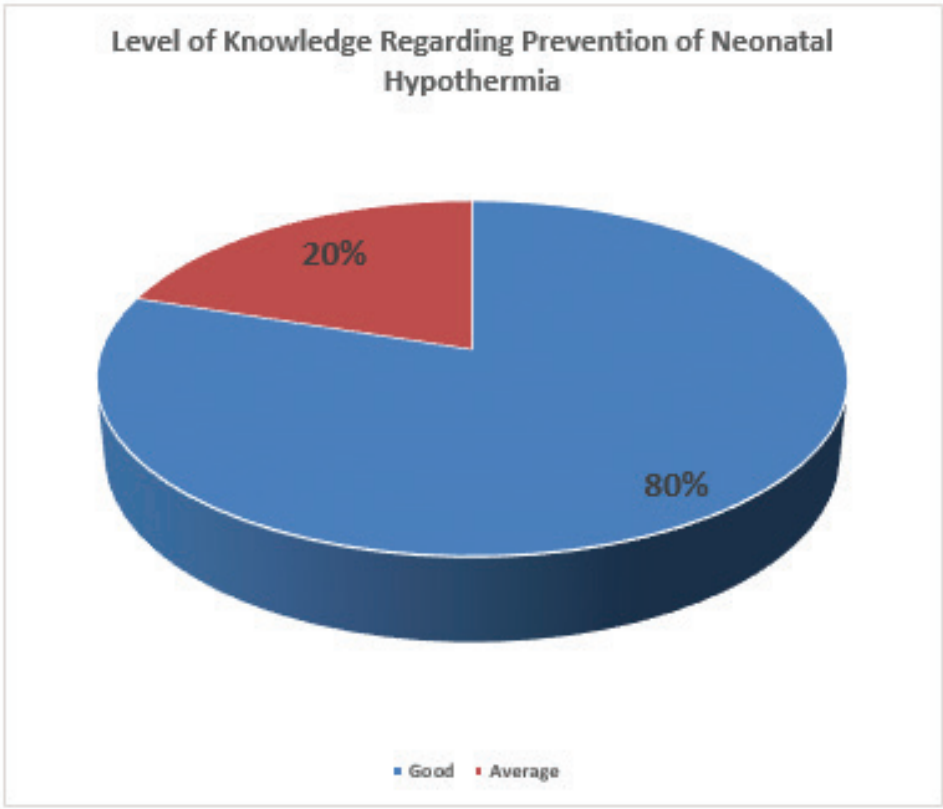
Above table reveals that the chi-square values showing the association between the selected demographic variables (age, education status, area of living, source of information, type of family) and the pre knowledge levels of the postnatal mothers regarding prevention of neonatal hypothermia.

It is seen in table that the chi-square values computed between pre knowledge scores and age (x^2= 5.275 in the pretest and df=4 and p=0.260), area of living (x^2 = 0.842 in the pretest and df =2 and p=0.657), source of information (x^2 = 9.231 in the pre test and df=6 and p=0.161) and type of family (x^2 = 0.074 in the pretest and df=2 and p=0.964) were not found to be statistically significant at 0.05 level of significance. So, there is no association of pretest knowledge score of post natal mothers with selected demographic variables.

Where as education status (x^2 = 8.585 in the pretest and df=2 and p=0.014) were found to be statistically significant at 0.05 level of significance. So, there is association of pretest knowledge score of post natal mothers with education.

FIG-2: Percentage Distribution of Pre Test knowledge regarding Prevention of Neonatal Hypothermia among post natal mothers

FIG-1: Percentage Distribution of post Test knowledge regarding Prevention of Neonatal Hypothermia among post natal mothers.



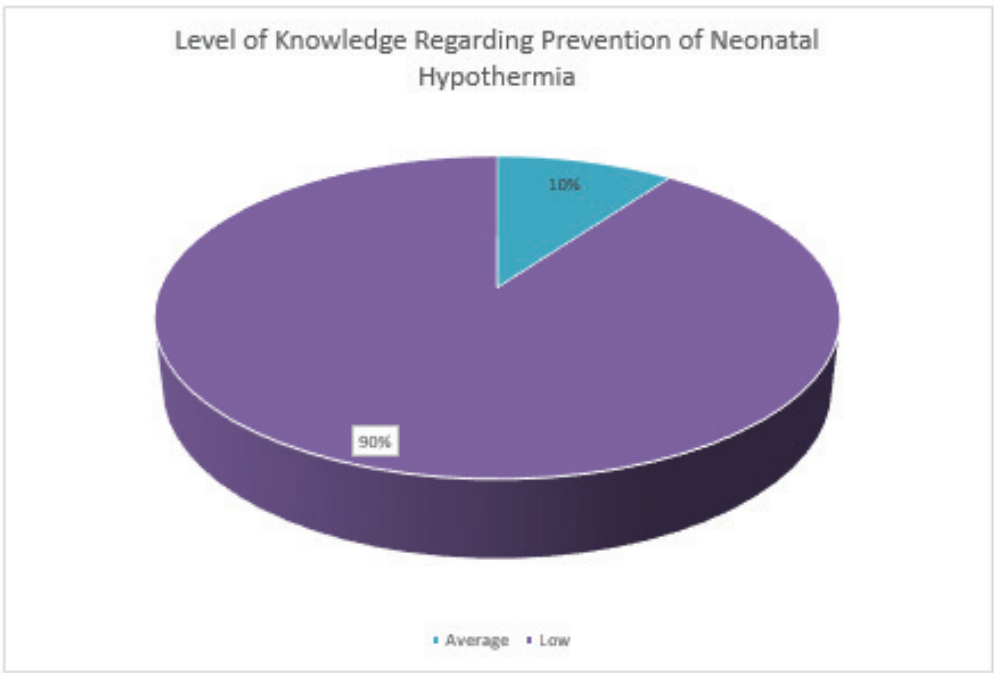


FIG-2: Percentage Distribution of Pre Test knowledge regarding Prevention of Neonatal Hypothermia among post natal mothers

Result

- The data reveals that 10% of the respondents were less than the age group of 20 years, 86.67% of them were between the age group of 20-30 years and only 3.33% were more than the age group of 30 year.100% of the respondents were married.
- None of them were single, divorced, widow.83.33% of the respondents were undergraduate, 16.67%were graduate, whereas no one was illiterate 100% of the respondents were Hindu.
- None of them were Muslim, Sikh, and Christian.76.67% of the respondents were living in rural area, 23.33% were living in urban area, whereas no one was living in slum area .
- The sources of information regarding prevention of neonatal hypothermia among the respondents from family and friends were 50%, mass media 26.67%, health personals 13.33% and from any other was 10%. respectively .
- The majority of respondent (66.67%) were living in joint family, 33.33% were living in nuclear family. None of them were living in the extended family.
- The mean knowledge scores in pretest was 10.133 and in post test was 16.133. This evidenced that there was a significant increase in the scores of post test when compared to pretest. So, we can summarize that the knowledge was increased after planned teaching program.
- The chi-square values computed between pre knowledge scores and age (x^2= 5.275 in the pretest and df=4 and p=0.260), area of living (x^2 = 0.842 in the pretest and df =2 and p=0.657), source of information (x^2 = 9.231 in the pre test and df=6 and p=0.161) and type of family (x^2 = 0.074 in the pretest and df=2 and p=0.964) were not found to be statistically significant at 0.05 level of significance.
- So, there is no association of pretest knowledge score of post natal mothers with selected demographic variables.Where as education status (x^2 = 8.585 in the pretest and df=2 and p=0.014) were found to be statistically significant at 0.05 level of significance. So, there is association of pretest knowledge score of post natal mothers with education.

Conclusion

1. The findings of the study revealed that majority (90%) had low knowledge, 10% had average knowledge regarding prevention of neonatal hypothermia in pre test. Similarly, the post test scores depicted that majority (80%) had good knowledge, 20% had average knowledge and none of them had low knowledge regarding prevention of neonatal hypothermia.

2. Most of demographic variables were not significantly associated with level of pre knowledge of postnatal mothers regarding prevention of neonatal hypothermia. Only mother's education status (x^2 = 8.585 in the pretest and df=2 and p=0.014) were found to be statistically significant at 0.05 level of significance.

3. There was significant difference between the knowledge of postnatal mothers before and after the implementation of planned teaching program (t = 11.720, P = 0.000 level).

This study showed that, the postnatal mother's knowledge regarding prevention of neonatal hypothermia was low and planned teaching program is effective to improve their knowledge.

Leeth Therapy (Jalaukavacharana) - A Novel Gift from Ayurveda for Treatment of Medico-Surgical Diseases

Saxena Varsha[1], Srivastava Niraj[2], Kumar Pradeep[3]

[1]Assistant Professor, Department of Shalya-tantra, Main campus, Uttarakhand Ayurveda University (UAU), Dehradun, Uttarakhand, [2]Associate Professor, Department of Kaumarbhritya / Bal-Roga, Sardar Patel Institute of Ayurvedic Medical Sciences & Research Centre. Lucknow, Uttar Pradesh, India, [3]Professor (Retd.), Department of Shalya Tantra, Faculty of Ayurveda, Institute of medical sciences Banaras Hindu University, Varanasi (U.P).

Abstract

Background: The first description of *Jalaukavacharan*a (leech therapy) was found in the text of *Sushruta Samhita* in 800 B.C. Recently, many researches proved that leech saliva have variety of bioactive compounds involving anti-thrombin (hirudin, bufrudin), anti-platelet (calin), factor Xa inhibitors, antibacterial and others property.

Aim: Main aim of present article is to explore about procedures of leech therapy and research works done over few decades on application of leech therapy in different medico-surgical diseases.

Methodology: The procedure of leech therapy is documented from authors own observations and Information of its application in different diseases was gathered from various published work of last ten years.

Result:-Many clinical researches show that leech therapy is very effective in various medico-surgical diseases. Total eight publications were included in the final selection after systematic analysis.

Conclusion: -Leech therapy or *Jalaukavacharan* is an ancient *Ayurvedic* bloodletting technique which having the great potential to manage many inflammatory, ischemic and infectious diseases. Leech's saliva contains many biologically and pharmacologically active compounds which exert effects anti-coagulant, profibrinolytic, anti-platelet, anti-inflammatory and anti-edema in the host's body. Arthritis, venous congestion, vascular diseases, abscess, ischemic heart disease etc. can be successfully manage by leech therapy/.

***Key words**: - Jalaukavacharan, Leech therapy, Hirudin, Vidradhi, Deep vein thrombosis (DVT).*

Introduction

Ayurveda is a system of medicine with historical roots in the Indian subcontinent and practiced from 5,000 years ago.[1] Leech sucks only impure blood so this is considered as blood purification therapy. *Sushruta Samhita* (dating 800 BC) is the treatise of surgery in which *"Jalaukavacharniya*" is one of its chapters, where everything about *Jalauka* and its application are scientifically described.[2] *Jalaukavacharana* forms by the addition of two words: *Jalauka* and *Avacharana*. *Jalaukavacharana* means the application of Leeches. The word 'leech' is derived from an old English word for physician, "laece". [3-4]. Therapeutic application of leech is practiced among the other system of medicine such as in *Unani* and *Siddha* also.[5] The treatment of disease with medicinal leeches is also known as Hirudotherapy (HT).[6] The bioactive substances that found in leech's saliva - commonly known as "hirudo substances" and also called Salivary Glands Secretion (SGS). SGS

contains more than 120 bioactive substances, which have strong anaesthetic, anti-inflammatory, analgesic properties some of them are still being examined. Haycraft (1984) discovered "hirudin" which is most important component.[7]

Aim: -. Main aim of present paper is to discuss about leech therapy, its procedures and research works done over few decades in the field application in different diseases.

Leech therapy (Jalaukavacharana):-

Leech therapy (*Jalaukavacharana*) is being used to treat diseases through *Raktmokshan* which is part of *Panchkarm* in surgical stream of *Ayurvveda.* This traditional method of curing diseases is considered as magical therapy because of its wide range of application in almost all the diseases.

Indication of leech therapy:-

In *Ayurveda*, *Jalaukavacharan* are indicated in delicate or weak patients, female patients, old aged or too young patients suffering from *Rakta-Pradoshaj vikaras* (blood originated diseases).[8] *Jalaukavacharan* are very effective in *Vidradhi* (abscess), *Visarpa* (inflammatory skin disorders), *Gulma* (inflammatory condition of abdomen), *Pidika*, *Kustha*, *Charmadala* (skin diseases) etc. [9]

Leech therapy is widely used in modern medicine for treating a variety of challenging medical and surgical conditions such as plastic surgery [10], Arthritis (Osteoarthritis and Rheumatoid Arthritis) [11-12], venous congestion[13], vascular diseases[14], and Thrombophlebitis etc.

Contraindication of Leech therapy:-

In *Ayurveda*, Leech therapy is contraindicated in *Pandu Rogi* (Anemic patient), *Sarvanga Sotha* (generalized edema), *Arsha Rogi* (hemorrhoids patients) *Udar Rogi* (individual suffer from gastro intestinal tract disorders), *Shosha Rogi* (cachexia patient) and *Garbhini* (pregnant women).[15]

Leech therapy is absolutely contraindicated in HIV patients or who take immunosuppressive drugs, Hemorrhagic diseases, Hypotension, Hypotonia, Absolute Hemophilia, Pregnancies, Severe Anemia (<5g/dl) and Allergy to Leech. [16]

Complication of leech therapy:

In *Ayurveda* not any specific complications are mentions but some complication of *Raktamokshana* such as *Paka* (inflammation) and *Daha* (burning sensation) can occur.[17] but modern sciences mention many complications such as-

§ Excessive bleeding can occur with leech therapy; it can be controlled by applying direct pressure or topical thrombin.[18] Excessive blood loss may necessitate blood transfusion, so patients should be informed of the possibility.[19]

§ The most common infections involving leech therapy are caused by *A. hydrophila,* infections with *Serratia marcescens, A. sobria,* and *Vibrio fluvialis* have been reported.[20]

Material and Method

Material Required:-

§ Two small glass jar, kidney tray, one big bowl.

§ Sterilized gauze, swab, gloves, Sterile needle, sterile dispovan syringe (10 ml)

§ Savlon and dressing material.

§ Turmeric powder

(Figure 1: Material required in Leech therapy)

Monitoring during leech therapy:-

During leech therapy, it's common to measure and record pulse, blood pressure and skin temperatures every three hours, with the goal of keeping the temperature of the area at or above 86^0F. A reduction in temperature below 86^0F may indicate problems with either arterial or venous circulation. Baseline laboratory values should also be checked, including a complete blood count (CBC), clotting time (CT), prothrombin time (PT), bleeding time (BT), HIV& HBsAg.

Method of Jalauka-vacharan (Leech therapy):- Method of leech therapy completed in three steps-

A. Purva Karma (Pre-Procedure Protocols): In *purvakarma* mainly *snehana* (oleation) and *swedana* (sudation) of the patient is done and cleaning of part of the body to which leech is going to be. For leeches to suck maximum amount of blood very quickly without any problem, they must be stimulated and energized. This is done by applying the paste of mustard and turmeric powder on the body of leech or drop leeches in the water containing turmeric powder and it is found that an inactive leech becomes active.

(Figure 2: Purva Karma in Leech therapy)

B. Pradhana Karma (Main Procedure Protocols):- Main procedure are completed in following steps-

§ Before application of leeches, patient's affected part is clean and sterilize with boiled warm water.

§ First *Shodhita* (Clean) the leeches by putting them in turmeric mixed water for 15 minutes and keep in plain water for 5 minutes.

§ Then affected part of the patient was clean thoroughly with boiled warm water.

§ Then adequate numbers of leeches were applying to the area of maximal congestion one by one.

§ Once the leeches attached, it will remain safely in place until fully distended and then detaches spontaneously. (30-50 mm.)

§ The blood was allowed to ooze out for 20-25 minutes.

§ If, at the biting site, needling pain and itching appear it indicates that it is sucking pure blood and then it should be removed; if it does not leave due to the smell of blood, the powder of rock salt should be sprinkled up on its mouth.

§ Leeches were again applied to the patient on every 4th day as required.

§ So maximum of five times leeches were applied to a single patient with dressing with Haridra.

(Figure 3: Pradhana Karma in Leech therapy)

Paschatya-Karma:-

§ **Removal of blood from the leeches (*Jaluakas*) and when leech fallen away, its body should be massaged with rice powder and its mouth massaged with oil and salt and gently squeezed till signs of proper vomiting appear.**

§ **The properly vomited one should be placed as before. *Vagbhata* described that the solution of *Haridra* and *Sarsapa* is also helpful to them to void their excreta.**

(Figure 4: Paschata Karma in Leech therapy)

Amount of blood sucked by leech—

§ In person who are strong, who have great accumulation of *Doshas* and who are of suitable age (middle age) more than 16 and less than70 years of age, experts desire, and after *Vaman, Virechana,* one *Prastha* (Thirteen and half pal i.e. 540 ml) of blood be allowed to flow out.

§ For calculating the amount of blood sucked, leeches were weighed before and after application.

Bite of the leech during leech therapy- After detachment of leech it leaves "Y" shape scar at leech site. The leech saliva is filled with a chemical that contains a painkiller, which stops you from feeling the bite. The saliva also has a chemical, which keeps the blood from clotting.

(Figure 5: Bite of the leech during leech therapy)

Observation and Result:-

Various published articles on "application of leech therapy (*Jalaukavacharana)* on various diseases" were studied and analyzed according to aim of the study. Total eight publications were included in the final selection after systematic analysis.

Leech therapy in various diseases: - Medicinal leech is a small "factory" manufacturing many biologically active substances. Leech saliva contains several compounds that exert effects in the host's body.

Table 1: Components of Leech saliva that exert effects in the host's body –

Hirudin	**Inhibits blood coagulation by binding to thrombin**
Calin	Inhibits blood coagulation and collagen- mediated platelet aggregation
Destabilase	Dissolves fibrin and have thrombolytic effects
Hirustasin	Inhibits kallikrein, trypsin and chymotrypsin
Hyaluronidase	Antibiotic, increases the permeability of the host skin
Tryptase inhibitor	Inhibits proteolytic enzymes of host mast cells
Factor Xa inhibitor	Inhibits the activity of coagulation factor Xa.
Carboxypeptidase' A inhibitors	Increases the inflow of blood at the bite site
Histamine like substances	Vasodilator and increases the inflow of blood at the bite site
Acetylcholine	Vasodilator
Anesthetics substance	Anesthetic, this is equally potent to morphine.
Chloromycetyn	Potent antibiotic.

A. Leech therapy in Deep vein thrombosis:-

Deep vein thrombosis (DVT) is semisolid clot in the vein which has more chance to develop pulmonary embolism due to thrombosis formation in the calf muscle.[21] Leech therapy is very effective in DVT because saliva of leech contain much bio-active substance like Hirudin, calin, factor Xa inhibitor which hampers the coagulation of blood. Leech dissolves clots of blood by its thrombolytic effect. Leech saliva contains three compounds that act as a vasodilator agent like acetylcholine etc. The saliva of leeches also contains anaesthetic substance. All compound work together to decrease the viscosity of blood, making thinner consistency of blood to promote better flow. [22]

B. Leech therapy in Non healing ulcer:-

Leech saliva provides Carboxypeptidase A inhibitors enzyme to ulcer area which reduces vascular congestion. Leech saliva has Histamine like substances and Acetylcholine like substance which act as peripheral vasodilator effects, improves blood circulation and manage ischemia around the wound, thus promotes

wound healing.[23] It was found that leech application improves the hypoxic condition and provides a moist environment for wound healing. It was also observed that it stimulates the enzymatic debridement of the slough material present in the wound.

C. Leech therapy in Abscess (Vidradhi):-

Vidradhi is a clinical condition can be correlated with spreading inflammation of skin & subcutaneous tissue. In modern system of medicine there is no alternative of antibiotic and anti-inflammatory drugs to manage inflammation. Some compound of leech saliva such as Bdellin etc. has anti-inflammatory effect by inhibits trypsin, plasmin and acrocin.[24] As per *Ayurveda* probable mode of action of *Jalaukavacharana* is due to its capacity of removing *Rakta Dhatu* along with *Pitta Doshas*.

D. Leech therapy in Micro-vascular & Reconstructive Surgery:-

Micro-vascular reconstructive surgery involves the relocate of autogenous vascularized tissue to renovate extensive tissue defects. The most obvious developments have been procedures developed to allow anastomosis of successively smaller blood vessels and nerves. It has been used by different specialists today, like plastic surgery, gynecological surgery, general surgery, opthalmoscopic surgery, neurosurgery etc. Leeches are used to reduce that congestion by removing blood that can't exit via the venous system. [25]

E. Leech therapy in Arthritis: -

Leech saliva have factor Xa inhibitor which inhibits the activity of coagulation factor Xa. It have very important role during the treatment of Osteo-arthritis and Rheumatoid arthritis. Anti-inflammatory effect of Eglins compound inhibits the activity of alpha-chymotrypsin, chymase, substilisin and elastase. So Leech is very effective in osteoarthritis, periarthritis and rheumatoid arthritis. [26]

F. Leech therapy in cardiovascular diseases (CVD):-

Cardiovascular diseases mainly related to heart, veins and arteries. Leech saliva contains thrombin inhibitors and hirudin which improves blood flow by its thrombolytic and anti-platelet activity. [27] Many studies exposed that hirudin is more effective than heparin in preventing deep venous thrombosis (DVT) and cardio-vascular patients with unstable angina.[28]

Leech therapy is also effective in Cellulitis (*Vranashotha*), Hypertension, Hemorrhoids, Thrombophlebitis (*Shirashotha*), Hematomas, External ear and chronic ear infections, dental problems, like gingivitis, gingival edema etc. and Chronic skin diseases, like scabies, psoriasis, eczematous dermatitis. [29]

Conclusion

Jalaukavacharan (Leech therapy) is an ancient *Ayurvedic* bloodletting technique which having the great potential to manage ischemic, inflammatory and infective disease by in removing the blood pertaining to the deep seated regions. Saliva of leech contains a numerous bioactive constituents which possess analgesic, anti-inflammatory antiseptic & antibacterial property etc. Leech therapy in the effective in the field of plastic surgery, Arthritis (Osteoarthritis and Rheumatoid Arthritis),Venous congestion, vascular diseases, Thrombophlebitis, cellulitis, sciatica, inflammatory reactions, blood purification, ischemic heart disease and hypertension is expected to be of paramount importance due to the ease of leech application and minimum side-effect. Leech therapy is of *Ayurvedic* origin but it is equally acknowledged by modern medicine due to its effectiveness in healing various kinds of diseases and it is also considered as wonder therapy.

Future plan: Till date some of the bioactive ingredients are still unknown and there is only limited knowledge of mechanisms of action of bioactive compounds present in Leech Saliva. Hence, widespread studies are essential to find out the exact mode of action of other bioactive compound to re-establish the leech therapy on scientific ground.

Abstract

Purpose: Determining barriers to eyecare amongst commercial truck-drivers in north India.

Method: Cross-sectional survey of 90 truck-drivers, of which 3 had visited a permanent eyecare facility before. Data was collected from the remaining 87, via a structured pre-tested questionnaire assessing demographics, previous eye check-ups, and eyecare awareness.

Results: 33.3% (95% CI:23.6-44.3%; n=29/87) drivers had never felt any need to undergo eye examinations and 53 out of the 87 (60.7%; 95% CI:49.9-71.2%) were unaware of the importance of undergoing routine eye examinations. These identified barriers to uptake of eyecare services were not associated with drivers' age, education level, marital status, or distance driven. 60.3% of drivers who marked lack of awareness and 68.9% of drivers who marked unfelt need as a barrier, were either illiterate, or educated only upto primary level. Cost of availing eyecare services and available time to undergo routine eye examination were least frequently marked barriers.

Conclusion: Drivers were unaware of the importance of undergoing routine eye examinations, with younger ones feeling no need to undergo one at all. Addressing these barriers could help improve eyecare service utilization amongst truck-drivers.

Keywords: *Truck-drivers, Eyecare services, Barriers, Awareness*

Introduction

Commercial truck-drivers in India are integral to a transport sector serving over one billion people. In 2007, Indian truck-drivers numbered five to six million,[1] reportedly leading a sedentary and unhealthy lifestyle,[2] with no fixed routine and irregular sleeping patterns. This has considerably deleterious effects on the health of this mobile population.[3]

50% of Indian truckers face health problems, of which 8% are eyesight issues.[4] Visual function, is the core of both safety, and performance, aspects of driving.[5-6] Lack of adequate visual function is also prohibitive to getting a commercial drivers' license- affecting livelihoods.

Our organization, in collaboration with Eicher Motors Limited, designed and implemented an eye screening program exclusively for these truckers, to better provide services. However, program reports indicate under-utilization of these services. Thus, this study assesses barriers to uptake amongst these truck-drivers. This knowledge would help program planners design interventions specific to truck-drivers' occupational situation and needs.

Methods

This prospective cross-sectional survey was conducted from January-April 2019, at transport hubs, workshops, local street-side restaurants, petrol pumps, transport unions, driver training institutes and parking areas. The pre-tested survey questionnaire was administered by a trained interviewer in the local language. All truck-drivers who gave informed consent were included. The study adheres to the tenets in the Declaration of Helsinki.

The study tool was developed with the help of experienced program managers and literature review. As per literature, the most common reported barriers to eyecare were cost,[7-12] trust,[8] lack of time,[9] unfelt need,[9,11-12] provider accessibility,[7-8,12] and awareness. The questionnaire encompassed seven demographic questions, three questions assessing awareness about eyecare, and four questions ascertaining previous eye check-ups. It was piloted on 30 in-house drivers not included in the final analysis.

Proportions were compared across categories through Chi-square test or Fisher's exact test using SPSS version 24. Further, cross-tabulation was done between barriers identified and drivers' demographics.

Results

90 drivers were administered the questionnaire, of which 87 had never visited a permanent eyecare facility. These 87 drivers were included in the barrier study.

Detailed demographics of these 87 drivers are given in Table 1. 74.7% (n=65/87) were below 35-years of age, and 25.3% (n=22/87) were of age 36 or above. The majority of drivers were either illiterate (18.4%) or educated upto primary level (47.1%), married (63.2%) and used to driving long haul (78.2%). In one tour, almost half the drivers were driving 16-30 days, and more than a quarter driving 8-15 days. Moreover, over a third of these drivers, covered more than 300 kilometers per day, with 62.1% reporting a resting time of less than 6 hours between consecutive days.

The barriers reported by the truck-drivers have been depicted in Figure 1. 60.7% reported lack of awareness (95% CI:49.9-71.2%; n=53/87) and 33.3% reported unfelt need (95% CI:23.6-44.3%; n=29/87) as the most common barriers. Out of the 5 drivers who reported time and cost as barriers, three drivers mentioned eye camps as sources of awareness, while the other two mentioned fellow drivers (one), and awareness sessions (one) as media of information regarding routine eye examinations.

The majority of both the illiterate drivers, and drivers who were educated till primary level, were unaware of the importance of routine eye screening (56.25% and 56.1%, respectively). The difference in awareness, across education levels was found insignificant. 68.9% of drivers who marked unfelt need as a barrier, were either illiterate or only educated upto primary level (Table 2).

Amid the married drivers, 60% (n=33/55) were unaware, 34.5% (n=19/55) reported unfelt need, and 5.5% (n=3/55) had time concerns. Within the unmarried drivers, 62.5% (n=20/32) were unaware, 31.25% (n=10/32) marked unfelt need, 3.1% (n=1/32) had time concerns, and 3.1% (n=1/32) had avoided eye examinations due to associated costs.

The majority (60%) of drivers below 35-years of age did not feel the need to undergo routine eye examinations, while the majority (63.6%) of drivers aged more than 35-years of age, lacked awareness regarding eyecare (Table 3). This difference was also found to be insignificant (p=0.63).

Lastly, comparing short and long-haul drivers, 61.7% of the short distance drivers were unaware, as compared, to 57.8% of the long-haul drivers (p=0.75). Further, 29.4% of the former and 6.7% of the latter, reported unfelt need for eye examinations. This difference was also insignificant (p=0.29).

Table 1: Demographics of truck-drivers

	Category	Frequency (%)
Education	Illiterate	16 (18.4)
	Primary	41 (47.1)
	10th	27 (31.0)
	12th	03 (3.4)
Marital Status	Married	55 (63.2)

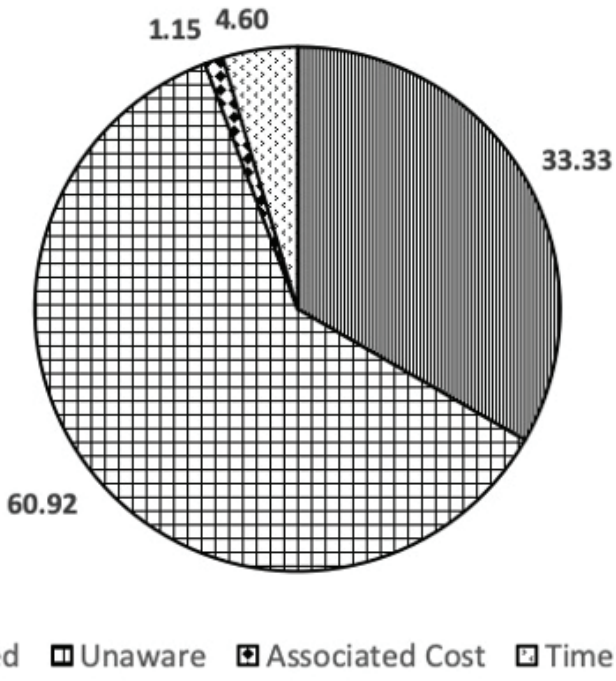

Figure 1: Barriers reported by truck-drivers (In Percentage)

Discussion

This study highlights the need of awareness about necessity of routine eye examinations amongst truck-drivers. 60.7% of surveyed drivers cited being unaware as the primary reason behind not getting their eyes examined, while unfelt need was the second most commonly reported barrier (33.3%). Only 8 of 90 drivers were aware regarding the need of eye check-ups, and of those only 3 had ever visited. Additionally, demographic factors-age, education, marital status and distance driven, were found not to be significantly associated with the barriers.

Global health issues of truck-drivers have been reported on extensively earlier, ranging from chronic, systemic conditions and occupational hazards, to even psychosocial problems.[2,3,13-17] However, literature on eyecare amongst truck-drivers, particularly in India, has focused on prevalence and types of refractive errors.[18-19] While a report does discuss spectacle usage by this mobile population,[20] our study would be the first of its' kind, both globally, and in India, to assess barriers to eyecare services for truck-drivers.

An earlier study amongst the general south Indian population reported unfelt need and cost as the most common barriers to uptake of eyecare services.[9] The former was reiterated in another south Indian study conducted seven years later, alongwith old age.[12] However, both these studies had a large proportion of participants over the age of 60-years, both male and female, while our study had men, mostly under 35-years of age. Although our study results did not show significant association with demographic characteristics, the referenced studies found socio-economic status, and level of visual impairment,[9] as well as, age, to be significantly associated with their results. Similar to our study, both studies had high proportions of illiterates, who have been shown to have a lower odds-ratio of accessing eyecare services.[9,11]

Low awareness about eyecare was one of the key findings of this study; a figure much less than those in studies of the general population emanating from both the north,[21] and the south,[9,12,22] of the country. This is further corroborated through later studies of the general population published across the world.[23-25] A main reason for this finding would be the nomadic lifestyle of truckers, rendering effective dissemination of information regarding eyecare problems difficult. Travel at odd hours, in the country's interiors, may also restrict availability of media through which information is transmitted, such as phone and data connectivity. Moreover, the sample participants surveyed by us had a high proportion of illiterate (18.4%) and semi-educated (47.1%) truckers, who have been shown to have less awareness of services, (56.25% and 56.1%, respectively). This could be a key determinant affecting their understanding and absorption of health-related information provided to them, thus decreasing uptake. Further, access to healthcare facilities where they could not only access eyecare, but are made aware of it's need, might be limited.[26] In our study, of the drivers aware about need for regular eye examinations, 60% mentioned eye camps as their primary source of information. Increasing access to sources of health and eyecare information may increase awareness amongst this mobile population. Lastly, 63.6% of drivers above the age of 35-years were less aware as compared to the younger drivers, a demographic characteristic found to be significant in explaining person-related barriers such as unawareness, in an earlier general population study.[12]

Unfelt need was the second most reported barrier to uptake of eyecare services (33.3%). It is part of person-related barriers, found to be significantly explained by age, in a general south Indian population.[12] 68.9% of these drivers, were either illiterate or semi-educated, possibly affecting their understanding and interpretation of signs and symptoms potentially manifesting and throwing light on their deteriorating visual function. Moreover, 60% of our study's truckers, below 35-years did not feel the need to undergo eye examinations. A possible explanation for this would be that functional vision in these young truckers may be good, regardless of the overall visual function. In a US study of long-haul truckers, 75% reported good health, but were later diagnosed with a range of lifestyle diseases.[27] Studies from north and south India, report prevalence of refractive error in truck-drivers to be 17.14% and 28.57%, respectively,[18-19] depicting the persistence of the problem, despite low felt need and awareness. Another explanation for this could be drivers' remuneration, which they may perceive as being adversely affected by sick days, thus, building pressure for non-top work to maximize earnings.[28]

Eye health promotion in developing countries has three components: education to increase service uptake; service improvements to increase accessibility and acceptability; and partnerships with the government

for prevention policies.[29] A 2003 sexually transmitted disease reduction program established clinics on specified corridors frequented by truckers,[30] introducing awareness activities like street plays, truckers' festivals, free consultation, etcetera. These clinics can be partnered with and eyecare programs included. Further, pictorial hoardings and billboards on national highways and roadside restaurants frequented by these truckers, would also help increase awareness regarding the need for routine eye examinations. Lastly, partnership with the government to run awareness campaigns via the radio, such as that for the Swachh Bharat Abhiyan, would help disseminate information via a medium truck-drivers are familiar and comfortable with.

This study had a few limitations, especially the low number of drivers surveyed, and the sample being restricted to north India. Bias may also have been caused due to the high level of illiteracy in the sample. However, a seminal strength of this study would be that it is the first of it's kind to report on barriers faced by truck-drivers in India.

Visual function is important to ensure safety while driving, as it affects drivers' reflexes on the road. This study found that very few truckers had ever undergone eye examinations, citing lack of awareness and unfelt need as the main barriers. Thus, interventions targeted at generating awareness and education in these truckers as to the need for regular eye examinations need to be brought under the umbrella of existing healthcare and road safety programs to overcome their unique occupational limitations.

Ethical Clearance: Taken from Institutional Review Board of Dr Shroff's Charity Eye Hospital (IRB/2019/OCT/08).

Benefits of Cochlear Implants in Children with Hearing impairment : Parental Perspectives from Tertiary Care Hospitals in Tamilnadu

Shankar S[1], Dawson Gladys Prathiba[2]

[1]District Differently Abled Welfare Office, Kanyakumari District, Tamil Nadu, [2]Department of Speech Language and Hearing Sciences, Sri Ramachandra Institute of Higher Education & Research (Deemed to be University), Porur, Chennai, India

Abstract

Aim: The current study explores the benefits in children with cochlear implants (CI) from the parental perspective. The objective is to understand the concerns of parents in order to plan appropriate recommendations for habilitation and educational programs.

Method: Fifty-three parents of children with CI completed the questionnaire titled, "Parental Perspectives on CI". The questionnaire consisted of 106 statements with 10 subsections that analyse the different aspects related to the pre and post –implantation process.

Results: The study reported that parents are satisfied with the overall development of the child. However, they expressed significant concerns regarding recurring cost of the implant, distance, travel and also the future of the child with CI.

Conclusion: Parents recognize that CI has made an overall positive impact on their children. They also recognize CI as a heavy financial liability post implantation that may not allow children to obtain the optimal benefit. The study also indicated that the government should initiate financial policies to provide the necessary support for habilitation and equipment maintenance.

Key words: *Cochlear implantation, Early intervention, Habilitation, Parental perspectives,*

Introduction

Cochlear implantation is established as a standard care of treatment for children with profound hearing impairment especially for children who do not benefit from hearing aids [1]. The development of spoken language and listening are cited as the most significant outcomes of children with cochlear implant [2]. Documenting outcomes or benefits of CI has radically changed the candidacy, patient care and habilitation of individuals with CI. There is a range of audiological assessment tools available to document the benefits of CI. However, these formal assessment tools are not designed to provide the information beyond the clinical setup. Though, formal audiological assessments measure the auditory response to speech, it does not reflect the outcomes in terms of speech, language and other related challenges in various environments of a child with CI. Earlier the benefits and limitations of cochlear implants have been discussed using questionnaire based studies. Parents have expressed concerns in educational and social settings post implantation [3]. Such specific information can be obtained using parents as informants to document functions of the child at home and in other challenging environments.

In this context the parental interview provide valuable information that help to understand the child's level of activities in different educational and social environments besides their clinical performance [1][4][5] in India, the numbers of CI recipients have increased in the last decade. The actual benefit from an implant may vary with the data from the rest of the world, due to cultural variations, different health care systems and the costs of the implants.

The aim of the current study is to explore the benefits in children with CI from a parental perspective using a questionnaire. The data was collected from three tertiary care cochlear implant centres from three different districts of Tamilnadu. Appropriate permission was obtained from these CI centres for data collection. A contact list of 80 parents of children with CI in the age range between 2.6 to 10 years was obtained from the hospital database. Parents were contacted and briefed about the purpose of the study over the phone to obtain appropriate consent to participate in the study. Out of 80 parents only 53 parents complied to participate in the study.

Method

A validated closed – set questionnaire (Appendix I) developed by O'Neill et al. [6] was used for the study. The questionnaire was administered to the participants of the current study. The statements in the questionnaire included aspects covered under the pre-implantation and post-implantation process. The questionnaire consists of 106 questions divided under 10 subsections. The aspects covered under the post-implantation were Communication (7), General functioning (7), Self-reliance (5), Well-being and happiness (8), Social relationship (13), Education (11), Effect of implantation (9), Supporting the child (9). The aspects of pre-implantation are covered under two sub sections, Process of implantation (23), Decision of implantation (14). The questionnaire consisted of a series of statements for which the responses were rated on a five point Likert scale from 'strongly agree' to 'strongly disagree'. The responses were coded in the range of 1-5, 1 being 'strongly disagree' to 5 being 'strongly agree'. A failure to respond was classified as a missing value and coded as 0. At the end of this questionnaire, parents were asked to give general comments about the benefit of CI which were not covered in the questionnaire.

Statistics Analysis

Percentage analysis was used to analyze the response of the parents of children with CI. Spearman's correlation was applied to detect the possible relationship between different subscales related to benefits of CI. Statistical significance was accepted at $p<0.05$ level. All data was calculated by using with SPSS 16. 0 versions.

Results

The following results are the analysis of the pre-implantation subscales the "Process of implantation" and "Decision to implant". Within the subscale of "Process of implant" there are 23 statements. It was noted that 94% scores were obtained for statement "The whole process of implantation was intrusive". 90% of the parents strongly agreed to the statement that "Only experienced teams should carry out cochlear implantation. There was high agreement (90%) among parents for statement 6 i.e., "It is important to observe his use of the implant as school/ home". Nearly 98.1% of parents showed agreement for the statement "A positive attitude is a great help towards successful use of the implant".

The statements 11-20 were related to support from the implant centre. The results indicate that the parents strongly supported statement 11 (94%) "Regular tuning and checking of implant system are essential" (94.3%), Statement 12 (98%) "Feedback from assessment at the implant centre is very useful. Parents also agreed to statement 13 (94.3%) "The most important factor in choosing a device is it's reliability. It was noted that parents agreed to the statements 16 (98%) "There is a need for life time support from the implant centre" and statement 19 (98%) "Travelling to the implant centre was a burden".

The other subscale under this aspect is the "Decision to implant" that consisted of 14 statements. All parents unequivocally agreed to the statements 4 (100%) "The whole process of implantation is stressful". Statement 5 (100%) "I am happy about his progress in school" and 11 (100%) "It was a difficult time waiting for results of the assessment before implantation". In this subscale of statements statement 2(38%) "I worry that he will blame me for my decision for him to have an implant".

The box plot (fig. 1) show that the mean scores of the subscales. The parents expressed themselves to be beneficiaries and were highly satisfied particularly in the aspect of supporting the child (mean 4.8, SD 0.23, range

4.5- 5.0), communication (mean 4.6, SD 0.13, range 3.0- 5.0) and education (mean 4.007, SD 0.08, range 3.0- 5.0).

Relationship between subscales in parental perspective:

Spearman's correlation coefficient was used to identify a possible degree of association between subscales such as communication, general functioning, self-reliance, Well- being and happiness, social relationships and education. It has been noted that the sub scale of spoken language communication (p=0.009) and self–reliance (p=0.003) had a strong significant correlation with supporting the child. Education (p=0.035) had significant correlation with supporting the child. Also, wellbeing and happiness (p=0.015) had significant correlation with effect of implantation.

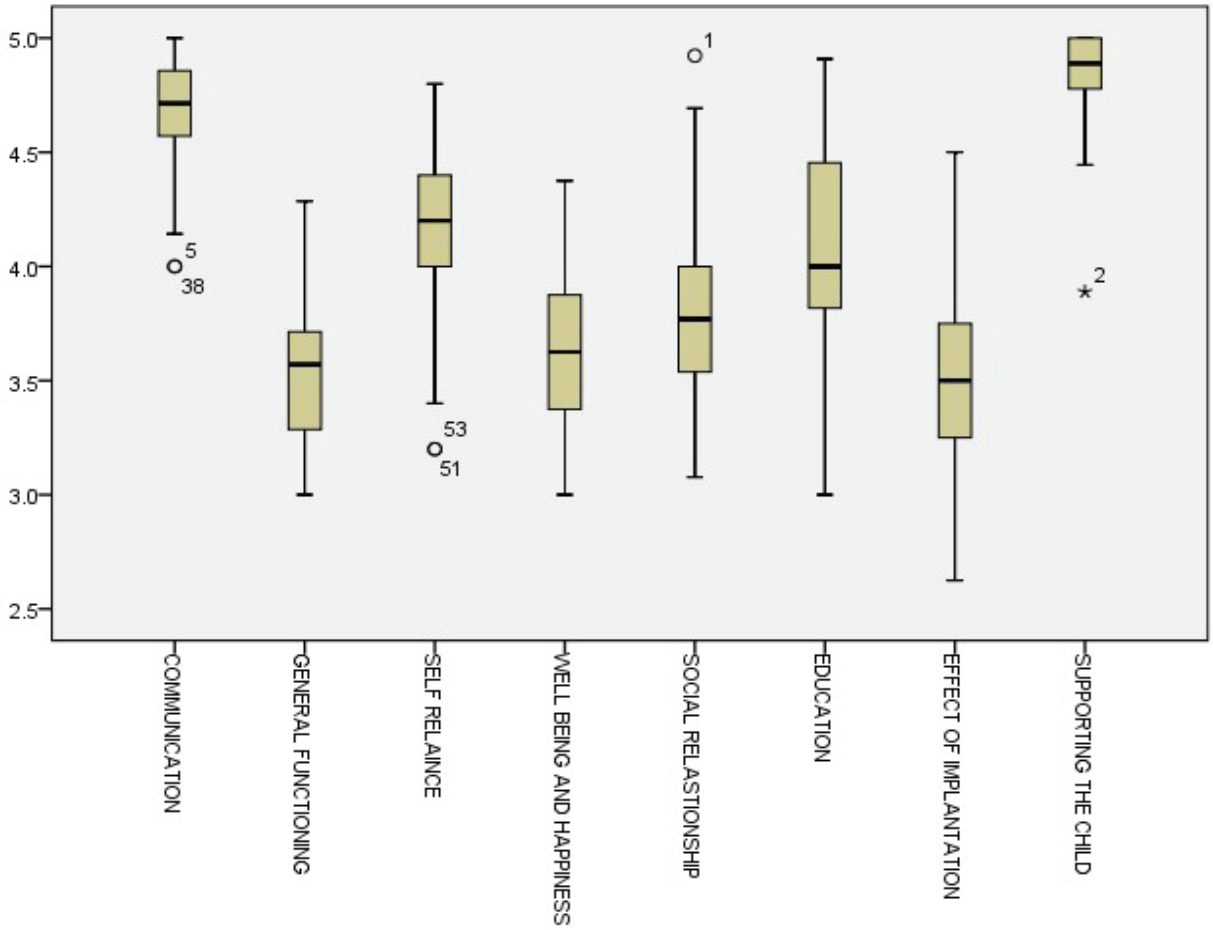

Fig . 1 : Indicates the mean scores of the subscales

Discussion

The present study strongly suggests that parents play an important role in assessing the day to performance of children with implantation. It is apparent from the responses to the questionnaire that the entire process of implantation, pre-implantation and post – implantations were reported to be highly stressful. The study also indicated that all parents who participated in the study considered implant as an option as they expected their children to be a part of the hearing world. Such high agreement has been reported only in India in comparison with the other parts of the globe. This decision to implant strongly suggests that in a country like India parents view implantation as a treatment for deafness that will allow their child to participate in the hearing world. The other reason that can be attributed is that parents feel tremendous stress to raise a child with a hearing impairment. Due to the above reason, their decision to implant was also directed to a treatment option that

will help the child to be an effective participant in the community. It is consequential that parents have perceived that only by learning verbal communication their child will be able to have a secure future with employment [1]. Parents agreed that CI has helped their child be employed in the future [7]. However, it is also suggestive that parents who participated in the study had high expectations for an implant. For this reason the professionals should establish a realistic view regarding the outcomes of CI during the pre-implantation counseling.

The qualitative subscales of the questionnaire that focuses the post -implantation benefits of the implant suggest, parents express satisfaction in various areas of development. They expressed that there was significant progress in the area of communication and academic achievement and also observed that communication changes post- cochlear implantation. The study also reflected that as the usage of implant increased the child performed better in speech production and speech perception. It also indicated that the parents were satisfied that the child was able to hear and communicate [8][4]. Children with CI also demonstrated significant development in the areas of mainstream education and social interactions. Parents also noted that children with CI performed in par with their hearing peers in academic skills. Similar results were also documented [4]. It also indicated that the parents have perceived that overall their child had become more self-reliant and social post -implantation.

The questionnaire explored the perceptions of parents to the entire process of implantation. The parents recognize that a good working relationship has to be established with the implant centre for future support. They also identify that periodic visits to the implant centre is extremely necessary post implantation.

Apart from the benefits of cochlear implantation parents had specific concerns regarding travel and distance to the implant centre [7]. The issue seemed to persist in Western world that parents had to travel distances to visit the implant centre. This was stressful as the parent had to organize logistics for the rest of the family, while they had to bring the child to the centre. Demands of rehabilitation often yield to high parental anxiety post-implantation. The current study demonstrated that 75% of the parents in India expressed great concern related to the cost of implantation. Parents also reported that implantation is expensive and is beyond the paying capacity, Unlike the West where CI is reported to fall within acceptable economic range. Until, recently the implant cost was paid by the parents. However, in the year 2013, the Government of India had initiated cochlear implant programs supported by the state government that provides free cochlear implants and rehabilitation for the economically underprivileged. Most of the parents participated in the study had received CI under this scheme in the state of Tamilnadu. The greatest concern of 75% of the parents was to pay for the recurring cost associated with the implants. Parents were extremely concerned with the high costs that will be incurred to maintain the device in the future.

Conclusion

The above information obtained from parents provides a better understanding to plan the individual habilitation programs and educational recommendations for the child with CI. The information can help the professionals to address the parental concerns during counseling and provide a realistic view of cochlear implantation. Specifically, parents expressed concerns regarding the recurring costs and maintenance of the CI device. As all the participants of the study received CI from the government scheme. It may be suggested that the government should initiate policies that can provide financial support for maintenance and accessories of the device. Travel to the implant centre was an important challenge indicated by the parents both physically and financially. In order to address the issue, it may be worthwhile to explore the possible network between the implant centres and district early intervention centres throughout the state of Tamilnadu. This network can be used to provide services at the nearest geographical distance eventually reducing the cost and time related to travel.

Also, India is going through digitization and making remarkable progress in the field of tele-health in reaching the remote areas of the country. It is imperative that the tele-health technology can be explored to deliver rehabilitation service to the children with CI to reduce travel time, costs and distance. The implant centres should be directed by the state government bodies to consider the above options during the candidacy for implantation. Understanding the parental perspectives help professionals and families to facilitate optimal benefit with CI for a child with hearing impairment.

Ethical Clearance: The ethical clearance was obtained from the department research committee prior to the study

Prevalence of Performance Related Pre- Competition Anxiety in Recreational Marathoners: An Observational Study

Sharvari. D. Wagh[1], Prasannajeet Pramod Nikam[2]

[1]Intern, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra, India, [2]Assistant professor, Department of Sports Physiotherapy, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra India

Abstract

Background: Anxiety in recreational marathoners is a common trait observed recently. These marathoners not only go through a lot of physical but as well as mental exertion due to which it burdens them and triggers more anxiety in them. Anxiety before the marathon creates an impact on the marathoner's performance. Anxiety is a natural human state and a vital part of an individual's life.

Objective: the primary objective of this study was to find if there was any relation between the level of anxiety and the performance of the marathoner. The secondary objective was to quantify the extent of pre-competition anxiety in recreational marathoners.

Methodology: 40 recreational marathoners, both male, and female who consented to participate were included in this observational study. Their previous marathon timing and level of anxiety were checked before the marathon and they were asked to record their current marathon timings.

Result: There was a positive correlation seen between the level of anxiety and performance of the marathoner. Females were found to have more significant somatic trait and concentration disruption whereas male marathoners were found to have more worry component significant.

Conclusion: This study concluded that there was a significant correlation between the performance of the recreational marathoner and the level of anxiety was found.

Keywords: *recreational marathoners. Anxiety, pre-competition, performance, somatic, trait, state*

Introduction

Anxiety is referred to as an emotional state consisting of subjective, consciously experienced feeling of tension, apprehension, nervousness and worry, and heightened arousal or activation of the autonomic nervous system[(1)]. It is an adaptive motivating behavior that helps an individual to cope with a threatening situation and the intense anxiety is found more prevalent in most psychiatric disorder[s (3)]. The study of stress in sports-related fields is of greater interest in both the academics researching and teaching sports science and to professionals who support and train the sports performers[(4)].The causes can be mainly due to a mental condition, a physical condition, effect of the drug or a combination of the above. Anxiety is found as a central explanatory concept in contemporary theories, and it is regarded as a principal causative agent for such diverse behavioral consequences such as insomnia, instances of creative self-expression, psychological and psychosomatic symptoms, etc[(10)].

State anxiety is one of the anxieties which varies in intensity and fluctuates over time; the physiological changes include elevated heart rate and blood pressure, faster, shallower, more intense breathing, dryness of mouth, dilatation of pupils, erection of hair and perspiration [(1)]. Arousal of state anxiety involves a process that may be initiated by an external stimulus [(10)]. Trait anxiety may or may not be manifested directly in behavior but can be inferred from the frequency that an individual experiences elevations in state anxiety; they perceive and/or appraise a wider range of situations as more dangerous or threatening than do individuals who

are low trait anxiety[1].

The pressure of competing on a larger scale affects the performance of a marathoner. Experimental evidences show that anxiety is a common occurrence in competitive situations and that the effects of anxiety on sports performance are extremely debilitating[12]. Training intensities is also one of the key factors in the performance of the marathoner as previous detraining and initial performance level could jeopardize success in spite of good adaptation to training[5].In some situations, it was found that where stressors gave rise to negative appraisals and emotions, through further appraisals of their experience, the athletes were able to interpret the thoughts and feelings as facilitative for upcoming performance through an increase in the focus and efforts [6]. Also, increasing self- control strength could reduce the negative anxiety effects of the individual in sports and improve athletes' performance under pressure [7]. Though findings suggest that before the competition the performer encounters more stress, he should consider these when preparing and implementing interventions to manage competition stress [8].

There has been an interest in the role of anxiety in sports competition has stimulated a substantial amount of research among sports psychologist over the past twenty years[1]. Each marathoner has his/her way of coping in these situations. Hanin has found that the athletes can predict their pre-competition anxiety up to several days before the competition, and the predictions tend to be more accurate in the difficult competition[11]. The experience of threat is essential, a state of mind which has two main characteristics one of which is future-oriented, involving the anticipation of a potentially harmful event that has not happened and the other is mediated by complex mental processes that are perception, memory, and judgment which are involved in appraisal process[1]. The setting of high standards is an integral part of an elite sports player and often beneficial for the athletes' performance whereas for a recreational marathoner are characterized by frequent cognitions about the attainment of ideal, perfectionistic standards, etc[9]. Anxiety is considered a normal and natural response that is necessary for survival but it may become a problem when it becomes a norm, rather than the exception, where the efforts executed by the recreational marathoners interfere with their ability to conduct the social events and competitions. . Anxiety before a marathon can be detected early and treated with a simple maneuver that will prevent the severity of the condition and improve the performance of the recreational marathoner which may affect the performance of the marathoner.

Aim

To study the prevalence of performance-related pre-competition anxiety in recreational marathoners.

Objective

The purpose of this study was to explore the performance-related anxiety in recreational marathoners, specifically the relationship with other psychological constructs involved in undertaking and maintaining participation a given sport.

Methodology

After obtaining the approval from the institutional ethical committee, the participants who fit in the inclusion criteria were elected. The participants were screened and an informed written consent was obtained. In this observational study 40 recreational marathoners (N= 40), where the number of male marathoners was 25 (n=25) and 15 female recreational marathoners (n=15), were included. Simple Random sampling method was used for choosing the individuals. Individuals who were not willing to participate and those who were elite marathoners were excluded. The study was conducted using the modified SPORTS ANXIETY SCALE-2 .

Statistical Analysis

Table 1 : Descriptive statistics of different study factors in recreational marathoners.

Factors	N	Minimum	Maximum	Mean	Std. Deviation
Somatic	40	6.00	15.00	10.5250	2.50115
Worry	40	5.00	18.00	11.1750	3.12055
Concentration	40	5.00	19.00	10.5250	3.61611

Statistical analysis of the recorded data was done by using the software Statistical Package for Social Science version2.0. Arithmetic mean & standard deviation was calculated for each outcome measure. The arithmetic mean was derived from adding all the values together and dividing the total number of values. MS Excel was used for drawing various graphs with given frequencies and the various percentages that were calculated with the software.

Table 2: Shows Gender wise Distribution in Marathoners.

Gender		**Somatic**	**Worry**	**Concentration**
F	Mean	10.6667	10.5333	10.3333
	N	15	15	15
	Std. Deviation	2.99205	3.62268	3.13202

	Std. Deviation	2.21886	2.78508	3.93573
Total	Mean	10.5250	11.1750	10.5250
	N	40	40	40
	Std. Deviation	2.50115	3.12055	3.61611

Table 3: Gender wise Distribution.

Gender	**Frequency**	**%**
Male	25	62
Females	15	38

Table 4: Shows Gender wise Distribution of among Marathoners.

Age (in years)		**Somatic**	**Worry**	**Concentration**
19-23	Mean	10.5833	11.1667	10.5833
	N	36	36	36
	Std. Deviation	2.55650	3.21159	3.65181
24-27	Mean	10.0000	11.2500	10.0000
	N	4	4	4
	Std. Deviation	2.16025	2.50000	3.74166
Total	Mean	10.5250	11.1750	10.5250
	N	40	40	40
	Std. Deviation	2.50115	3.12055	3.61611

Table 5: Age-wise Distribution.

Age (in years)	Frequency	%
19-23	36	90
24-27	4	10

Table 6: Correlation between marathon completion timing and Anxiety.

The difference in Time Vs. Anxiety	Correlation Value	r2	95% CI	p-value
Pearson's R	.320	.103	0.01 to 0.57	0.0436

Discussion

This study "performance related pre competition anxiety in recreational marathoners", conducted in Krishna hospital, Karad, is a theoretical and methodological proposal mainly aimed to find the relation between the performance of the recreational marathoners. A gender wise study was done for the 25 males and 15 females participated in this study. Under the three components namely somatic anxiety, worry and concentration disruption, study was conducted.

A remarkable effect was found in females on the basis of somatic anxiety score compared to that of males. The subjects aged between 19-23 (10.58±2.55) also had a more significant somatic anxiety score. Somatic complaints were more often among anxiety- disordered youth with complaints including a range of physical symptoms such as headaches, stomachaches, muscle tension/pain, difficulty breathing, shaking, pounding, or racing heart, sweating, blushing, and fatigue.[15]

However, the female recreational marathoners and subjects aged between 19-23 years were also found to have more significant worry score. Excessive rumination and worry associated with cognitive anxiety had shown to interefere with attentional and cognition processes necessary for an adequate cognitive performance, such as test taking but had interference on motor- based tasks was suggested by John S. Raglin.[17]. Stressors which have been found to facilitate the development of anxiety in practice or competitive settings also contribute to sport injury occurrence thus an individual's poor stress response to a stressful practice or competitive situation can influence their increased risk of sport injury[20] .

The "concentration disruption" was also taken into consideration which showed more significance in males (10.64±3.93) compared to that of the females and in the subjects categorized in the age group of 24-27 years. Relationship between emotions, cognitive interference, concentration disruption was done which showed that anxiety and dejection were associated with more interfering thoughts and greater disruptions in concentration whereas the effects of anger and happiness showed that interfering thoughts were differed. [18]

Anxiety has been considered to play a major role in an athletes life as the athlete's skills are being evaluated which often regards to a typical response which can be characterized by a psychological, behavioral and/ or cognitive signs and symptoms[20]. Every athletes will have an unique response to the stress and anxiety which will differ in the signs and symptoms, as in the cognitive signs and symptoms of a stress disorder are frustration, worries, distortion, exaggeration, unrealistic performance expectations, self-defecting statements and self- handicapping, which makes it difficult to diagnose and treat[2].

At the highest level, athletes are well-matched in terms of their physical abilities, conditioning, and skill level. But often that is not enough to win and perform on the biggest of stages which is why developing strategies and techniques to get athletes minds in the best possible condition for optimal performance is increasingly important for sports teams and coaches.

A study suggested that female participants utilized social support, emotional release, and humor/fun as their primary coping responses which is much more different mechanism compared to that of males which might be the primary reason for the differences in the components of the anxiety evaluated. The factors which can increase stress and anxiety can be physical demands, psychological demands, expectations and pressure to perform to a higher standard according to which the coping mechanism of the athletes should be considered. [2]. The earlier studies that suggested that when the athletes from Spain, Belgium and Portugal competed as a an individual alone, the pressure built up to achieve a desired outcome increases which then intensifies the total anxiety score [19].

Positive correlation between the difference in time after anxiety using its score and it was found significant. This indicated that there was a definite relation between the difference of the previous marathon timing and current marathon timings and the anxiety score with positive correlation (which mean time for recreational marathoners increases with increase of anxiety) where $p<0.05$. The results derived from this study conclude that there is a significant correlation between the level of anxiety and the performance of the recreational marathoners.

Conclusion

By this study it is concluded that there is a marked significance between the anxiety level and performance of recreational marathoners.

Conflict of Interest

The authors declare that there is no conflict of interest concerning the content of the present study.

Ethical Clearance

An ethical clearance certificate was obtained from the instituitional committee Krishna Institute of Medical Sciences Deemed to be University, Karad.

Assessing the effect of *"Ushnodaka Pana"* (Warm Water Consumption) on the Overall well being of I.T Professionals in Pune - A Clinical Study

Sheetal D. Gadhe[1], Shital R. Rasane[2], Shital P. Pachpute[3], Pradnya Kakodkar[4]

[1]Lecturer, Department of Ayurved Samhita, Ashtang Ayurved College, Pune, [2]Associate Professor, [3]PG Scholar, [4]Dy Director, Department of Ayurved Samhita & Siddhanta, Dr D Y Patil Vidyapeeth, Dr. D. Y. Patil College of Ayurveda and Research Centre, Pimpri, Pune

Abstract

Context (Background): Amongst the IT professionals, the consumption of nutritious food and sufficient quantity of water is greatly reduced which has resulted in health problems like complains of regular headache, migraine, acidity and other digestive problems.

Aim: To explore the beneficial effects of "USHNODAKA PANA" (warm water consumption) on the overall well being of the I.T professionals in Pune.

Method and Material: 60 participants from IT field having sedentary lifestyle aged 25 to 50 were recruited from two IT companies. In this "before and after" clinical study, the participant had to prepare and consume USHNODAKA for 7 days. Baseline data (information on appetite, digestion, feeling of lightness, belching, flatulence, bowel habit and consistency, urination, oral malodor, taste sensation and senses stimulation) was collected through interview using a closed ended 12-item questionnaire. Follow up data through telephonic conversation was obtained on 2nd, 4th and 8th day. Z test was use for comparison at $p<0.05$.

Result: At the end of second day, maximum improvement was seen in bowel habits and urination. On the fourth day, maximum improvement was seen in belching (77.77%) and flatulence (69.56%). At the end of 7th day most improvement was seen in oral malodor (80%) and taste sensation (76.47%). There was a statistically significant difference before and after in the 10 parameters except for one (senses stimulation) which did not change even at the end of 7 days.

Conclusion: Overall, it indicates that USHNODAKA can improve the well being of the IT professionals.

Key words*: warm water, IT professional, digestion, well being.*

Introduction

The science of Ayurveda, has put forth two methods for the maintenance of health. They are: "*Swasthasya Swasthya Rakshana"* (maintaining health by adopting proper preventing measures) and "*Aturasya Vikara Prashamana"* (curing of disease by giving suitable treatment for the ailment)[1] .

Globalization has changed the way people do their jobs and business across the world. New employment opportunities are created worldwide on daily basis in Engineering, Medical, Law, Entertainment, Real estate, service sector etc and these sectors need skilful and dedicated workforce willing to put extra efforts to achieve business objectives. The sedentary lifestyle, long working hours and consumption of food at abnormal time explains the lifestyle of a working corporate. Amongst the IT professionals, the consumption of

Phone No:+919503330831

nutritious food and sufficient quantity of water is greatly reduced. Now a days the fast life forces people to take fast food and soft drinks[2]. Most of the times, their meals include fast food along with different *ANUPANA (*liquid consumption after food) like cold coffee, hot coffee, tea, ice-creams, juices and milkshakes. The liquid medium which is consumed with or after food or medicine is called as *ANUPANA*[3].

Ayurvedic science has given utmost importance for choosing the right *ANUPANA* during food. It should not have opposite properties of food. The wrong choice of *ANUPANA* has created health problems among the IT professionals like complains of regular headache, migraine, acidity and other digestive problems[4] .

Water is the best *ANUPANA* which is easily available and can be taken as USHNODAKA[3] **.** It refers to the warm water which is prepared by boiling and reducing it to one half [5]. Aacharya Sushruta said, "***USHNODAKA"*** is *pathyakar (for consumption)* for anytime to everyone and it has potential to bring changes in people who are having sedentary lifestyle[6]. It has surprising health benefits on kidney, leads to more energy, better mood and metabolizes body's excessive fat[7] .

As against this background, the present study was undertaken to explore the beneficial effects of "*USHNODAKA PANA*" (warm water consumption) on the overall well being of the I.T professionals in Pune.

Materials and Method

60 healthy participants from IT field having sedentary lifestyle (persons who are working in sitting posture more than 6 hours/day, since 6-12 months in A.C or without A.C) of both sex and aged 25 to 50 years , willing to participate in the study were recruited. Two IT companies were contacted to obtain the required number of samples. *Pitta prakruti* dominating people were excluded. Approval was obtained from the scientific committee and Institutional Ethics committee (No: AY/ PG/130/2014/15/IEC) . Every participant signed an informed consent form before starting the study. Baseline data regarding the following *LAKSHANAS* (parameters) were recorded (Table 1) : Daily intake of water , *AGNIDEEPANA (*appetite*)*, *PACHAN* (digestion), *UTTAM RASBODH* (taste sensation), *LAGHAV* (feeling of lightness), *UDGAR VISHUDI* (belching) , *MUKHA VISHUDDHI (*oral malodor), *SHOUCH VIDHI* (bowel habits), *SRUSHTA MALA PRAVRUTTI* (consistency of stool) , *SRUSHTA MUTRA PRAVRUTTI* (frequency of urination), *ADHOVATA SARANA* (flatulence) and *INDRIYA NIRMALATA* (senses stimulation).

The enrolled participant had to consume *USHNODAKA* for 7 days as and when the participant felt thirsty. The participant had to prepare fresh *USHNODAKA* everyday morning for the use throughout the day[5]. For example if the participant consumed 2 litres throughout the day, than 4 liters of water had to be boiled and reduced to half (2 litres) , stored in thermoflask and used. During the study period the participant can have their routine food, however they are restricted from consumption of cold water and any other cold beverages.

Follow up data through telephonic conversation was obtained on 2nd, 4th and 8th day. The collected data was entered in Microsoft Excel 2013 and descriptive and inferential analysis using z test was performed. P value of <0.05 was considered as statistically significant.

Results

A total of 38 males and 22 females participated in the study. All the 60 participants completed the study. 12(20%) participants were working in the IT field for <2 years, 16(27%) for 2-4 years and 32(53%) participants have >4 years experience.

5(8.47%) belonged to *Vata Kapha Prakruti*, 13(22.03%) belonged *to Vata Pitta Prakruti,* 20(33.90%) belonged to *Kapha Vata Prakruti* , 12(20.34%) belonged to *Kapha Pitta Prakruti ,* 7 (11.86%) belonged to *Pitta Vata Prakruti* and 2 (3.39%) belonged to *Pitta Kapha Prakruti*.

During the study period , 1(1.67%) participant reported that he consumed 1 litre of water, 16 (26.67%) drank 2 litres, 33 (55%) drank 3 litres and ≥ 4 litres consumption was reported by 10 (16.67%) participants per day.

Table 2 shows the frequency distribution of the11 parameters considered in the study. There was a statistically significant difference in all the *LAKSHANAS* except for one (senses stimulation) which did not change even at the end of 7 days.

Table 3 shows the frequency distribution of the participants as per improvement in their *LAKSHANAS.* At the end of second day, improvements in five *LAKSHANAS* was observed among 4.25% to 9.8% participants, bowel movement improved in 19.35% participants , urination in 22.72% participants and no

change was noted for three *LAKSHANAS (*oral malodor, senses stimulation and taste sensation). Further, on the fourth day, improvement was seen in seven *LAKSHANAS* in the range of 20% -77.77%. Maximum improvement was seen in belching (77.77%) and flatulence (69.56%). At the end of 7th day maximum improvement was seen in oral malodor (80%) and taste sensation (76.47%). Improvement in other LAKSHANAS was in the range of 26.08% to 61.29%. Throughout the seven days there has been no change in the senses stimulation. After 7 days of *USNODHAKA PANA* , all the 60 participants showed normal values for 10 parameters.

Table 1: Data collection proforma

S.No	Questions	Options
1.	What is your daily intake of water?	1lt /2lt /3lt />3lt
2.	Do you feel hungry during meal time? (breakfast/lunch/dinner)?	Yes/No
3.	Do you have any problem in digestion?	Yes/No
4.	Do you have normal taste sensation?	Yes/No
5.	Do you feel heaviness after meal?	Yes/No
6.	Do you get normal belching after intake of food?	Yes/No
7.	Do you feel unpleasant odour in mouth?	Yes/No
8.	Do you have normal bowel habits?	Yes/No
9.	What is the consistency of stool?	Hard/sticky/loose/normal
10.	What is your daily urine frequency?	Less than 3 times/ 3-5 times/ 5-7 times/ more than 7 times
11.	Do you have flatulence problem?	Yes/No
12.	Do you feel all the senses are normal?	Yes/No

Table 2: Comparison of the baseline and follow up *LAKSHANAS*.

	Before (baseline)		After (end of 7 days)

Discussion

USHNODAKA PANA is the best favor we can do to our body[7]. It not only quenches thirst but also helps in the maintence of health of an individual[8]. The result of this study indicate that the overall well being of the IT professional improves by *USHNODAKA PANA* .

It is found to stimulate appetite and digestion[6-9]. It maintains the *samastithi* (balance) of *AGNI* (digestive fire)[4] . Literature reports that consumption of warm water cause expansion of STROTAS (channels) carrying digestive juices, leading to increase in its flow which results in proper digestion of food[10].

USHNODAKA PANA induces noteworthy changes in feeling of lightness in the body after eating meals. This is because it improves the digestion and softens the *DOSHAS*[11] . It is found that *USHNODAKA PANA* reduces belching due to indigestion[12].

USHNODAKA PANA also has notable effect on bowel movements and constipation . The property of warm water is such that , it softens the stools and pushes it out, hence clearing the obstructions of STROTAS (channel)[7,13].

USHNODAKA PANA cleanse the urinary bladder[9,11]. The process of boiling changes the nature of the water making it lighter. This warm water allows it to cleanse the STROTAS (channels) and penetrate in the deeper levels, causing hydration of the tissues and thus making it easier for the body to flush out toxins and impurities[10]. Further, warm water has marked effect on flatulence[12]. It relieves the obstruction of the STROTAS (channels), thus relieves *APANA VAIGUNYA* (*Vata* defect) .

Impressive effects on oral malodor and taste sensation are noted due to *USHNODAKA PANA*, because it helps in downward movement of *Vata* , stimulation of *Agni* (digestive fire) , easy digestion and drying of *kapha*. All these factors put together has an effect on eliminating oral malodor and improving taste sensation[14] .

USHNODAKA PANA on senses stimulation takes a longer time to show beneficial effects[11]. The present study was undertaken for only 7 days and hence no

effect has been noticed on senses stimulation.

There are a few limitations in the present study. The assessment parameters are subjective in nature and are based on the response of the participants. There were no physical checks, if the person prepared and consumed warm water as instructed. However, daily reminders were given to the participants. The ideal study deign would have been the randomized controlled trial, but in the present study the "*before and after study*" design was used.

Conclusion

USHNODAKA is the easily available *ANUPANA* . The study result show that the people with sedentary lifestyle and working in the IT field for more than 4-6 years who have complains of constipation, flatulence, poor appetite, belching, malodor and heaviness in the body after meals have shown noteworthy improvements in these symptoms after taking *USHNODAKA* for 7 days. Overall it indicates that *USHNODAKA* can improve the well being of the IT professionals.

Does Maternity Care Expenditure is Catastrophic? A Cross-Sectional Study of Household`s Expenditure on Maternal Health Care Services in EAG States of India

Shekhar Saroj[1], Rajesh Kumar Shastri[2], Ravindra Tripathi[3]

[1]Research Scholar, [2]Associate Professor & Head, [3]Associate Professor, Department of Humanities and Social Sciences, Motilal Nehru National Institute of Technology Allahabad, Prayagraj, UP, India

Abstract

Objectives: The main aim of this study is to analyze the differentials in average expenditure on prenatal, delivery and postnatal care by socio-economic characteristics of households in EAG states and assessment of the number of households incurred catastrophic health expenditure on maternity care.

Method: We have used 71st round of the NSSO data held on June 2014. For the analysis of prenatal care, delivery care, postnatal care, total maternity expenditure and Out of Pocket Expenditure (OOPE) have been taken as dependent variables and the independent variables have been chosen based on previous studies as well as socio-economic aspects, especially in EAG states of India. Bivariate analysis and binary logistic method have been used for the data analysis.

Results: Results shows that MCE is high in urban sector specially in Orissa among all EAG states. We also found that Orissa has the maximum number of household that incurred high catastrophic-health-expenditure.

Conclusion: We can conclude that women belong to better socio-economic condition spent more money on maternity care and incurred high OOPE where is, it is less among women who belong to poor socio-economic condition, due to lack of awareness and other socio-economic hurdles.

Keywords: *Prenatal Care, Delivery, Postnatal Care, Maternity Care, Out of Pocket Expenditure, Catastrophic Health Expenditure.*

Introduction

India is a developing country comes under the South Asian region, facing a high MMR of 190 per 100,000 livebirth.[1-2] EAG states & Assam covered maximum share of MMR and IMR, out of which 71% of infant deaths, 72% of under age-5 deaths, and 62% of maternal deaths.[3] Xu et al., (2003) found that the proportion of households is positively associated with the catastrophic-health-expenditures and the share of out of pocket payments in total health expenditure.[4] Leone et al., (2013) found that the expenditures on delivery care are substantially higher in socio-economically weak states than the average spending on delivery care in India.[5] The current pattern of health care expenditure shows that only 71% of their total health expenditure born by the household and remaining 29% expenditure covered by the government and other welfare agencies in which 20% (Central), 6% (State) and 2% expenditure covered up by different internal and external welfare agencies, respectively.[6] The rises in OOPE on health care disrupts the consumption of other consumable goods and services which directly affect the living standards of the household, in result health care expenditure become catastrophic.[7]

Catastrophic expenditure is defined as the share of out of pocket payments in total health expenditure, the share of total health expenditure in Gross Domestic Product (GDP/NI) and the percentage of households below the capacity to pay or poverty line.[8] Here, catastrophic expenditure on maternal care are considered those expenditure who covers the expenditure of maternal care from conception to postnatal period.

Although lot of studies have been done on OOPE on delivery care at the country level, this study is the first of its kind to explore the burden of overall maternity care on

households in EAG states. So, there is need for separate research of EAG states to know the consequences and nature of expenditure on maternity care, especially the nature of the OOPE of the households.

Objectives

- To assess the differentials in expenditure on prenatal, delivery and postnatal care by socio-economic characteristics of the households in EAG states.
- To analyze the households incurring catastrophic health expenditure.

Methodology

Data Source

The 71st round of the NSSO data has been used for the analysis which was conducted from January to June 2014 on the title of "Key Indicators of Social Consumption in India: Health." For the analysis, women aged 15–49 years were included who were pregnant in the 365 days before the survey or who delivered the baby and received any maternal care services. For analyzing the maternity care expenditure (MCE), we received the data from those 4,811 women who gave birth in any public or private hospitals. However, information on prenatal and postnatal care expenditure was collected as an aggregate level. Total Maternal expenditure was collected by the source of all three components of health care from prenatal, delivery and postnatal care.[9]

Method

Dependent Variables:

In this analysis, dependent variables have been taken from the four different aspects of Maternal Care Expenditure such as prenatal care, delivery, postnatal care, and total maternal expenditure. Additionally, we have taken OOPE as a dependent variable to examine whether the household incurred any catastrophic medical expenditure (CME) on maternal care. OOPE or net expenditure derived by subtracting insurance reimbursement to total medical expenditure. Prenatal care expenditure, delivery care expenditure and postnatal care expenditure includes expenses incurred in obtaining prenatal, delivery care and postnatal care services separately, whereas the total MCE is the summation of all three expenditure (prenatal, delivery, and postnatal care).

Independent Variables:

The independent variables in this analysis were selected based on social and economic characteristics of the EAG states of India. The variables which have more significance in this analysis is the socio-economic disparities, level of female education (Illiterate & Literate), religion (Hindu & Others), social groups (SC/ST, OBC and General), economic status (Monthly Per Capita Consumption Expenditure of household (MPCE)) and working status of women. We have also used some demographic variables of women such as age (15-24, 25-29, and 30-49) and place of residence (Rural and Urban).

Model for Catastrophic Expenditure:

We have used the proportion method to estimate the catastrophic health expenditureas given by Wagstaff & Van Doorslaer, (2003). This method categorizes the proportion of household incurring catastrophic health expenditure based on the share of health expenditure in the household's total consumption expenditure at 10 percent cut-off levels. This cut-off level provides a chance to estimate the concentration of the problem. An OOPE for healthcare turn into catastrophic expenditure when the payment exceeded some threshold (cut-off) level and defined as a part of total household non-food consumption. If T represents OOPE for healthcare, x represents total households expenditure, and f(x) stands for food expenditure, then a household is said to have incurred catastrophic payments when T/x or T/[x-f(x)] exceeds a specified threshold, Z.[8]

Statistical Method

In this study, we have used descriptive statistics to explain the charrecterstics of the variables, and Bivariate-analyses to examine the unadjusted association among dependent and independent variables. A Binary-logistic-regression model was also used to assess the independent association between dependent and independent variables. We have taken the net maternity expenditure 1 when it is higher for the cut off level and 0 when it is less than cut off level to run the binary logistic model where 1 shows the high OOPE. The whole analysis has been carried out in STATA-13 software.

Result

Average Expenditure on Maternity Care:

Table 1 explain the expenditure pattern of households by their various socio-economic characteristic among all age groups. The MCE, prenatal, delivery and postnatal care expenditure is highest in 15-24 age group and lower in 30-49 age group. The MCE is high in urban sector (Rs.10274) as compared to the rural (Rs. 6369). The literate woman incurred high MCE as compared to illiterate woman, and delivery care expenditure is higher (Rs. 6944) among all three MCE. The General category women incurred higher MCE which is twice higher than women belongs to SC/ST category. Table-1 shows that as quintiles increases (poorest to richest), expenditure on all maternity care also increases. MCE is highest (Rs. 17247) in richest quintile and lowest (Rs. 4907) in poorest quintile. Women involved in casual labour spend less than Other working groups. There is high MCE incurred by Orrisa (Rs 8050) followed by Bihar and Uttar Pradesh and least expenditure incurred by Chhattisgarh (Rs. 5246).

Out Of Pocket Expenditure on Maternal Care at 10% Cut off Level

Table 2 shows the percentage of households incuring high OOPE. In the age group (25-29), maximum (9.2%) of household incurred high OOPE. Percentage of household having high OOPE is higher, where women are literate and belongs to Hindu religion and in a social group, it is highest (7.5%) in the general category women. In MPCE quintile, percentage of household incurred high OOPE is showing an increasing pattern as wealth quintile shifting from poorest to richest quintile. In Orrisa (9.1%) of household are incurring high OOPE on maternity care followed by in Bihar (6.8%) and Uttar Pradesh (6.4%) where is household of Rajasthan incur least OOPE.

Age group (30-49) shows the significant association where age group (30-49) is 54% more likely to incur high OOPE on maternity care. Table 2 shows the general category is significantly associated with the net MCE where the odds of occurrence of high OOPE on maternity carries 20% more as compared to SC/ST category. An increasing trend can be observed in case of wealth quintile where odds of incurring high OOPE on maternity care is increasing as wealth quintiles shifting from poorest to richest quintile. In EAG states, Bihar is 34% more likely to incur high OOPE on maternity care.

Discussion

This paper is a quantitative analysis of expenditure incurred in the utilisation of maternal health care services in EAG states, and also talks about the critical socio-economic and demographic factors influencing the catastrophic health expenditure of the households. Study said that literate women are more concern about their health and to avoid the maternity related complications they spent more on maternity care services than illiterate women. The MCE is high among women belong to the urban area than their rural counterparts because of education and decision making power. We also found the same result where socially and economically better off women spent more on maternity care than economically poor and socially disadvantaged group of women.[10-11] Similarly, Average OOPE is higher among the literate women who belongs to higher quintile than illiterate women who belongs to lower quintiles, because mostly literate and economically strong women have the ability to pay higher prices and they ask for better quality health care services.[12] In rural areas, women are mostly less educated, dependent, poor and unaware about the maternity-related services and complications than urban area, in result they spent less money on maternity care. In our study, we found that OOPE on maternity care is higher among women those belong to General Category and Non-Hindu religion than their counterparts.[10] We found the differentials in MCE and OOPE among EAG states where Orrisa incurred the highest MCE than other EAG states and also maximum number of household incurred OOPE in this state.

Conclusion

Based on the above findings, we can conclude that women belong to poor socio-economic condition spent less money on maternity care due to lack of awareness and other socio-economic hurdles. The government should give more emphasis on policy implementation on community level and give more focus on maternal and child health-related awareness programmes especially in EAG states where people are less educated and economically poor. The government should also look into policy consideration on the implementation of community health insurance to reduce the economic burden of maternity care, especially in EAG states.

Due to the limitation of NSS dataset, we could not do extensive and in-depth study on factor influencing on catastrophic expenditure on maternal care, it can be suggested that the state-wise rural-urban analysis and public-private hospital based differencial analysis could be done in the future for in-depth information about catastrophic expenditure on maternal health care.

Ethical Clearance- This study is based on secondry data base, NSSO 71st round survey which were conducted by Government of India. So, there is no need of ethical clearance for data collection from any research committee.

Source of Funding- The authors have not received any funding or benefits from industry elsewhere to conduct this study.

Evolving Patterns of Adjustment to Maintain the Functional Health of Elderly Living Alone in NCR

Shikha Kumari[1], Alka Sharma[2]

[1]Doctoral Research Scholar, Department of Humanities and Social Sciences, Jaypee Institute of Information Technology, Noida, [2]Dean, Department of Humanities and Social Sciences, Jaypee Institute of Information Technology, Noida

Abstract

Background- One of the most important determinants of the quality of life of older people is their functional health status that refers to their capacity to perform normal daily activities. With the advent of globalization and changing family structures, there are elderly who are left alone to fend for themselves without any formal support. **Aim & Objective:** to find out the evolving patterns of adjustment in the absence of care giver of elderly who are living alone in Delhi/ NCR. **Material and Method:** The study is carried under descriptive research design. One Household Proforma was used for the purpose of obtaining their demographic information and a pretested scale is used to elicit the information on their IADL after taking consent from the elderly. Snowball sampling technique is incorporated for data collection. Data is collected from a structured questionnaire and Focus Group Discussions with 80 respondents above the age of 60 years, living alone from Delhi/NCR to find their adjustment patterns. **Result:** the results show that respondents are independent for their ADL and IADL and in case of dependency the respondents have two types of support- support on daily basis i.e, house-help and support available for in absentia of routine care takers i.e, their kin living in the vicinity and elderly groups formed in the community. **Conclusion:** The respondents have formed their own community networks that provide assistance to them in case of need or they reconcile to avoidance.

Keywords: *elderly living alone, functional health, instrumental activities of daily living, community support*

Introduction

Recently, the proportion of elderly people in India has risen at a high rate, and this trend is likely to be similar in the decades to come. The elderly would represent about 34 percent of the nation's total population before the end of the 21st century [1]. There are nearly 104 million elderly people in India, consisting of 53 million females and 51 million males, according to the 2011 Population Census. Around one-fifth live either alone or with the partner of life alone. Those who live alone or just with their partner in life have to deal with their own material, physical needs and health needs. Older people living alone without a partner (living alone) have increased over time from 2.4% in 1992–1993 to 5% in 2004–2005 [1]. Approximately 5% of the elderly live alone, while another 4% live with other relationships and non-relationships. The well-being of older people depends heavily on who they live with [1], especially in developing countries where the elderly have a limited option for the formal social care system, including other related welfare services [2]. Living alone elderly persons have to face different type of challenges in their day to day activities. The major reason behind these challenges is their deteriorating health. A number of studies show that elderly living alone in the community has to face lack of support and limited resources [3], they are in need of medical facilities, leisure and social settings and financial subsidies [4]. The lack of familial support and social services in monitoring their health status and medical appointments [5] and caregiving [6] are linked with poor self-management of the health of elderly living alone. Based on the desire and constraints of their children's

daily lives, the children may or may not support the elderly. By and large the welfare state is unable to pay for or provide for the delivery of formally organized health and social care programs and associated support services like personal care services for the elderly [7]. Functional status assessment is important for the care of older adults. Functional health can be described as the ability to carry out all one's daily living activities [8]. Daily living tasks are self-care, such as washing, dressing, using the toilet, shaving and feeding yourself. These are the activities that need to be done every day. IADLs (Instrumental activities of daily living) are not necessary for essential functioning of the individual but they allow them to live independently in the community [9]. Changes in aging, disease, deteriorating chronic disease, and hospitalization may lead to a decline in the capacity to perform these tasks needed to live independently in the community.

Aims & Objectives: to find out the evolving patterns of adjustment in the absence of care giver of elderly who are living alone in Delhi/ NCR.

Material & Method

Study Type: Exploratory and Descriptive study

Study Area: National Capital Region (NCR) has been selected as the location for conducting present research work.

Sampling Frame: Residential colonies

Sampling techniques: Purposive and snowball sampling methods have been employed for identifying the respondents.

Sample Size- For the collection of data the researcher has identified 100 respondents to get the questionnaire filled but some of the respondents were not able to continue the interviews due to their non-availability as they went to their children's home and ill-health. So they had to drop out. 80 complete questionnaires were filled.

The study is carried under descriptive research design. One Household Proforma was used for the purpose of obtaining their demographic information such as age, gender, religion, educational qualification, current work status, income, expenditure and savings. Assessment of older people: self-maintaining and instrumental activities of daily living by M.P. Lawton & E.MBrody[10] is used to elicit information on their functional health after taking consent from the respondents. Focus group discussions are conducted to explore the evolving patterns devised by the respondents to maintain their functional health in the absence of care givers. Snowball sampling technique is incorporated for data collection. Data is collected from a semi structured interview schedule with 80 respondents above the age of 60 years, living alone in Delhi/NCR to find their adjustment patterns.

Results

The above table represents socio-demographic profile of the study participants. Out of the total 80 participants, 60% of participants are in the age bracket of 65 to 70 while 20%- 20% are of 60-65 and 70 and above. 80 % are female while 20% are male participants. A large percentage of respondents, i.e. 80% are widow/ widower, 10% are never married and 10 % are divorced or separated. 40% of the respondents are graduate. In the work status, the researcher finds that 10%, 40%, 10%, 10%, 30 % are retired from government services, Retired from private service, Self-employed, Home maker and take care of properties respectively.

Assessment of functional health in terms of ADL and IADL

The scale developed by Lawton and Brody 10 is used to measure the ability of respondents to perform IADL (instrumental activities of daily living). The instrument has been widely accepted as a valid and reliable measure for use in elderly community populations. This scale is consists of eight items. The questionnaires are completed by the respondents and researcher (in cases where elderly are illitrate) at their homes. Responses were recorded for each item, regardless of a client's sex. Scores increased with level of dependence on the range of 1-5, and the same scoring system was used for both sexes.

Frequency data were obtained from the IADL scale to determine dependency in each of the IADLs. All the respondents are fully independent for self-care activities such as toilet, bathing, feeding and grooming. For IADL activities, most of the respondents (90%) reported being independent in using the telephone and 10% reported being partially dependent. 60% of the respondents reported being independent for shopping while 40% are partially dependent. Half of the respondents reported being self-sufficient in food preparation and 20% and 30% are partially and fully dependent for preparation of food. Majority of respondents (70%) were dependent for their housekeeping needs out of which 30% and 40% are

partially and fully dependent. 50% of respondents are fully dependent for their Laundry on someone. 80% of respondents are fully independent for their transportation activity. A large no of respondents, i.e, 90% said they take their medicines without others help. 75% of older adults said they are fully independent in handling their finances while 25% are partially dependent [Table 1].

Emerging patterns of IADL support

All the respondents are self-dependent for activities such as toilet, bathing, feeding and grooming. Some of the respondents reported being slow and clumsy sometimes in self-care activities but they are not dependent on anyone for self-care activities. They avoid such activities that time. In case of dependency the respondents have two types of support- support on daily basis and support available for in absentia of routine care takers. For day to day assistance in telephone use, 8 respondents reported relying on house help while 3 get some help from their grandchildren. House help, daughters, niece and son are reported to provide help for the shopping activities of elderly. 36 respondents reported to be dependent on house help for food preparation and housekeeping in case of need. House help is again the main point of care provider for 56 elderly for their laundry needs. In case of in absentia routine care takers dependency the elderly rely on their friends, the elderly group from their residential societies of which they are also a part and sometimes the children of their friends. In some situation their coping mechanism is avoidance [Table-2]. For IADL, the support can be divided into three categories- self, paid and unpaid. House help are the paid care providers and community support provides the unpaid help to the elderly. In every residential society, elderly have formed their own groups.

These elderly groups (formed on the basis of activity for example, laughing clubs, walking groups and yoga groups) of the same society are connected through personal and telecommunication modes such as WhatsApp and always support, promote and motivate each-others. If the house help is absent, others cook food and bring it to them. If anyone needs anything, they post it on WhatsApp and others try to facilitate and help.If someone does not turn up for the get together, others call them to enquire and if necessary pay visits. If someone is found to be in low mood, the others invite them to their houses or visit them for a chat to make them feel good. Sometimes such persons are accompanied to temples or shopping complexes for an outing. If someone is down with routine medical issue such as fever, cough and cold, pain etc, others help them homemade remedies. Most of the times they themselves prepare the remedies and bring it along with some tea and snacks to the houses of the ones they are visiting,so that the host is freed of chores. These finding is in line with the study published by Black in 2012 which had revealed that older adults themselves were actively helping each other in maintaining their home. Black's study also suggested that the older adult with similar life experiences value other's opinion [11].

Ability to handle finances	daughter	8	Avoidance	15
	son	12		

Conclusion

In this study setting, the family is absent. Also, there is no formal system of providing assistance in home based care of elderly. This situation has led the elderly to find and create their own ways to adjust to this situation. The immediate solution to this situation is house help but this help is unskilled, uneducated and untrained for their needs and care taking. They have to deal with their absenteeism, irregularity, misbehavior. There are also the issues of their reliability.

It is in this background that the elderly appears to have reconciled to community networks. There seems to be an evolving pattern of adjustment where elderly persons form and become part of community networks

of similar age cohorts that support, promote and motivate the group members.

However, when the support from the community network is unavailable at times, the elderly seems to avoid performing daily activities. This avoidance may lead to functional health decline.

Limitation of the study-

Future research should be done on larger populations. There is a scope of exploring more ways of adjustment of elderly. Level of community support should also be measured.

Relevance of the study-

This study explores the emerging patterns of adaptation of elderly to maintain their functional health. It reports new emerging social phenomena where older adults are active care providers to self and others. This study also adds to the existing body of knowledge on the emerging living arrangements of older people in India.

Ethical Clearance- It will take 15-20 days to get the ethical clearance from the committee.

Correlation between BMD Level and Preventive Osteoporotic Practice among Menopausal Women

Shiney Paul[1], Timi Thomas[2], Agy Sebastian[3]

[1]HOD- Department of OBG (N), Nitte Usha Institute of Nursing Sciences, Paneer, Mangalore, [2]Assistant Professor, Department of OBG (N), Nitte Usha Institute of Nursing Sciences, Paneer, Mangalore, [3]Staff Nurse, Justice K.S Hegde Charitable Hospital, Deralakatte

Abstract

Introduction: According to Asian Audit Report 2009, Osteoporosis is the most emerging health problem among Asians. Rapid bone loss occurs when menopause is attained. It is found to be the greatest in the early stage of postmenopausal period. The objectives of the study were: assess the BMD level and preventive osteoporotic practice among menopausal women, find out the correlation between BMD level and preventive osteoporotic and to find the association between BMD levels with selected demographic variables. Lifestyle practices like adequate exposure to sunlight, regular exercise and appropriate diet proves to have positive impact on bone health among menopausal women. These measures prove to be safe and cost-effective. Promoting and maintaining health of women by educating them to adopt healthy lifestyle practices is role of an advanced nurse practitioner. Therefore, the investigator was interested in preparing an information booklet on preventive practices for osteoporosis among menopausal women.

Method: Non-experimental research approach was used and the design selected for the study was cross sectional survey. Sample comprised of 100 menopausal women attending orthopaedic OPD at K.S Hegde hospital, Deralakatte, Mangaluru. Convenience sampling technique was used to select the samples. Data was collected from 05/09/2018- 28/12/2018 by using demographic performa, BMD level and osteoporotic preventive practice checklist. The collected data were entered systematically in the SPSS for data analysis.

Results: The results of the study shows that the P value of chi square test for association between BMD level with demographic variables such as age (0.000), total number of children (0.005), age at menopause (0.003) and source of information (0.000) are at 0.05 level of significance. Hence the research hypothesis interpreted that there is significant association between BMD level with selected demographic variables.

Conclusion: The measures adopted by menopausal women to achieve and sustain an optimum level of bone health vary from individual to individual, community to community and country to country. The nurse practitioner has a primary responsibility of enhancing the knowledge, positive attitude, good health status among menopausal women.

Keywords: *Menopausal women, osteoporosis, BMD level*

Introduction

Osteoporosis is the major fitness concern in the world affecting greater than 200 million menopause women. No symptoms are found in it as such but responsible for over 80% of all fractures in post-menopausal women[1]. The prevalence of hip fracture throughout the world is 17 lakhs and it is likely to increase to 2.6 million by 2025. Women are four times at greater risk to develop this condition when compared to men. Twenty- eight percentage of women die in a year due to sustainment of hip fracture[2]. In developing countries hip fracture consumes more hospital bed days than heart attack, stroke and diabetes in overall.

Corresponding author:
Timi Thomas, MPhil (N),
Assistant Professor, Department of OBG (N), Nitte Usha Institute of Nursing Sciences, Paneer, Mangalore.
e-mail: timjith@gmail.com

In India osteoporotic fractures commonly occurs at younger age when compared with that of the West. A study published in recent times enumerates the prevalence of vitamin-D deficiency all across the country particularly in the urban areas including both the gender and all age groups[3].

Background of the Study

According to Asian Audit Report 2009, Osteoporosis is the most emerging health problem among Asians. Most of the elderly population in our country is prone to get fragility fractures at the hip, spine and wrist which are associated with osteoporosis. Hip fracture is more serious than the other fractures associated with osteoporosis, because of the complications like chronic pain, disability and diminished quality of life[4].

WHO reports that osteoporosis accounts greater co-morbidity second only to cardiovascular disease and studies proved that post-menopausal women chance of getting hip fracture and breast cancer risk is almost equal to it. The burden among health care system on elderly population which escalates day to day is more as the treatments are costly. Rapid action need to be taken to counter this economic threat[5].

Need for the study

After the onset of menopause women are generally at greater risk of osteoporosis due to lowering of oestrogen hormone in the body. Reduced level of this hormone initiates bone loss with subsequent reduction in bone production leading to osteoporosis[6]. Surgical menopause also may pave way to the condition when the ovaries are removed surgically resulting in lowered oestrogen level[7].

As elderly women population continues to climb, the incidence of osteoporosis will increase. Osteoporosis is caused by a combination of genetic, hormonal, environmental and dietary factors[8]. Attempts to monitor, identify and where possible, control these factors are the only ways to prevent this diseases. Health care providers must also explore strategies to deal with the increasing numbers of elderly people who are susceptible to a condition known as osteoporosis.

Good lifestyle practices like adequate exposure to sunlight, regular exercise and appropriate diet proves to have positive impact on bone health and metabolism among Indians. These measures prove to be safe, cost-effective and efficient to large populations and are recommended as an important health measure to overcome the condition[9]. Promoting health is the role of a advanced nurses practitioner in maintaining and improving client and community well-being[10]. Educating and empowering the individuals to integrate healthy lifestyles practices is an important task in the hand of health care provider Therefore, the investigator was interested in preparing an information booklet on preventive practices for osteoporosis among menopausal women.

Title of the study

Correlation between BMD (Bone Mineral Density) level and preventive osteoporotic practice among menopausal women attending Orthopaedic OPD at selected hospital in Mangalore with a view to develop an information booklet.

Objectives

1. To assess the BMD level among menopausal women.

2. To assess the preventive osteoporotic practice among menopausal women.

3. To find out the correlation between BMD level and preventive osteoporotic practice among menopausal women.

4. To find the association between BMD level with selected demographic variables.

Protection of human subject

1. Ethical clearance was obtained from Institutional ethics committee after presenting the research proposal.

2. Permission for conducting the study was obtained from concerned authority of NUINS College and Justice K.S. Hegde Charitable Hospital, Mangaluru.

3. Informed consent and subject information sheet was explained and the same was obtained from the subjects prior to the study. Assurance was given regarding confidentiality of personal information and no harm to the participants during the study period.

Research Methodology

Quantitative non-experimental research approach was adopted in the study and the research design was

cross sectional survey. The study was conducted in Orthopaedic OPD at Justice K.S hedge Hospital, Deralakatte. A total of 100 menopausal women who are attending the Orthopaedic OPD and who met the inclusion criteria were selected for the study. The inclusion criteria's were women who have attained menopause and who are both physically and mentally sound. Menopausal women with Gout, bone TB, and rheumatoid arthritis diseases were excluded from the study. The data collection instruments were used for the study was demographic performa, BMD level and preventive osteoporotic practice checklist. The demographic Performa included: age, education, occupation, monthly income, total number of child, religion, source of information, age at menopause. The preventive osteoporotic practice checklist consists of 25 items related to life style practices. Content validity of the tool was done by 8 experts in the field of Obstetrics and gynaecology and the corrections were incorporated in the tool as per the suggestions given by the experts. The data collection instrument on preventive osteoporotic practice checklist was administered to 10 menopausal women to measure the reliability and the internal consistency and the same was measured with Cronbach's Alpha using SPSS statistics and it is found to be reliable with the score of 0.889. The data was collected between 05/09/2018- 28/12/2018 from 100 menopausal women who aged above 50 and attained menopause and the data were entered systematically in the SPSS for data analysis.

Result

The data were analyzed and presented under the following headings.

Section I: Description of demographic characteristics.

Section II: Description of BMD level among menopausal women.

Section III: Description of preventive osteoporotic practice among menopausal women.

Section IV: Correlation between BMD level and preventive osteoporotic practice

Section V: Association between BMD level with selected demographic variables.

Section I: Description of demographic characteristic

The demographic details shows that, majority of the menopausal women (40%) were between the age group of 41-50 years, out of 100 samples 46% menopausal women were having primary education, 47% of the menopausal women were homemaker, 67% were having a monthly income of <10,000, 50% is having 4-6 number of children, In this study out of 100 sample 43% attained menopause at 49 years of age and none of the participants had source of health information regarding osteoporosis.

Section-II: Description of BMD level among menopausal women.

Table 1: Frequency and percentage distribution of subjects according to BMD level n=100

BMD Level	Frequency (f)	Percentage (%)
-1 or above	85	85
-1 to -2.5	10	10
-2.5 or below	5	5

The data in the table 1, shows that out of 100 sample 85% is having a BMD level of -1 or above, 10% having -1 to 2.5 and 5% having -2.5 or below.

Section- III: Description of preventive osteoporotic practice among menopausal women.

Table 2: Frequency and percentage distribution of preventive osteoporotic practice among menopausal women. n=100

Items	Never (0)		Sometimes (1)		Always (2)	
	f	%	f	%	F	%
Consume dairy products such as milk, curd and cheese	9	9.0	56	56.0	35	35.0
Consume sea foods such as sardines and salmon with bones	21	21.0	50	50.0	29	29.0
Consume fatty fish (mackerel or tuna) and egg yolks	28	28.0	55	55.0	17	17.0
Eat fruits like papaya, banana, orange, apple and grapes	5	5.0	53	53.0	42	42.0
Eat green leafy vegetables, cabbage, spinach, beet root and cauliflower	3	3.0	34	34.0	63	63.0
Consume protein rich food like beans, peas, legumes, black gram, dal and chicken liver	15	15.0	57	57.0	28	28.0
Consumption of soft drinks like sprite, pepsi, coca cola and lime soda	25	25.0	41	41.0	34	34.0
Drink coffee	22	22.0	58	58.0	20	20.0
Consume red meat like pork and mutton	37	37.0	57	57.0	6	6.0
Eat nuts like ground nut and almond	41	41.0	40	40.0	19	19.0
Consume cereals like ragi gingelly and whole wheat	19	19.0	53	53.0	28	28.0
Expose to sunlight minimum of 6 minutes/day	30	30.0	30	30.0	40	40.0
Consume canned food, pickle or papad	16	16.0	66	66.0	18	18.0
Consume alcohol	100	100	0	0	0	0
Use smokeless pan	100	100	0	0	0	0
Perform weight bearing exercise such as lifting the objects or stair climbing	14	14.0	69	69.0	17	17.0
Walks for minimum of 20-30 minutes per day	21	21.0	39	39.0	40	40.0
Perform yogic measures like suryanamaskara	74	74.0	23	23.0	3	3.0
Does household activity such as mopping the floor, cleaning and washing clothes	25	25.0	45	45.0	30	30.0
Use of drugs like corticosteroids, chemotherapeutic drugs, anticonvulsants and proton pump inhibitor	4	4.0	96	96.0	0	0
Personal history of medical illness like hyperthyroidism or hypothyroidism	61	61.0	27	27.0	12	12.0
Perform Bone Mineral Density test to assess bone loss	83	83.0	14	14.0	3	03.0
Check the nutritive value of the content in the packed food	66	66.0	23	23.0	11	11.0
Check the serum calcium and vitamin D in the blood as per physicians advice	66	66.0	29	29.0	05	5.0
Consult a health care provider for any falls or aches and pain	12	12.0	58	58.0	30	30.0

The data in the table 2 shows that out of 100 menopausal women, 56% are consuming dairy products sometimes. 29% are consuming sea foods always, 28% are not consuming fatty fish and egg yolks. 53% are taking fruits sometimes, majority 58% are consuming coffee sometime, 28% are consuming cereals always. Majority 69% are performing weight bearing exercise regularly. Out of 100 menopausal women only 3 participants are performing yogic measures very regularly and 11 menopausal women check for the nutritive value of the product before they buy. In the study none of the research participants had a habit of chewing smokeless pan or consuming alcohol.

Section IV: Description of correlation between BMD level and preventive osteoporotic practice among menopausal women. The study findings showed that there is no correlation between the BMD level and preventive osteoporotic practice.

Section- V: Description of association between BMD level with selected demographic variables.

Table 3: Association between BMD level with selected demographic variables

Demographic variables	Chi square	df	P value
Age in years	33.797	1	0.000
Education	12.103	1	0.017
Occupation	12.138	1	0.059
Monthly income	4.478	1	0.345
Total number of children	15.012	1	0.005
Religion	13.863	1	0.008
Age at menopause	19.737	1	0.003
Source of information	33.797	1	0.000

The table 3 shows that the P value of chi square test for association between BMD level with demographic variables such as age ($\chi 2$ =33.797, p= 0.000), total number of children ($\chi 2$ =15.012, p=0.005), age at menopause ($\chi 2$ =19.737, p=0.003), and source of information ($\chi 2$ =33.797, p= 0.000) are at 0.05 level of significance. Hence the research hypotheses interpreted that there is significant association between BMD level with demographic variables like age, total number of children, age at menopause and source of information.

Discussion

Section I: Description of demographic characteristics.

Majority of the menopausal women (40%) were between the age group of 41-50 years, out of 100 samples 46% menopausal women were having primary education, 47% of the menopausal women were homemaker, 67% were having a monthly income of <10,000, 50% is having 4-6 number of children, In this study out of 100 sample 43% attained menopause at 49 years of age and none of the participants had source of health information regarding osteoporosis. The study findings are supported by another study conducted by Seang-Mei Saw et.al, in which the results are showed that, 68.8% women were post-menopausal and none of the participants heard about osteoporosis[11].

Section II: Description of BMD level among menopausal women.

This study shows that out of 100 sample 85 (85%) is having a BMD level of -1 or above, 10 (10%) having -1 to 2.5 and 5 (5%) having -2.5 or below.

Section III: Description of preventive osteoporotic practice among menopausal women

The study shows that out of 100 sample majority of the menopausal women (56%) are consuming dairy products sometimes. The present study was compared

with another study conducted by Roberto HR et.al[12] shows that the risk factors vary from one another: women with low calcium intake (85.7%), lack of exercise (43.7%) and family history of osteoporosis (30.5%) had high incidence. Majority (79.1%) of the females are of the opinion that osteoporosis is not serious but only a proportion (15.2%) of it considers that osteoporosis was more serious than cancer.

Section IV: Description of correlation between BMD level and preventive osteoporotic practice among menopausal women. Comparative studies are not found.

Section V: Association between BMD level with selected demographic variables. No comparative studies are found.

Conclusion

The measures adopted by menopausal women to achieve and sustain an optimum level of bone health vary from individual to individual. The nurse practitioner has a primary responsibility of enhancing the knowledge, positive attitude, good health status among women. Awareness about maintenance of health status and reducing the risk among post-menopausal women can be created and followed by guidance and counseling and even referral services can be provided after screening.

The limitation of the present study was shorter duration period.

Recommendations for future research:

- The study can be replicated in different settings, with different categories of participants
- Interventional study can be conducted in high risk samples with calcium supplements, regular exercise, appropriate dietary pattern and exposure to sunlight.

Acknowledgment: The authors deeply acknowledge the menopausal women for their participation in the study.

Rural Oral Health: Challenges and Pit Falls: Time to Recover And Rebuild the Pathway: A Review Article

Shivanjali Grover[1], Meetika Pahuja[2], Sanchit Pradhan[3], Mohd. Akif, Kanchan Shukla[4]

[1]Associate Professor, [2]Assistant Professor, [3]Assistant Professor, [4]Lecturer. Department of Public Health Dentistry; Subharti Dental College and Hospital, Swami Vivekanand Subharti University, Meerut

Abstract

Health or oral health is right of every individual. Oral Health is basically a complete state of health which is free of all discomforts. A state where eating, smiling and speaking is not hampered by any kind of discomfort or disability.

Rural oral health care faces challenges both ways for dentists as well as for people residing in the particular vicinity. These challenges can be listed as follows: dentist: population Ratio, literacy rate, accessibility, availability, affordability, socio – economic status, malpractice.

There are few common barriers that a dentist faces while thinking of serving at a rural area. They can be summarized as safety, basic amenities, monetary constraints, lack of professional skills, distance and a compromised lifestyle.

Government and various Dental Associations are making repeated efforts to overcome these challenges and pitfalls to uplift the rural oral health care.

***Key Words**: Rural Oral Health, Dentist: Population ratio, accessibility, affordability, challenges*

Introduction

Oral health is right of every individual as good health is right of every individual. Oral health can be defined as "a state of being free from chronic mouth and facial pain, oral and throat cancer, oral infections and sores, periodontal diseases, tooth decay, tooth loss and other diseases and disorders that limit an individual's capacity in biting, chewing, smiling, speaking and psychosocial well-being"[1].

According to World Bank every country has a percentage of rural population that is deprived more of oral health services. In India 66% of the population resides in rural parts of the country. There are countries which have a large percentage of rural population like Nepal (80%), Sri-Lanka (82%), Zimbabwe (68%), and many more such countries are there that have a large number of population residing in the remote part of their countries. Such kind of population generally has quacks that provide all sorts of malpractice treatment which are not only threat for oral health care of the patients but they are also threat for the field of dentistry[1].

As per Kimberly K. McFarland et al., approximately 20 percent of the U.S. population lives in rural areas, whereas only 14 percent of the dentists practice in rural locations. 4 percent of small areas and 2 percent is isolated in rural areas that are deprived of all kind of dental services. As per Nastaran Sharifian et al., there is chronic shortage of dentists in rural communities of Canada may affect the quality of care provided to these communities.

Hence this article has been written to focus on the common challenges and pit falls that the population and the dentist face due to which the rural population still is deprived of good oral health care.

Challenges and Pit Falls

Challenges for Establishment of Successful Oral

Health Care Delivery

1. Dentist: Population Ratio:

There is huge imbalance in the dentist population ratio. This imbalance is not only faced in India but also in various developed countries. As per World Health Organization the idle dentist population ratio is 1:7500 but there are only 93% of the members short of this ratio either the ratio is more or less that the idle ratio. Therefore, it is resulting in Imbalance.

In India the dentist: population ratio is 1:9000 in the urban areas and 1: 200,000 in rural areas. Similarly, dentist: population ratio in U.S. is 1:1000, in U.K. it is 1:2000, in Canada 1:1500, Australia 1: 2573. These are the data for urban population mostly. Repeated studies have shown chronic shortage of dentist in rural areas of almost every country.

2. Literacy rate:

Literacy rate plays an important role in maintaining of oral hygiene. This statement is false and true both ways. In India highest literacy rate is 93.68% and lowest is 63.52% but still the oral health of the population varies from good to very poor. Even the rural population where literacy rate is low there also there are people who have good oral hygiene. Literacy rate of the particular family matters as generally we tend to inculcate habits and routine seeing the family members. A well literate family who has a hygienic lifestyle generally have the trend of good oral hygiene in the complete family.

In India, use of dantoons and various kinds of toothpowders is still prevalent in remote parts of the country. Even after companies like Colgate – Palmolive run oral health month campaign every year in which they distribute toothpaste and toothbrush to population of rural areas of India.

In India there are few barriers which play a significant role in rising of oral health services. They are:

1). Lack of Respect and trust on dentists. The population is rural areas are at times blinded with myths. These myths act as barrier for reaching of right kind of oral health care to the population.

2). Different mindsets: Myths play a very negative role when it comes to providing of dental services in the rural population.

3). Poor listening skills: Reinforcement of things is a kay to successful rural oral health. Repeated awareness programs need to be conducted for implementation of successful oral health services.

4). Knowledge deficits

5). Lack of alignment around goals

6). Internal Competitiveness

7). Information Hoarding

3. Accessibility and Availability

Accessibility of services for upliftment of oral health at rural areas is a real challenge. With increase in number of dentists yearly the congestion of clinics is more in urban areas as compared to rural areas. Even the government has started taking initiative to place dentists in primary health centers with the aim to uplift the oral health of the rural population. Accessibility and availability are inter-related. With 313 dental colleges across India availability of dentists have become little easier. On a positive every dental college has mandatory Department of Public Health Dentistry which works with the motive to uplift rural oral health mostly.

4. Affordability

Dental services that are provided to population has a range of fees for all kinds of treatment available. When deciding on the fees for dental services with the aim to treat rural population one thing should always be kept in mind to work with aim of no profit. At a less or a nominal fee the treatments can be provided very much.

The government also should launch health schemes that include coverage for oral health services as well.

5. Malpractice

It is one of the challenges which is on rise extremely. Every rural locality has some quack present who is providing malpractice and the treatment provided are so reasonable that the population in mass is blinded with the treatment irrespective of whether it would really cure the problem or aggravate the problem. Such kind of malpractice is a big threat. This threat is not only in India abut across the world.

Challenges for the Dentists:

There are certain challenges that a dentist has to face when planning for a rural setup.

1. Safety:

We are well aware about the attacks happened at doctors by patients or their relatives while treatment of the patients. Such incidences have questioned the safety issue of the dentists. A fear or threat to life in rural areas is prevalent. Lack of awareness is the basic problem that is faced. Repeated Awareness programs for the masses is one solution to this challenge.

2. Basic Amenities.:

It is a well-known fact that rural areas are deprived of basic amenities like electricity, water, etc. But as of now the government has worked immensely on such issues therefore making it little easier. But schools and education system in rural localities is still quite compromised. Any dentist who plans to setup a clinic is rural areas always has a hesitation as compared to setting up clinic in urban areas.

3. Monetary constraints:

As the population in rural areas are employed in a basic manner where their income is very nominal, so affording dental treatment is a big challenge for them as well. The income at rural setup is challenging. Where patients in urban areas are ready to pay fees for the treatment modalities rural population is still on the back foot for it. Therefore, monetary constraint is always a challenge too.

4. Lack of professional skills:

Rural dentistry demands only basic oral health care treatments. Specialization work in rural population is a rare. Public Health Dentists are trained during the post-graduation period in the similar manner so that they can serve the rural population efficiently.

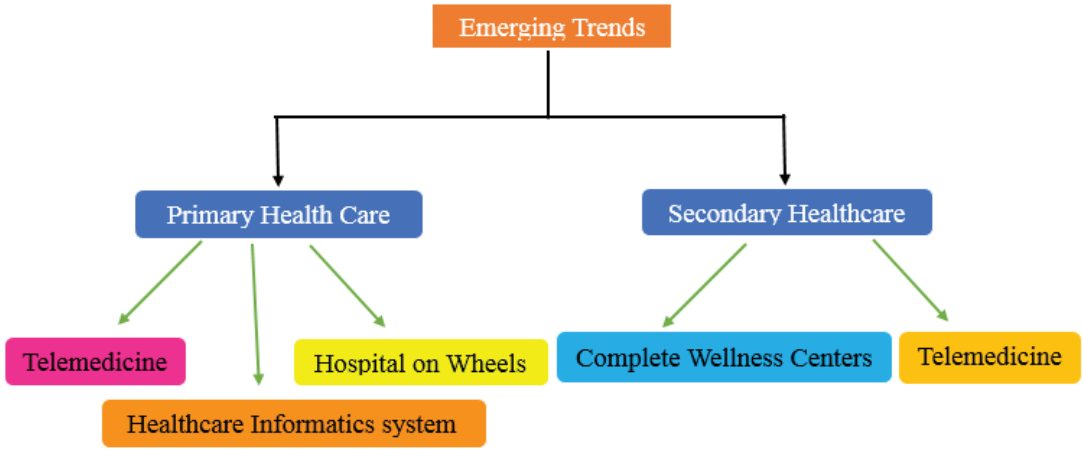
5. Distance and Compromised lifestyle:

It is another one big challenge for any dentist who plans to setup to serve in rural area. As the rural areas are at a respectable distance from the cities therefore the lifestyle is also compromised. But on the other side with number of dental colleges in the country this challenge has also come to some ease for people. As most of the dental colleges are located at a place that surrounds number of villages and are at the outskirts of the city, making it easier for the population of rural areas easier to access dental services.

Role of Government and Different Dental Associations for Upliftment of Rural Oral Health

Government is presently actively working in the field of rural areas for strengthening of health services as well as oral health services at primary and secondary health care level.

The emerging trends in India in field of health services is changing. Earlier the trend was strengthening of tertiary level health care but now with the changing concept the trend has shifted to strengthening of primary and secondary level health care.



Ayushmann Bharat.

Some of the initiatives taken by the Health ministry and Government of India are Ayushmann Bharat Scheme. The Scheme was started by our Hon' Prime Minister on 23rd September 2019 with a goal for universal healthcare for all. This goal was initially the aim of World Health Organization. The scheme has been formulated completely on Public private partnership model[3].

This scheme is specially formulated for the upliftment of rural health sector. The main motive of the scheme is to convert all the primary health center to complete wellness centers. It is an overall national health protection mission.

National Oral Health Programme

The vision of this program is networking for optimal oral health of the nation that contributes to lead healthy and satisfying life. To develop the standard of health, free from diseases, which enables a person to eat, speak, socialize and carry out the activities of daily living without pain, discomfort or embarrassment and contribute to general well – being.

There are various programmes/ initiatives that have been started under this programme which are basically designed to uplift overall oral health for all.

1. Tobacco cessation Initiative.
2. Child Dental Care
3. Oral Cancer Foundation
4. Healing Smile Foundation
5. National Oral Cancer Registry
6. National School Oral Health Programme
7. Swwach Mukh Abhiyan

Role of Public Health Dentist.

Public Health Dentistry is branch of dentistry that trains the person to work not only in rural areas but also evaluate and plan schemes to uplift the oral health of the population in mass. In a similar term it is population-based dentistry.

In India there are 313 dental colleges across the country. These dental colleges have a mandatory Public Health Dentistry Department. This department of every institute works to uplift the rural oral health for the population around the institute. They evaluate and plan schemes to benefit the population with the oral health services in a very cost – effective way.

Conclusion

Health is necessary for all similarly oral health is also part of general health. Maintaining oral health is as mandatory as maintaining of health. With a mass population residing in rural parts of country creating awareness and planning schemes to uplift the rural is one of the missions of Government as well as dental associations[4,5].

Awareness programmes along with outreach activities time to time need to be planned to make the mass aware and reinforce the importance of oral health. Strengthening of primary and secondary level health care on the model of public private partnership is the only key to achieve success completely in the mission.

Marathi Translation, Cross-cultural Adaptation, Reliability and Validity of Motion Sickness Susceptibility Questionnaire-Short form

Rasika Panse[1], Tushar Palekar[2], Ujwal Yeole[3], Kartikee Patange[4], Saloni Gundecha[5]

[1]Assistant Professor, Department of Physiotherapy,Tilak Maharashtra Vidyapeeth, Pune, Maharashtra, India,
[2]Professor and Principal Dr D.Y Patil College of Physiotherapy, Pimpri Pune Maharashtra, India,
[3]Associate Professor, [4]Intern, [5]Student BPT, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune, Maharashtra, India

Abstract

Background: Marathi is the fourth most common spoken language in India. English serves as a barrier to the population of the state where Marathi is the prime language. A Marathi version of the Motion sickness susceptibility questionnaire would provide Maharashtrian community Children and adults would be provided opportunity to communicate more effectively with their therapist. Hence, there is the need to translate the MSSQ short form into Marathi for the ease of its use. Motion sickness is a feeling of unwellness and introduces a significant safety risk. Motion sickness is nausea caused by motion, especially when travelling in a vehicle. Other symptoms include vomiting, headaches, sweating, increased salivation, drowsiness dizziness and warmth/flushing. Motion sickness susceptibility questionnaire Short form can be used for paediatric population. Validity of MSSQ Short form is better than other motion sickness scale hence Cross Cultural Adaptation and translating the scale was done for the better understanding in paediatric population. **Methodology:** The main version of the MSSQ short form was translated into the Marathi language. The translation and cultural adaptation Guidelines given by WHO were as follows , Forward translation, expert panel back-translation, pre-testing and cognitive interviewing, and final version. The Final agreed Marathi version was administered to 50 patients. **Results:** After an exact translation process, the Marathi version MSSQ short form was found to exhibit face validity. The reliability was tested by measuring internal consistency and test-retest method. The Cronbach's alpha for MSSQ = 0.94 with 95% confidence interval. Correlation between MSSQ-M on day 1 and day 15 were highly significant. The interclass coefficient was 0.8 with 95% confidence interval. **Conclusion:** The Marathi, non-English version MSSQ-short form is reliable and valid.

Keywords: *MSSQ short form, Translation, Marathi version, Motion sickness, Reliability , Validity, Children.*

Introduction

Motion sickness is a unpleasant feeling of unwellness exhibiting varied signs and symptoms[1] . Motion sickness is physiological state that can be defined along four dimensions: gastrointestinal, central, peripheral, and sopite. Broadly the symptoms are nausea caused by motion, especially when travelling in a vehicle. Gastrointestinal symptoms include queasiness, disorientation, vomiting, and stomach discomfort. Central symptoms include feeling faint-like, dizzy, lightheaded, and a sensation of spinning ,also exhibit pallor. Peripheral symptoms include feeling clammy, sweaty, and hot/warm. Sopite related symptoms include feeling annoyed, drowsy, fatigued, and uneasy.(2)

Motion sickness occurs when spatial orientation- in which direction the body is pointed, in which direction it is moving, and about which axes it is rotating- is disrupted. Motion is sensed by the brain through 3 pathways of the nervous system, (1) the inner ear(sensing motion, acceleration, and gravity), (2) the eyes(vision), and (3) the deeper tissues of the body surface(proprioceptors). Feedback from the muscles and joint sensory receptors can also be important. A second explanation is the postural instability theory and the importance of the

vestibular system in maintaining a stable posture and minimizing swaying.[3]

Motion sickness susceptibility is important for research related to motion sickness for two reasons. Firstly, repeating and understanding research results depends upon who the subjects were, and some means to identify the susceptibility of those serving as subjects is therefore important. Second, there is often a desire to screen out subjects who are particularly susceptible because getting people sick is sometimes a consequence to be avoided. The original standard questionnaire for this is Reason and Brand (1975) Motion Sickness Susceptibility Questionnaire (MSSQ). Golding (1998) describes research to improve that standard questionnaire, but only found moderate correlations between MSSQ scores with sickness tolerance to laboratory motion devices (r=0.45). Golding (2006) examined individual differences using a short version of the Motion Sickness Susceptibility. The short form was developed by removing items with low sickness prevalence such as wide screen movies and virtual reality. It was found to be a reliable and valid alternative to the long form.[2] Motion sickness susceptibility questionnaire (MSSQ) predict individual differences in motion sickness caused by a variety of stimuli. [4]

India is diverse nation with varying cultures and languages. Marathi is the language that is spoken widely along the western coastal region in the state of Maharashtra. However, English serves as a barrier in the state where Marathi is the prime language.[5] Hence, the MSSQ short form needs to be translated into Marathi for the ease of its use.

The translation and cultural adaptation of instruments is an internationally recognized and valid method. The process involves translation of instrument from one language to another, synthesis, back translation, expert committee review to finalise the pilot testing, pretesting, feedback, and psychometric evaluation.[5]

Therefore, the present study had two objectives. In the first phase, cultural adaptation and translation of the MSSQ short form into Marathi were performed. In the second phase, preliminary assessment of the reliability was conducted for the final version of the MSSQ short form Marathi (MSSQ-M) in patients with Motion Sickness.

Materials and Method

After seeking permission from the Institutional Research Review Committee, the study was conducted in two phases.

Phase 1 involved translating the original MSSQ into Marathi using forward-backward translation process given by WHO.

Stage I: Initial translation- The first stage in adaptation is the forward translation. Two forward translations were made from the original language (English) to the target language (Marathi). In this way, the translation was compared for discrepancies. It is necessary for the bilingual translators to have the target language as their mother tongue. Discrepancies was then discussed and resolved with unbiased bilingual translator who was not involved in previous translation.

Stage II: Backward translation- Totally blind to the original version, a translator then translated the MSSQ short form of Marathi back into the original language (English). This is a process of validity checking to make sure that the translated version is reflecting the same item content as the original versions.

Stage III: Expert Committee Review- The composition of this committee is crucial to achievement of cross-cultural equivalence. The committee consisted of translators and two senior physiotherapists. Committee reviewed all the translation and reached a consensus on discrepancies. This formed the prefinal version.

Stage IV: Preliminary Pilot Testing- A group of 10 students with Motion sickness were selected for pretesting the prefinal version. These students spoke and understood both English and Marathi language equally well. Each of them were given the translated MSSQ-M and MSSQ English. They were also asked for their general comments on the questionnaire.

Phase 2 consisted of testing the reliability of the MSSQ-M.

A study population of 30 participants, age group between 7-12 years, with motion sickness participated in the study. Patients not experiencing motion sickness and not willing to participate were excluded. To assess the test-retest reliability MSSQ-M was administered twice, the repeat administration being after 2 weeks in order to minimize the clinical and cognitive changes.

OUTCOME MEASURE

Motion sickness susceptibility questionnaire-short form

STATISTICAL ANALYSIS

Test-retest reliability was tested in a test-retest design and was evaluated using the intra-class correlation coefficient (ICC). The ICC was interpreted as follows: <0.40,poor reliability; 0.40-0.75,moderate reliability; 0.75-0.90, substantial reliability; and >0.90, excellent reliability. The internal consistency was evaluated by cronbach's α coefficient, which is considered statistically significant when between 0.70 and 0.95.

Results

The study included a total of 30 participants with 13 boys and 17 girls with a mean age of 10.3 years (SD=±1.39). MSSQ was successfully translated in Marathi version using forward-backward translation. It took 30 days to complete a culturally adapted version. At the end of the pilot study, results showed that the patients understood the meaning of all questions properly. After an exact translation process, the Marathi version MSSQ short form was found to exhibit face validity.

The reliability was tested by measuring internal consistency and test-retest method. The Cronbach's alpha for MSSQ = 0.94 with 95% confidence interval. Correlation between MSSQ-M on day 1 and day 15 were highly significant. The intraclass coefficient was 0.8 with 95% confidence interval.

Discussion

This is the first study to translate, culturally adapt, and validate the MSSQ for Marathi speaking patients with motion sickness. The translation and cross-cultural adaptation of the MSSQ-M was successfully carried out by the guidelines given by WHO. The pilot testing showed us that all the translated questions were properly understood without any difficulties. Hence, it was finalized without the need for any modifications.

MSSQ-M was further administered on 30 participants to assess the reliability of the questionnaire. A good internal consistency (0.94) was found for MSSQ-M which is consistent with other reports. Our findings are in line with the Thai (MSSQ-T 0.80). MSSQ-M demonstrated good test-retest reliability when the instrument was administered to participants 2 weeks apart. The ICC scores fell within the substantial reliability range of 0.75-0.90. Test-retest reliability was found to be (r=o.9) that indicates it is highly significant correlation between results of MSSQ obtained on day 1 and day 15.

The limitation of the study was that it being a cross-sectional study and no physical assessment tests were included.

Conclusion

This study showed that the MSSQ-M is cross-culturally adapted and is reliable questionnaire. This newly formulated questionnaire can be used to determine the motion sickness susceptibility in paediatric population. It is easy to administer and can be recommended for use in routine clinical practice in Marathi-speaking population.

Effectiveness of Mobilization with Movement in weight bearing position on pain, shoulder range of motion and function in patients with shoulder dysfunction

Reshma Subhash[1], Meena Makhija[2]

[1]Physiotherapist, Max hospital, Gurgaon, Haryana, India,
[2]Assistant Professor, ISIC Institute of Rehabilitation Sciences, New Delhi, India

Abstract

The purpose of the study was to investigate the effectiveness of mulligan mobilization with movement in weight bearing position on pain, shoulder range of motion and function in patients with shoulder dysfunction. The study was conducted on 32 patients of age between 18-50 years, who are diagnosed with shoulder dysfunction and follow the inclusion and exclusion criteria. Subjects were randomly allocated to two groups. The control group (n=16) received stretching, strengthening and shoulder active range of motion exercises with hot pack. The experimental group (n=16) received the same with an additional mulligan's mobilization with movement in weight bearing. Clinical outcome measures were pain intensity on numeric pain rating scale, pain free shoulder range of motion in flexion, abduction, internal rotation and external rotation as measured with a goniometer and disability of the shoulder with the help of shoulder pain and disability index. Data was collected at baseline and after 2 weeks of intervention in both groups. The results revealed that there was a statistically significant improvement in pain scores and flexion range of motion of shoulder in the experimental group when compared with control group, however no significant change was observed in disability and other ranges measured.

Key words: *Mobilization with movement, Shoulder dysfunction, Mulligan's mobilization, Shoulder pain*

Introduction

Shoulder dysfunction is the second most common health problem affecting approximately 16%-20% of the population [1]. It is characterized by restrictions in activities of daily living due to pain and limitation of range of motion (ROM) of the shoulder [2]. It includes various causes such as tendinopathy, bursitis, rotator cuff tears, adhesive capsulitis, shoulder impingement, glenohumeral osteoarthritis and trauma from injury.

Alterations in scapular position and motion occur in 68% to 100% of patients with shoulder injuries[3]. The scapular position have a mechanical effect on acromio and sternoclavicular joints[4]. The reductions in scapular upward rotation and posterior tilt during arm elevation could reduce the available sub acromial space, thus contributing to the development or progression of impingement[5]

Conservative treatment recommends physical therapy which includes electrotherapy, exercises and mobilization techniques. Amongst a well-known technique is mobilization with movement [MWM] developed by Brian Mulligan that is based on analysis and correction of minor positional faults at a joint. These faults are recorded in painful shoulder in various kinetic studies.[6–9].

There is a dearth in trials supporting or disapproving the use of mulligan's MWM in shoulder dysfunction. The MWM in weight bearing position of the shoulder girdle involving correction of scapulothoracic positional faults is a novel technique and its effectiveness is relatively unexplored in shoulder dysfunction patients. Weight bearing can have additional proprioceptive benefits

on clinical measures. Hence, the aim of the study is to evaluate the effectiveness of MWM in weight bearing position on shoulder pain, ROM, and function.

Material and Method

After approval from the research review committee and the institutional ethical committee of Indian Spinal Injury Centre, New Delhi, and a sample of 33 patients were screened for inclusion and exclusion criteria. Inclusion criteria for the study were Age: 18-50 years, Gender: Male & Female, Sub-acute shoulder pain (2-12 weeks), Patient diagnosed with shoulder dysfunction (shoulder impingement, AC joint lesion, Rotator cuff tendinopathy, sub acromial bursitis). Exclusion criteria involved subjects diagnosed with complete rotator cuff tears, adhesive capsulitis, shoulder pain of cervical origin[1], traumatic onset of shoulder pain, previous shoulder or cervical spine surgery, systemic illness[11], subjects contraindicated for Mulligan mobilization, patients unable to do weight bearing in all fours position.

GROUP A (Experimental group)

Patient is on all fours (lion position). The therapist stands on the painful side and places one hand beneath and over the clavicle, the thenar and hypothenar eminences lie along the lateral border of the scapula. A sponge may be used under the hand on the clavicle for patient comfort. Pull the scapula caudally, externally rotate it, move it medially towards thoracic spine and proximate the hands. Patient now rocks back slowly towards heels causing shoulder to flex. (Fig 1)[5]

The aim is to flex the arm with no pain. When movement without pain is achieved repetitions are done. Three sets of ten is the usual prescription. Patients were also given 10 minutes of hot pack and conventional physiotherapy treatment as described below.

GROUP B (Control group)

It included active assisted range of motion using a cane, pendulum exercises, corner push up and cross body adduction, Strengthening exercises consisting of internal and external rotation with 1 kg weight in side lying, active pain free range of motion in scaption, chair press, push-ups plus and upright rows[13].

Fig1

Mulligans MWM in weight bearing position

Statistical Analysis

The statistical package of social science (SPSS) of window version 20 was used for data analysis. Between group analysis was done by using independent t-test for outcome measures of pain (NPRS), range of motion and disability (SPADI). Within analysis was done by using paired t-test. The probability level of 0.05 was selected as the criteria for the level of significance in all test. Value of confidence interval was set at 95%.

Results

The mean Age±SD was 30.87± 9.373 years for group A and 32.37±9.743 for group B. On comparing the mean age of two groups, independent t-test revealed no significant difference (p=0.830) between the groups. Comparing the mean BMI of two groups, independent t-test revealed no significant difference (p=0.202) between the groups.More

The results revealed significant difference between the groups using independent t test for range of motion for flexion (p=0.045) and NPRS for pain (p=0.012) at 0.05 level (Table 1). Within group analysis revealed significant difference with all outcome variables except

external rotation (p=0.060) in group A and group B (p=0.158

Table 1 Baseline measurement between Group A and Group B

Outcome	Group A (Mean+ SD)	Group B (Mean+ SD)	t-value	Sig(P value)
NPRS	5.33± 0.724	5.69± 0.479	-1.617	0.117NS
Flexion	134.80±17.387	135.25± 14.540	-0.78	0.938 NS
Abduction	130.40±16.783	137.44±15.874	-1.200	0.240 NS

Internal rotation	81.47±10.315	78.75±8.363	0.802	0.429
External rotation	84.07±12.719	88.25±3.624	-1.228	0.237
SPADI	26.27±10.074	27.50±6.272	-0.406	0.688

*Indicates significant difference at the 0.05 level

Discussion

The aim of the present study was to find out the effectiveness of mobilization with movement in weight bearing in conjunction with conventional physiotherapy treatment .It has been seen that for pain in between group analysis there was a significant difference between group A and group B.

Our result is supported by Kachingwe et al[14] whose result suggested that MWM group showed the highest percentage of change in decreasing pain and improving function from pre- to post-treatment. This may be attributed to the fact that the MWM technique is designed specifically for decreasing shoulder pain during active shoulder motion, and the amount of manual force applied is dependent on the ability of the technique to decrease pain with active movement. MWM has the additional benefit of being performed throughout AROM, which may engage additional proprioceptive tissues, such as the Golgi tendon organs activated by tendon stretch.

Satpute et al[11] suggested that MWM evokes a non-opioid descending pain inhibitory system(non–endorphin based) inducing mechanical hypoalgesia. The mechanical stimulus provided by MWM may

trigger central nervous system descending pain inhibitory system's causing hypoalgesia. Mobilization with movement also potentially modulates mechanical local hyperalgesia, which results from the sensitized peripheral nociceptors within the area of dysfunction. The improvement in pain in Group B can be attributed to hypoalgesic effect of exercise

For range of motion- statistically significant improvement in flexion shoulder range of motion when Group A and Group B were compared. The shoulder range of motion of flexion, abduction, increased by 22^0 and 22^0 respectively after MWM application in group A and 12^0 and 9^0 in group B.

The potential reason for more improvement in Group A as compared to Group 2 can be attributed to Mulligan Mobilization which was not given to Group 2. The improvement in mulligan group might be attributed to positional fault concept of mulligan. According to this concept, a minor positional fault of the joint may occur following any pathology, an injury or strain which ultimately leads to altered joint kinematics. Altered joint kinematics in shoulder dysfunction have been previously recorded by various studies.[3,5]

These positional faults affects the joint kinematics which contributes to reduced ROM. Mulligan mobilization aims to correct this minor positional fault and hence improves the range of motion.

Our result are in sync with Teys et al who found significant improvement in range of motion score after 3 sessions. However in our study we gave 6 sessions spread over 2 weeks time. Their study didn't take shoulder disability as an outcome measure which we assessed. The result of this study is similar to previous studies on effectiveness of Mulligan's MWM on various shoulder conditions in non weight bearing position.

For Function - No significant difference in disability can be due to shorter intervention time however within group analysis showed that there was significant improvement in disability of shoulder when pre and post intervention scores were compared. Reduction in pain, improved ROM, and changes in muscle function may be responsible for the improvement we found in shoulder pain and function which was measured with the SPADI questionnaire. This was supported by Satpute et al. who found improvement in shoulder pain and function measured with SPADI.

Improvements in pain, ROM, and disability over the intervention period in both groups may be explained to some degree due to natural resolution and/or,exercise/hot packs. One potential mechanism for this improvement may be that exercise improves joint function by improving muscle strength and control of the scapular and glenohumeral joint stabilizers as well as improving extensibility of shortened ligamentous and capsular tissues.

Our study had the following limitations of non-differentiation of primary and secondary impingement and shorter intervention on small sample size. Future studies can be done keeping in mind the above limitations.

These results provide evidence to support the clinical notion that when the positional faults are corrected shoulder pain, range of motion and function are improved.

Conclusion

MWM in weight bearing position is a useful manual therapy technique to be considered for subjects with shoulder dysfunction.

Effect of Stability Trainer Exercises with Mirror Feedback on Balance and Level of Physical Activity in Community Dwelling Elderly

Rima Musale[1], Ujwal Yeole[2], Ankit Shinde[3], Venkatesh Mane[3]

[1]Associate Professor, [2]Associate Professor and Principal, [3]Student, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth Pune.

Abstract

Background: Balance is always dependent on feedforward and feedback mechanism which can be classified as intrinsic and extrinsic factors; with advancing age individuals will become more independent on external factors. Stability trainer with mirror feedback will give sensory as well as visual feedback to train balance in elderly. **Objectives:** To study the effect of stability trainer exercise with mirror feedback on Dynamic balance using (FRT) & (TUG), functional balance task using (BBS); and on level of physical activity using (PASE). **Method:** Our study was conducted amongst 60 subjects who were selected as per the inclusion and exclusion criteria. Subjects were divided into 2 groups namely experimental (Group A) and control (Group B) consisting of 30 individuals in each group. Demographic data including name, age, gender were noted. The participants of Group A and B were assessed before and after treatment. Dynamic balance was assessed using (FRT) & (TUG), functional balance task was assessed using (BBS); and on level of physical activity was assessed using (PASE). Data was collected & statistically analysed. **Results:** Data was statistically analyzed using Man-Whitney's test for among the groups. On comparing TUG mean values of group A=3.8secand group B=1.8sec with p value <0.0001 which is found to be significant. On comparing FRT mean values of group A=6.37and group B=2.47 with p value <0.0001 which is found to be significant. On comparing BBS mean scores of group A=31.93and group B=40.63 with p value <0.0001 which is found to be significant. On comparing PASE mean values of group A=39.43and group B=42.27 with p value=0.0014 which is found to be significant. **Conclusion:** The study concluded that stability trainer exercises with mirror feedback is extremely effective for balance training and improving level of physical activity in community dwelling elderly.

Keywords: *Balance, stability trainer, mirror feedback, TUG, BBS, FRT, PASE*

Introduction

Aging is referred as gradual dimination in physiological capacity of various systems with increasing age related balance issues have to be focused and treated mainly in community dwelling elderly in order to improve their level of physical activity to reduce fear of fall. Balance is always dependent on feedforward and feedback mechanism which can be classified as intrinsic and extrinsic factors with advancing age individuals will become more dependent on feedback from external environment than body because of declining function of the body.Stability trainer are nothing but foam pads which are oval shaped which provide sensory feedback that challenges proprioceptive system and mirror feedback will give sensory feedback which is important for balance training.[1]

A predictable, progressive, universal deterioration is found in various physiological systems, mental and physical, behavioural and biomedical system. In India, individuals above 60 years of age are called as aged/ elderly. [2]There has been a sharp increase in the number of elderly individuals between the year span of 1991 and

Corresponding Author:
Dr Rima Musale
Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Gultekdi, Pune 37 Mobile No. 9960842001, Email id: drrimamusale@gmail.com

2001 and it has been projected that by the year 2050, the number of elderly people would have risen upto 324 million. India has thus been acquired the label of "an ageing nation" with 7.7% of its population being more than 60 years of age. [2]

Balance is defined as the ability to maintain an upright posture during static and dynamic tasks which requires complex interactions between peripheral and central factors such as vision, somato-sensation, vestibular sensation, motor output, and musculature.[3] Balancing is an interplay and integration of contributions from vision, vestibular sense working in conjunction with the cerebellum, proprioception, muscle strength and reaction time.[4]

This proportion of the population faces numerous problems owing to the social and cultural changes that are taking place within the society. The health of the elderly with multiple medical and psychological problems is considered to be the major area of concern. Balance is referred to be one of the major problems in the elderly and are considered one of the "Geriatric Giants". Balance is an important cause of morbidity and mortality in the elderly and are a marker of poor physical and cognitive status. Following are the physiological changes according to the age. [5-8]

Dynamic balance indicates the ability to control posture during active motion; i.e., keeping the center of pressure (COP) of the body mass within the allowable area of the base of support. In controlling dynamic balance, anticipatory postural adjustments are required. Anticipatory adjustments of the posture prepare a person's balance prior to or parallel to postural disturbance induced by any subsequent voluntary motion which follows. Thus, it is important to note that dynamic balance depends on an anticipatory feed-forward adjustment of the posture.[9-11] When the COP deviates beyond the allowable area in standing balance, the postural response of the whole body is elicited to return the COP to within the controllable area of the base of support.[12,13] When this postural response does not function adequately, falling is inevitable. The postural response is therefore the final response acting to prevent falls.

Method

A experimental study was conducted on 60 elderly population with age group 65-84 years. The participants were selected according to the inclusion criteria exclusion criteria. Inclusion criteria were elders between age group of 65-84 years, both male and female population were included in the study, participants willing to participate. Exclusion criteria were Patients who had undergone any recent spine and lower limb surgeries, Patients having any neurological defect, Patients having cognitive dysfunction, Patients who are using assistive device. The participants are divided into 2 groups namely Group A (Experimental Group) and Group B (Control group) by randomised sampling each group having 30 elderly. The aim, objectives and method of study is explained to the participants. Consent is taken on the consent form.

Procedure

Permission was taken from the institutional ethical committee of Tilak Maharashtra Vidyapeeth, Department of Physiotherapy, Pune. Different centres were approached and permission will be obtained prior to the study. Explanation of the experiment was explained to the patient. Patients willing to give consent to participate in the study was included. A pilot study was conducted and the errors were resolved with approval of the guide. Subjects were interviewed for their demographic history and instructions were given to them. Pre-treatment dynamic balance was assessed by using (FRT) & (TUG) scale, functional balance task was assessed by using (BBS) scale; and level of physical activity was assessed by using (PASE).Group A was taken on stability trainer and following balance exercises were given for 20 min for a period of 4 weeks for 3 times per week:-

1) Stand on the stability trainer and raise both the heels and hold for 20 sec and release it repeating for 5 times.

2) One leg standing holding for 20 sec and release it, repeating it for 5 times. Same should be done with the other leg.

3) Single leg standing with the same sided upper limb giving reach out for 30 sec followed by other upper limb and repeating it twice.

4) March for 2 min

5) Stand on the stability trainer holding a stick performing side rotations for 2 min.

Group B (Control group) was given conventional balance exercises.

The treatment plan was given 3 times a week for

consecutive 4 weeks. Post-treatment dynamic balance was assessed by using (FRT) & (TUG) scale, balance task was assessed by using (BBS) scale and level of physical activity was checked by using PASE.

Data was collected and statistical analysis will be done.

Materials used in the procedure were demographic data sheet, consent form, stability trainer, inch tape, stopwatch, chair, pen and paper.

Statistics

The analysed data showed that it was not a normal distribution using Stability trainer exercises, hence Non parametric Man-Whitney's test was performed to analyse the data among the groups.

Results

The present study was done on 60 elderly population which were divided into 2 groups i.e Group A which was an Experimental group containing treatment by Stability trainer and Group B which was Control group containing conventional exercises.

Table no. 1: Comparison of FRT between Group A and Group B

FRT	Group A	Group B	P value
Mean	6.37	2.47	<0.0001

Interpretation: Above table shows a comparison of mean of FRT values of group A & group B; with (p value=<0.0001), extremely significant.

Table no. 2: Comparison of TUG between Group A and Group B

TUG	Group A	Group B	p value
Mean	3.8	1.87	<0.0001

Interpretation: Above table shows a comparison of mean of TUG values of group A & group B; with (p value=<0.0001), extremely significant.

Table no. 3: Comparison of BBS between Group A & Group B

BBS	Group A	Group B	P value
Mean	31.93	40.63	<0.0001

Interpretation: Above table shows a comparison of mean of BBS values of group A & group B; with (p value=<0.0001), extremely significant.

Table 4:- Comparison of PASE between Group A & Group B

PASE	Group A	Group B	P value
Mean	39.43	42.27	0.0014

Interpretation: Above table shows a comparison of mean of PASE values of group A & group B; with (p value=0.0014), extremely significant.

Discussion

The present study was done to find out the effects of stability trainer exercises with mirror feedback on balance and level of physical activity in community dwelling elderly of age group 65-84 years. Pre-treatment dynamic balance was assessed by using (FRT) & (TUG) scale, functional balance task was assessed by using (BBS) scale; and level of physical activity was assessed by using (PASE).

In this study the outcome measures used are TUG(validity=0.75; reliability=0.99), FRT(validity=0.71; reliability=0.89), BBS(validity=0.96; reliability=0.98) and PASE(validity=0.48; reliability=0.75). In the present study subjects were divided into 2 groups Group A & Group B. Group A was given stability trainer exercises as an intervention for 20 min for a period of 4 weeks for 3 times per week and Group B was given conventional exercises for a period of 4 weeks. Post-treatment dynamic balance was assessed by using (FRT) & (TUG) scale, functional balance task was assessed by using (BBS) scale; and level of physical activity was assessed by using (PASE). Data was collected and statistical analysis was done. Our study noted that patients who were been given treatment using stability trainer exercises with mirror feedback had a great improvement in their balance as compared to the ones treated conventionally.

There was a study done by Chavan U et.al (2017) on Effect of Stability Trainer Exercise Program on Balance in Geriatric Population to study the effect of stability trainer exercise program on Static balance, Dynamic balance, Static functional and Balance confidence concluded that Stability trainer exercise program (STEP) is extremely effective for balance training and improving the quality of life in the elderly.

In our study, there was a significant difference in the mean TUG before and after administration of stability trainer exercises indicated by p value (p value<0.0001) which is extremely significant.Inputs to the internal and external environment play an important role in reducing the response of the body to any stimulus. With the increasing age our body becomes more dependent on the feedback from external environment rather than internal environment which in deed results in reduction of body's internal functions. The exercises included in the stability trainer exercise program had a very good effect on the proprioception, lower limb muscle strength and vestibular system which helps our body to work on our internal functions. The feedback from internal environment starts redeveloping which increases body function because of which our body responses in a right way to any stimulus. This would help the elderly to balance themselves which could be seen as improvement in reducing the risk of fall in elderly assessed by Timed Up and Go scale.[14]

There was a significant difference in the mean FRT before and after administration of stability trainer exercises indicated by p value (p value<0.0001) which is extremely significant. As per the age our tensile structures i.e our muscles loose their flexibility. With the stability trainer exercises, the muscle strength increases and hence the flexibility of the muscle increases which could be possibly seen in the increased FRT ranges.[14,15]

There was a significant difference in the mean BBS before and after administration of stability trainer exercises indicated by p value (p value<0.0001) which is extremely significant.The stability trainer exercises helps in the development of the vestibular system. The vestibular system helps the body to recognize its position by the sensory feedback mechanism. The increasing sensory feedback would result in improved balance which is proved by the improvement in the Berg Balance Score.[14,15]

There was a significant difference in the mean PASE before and after administration of stability trainer exercises indicated by p value (p value=0.0014) which is extremely significant.With the increasing age response of our body towards any stimulus reduces. Due to which the body becomes incapable of any movements which in return reduces the activities. As the stability trainer exercises are given it works on balance and stability, the body becomes stable and could balance. Once our body's internal functions are improved and maintains his balance, the activities of their life improves. The effectiveness in performing in their activities increases which could be seen in the improvement of PASE score. [14]

The significant improvements in the exercise adherers indicate that the program was of an appropriate nature, the stimulus sufficiently intensive, and the program of adequate duration to produce considerable improvements in stability in the intervention group. The exercisers showed continued improvement in both stability tests throughout the study year, which indicates that long-term exercise trials (of the frequency and intensity of the present study) are necessary to assess the maximal beneficial effect exercise can have in improving dynamic stability and related measures in older people. Balance control is a complex process, with inputs and control is from a diverse array of sensory and motor systems.

Balance is always dependent on feedforward and feedback mechanism which can be classified as intrinsic and extrinsic factors; with advancing age individuals will become more independent on external factors. Stability trainer with mirror feedback will give sensory as well as visual feedback to train balance in elderly.

A study conducted by Sukwon Kim etal concluded that fear of falling and social activity levels are associated with each other. Improving physical activity can act as an effective measure to improve quality of life.

Conclusion

The study concluded that the stability trainer exercises with mirror feedback is extremely effective for balance training and improving level of physical activity.

Effectivnesss of Physiotherapy Interventions on Stress Urinary Incontinence in Female Dancers

Rima Musale[1], Ujwal Yeole[2], Mansi Jain[3], Swarada Mahatre[3], Chinmoyee Panigrahy[4]

[1]Associate Professor, [2]Principal, [3]Student, [4]Assistant Professor, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune

Abstract

Background: Dancing involves high as well as moderate impact activities, interplay between aesthetic and physical demands which collectively increases intra-abdominal pressure responsible for stress urinary incontinence in female dancers. Practicing Kegel's and Behavioural Intervention therapy can minimize severity of problem. **Objectives:** To find out effectiveness of Kegel's exercises, Behavioural intervention therapy and combination of both on stress urinary incontinence in female dancers using IIQ and Pad test **Methodology:** Permission was taken from institutional ethical committee. 90 female dancers were assessed using QUID and dancers having stress urinary incontinence aged 18-25 years; practicing since 5 years were selected. Pre intervention evaluation was followed by Kegel's exercise for Group A, behavioral intervention therapy for Group B and combination of Kegel's exercise along with behavioral intervention therapy for Group C. Post intervention assessment was carried out. **Results:** Data was statistically analyzed using Wilcoxon test for within the groups and among the groups by using Kruskal-wallis test. IIQ for group A pre-intervention mean was 5.5± 1.45 and post intervention mean was 4.7±1.04 with $p < 0.00048$, For group B pre-intervention mean was 5.8 ± 1.27 and post 5.1± 1.27 with $p<0.003$ and For group C pre-intervention mean was 5.9±1.18 and post intervention mean was 4.4±0.85 with $p<0.0001$ which is very significant, while comparing group A B and C IIQ post values $p<0.08812$ which is not significant. Pad test for group A pre-intervention mean7.3±1.78 was and post intervention mean was 6.4±1.4 with $p<0.0001$, For group B pre-intervention mean was7.5±1.48 and post intervention mean was 6.7±1.44 with $p<0.0001$, For group C pre-intervention mean was7.8±1.47 and post intervention mean was 6.2±1.21with $p<0.0001$ which is significant while comparing group A B and C Pad test post values $p<0.08812$ which is not significant. **Conclusion:** Our study concludes the effectiveness of various Physiotherapy interventions within the groups and all interventions being equally effective.

Introduction

Urinary incontinence is defined as an involuntary loss of urine which is objectively a demonstrable, social and hygienic problem. There are mainly three types of urinary incontinence stress, urge and mixed[1].

Stress Urinary incontinence is a condition in which there is involuntary loss of urine, when the pressure in the abdomen increases, as in coughing and jumping. Urinary incontinence is the complex coordination of bladder, urethra, Pelvic floor muscle exercise and supporting ligaments. With increased abdominal pressures, the Pelvic floor muscle exercise contraction causes a pull on the anterior vagina wall toward the pubic symphysis, leading to the occlusion of the urethra which prevent urine leakage. This mechanism is disturbed during physical exercises, when there is a variation in the intra-abdominal pressure[2].

Different Studies have shown a relationship between Stress Urinary incontinence symptoms and the performance of high-impact physical activities.

There have been a large number of surveys done where questionnaires are the primary tool for evaluating the presence of incontinence[3].

Urinary stress incontinence is a serious medical condition that it can lead to urinary tract infections, pressure ulcers, perineal rash or any social problem creating embarrassment and negative self-perception. Urinary stress incontinence reduce both social interactions and physical activities and it is also associated with poor self-related problems[4].

It is important to have concern about Urinary incontinence in female dancers, as there are various dance forms like western (hip-hop, ballet, contemporary, etc.) as well as classical (Kathak, Bharatanatyam,) which involve moderate to high impact activities as well as steady postures required for long period of the time. To stabilize different postures while dancing it involves both the activation of abdominal pressure and pelvic floor muscles, which give rise to increase in intra-abdominal pressure and due to practicing dance over long time of period there might be increase in the flexibility of lower extremity which may be the another cause for urinary incontinence[2].

Dancers have to perform moderate as well as high impact activities in the form of dance. Strengthening of pelvic floor muscle can minimize the severity of stress urinary incontinence in high impact activities.

Kegel's exercises were first descried by Dr Arnold Kegel in 1948 to prevent urinary incontinence especially in postpartum female, and these exercises we can consider as one of the safest without any side effects and complications. The teaching of PFM contractions is the most difficult task because muscles aren't directly visible, requires a high level of skill particularly in communication. Visualization: A large diagram of the pelvis, pelvic organs, PFM. Throughout the teaching sessions the language and employing words must be chosen specifically i.e stopping of urine. Kegel's can be performed in any position, but the initial position is sitting on a hard chair leaning forward with support from the forearms on thighs, with the knees apart. This is the ideal position for teaching PFM contraction as it provides sensory stimulation feedback[5]. Kegel's exercises needs more of accuracy and understanding of muscles need to be contracted; avoiding unwanted contractions of gluteal muscles, lower abdominals. Pelvic floor muscle exercise is that a strong and fast contractions which clamp the urethra and increases the urethral pressure and the abdominal pressure[6].

Different behavioral interventions are mentioned to overcome from stress incontinence. Behavioral interventions are a group of treatments that improve urinary symptoms by altering bladder habits and teaching new skills. They have been used to improve incontinence and other lower urinary tract symptoms in women of all ages. Behavioural intervention therapy include patient education, bladder training, voiding schedules, fluid management etc. Patient education plays important role, includes an explanation of anatomy and physiology of continence and Pelvic floor muscles orientation Bladder training was originally developed for treatment of urgency incontinence. The reason behind giving bladder training is that frequent voiding can reduce bladder over activity which ultimately cause bladder overactivity[7]. The goal of bladder training is to reduce voiding frequency, increase bladder capacity. Changes in fluid intake with proper knowledge is beneficial for e.g. avoiding excess of consumption of fluid (>2100 ml/day), reducing fluid intake will help with sudden fullness of bladder[8]. Caffeine is also one of the bladder irritant for many women. Studies has shown that caffeine increases detrusor pressure and is a risk factor for detrusor overactivity[9].caffeine should be reduced gradually and caffeinated beverages should be replaced with decaffeinated one. Obesity is one of the risk factor for developing stress incontinence, weight control is must[10]. Behavioural intervention therapy contains group of treatments to improve stress urinary incontinence and very few studies are available.

In this study, we aimed to find out effect of Physiotherapy interventions (Kegel's exercise, behavioural intervention therapy and combination of both Kegel's and both behavioural intervention therapy) on stress urinary incontinence in female dancers.

Method

Ethical clearance was taken from institutional ethical committee. 90 female dancers practicing any dance form were selected from different dance institutes with convenient sampling method. Subjects were assessed using QUID to find out type of urinary incontinence[11], those who has only stress urinary incontinence, aged 18-25 years, nulliparous female dancers practicing since 5 years were assessed using IIQ[12] and Pad test[13] before giving physiotherapy interventions. Pre- intervention

evaluation was followed by implementation of exercise program in the term of Kegel's exercises for group A. Behavioural intervention therapy for group B and combination of Kegel's along with bit for group c for period of 6 weeks. Post intervention assessment was done

Exercise program:

Kegel's exercise (Pelvic floor contractions):

Starting position: sitting on a hard surface

Hold for 7 seconds, Relaxation for 1 second and repetitions 15-20

3 times a week for 6 weeks

Behavioural Intervention therapy:-

Stress Urinary incontinence education:

Going to the bathroom to urinate every 2 to 3 hours, daily fluid intakes, pelvic muscle exercises, and medications.

Bladder training:

Requires a fixed voiding schedule, whether or not you feel the urge to urinate. Empty your bladder as soon as you get up in the morning. Go the bathroom at the specific times. At night, go to the bathroom only if you awaken and find it necessary.

Lifestyle modification:

It includes fluid management, reducing caffeine, Bladder irritants, and weight control

Stress management:

Relaxation techniques, meditation, exercise regularly.

Kegel's exercises and Behavioural Intervention therapy: Combination of the treatments are given.

Statistics

The analysed data showed that it was not a normal distribution using Shapiro -Wilk test, hence Non parametric Wilcoxon signed-rank test was performed to analyse the data within the groups. Non parametric Kruskal-Wallis test was performed to analyse the data among the groups.

Results

Incontinence Impact Questionnaire

	Group A	**Group B**	**Group C**
Pre	5.5±1.45	5.8±1.27	5.9±1.18
Post	4.7±1.04	5.1±1.27	4.4±0.85
p Value	< 0.00048	<0.0003	< 0.00001
p Value	<0.08812 (comparison between the groups A, B and C)		

Interpretation: Table showing within the group comparisons and between the group comparisons within confidence interval of 95%, showing difference within the groups (group A p< 0.00048, group B p<0.0003 group C p< .00001) is significant and between the groups is not significant (p>0.08812)

Pad Test

	Group A	**Group B**	**Group C**

p Value	< 0.00001	< 0.00001	< 0.00001
p Value	<0.49493(comparison between the groups A, B and C)		

Interpretation: Table showing within the group comparisons and between the group comparisons within confidence interval of 95%, showing difference within the groups (group A p<0.00001, group B p<0.00001 group C p<0.00001) is significant and between the groups is not significant (p<0.49493)

Discussion

The present study was conducted to find out effectiveness different physiotherapy interventions like effect of Kegel's exercises, effect of Behavioural intervention therapy and combined effect of Kegel's exercises and Behavioural intervention therapy on stress urinary incontinence in nulliparous female dancers; practicing since 5 years within the age group of 18-25 years.

Dance is an art where human movements are strictly selected in particular sequence, which is based on aesthetic and symbolic value. There are different types of dance forms in the world and established by different places and culture. In India according to states different dance forms are known like Bharatnatyam, Kathak, Kuchipudi, Manipuri and more and western dance forms are hip hop, locking and popping, salsa, ballet etc. health issues in dancers should be more focused as most dancers begin training at young age which will be giving more impact in future health, however there is increase in physical demands in dance which can lead to health issues[14]. Dance practice with specific training regimen can develop specific flexibility characteristics. Koutedakis et al. underwent study on the dancer as a performing athlete, suggested that dancers also have specific conditions like disordered eating, osteoporosis, amenorrhea and urinary incontinence[15].

In the present study, incidence of stress urinary incontinence is more in female dancers in between 5-12 years of dance training period which might be due to more years of practicing causes overuse of PFM while maintaining long standing postures; and practicing moderate to high impact activities for a prolonged period of time. The interplay of aesthetic demands and physical demands in dance; along with strict selection of dance practice and physical demands develops flexible characteristics compared with athletes. H H Thyssen underwent study on Urinary Incontinence in Elite female athletes and dancers, which demonstrated 50% elite athletes and professional ballet dancers have experienced urine loss.[16]

In this study, the outcome measures used are QUID (validity: 80%, reliability: ≥0.70%) IIQ (validity: 0.58 reliability0.84) Pad test (Sensitivity: 34-83%, Specificity: 65-89%). The Questionnaire for urinary incontinence diagnosis (QUID) is a self-administered 6- item scale which is designed to differentiate between Stress Urinary Incontinence and Urge Urinary Incontinence. Incontinence impact questionnaire (IIQ-7) is 7 – item scale to assess the impact of urinary incontinence on activities and emotions, which cover 4 domains: physical activity, social relationships, travel and emotional health. Pad test is a non-invasive method of detecting and quantifying severity of urine leakage, 1- hour pad test is used in this study. In present study subjects are divided into three groups; named Group A, Group B and Group C. This study examined the three forms of intervention in female dancers with stress urinary incontinence. Group A was given Kegel's exercise as an intervention for 6 weeks with specifications such as contraction for 6-7 seconds and relaxation 1 sec hold, 15-20 repetitions, 3 times a day for thrice a week for 20 to 30 minutes. Group B was given Behavioural intervention therapy which included urinary incontinence education proper counselling, bladder training, lifestyle modification, stress management and Group C was given both Kegel's

and Behavioural intervention therapy.

Kegel's exercises are nothing but pelvic floor muscle contractions; in which subject should contract her pelvic floor muscle without contracting gluteal region, abdominal muscles and back muscles. It treats stress urinary incontinence by strengthening PFM and improving elasticity. In our study group A Kegel's exercise intervention of variable IIQ ($p<0.00048$) and pad test ($p<0.00001$) shows there is significant difference between pre and post treatment. Theory behind Kegel's exercise is that a strong and fast contractions will help to clamp the urethra, which causes increase in urethral pressure during an abrupt increase in abdominal pressure. De-Lancey has suggested that; Pelvic floor muscle exercise contractions can cause urethra to get pressed against pubic symphysis, producing a mechanical pressure[6]. James R Balmforth et al. underwent study on A prospective observational trial of pelvic floor muscle training for female stress urinary incontinence suggested that PFM strengthening leads to hypertrophy of muscle fibres, an enhanced cortical awareness of muscle groups, strengthening of connective tissue in the muscles and more effective recruitment of active motor neurons[17].

In our study, group B Behavioural intervention therapy intervention of variable IIQ ($p<0.0003$) and pad test ($p< 0.00001$) shows there is significant difference between pre and post treatment. Behavioural intervention therapy are group of treatments that improve urinary incontinence by changing the patient's daily habits and helps to focus on improving bladder control by modifying voiding habits. Behavioural intervention therapy is group treatment which reduced overall mental stress and helped to improve quality of life. A study conducted by Diane Borello stated that Behavioural intervention therapy for Stress Urinary incontinence can help women beneficially[18].

Possible reasons behind effectiveness of combination therapy can be practice of Kegel's exercises i.e. strengthening of pelvic floor muscles but also behavioural intervention therapy working on behaviour, and faulty habits of the subjects. Group C combination of both interventions of variable IIQ ($p<0 .00001$) and pad test ($p<0 .00001$) shows there is significant difference between pre and post treatment. These both interventions are recommended as first line treatments for stress urinary incontinence. The combination of both the treatment shows that the treatment is effective in reducing incontinent episodes. Although the combination therapy group showed greater improvement after 6 weeks, no significant difference were observed between the groups.

While comparing all the groups with the variables of IIQ ($p<0.08812$) and Pad test ($p<0.49493$) which didn't show significant difference.

Our study shows that effect of physiotherapy interventions like effect of Kegel's exercises and Behavioural intervention therapy and combined effect of Kegel's exercises with Behavioural intervention therapy shows significant results within the groups. It is remarkable that each treatment is effective and beneficial but the study does not address which treatment is more effective.

Conclusion

Our study concludes the effectiveness of various Physiotherapy interventions within the groups and all interventions being equally effective.

A Study on Students Performance Based On Their Learning Approaches in Cadaveric Dissection

Sangeetha Arumugam[1], Nandha Kumar Subbiah[2]

[1]Associate Professor, Department of Anatomy, Katuri Medical College and Hospital, Guntur, Andhra Pradesh, India, [2]Assistant Professor, Department of Anatomy, All India Institute of Medical, Sciences, Mangalagiri, Andhra Pradesh,India

Abstract

Introduction: Introduction of competency based integrated syllabus has led to decrease in dissection lab hours. This limitations has induced students to learn gross anatomy from alternative methods other than the traditional dissection. Any approach should yield good results to students. Aim of this survey is to compare the performance of medical students with their anatomy learning style in dissection lab hours.

Method: A cross sectional study was conducted among 120 students belonging to first professional year of Katuri Medical college and Hospital, India. After completion of limb region, theory and Practical test was conducted as part of assessment. Test scores of each student was noted.50% marks in each test was considered as pass. After the test, students were interviewed about their method of learning style which they followed in dissection lab. Responses were noted. Descriptive statistics such as percentages was used to summarise data.

Results: The study revealed that 75 students (62.5%) chose prosection, 20 (16.7) chose dissection,and the remaining 25(20.8%) students chose prosection followed by dissection approach. Pass percentage of Students who chose prosection was 86.7%, 80% by students who chose both approaches and least 50% by dissection approach.

Conclusion: Prosection approach has overall benefits in terms of gaining anatomical knowledge, stimulating self-directed learning, enhance group activity and finally better performance in examination.

Key words: *Gross anatomy education, cadaveric dissection, prosection, dissection laboratory, theory and practical examination*

Introduction

Anatomy is one of the basic science subjects and the corner stone of Medicine. It is a challenging subject due to its subdivisions and holds a major share among other subjects in the first professional year. Most often students have difficulty in learning anatomy due to its volume and usage of newer terminologies. The best method for learning anatomy is always a debatable topic till date [1,2,3]. In the year 2003, Brenner et al [2] categorized approaches to learn anatomy into (i) dissection by students, (ii) inspection of prosected specimens, (iii) didactic teaching, (iv)use of models, (v) computer-based learning (CBL) and (vi) teaching of living and radiological anatomy.

Anatomy teachers emphasize the importance of learning anatomy by dissection [4]. Alternatively, prosection based pedagogical approach is gaining popularity due to drastic reduction in cadaver-based anatomy teaching. This is supported by reports of Lockwood and Roberts[5] and Drake et al[6]. Implementation of any newer pedagogical approach should benefit the students in gaining knowledge and better results in examination. Various authors [6,7, 8] have done multiple studies regarding anatomy curriculum framework, type of pedagogical approaches to learn anatomy. Any newer approach should be considered based on the availability of cadavers, trained faculties and for the benefit of students in their examination.

With introduction of competency based integrated curriculum in Indian medical colleges, there is a significant decrease in the dissection contact hours. Every student gets to learn from cadaver specimens for only 6-8 hours per week in comparison to 10-12 hours earlier. We opine that the time spent in anatomy laboratory is extremely valuable and used wisely. With this scenario, the present study was conducted over a period of three months to obtain students feedback on the type of pedagogical approach they chose to learn anatomy in dissection laboratory and correlate the same with their performance in the exam.

Materials and Method

After obtaining Ethical clearance from the Institute Ethics Committee, a cross-sectional study was conducted among first year Medical students in the Department of Anatomy, KMCH, Andhra Pradesh, India. The study period extended from September 2019 to November 2019. A total of 120 students were included in the study. Written consents were obtained from the participants.

Gross Anatomy syllabus is divided into different regions of human body. To begin with upper limb and lower limb is taught followed by other regions of the body. Each region is taught first by large class room didactic lecture. This is followed by cadaveric dissection/ prosection sessions in the in laboratory. On an average, 6-8 hours per week is devoted for dissection practical. Following completion of each region, student learning is assessed by written theory and practical gross spotter examination. Theory examination comprises of modified essay, short notes and brief questions. Practical exam is conducted using cadaver specimens. The students are asked to spot the flagged structure and answer relevant questions regarding function /branches /or applied aspect of the same. For both theory and practical examination, 50% aggregate in each is considered as pass. Marks obtained by each student in both theory and practical examination is recorded.

Following completion of examination, 120 students were recruited for the present study. The purpose of the study was explained to them and were ensured that their names and responses would be kept confidential and used for research purposes only. They were asked to respond by choosing any one of the following learning styles which they adopted during the practical classes and include comments if any. Learning style 1-Dissection, Learning style 2-Prosection and Learning style 3-Both Dissection and Prosection. They were strictly told not to give multiple options. Their responses were calculated as percentage and their comments were taken into consideration for correlation. Descriptive analysis was made between the test scores and the response given by each student regarding their choice of learning.

Results

The responses given by each student was entered into Microsoft excel sheet and the percentage was calculated. Out of 120 students, 20 students (16.6%) opted for Dissection, 75 students (62.5%) for prosection and the remaining students 25(20.3) % for both as shown in Table 1, Figure 1. Responses of each student were compared with their theory and Practical marks. Among 20 students who opted for dissection, 40% (n=8) students scored ≥ 50% and the remaining 60% (n=12) students scored below 50 %. Out of 75 students who opted for prosection, 86.7% (n=65) scored ≥ 50% and the remaining 13.3% (10) scored < 50%. 80% (n=20) of students who chose both dissection and prosection scored ≥ 50% and the remaining 20% (5) students below 50% as shown in Table 2 and Figure 2.

Table 1: Percentage Distributions of Students' preferred Learning Method.

Learning Methods	Number of Students Responses(n=120)	Percentage (%)
Dissection only	20	16.6%
Prosection only	75	62.5%
Both Dissection and Prosection	25	20.8%

Table 2: Distribution of Students'Test scores according to their Preferred Learning Method

Learning Methods	**Number of Students Responses(n=120)**	**Students with Test score ≥ 50%**	**Students with Test score < 50%**
Dissection only	20	40% (8)	60% (12)
Prosection only	75	86.7% (65)	13.3%(10)
Both Dissection and Prosection	25	80% (20)	20%(5)

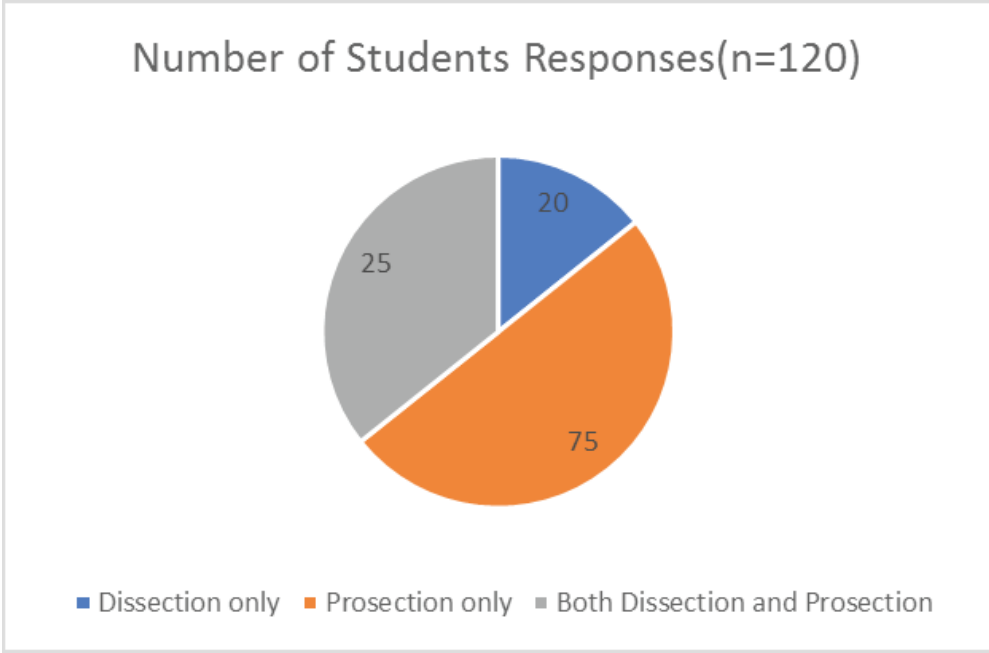

Figure 1: Showing number of students and their choice of learning Style/Approaches

Discussion

Cadaveric dissection is considered to be the traditional and best method of learning gross anatomy in lab. Routine cadaveric dissection by students arouses their interest to explore and identify the structures, provide a feeling of surprise at the identification of anatomical variations [9,10]. It also facilitates them to acquire skills which is later useful for holding instruments necessary in clinical practice [11,12]. However, there are contrast opinions and views on whether cadaver dissection is still appropriate for today's undergraduate training. It has drawbacks with regard to availability of trained anatomy faculty, adequate number of cadavers to maintain an optimal student – cadaver ratio and decreased course duration compared to earlier gross anatomy courses. From the reports of the present study, only 20 students opted for dissection. Among them 10 students performed well in their test scores. They were interested in doing dissection due to their inclination to pursue surgical field in their later years (based on their comments). Other students felt cadaveric dissection is a laborious process which requires lot of time and skill to dissect the body meticulously. Also, there is lack of adequate time for learning and revision resulting in poor performance. Medical schools in UK, US, Australia and New zealand, follow integrated /system based medical curriculum. The practice of cadaveric dissection is no longer used as the principle method of teaching. Reports from these countries reveals that though adequate resources are available like cadavers and trained faculties, this method is not considered as the best method [13,14] .Alternatively, prosected specimen, plastinated specimen, models and other computer assisted learning (CAL) are implemented in these medical schools.

Though both dissection and prosection have the benefits of multisensory learning, there are various benefits of Prosection over Dissection. Prosection is learning anatomy from pre dissected cadavers and specimens. This method of learning anatomy started in the Middle Ages and early Renaissance [15,16]. In view of the current integrated curriculum, revising the methodology of learning anatomy is needed. Due to less contact hours, students are not able to complete the dissection in accordance to the theory lecture schedule. As a result, there is lack of coordination in carrying out dissection in a timely manner. Learning anatomy from prosected specimens of previous years or freshly prosected specimens by the faculties enhances quick review of all the structures in the given lab hours. From student's perspective, it removes the fear and stress of dissection. It largely enables them to identify the structures by themselves without the guidance of faculties. Constant support/ guidance of faculty is not necessary unlike dissection. It also gives them adequate time for repeated self - learning and an opportunity for peer -teaching. All the above characteristics are very essential for a medical graduate according to the new competency based curriculum. Reports of the present study shows that 75(62.5%) students chose prosection as their choice which is comparartively higher than other choices. Out of 75 students, 60 students scored above 50% and the remaining 15 scored below 50%. This clearly states that performance of students is higher among those who chose prosection over dissection as the method of learning anatomy. The results of the present study is similar to studies based on student feedback and assessments that showed that prosections are efficient learning approach [9,17,18] .McWhorter and Forester [7] in their study concluded that prosections is always better and should be applied for all simple dissections rather than complicated dissections alone .

Students who chose both choices commented that they would first learn from prosected specimens followed by cadaveric dissection. About 25 students chose this approach. Each student gets to completely view all the structures to be identified using prosected specimens within a short duration of time. Thereby, students have adequate time to conceptualise, discuss among peers and also self-learn with the aid of Atlas. After completion of learning from prosected specimens, students feel free of stress to carry out dissection. This enables them to easily dissect without damaging important anatomical structures. Prosection followed by Dissection largely helps them to acquire all the anatomical knowledge of a particular region in a time efficient way. Moreover, overall student's performance is enhanced by this approach. Test scores of Students who chose this approach was comparatively better compared to dissection alone with 20 out of 25 students scoring above 50%.

Conclusion

According to the new competency based integrated curriculum, a suitable method of teaching gross anatomy in practical laboratory is warranted. Hence, the reports of the present cross-sectional study conducted among 120 first year Medical students indicates that students have different learning approaches to Anatomy. Prosection

is favoured by the majority over other approaches. The study recommends adoption of cadaveric prosection as a primary approach to learn Anatomy rather than dissection. Learning anatomy thorough prosected specimen is time efficient, imparts same anatomical knowledge, develops self-directed learning attitude, enhances group activity and results in better performance. This method also ensures optimal utilization of available recourses in terms of cadavers, faculties and Cadaver-students ratio.

Abstract

Background: Stress is the emotional and physical strain caused by the response to pressure from the outside world. The problem of stress among the family members of alcoholics is currently a major concern in the health policy. Family burden due to alcoholism might be social, financial, emotional and physical but it disrupts the life of a whole family. **Objective:** To assess the stress of the family members of alcoholics. **Materials and Method:** Descriptive research design was adopted in the study. Subjects of 100 family members of alcoholics admitted in de-addiction centre were recruited by non-probability convenience sampling technique. The data was gathered by using stress rating scale and informed consent was obtained from the subjects. **Results:** shows that most (54%) of the family members of alcoholics had moderate stress whereas (42%) of them had severe stress and only (4%) of them were having mild stress. There is no significant association between the level of stress of the family members of alcoholics and selected demographic variables. **Conclusion:** The study findings revealed that most of all family members of alcoholics are having one or another stress which make them suffer in their life. Hence need to adopt effective measures to reduce stress and improve their wellbeing which promotes health of family members

Keywords: *Stress; Family members; Alcoholics; Descriptive study.*

Introduction

Alcoholism is a chronic, progressive health problem which affects not only the individual but also his entire family members. Today, many families in the world are disturbed due to substance abuse, of which the most widely abused substance is Alcohol. Even though dependents are the victims of the Alcohol, but the major consequences are faced by the family members of the Alcoholics.[1]

Family members of alcoholics can experience stress, anxiety, depression and shame related to their loved ones addiction[2]. Family members may also be the victims of emotional or physical outbursts.

Family burden due to alcoholism might cause physiological problems such as hand tremor and blackout as well psychological problems such as obsessive desire to drink, behavioural problems that disrupt social or work life [3]. Alcoholism can be of any age background, income level, social or ethnic group.

It was estimated according to the national survey about alcohol consumption standards. About 25% of people life irritated with his drunkenness behaviour when they drink. 12% said they had started an argument or fight with the partner while drinking which points out the importance of working with these peoples family [4].

Stress is the body‘s reaction to change that requires a physical, mental or emotional adjustment or response. Stress can come from any situation or thought that makes you frustrated angry, nervous or anxious. Stress is the body and minds response to any pressure that disrupts in

normal balance. It occurs when our perception of events doesn't meet our expectations and we are unable to manage our reaction. When body is unable to resist the stress and strain the physiological and the psychological equilibrium is disturbed, that in turn can lead to numerous health hazards[5].

Alcoholism also has negative effects on the spouse of an alcoholic. The spouse may have feelings of hatred, exhaustion and become physically or mentally ill. Very often the spouse has to perform the roles of both parents. As a result, the non –alcoholic parent may be inconsistent, demanding and often neglect the children [6].

Common stress reactions include change in activity levels difficulty in communicating, in ability to rest, relax, irritability, outburst of anger ,sleep disturbance, periods of crying, gallows humour, headache ,tunnel vision, sweating or chills, increase heart rate, stomach upset, intolerance, withdrawal, isolating from people. Family members involves in this study were exposed to tension of which may negatively impact their physical and mental health.

From all the above statistics it is evident that there is a stress among family members of alcoholics, which leads unhappy life with multiple health problems.

Materials and Method

A quantitative approach with descriptive research design was adapted in this study to assess the stress of family members of alcoholics. The study was conducted in a de-addiction centre, a unit Father Muller Medical College Hospital, Mangalore. Total of 100 family members of alcoholics who were admitted in de-addiction centre were recruited through non-probability convenience sampling technique. Family members of alcoholics are the women related to alcoholic by marriage, children by him, his parents, sisters and brothers who are common living with him at the time of the study were selected as subjects. Ethical clearance: obtained from Institutional Ethics committee of Father Muller Medical College, Mangalore.

Inclusion Criteria: The study includes family members of alcoholics

- who are willing to participate in the study
- who are available during the time of data collection
- who never consumed alcohol and without any kind of major medical or psychiatric illness

Exclusion Criteria: The study excludes family members of Alcoholics

- who are not co-operative
- who are unable to communicate due to any other reasons like hearing impairment, mental disorders, below 18 years or chronic illness
- who are not available at the time of data collection

The permission to conduct study was obtained from Director, Father Muller Medical College Hospital, Mangalore. Informed consent was obtained from the study subjects. The need and purpose of the study was explained to the participants in their local language and confidentiality was assured. The stress among family members of alcoholics was assessed by using self prepared stress rating scale in the areas such as Physical, Psychological, Social and Financial with a total of 20 items..The data gathered were analyzed by using descriptive and inferential statistics.

Results

Section –1: Description of Sample characteristics

This section deals with the description of the baseline characteristics of 100 subjects presented in frequency and percentage.. The demographic characteristics of the family members are age, education, income; types of family, number of children duration of drinking and relationship with the patient with alcoholics are depicted in the table.

Table 1: Frequency and percentage distribution of family members of alcoholics

n=100

Sl. No	Variables	Frequency (F)	Percentage (%)
1	**Age (in years)**		
	a. 20-40	39	39
	b. 41-60	48	48
	c. 61-80	13	13
2	Education		
	a. Illiteracy	8	8
	b. Primary	27	27
	c. High School	35	35
	d. PUC	18	18
	e. Graduate & Above	12	12
3	**Income**		
	a. 5000	17	17
	b. 5001-10000	49	49
	c. 10001-15000	25	25
	d. 15001above	9	9
4	**Types of family**		
	a. Nuclear family	61	61
	b. Joint family	35	35
	c. Other	4	4
5	**Number of children**		
	a. No children	22	22
	b. 1 child	40	40
	c. 2 children	25	25
	d. 3 and above	13	13
6	**Drinking**		
	a. 1 year	8	8
	b. 1-5 years	32	32
	c. 6-10 years	33	33
	d. Morethan10years	27	27
7	**Relationship with patient**		
	a. Wife	32	32
	b. Parents	19	19
	c. Son and daughter	32	32
	d. Siblings	14	14
	e. Others	3	3

The data presented in table 1 shows that Majority (48 %) of the subjects belongs to the age group of 41-60 years. Highest percentage (35%) had high school education. Family income (49%) had income of Rs.5001 to 10,000 per month. About (61 %) of them belongs to nuclear family. Most (40%) of the family members had one child. About (33%) of them had duration of drinking about 6-10 years. Majority (32%) of each had relationship of wife, son and daughter with alcoholics.

Section II: Stress level of the family members of alcoholics

Table 2: frequency and percentage distribution of subject according to the stress score of the family members of alcoholics. n= 100

Sl.No	Score	Grades	Frequency (F)	Percentage (%)
1	0-20	Mild	4	4
2	21-40	Moderate	54	54
3	41-60	Severe	42	42

The data presented in table 2 shows that majority (54%) of family members had moderate stress due to alcoholics, about (42%) of them had severe stress and only (4%) had mild stress because of an alcoholics in the family.

TABEL 3: Mean, standard deviation (SD) and mean percentage according to their stress score of the family members of alcoholics. n= 100

Family members of alcoholics	Minimum score	Maximum score	Mean + SD	Mean %
Overall stress score	10.00	53.00	36.9500+ 9.73526	69.71%

The data in the table 3 shows that maximum score is (53.00) and minimum score is (10.0). The mean $\pm$ standard deviation of stress score of the family members of alcoholics are 36.9500 $\pm$9.73526 and mean percentage of stress score is (36.95%) respectively.

Section IV. Association of stress level of subjects with selected demographic variables

Chi square test was computed to determine the association between the stress level and selected demographic variables. The following null hypothesis was stated:

H_{01}: There is no significant association of level of stress among family members of alcoholic with selected demographic variables

There is no significant association between stress level of the subjects and the selected variables since the calculated chi square value is less than the tabled value .Hence the null hypothesis is accepted and research hypothesis is rejected.

Discussion

Alcohol abuse has the potential to destroy families. Research shows that families affected by alcoholism are more likely to have low levels of emotional bonding, expressiveness and independence[7].

The present study aimed at to assess the stress of the family members of alcoholics and the findings revealed that majority about (42%) of them had severe stress, due to various factors. A cross-sectional study was carried out to evaluate quality of life and presence of stress in caregivers of drug-addicted people. Results revealed that, 55.9% were mothers with a mean age of 47.66 years; 23.8% had depressive symptoms. The SF36 scores most compromised were emotional aspects, vitality, pain and mental health. Mean stress among caregivers was 2.24. A significant correlation in quality of life, depression and stress of caregivers was seen[8]. The present study also showed that there is no significant association between stress level of the subjects and the selected variables since the calculated chi square value is less than the tabled value .Hence the research hypothesis

is rejected and null hypothesis is accepted

CONCLUSION

Alcoholism is a family disease. Due alcoholic member in the family there are various consequences are faced by the family members. The present study envisaged to assess the stress of the family members of alcoholics. The findings of the present study revealed that majority of the family members had severe stress due to various factors. So the researcher felt the need to further to undertake some essential interventions to the family members to train them how to cope up with situations.

Effect of Functional Task Exercises on Hand Function and Grip Strength in Patients with Lateral epicondylitis

Shreya Deshak[1], Ujwal Yeole[2], Saikrupa Moralwar[3]

[1]Assistant Professor, [2]Principal, Associate Professor, [3]Intern, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth Pune, India

Abstract

Background: Tennis Elbow is the most common overuse syndrome in the elbow. It is a tendinopathy injury involving the extensor muscles of the forearm. The lateral epicondylitis is characterized by pain and tenderness at the lateral epicondyle of the humerus as there is non-specific inflammation at the origin of the extensor muscles of forearm. As there is pain and inflammation, the grip strength in decreased and hand function is affected. But there are few research done on intervention regarding same. Hence a comparative study was carried on 60 patient, 30 subjects were grouped in Group A which were given functional task exercises and Group B was given Conventional therapy. The stastical analysis showed that out of 30 subjects, mean age of group A patients was 25±6.23 and mean age of group B patients was 27.2±4.8. Grip strength in between Group A (63.5± 14.2) and Group B (60.4± 12.9) with p value 0.04, Patient rated tennis elbow evaluation scale in between Group A (44.1± 6.8) and Group B (43.8±10.6) with p value 0.002 and Michigan hand outcome measures in between Group A (62.5±14.4) and Group B (54.3±14.7) with p value 0.0005. Hence the study concluded that there is significant effect of Functional Task Exercises on Grip strength and Hand function in lateral epicondylitis.

Key words: *sphygmamometer, tennis elbow evaluation scale, Michigan hand outcome questionnaire , hand function grip strength.*

Introduction

The lateral epicondylitis is characterized by pain and tenderness at the lateral epicondyle of the humerus as there is non-specific inflammation at the origin of the extensor muscles of forearm.It is sometimes seen in tennis player , other activities such as squeezing clothes, carrying a suitcase etc are frequent responsible.[1]

The lateral epicondylitis is a chronic symptomatic degeneration of the tendons that are attached extensor muscles of the lateral epicondyle of the humerus. It is also most common cause of chronic musculoskeletal conditions affecting the elbow. The results of lateral epicondylitis is pain, disability, and leads to loss of productivity.[2]

There are some neurological symptoms, namely cervical spine diseases with radiculopathy and posterior interosseos nerve involvement and also bursitis is also associated with lateral epicondylitis .In lateral epicondylitis the pain thresholds are at lateral epicondyle with pain on palpation and with positive Millis test. The results of the resisted wrist extension reflects decreased strength.[3]The patients has pain and there is decrease in function which affects basic activities in daily life.[4]

It is also termed as tendinosis that specifically involves the origin of extensor Carpi radials brevis muscle. It is mostly work related or sport related pain syndrome of the arm. The quick and repetitive movements of the wrist and forearm can rupture the proximal attachment of the long extensor muscles also causes inflammation and pain.[5]

Corresponding Author:
Dr Shreya Deshak
Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Gultekdi, Pune-37,
Mobile No. 9730825470,
Email id: shreyad.2010@gmail.com

There is pain on palpation of lateral epicondyle of humerus and weakness during gripping activities. The grip strength is mostly affected due the damage caused to the muscles which work in gripping activities. The grip is affected due to the repetitive activities performed in same manner for long duration. The repetitive activities such as driving for long hours, tying ,using rolling pin for making rotis, etc. Due to this repetitive activities the hand function is also affected. The hand function like turning a knod, lifting a heavy weight bag, driving a bike, etc.[6]

There has been research done that due to pain, there has been affection of grip strength and hand function. Functional task exercise is more effective in improving functional performance, and that Functional task exercise is the first exercise programme with sustainable effects. But there is little research done on effects of functional task exercises on grip strength and hand function in lateral epicondylitis, hence need of this study.

- **Methods:**

- **Study Design**: Experimental

- **Selection of subjects**: Total 75 patients were approached for the study out of which 60 patients were selected according to inclusion and exclusion criteria. The patient included were patients diagnosed with lateral epicondylitis more than 6 weeks and patient excluded were patient with bilateral involvement and with cervical radiculopathy. The patient were divided into 2 groups by convenient sampling each having 30 patients. The aim, objectives and method of study was explained to the participants. Consent was taken on the consent form.

Materials: Demographic data sheet, Consent form, scale, sphygmomanometer, paper, plastic bottle, cards, door knob, clay, cloth.

Procedure:

Ethical clearance was taken from the Institutional Ethical Committee, Tilak Maharashtra Vidyapeeth, Department of Physiotherapy, Pune. Participations were selected according to inclusion and exclusion criteria. The aim, objectives and method of study was explained to the participants. Consent was taken on the consent form. The assessment of patient was done as below.

Patient rated tennis elbow evaluation scale: In the patient rated tennis elbow evaluation scale there are three sections Pain, functional disability and usual activities. All the questions are numbered between 0-10 and the patient is asked to select on basis of the how much pain is present and affected activities.

Sphygmamometer: Grip assessment was done by the sphygmomanometer: The sphygmomanometer is rolled to cylinder and the cuff is inflated to 20 mmhg and patient is asked to press the cylinder 3 times . The highest reading among the 3 is considered and if the increments 2mmhg then the grip is affected [18].

Michigan hand outcome questionnaire: The scale contains 6 scales: (1) overall hand function (2) Activities of daily living (3) work performance (4) pain (5) anestheics (6) satisfaction with hand function. The scale score for each of 6 scales is the sum of the reading of each scales. The score is converted to a score range from 0 to 100.

Treatment protocol: Pre-training: The grip strength will be checked by sphygmamometer. The hand function can be checked by Michigan hand outcome questionnaire. The physical function,pain and disability will be checked by using patient rated tennis elbow evaluation scale.

The treatment will be divided into 2 groups : [A] Functional Task exercises

[B] Conventional therapy

45 minutes session 10 repetitions for 4 weeks.

Functional task exercises: 45 minutes session 10 repetitions for 4 weeks

Functional task exercises was given additional along with the conventional treatment.

Functional task exercises were transfer of sandbag from one hand to other hand, gripping the door knob, carrying the water bottle from one hand to other hand, turn the cards over, do typing movements, wringing the wet clothes, crumble the paper and try to spread back paper.

Post-training: The physical function , pain and disability will be checked by using patient rated tennis elbow evaluation scale. The grip strength will be checked by sphygmomanometer. The hand function can be checked by Michigan hand outcome questionnaire.

Data will be collected and statistical analysis will be

done.

Stastistical Technique: Wilcoxon's test was used for within the groups not passing the normality and mann witney u test was used for between the groups not passing the normality.

Results

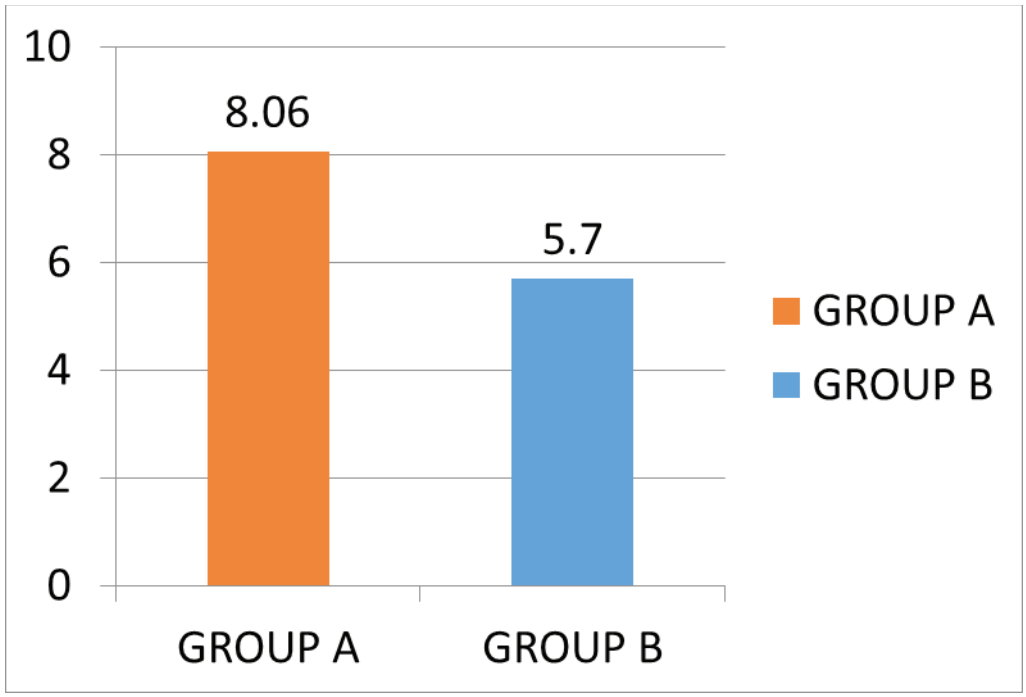
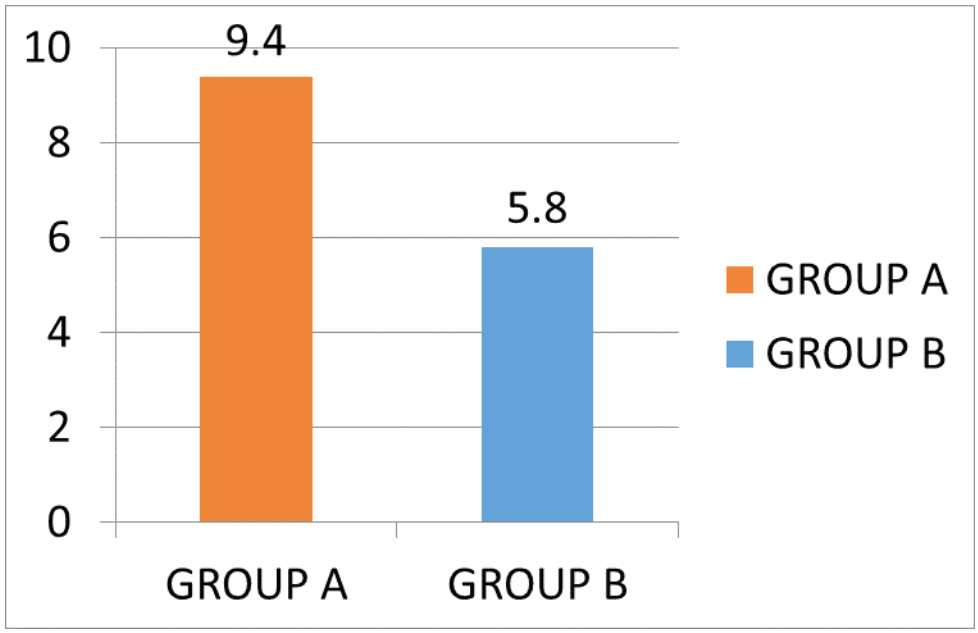


Graph 2 : It shows in comparison, the group A(functional task exercises) which is significantly improved than Group B (control Group) in patient rated tennis evaluation scale in patients with lateral epicondylitis with p value (0.002).



Graph 3: This graph shows in comparison, group A (functional task exercises) which is significantly improved than group B of Michigan hand outcome questionnaire in patients with lateral epicondylitis with p value (0.005).

Discussion

In this study of the effect of functional task exercise vs conventional therapy on grip strength and hand function in patients with lateral epicondylitis. The patients are evaluated pre and post treatment for grip strength and hand function by sphygmomanometer, patient rated tennis elbow evaluation scale and Michigan hand outcome questionnaire.

The functional task exercise are related to the daily life activities and it can performed easily and things required for that are also easily available in environment. This exercise allows to patient to perform daily activities which are related daily living also declines chances of

decrease of grip strength and hand function due to lateral epicondylitis.[10]

Functional task exercises showed more beneficial because these components are practised in relevant functional positions only. Functional task exercises attempts to adapt or develop the training which allows individuals to perform activities of daily life more easily and without injuries.

The performance of functional task exercise includes the teamwork of cognitive, perceptual, and motor functional and it is also related to the individual's active environment. The functional task exercise trains the patient to perform daily life task easily by increasing the grip strength and hand function. It makes the patient functionally independent to perform daily life grips and hand function which required to perform in individual's daily life. (15)

Functional task exercises increase the upper body strength and balance and coordination. The strength of the muscles is also increased which contributes to grip strength, Thus showing positive effect on grip strength and hand function in patients with lateral epicondylitis. (15)

In functional task exercises there were wider range of exercises and performed in optimal manner. Exercises are performed in structured manner.(16) Functional Task exercises increase blood flow, prevent injury to damaged area and cause neovascularization.(16)

Literatures suggest that strengthening and stretching both are main components of exercise programme, because tendons must be flexible along with strong. Positive effects of exercise programme for tendon injuries may be attributable to lengthening of muscle tendon unit by stretching and strengthening exercise which could achieve loading effect within muscle tendon unit along with hypertrophy and increased tensile strength of the tendon.[21]

Tipton et al (1987) say that "prescribed exercises which increase the forces being transmitted to ligaments, tendons and bones will maintain and generally increase the strength and functional capacity of these structures". The same principle seems to be valid in the treatment of chronic tennis elbow syndrome. [21]

Conclusion

Hence the study concluded that there is significant improvement in hand function and grip strength with the functional task exercises in comparison with the control group.

Acknowledgment: All the authors and participants contributed equally to the conception and design of the study. We are grateful to clinics for the support of this study.

Endovascular Treatment (Stenting) of Total IVC Obstruction with Collaterals in Young Adult with Crohn's Disease Maharishi Markandeshwar (Deemed to Be University)

Sivaji Patibandla[1], Abhinav Rastogi[1], Sajaad Manjoor[2], Vishal Singh[3], Himanshu Tanwar[1]

[1]DM Cardiology Resident, [2]Director Interventional Cardiology, [3]Assistant Proffessor Department of Cardiology)

Abstract

We present a case of clinically extensive bilateral DVTs associated with chronic total inferior vena cava thrombosis with underlying crohn's disease and who is on steroid therapy. Young patients presenting with symptoms of DVT should be investigated not only to establish any thrombophilic pre-disposition but to ascertain the proximal extent of thrombus which may itself influence treatment. Treatment options in the case of IVC thrombus without anatomical variance include anticoagulation, mechanical thrombectomy, systemic thrombolytic therapy, transcatheter regional thrombolysis, and angioplasty

Keywords: *Deep vein thrombosis, inferior vena cava thrombus, IVC stenting, Chronic total IVC occlusion, chron's disease*

Introduction

Inferior vena cava (IVC) thrombosis is an entity which is given less importance that is associated with significant morbidity and mortality [1]

About 2.6% to 4.0% of patients will have DVT [2]

The incidence of unprovoked DVT in young patients is rare, especially below 30 years of age.

There is a paucity of data and societal guidelines with regards to the diagnosis and management of IVC thrombosis

The clinical presentation of IVC thrombosis is often ambiguous and varies significantly according to the acuity, the level, and the extent of thrombosis.

Similar to those with lower extremity DVT, patients with IVC thrombosis commonly complain of leg heaviness, pain, swelling, and cramping.

Even the total occlusion of IVC can remain silent or else can present with acute symptoms

Hypercoagulability which is related to neoplastic or hematological abnormalities, venous stasis secondary to extraluminal pressure from tumors or inflammatory processes and vessel injury due to trauma have all been implicated as primary mechanisms in the pathophysiology of IVC thrombosis [3]

Endovascular interventions play a major role in treatment of venous obstructive diseases.

Catheter-directed thrombolysis (CDT) has become a pivotal adjunctive therapy in the management of both acute and chronic thromboembolic venous disease.

This therapy is most successful in acute thrombus(<14 days) and less effective in chronic clot(>4 weeks)[9]

Percutaneous mechanical thrombectomy has evolved in treating complex veno-occlusive diseases.

These devices work by simple thrombo aspiraton(venturi effect) .

Endovascular therapy offers less morbidity and

Address: flat no 191, I block, MM University, Mullana, Ambala.Pincode:133207

mortality when compared to surgery. In one of largest reported series of endovascular therapy for IVC occlusion, 82% of the lesions in 120 patients were infrarenal, with suprarenal involvement in 18% of cases[10]

Underlying lesions are identified and should undergo high-pressure angioplasty and stenting. The advantage of self-expanding venous stents include the ability to oversize them so as to allow proper fixation and reduce the risk of stent migration in these highly compliant vessels

Case History

22 years male patient presented with complaints of bilateral lower limb pain associated with swelling of limbs for 15 days. H/O shortness of breath for 15 days. H/O anorexia, decreased appetite, nausea for 15 days. He was diagnosed as CHRON'S disease for 6 months and was on steroid therapy. There was no history of trauma, surgery, long-distance travel, prolonged immobilization.

On examination, his BP was 120/70 mmHg and has tachycardia of HR: 126/min

Bilateral lower limbs swelling symmetrically with pitting edema is present

Cardio-respiratory was unremarkable and his abdomen was soft

All routine Lab investigations (hematological, coagulation, and biochemical) were normal.

ECG suggestive of sinus tachycardia

2DECHO suggestive of RA an RV dilated, moderate TR, moderate to severe PAH.

USG COLOUR DOPPLER bilateral lower limbs found to have DVT extending up to infra hepatic inferior vena cava.

CT pulmonary angiography was done suggestive of pulmonary embolism

IVC venogram via the right femoral vein demonstrated total occlusion of the IVC with high-grade multiple collaterals (Figure 1)

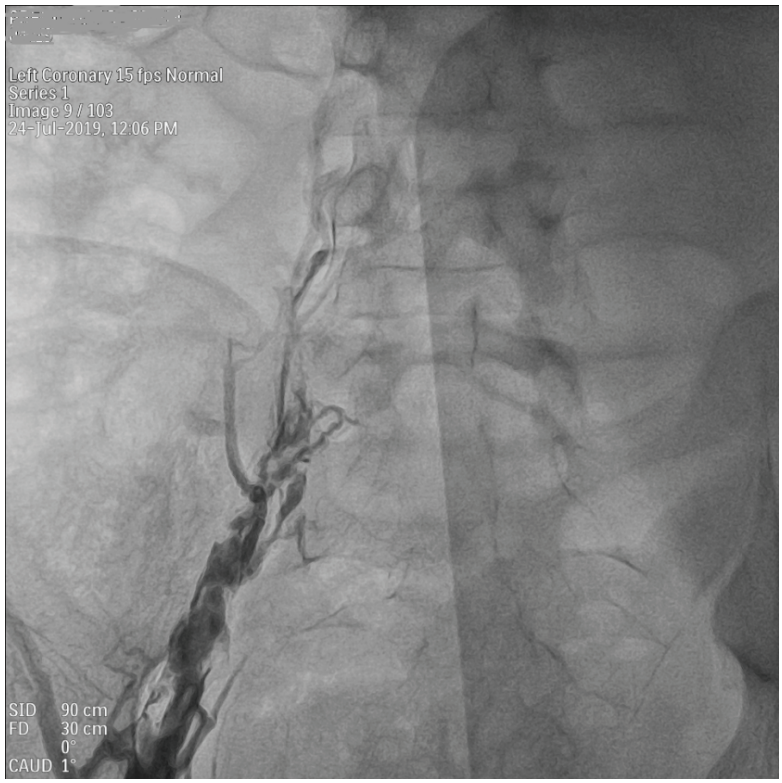

Figure 1 : Venogram showig total occlusion of IVC

IVC filter(Cook Celect Platinum vena caval filter) was placed in view of pulmonary embolism (Figure 2)

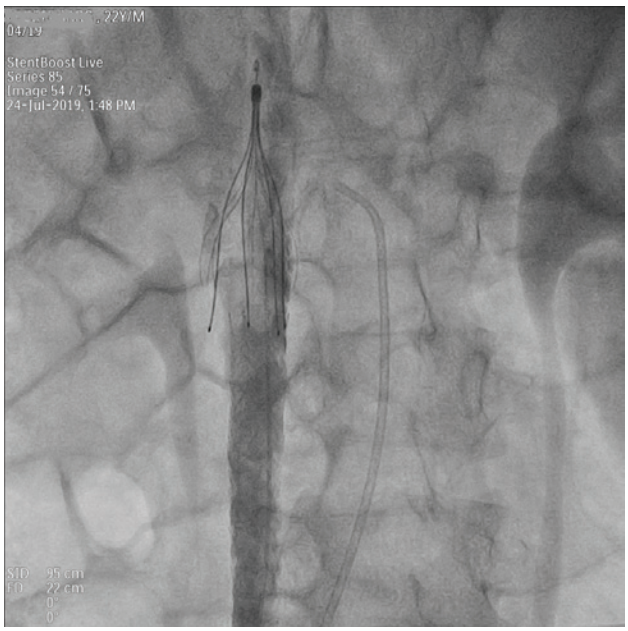

Figure 2 : IVC filter placed

Balloon angioplasty of IVC was done along with mechanical thrombectomy resulting recanalization of IVC.

A self-expandable stent (Abbott Vascular –Absolute Pro) (10×100 mm,135 cms) was placed in IVC. (Figure 3)

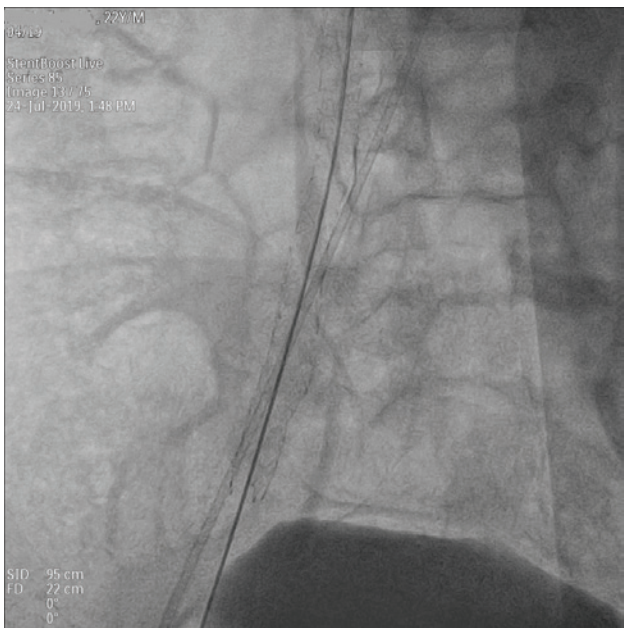

Figure 3 : Stent was placed

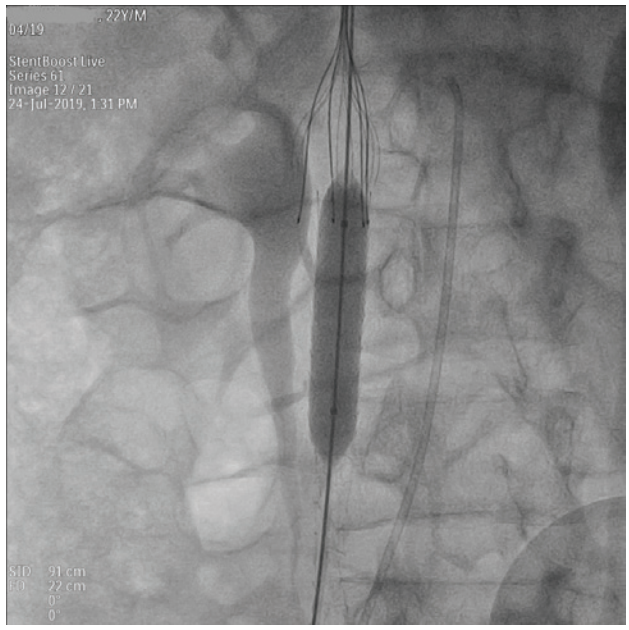

Figure 4: dilatation of stent

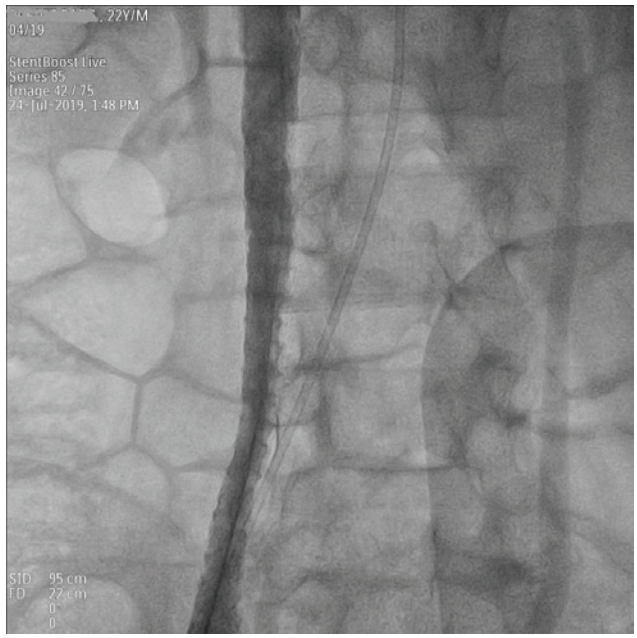

Figure 5 : final result after stent placement and post dilation of stent

The patient was started on anticoagulation with intravenous injection heparin bridging with oral anticoagulants.

The patient was started on oral anticoagulants-warfarin 3 mg OD and advised to maintain INR between 2-3

Discussion

It is a known fact that Virchow's triad (stasis, endothelial injury, hypercoagulability) most common pathophysiology for predisposing to DVT. But

unprovoked DVT, especially in young patients, needs thorough workup.

Recent advances in the utilization of ultrasound, CT and as well as endovascular procedures have resulted in an increase in detection rates of IVC thrombosis.

About 12% of patients with a diagnosis of IVC thrombus may present with pulmonary embolism. So, CT pulmonary angiogram is needed to evaluate for pulmonary embolism

Treatment options in the case of IVC thrombus without anatomical variance include anticoagulation, mechanical thrombectomy, systemic thrombolytic therapy, transcatheter regional thrombolysis, and angioplasty [4]

There is no specific literature describing the ideal duration of anticoagulation in these instances, however, case evidence identifies a trend toward treatment for a minimum of one year with maintaining the target INR

Endovascular stent placement in combination with angioplasty is recommended in the cases of residual stenosis and chronic IVC occlusion [5]

Learning Points

 Deep venous thrombosis (DVT) of the inferior vena cava (IVC), iliac veins and femoral veins in young adults is rare, but it is associated with significant morbidity.

 Understanding the embryological IVC development and pathophysiology of thrombus formation is critical to suspecting congenital anomalies of the IVC, especially with bilateral DVT.

 The initial diagnostic procedure should be an ultrasound of the lower extremities. Further investigation modalities are mandatory with the detection of iliofemoral thrombosis. CT or MRI is required to identify the extension of the thrombus and IVC anatomy. For the complete evaluation, thrombophilia workup should be performed[6,8]

 Treatment options include anticoagulation, thrombolytic therapy, and mechanical thrombectomy. In a case of IVC development abnormalities, the location and type of the defect determine the surgical approach. Even with extensive therapeutic modalities, long-term or even life-long anticoagulation is often required [6,7]

Neuroendocrine Tumors of the Oral Cavity: A Summarized Overview

Sona Baburathinam[1], Devi.M[2], Therraddi Muthu R.M[3], Chitra N[4]

[1]Senior Lecturer, [2] Head of the Department,[3] Reader, [4]Senior Lecturer, Department of Oral Pathology and Microbiology, Asan Memorial Dental College and Hospital

Abstract

The neuroendocrine system is made up of neuroendocrine cells that are distributed throughout several organs, including digestive system and lungs. The neuroendocrine cells have characteristics of both nerve and endocrine cells. The neuroendocrine cells are locally aggregated constituting certain endocrine organs, such as adrenal medulla or are scattered throughout all organs with an epithelial lining (disseminated/diffuse neuroendocrine system- DNES). This article provides an overview of the neuroendocrine tumors that arise in the oral cavity.

Keywords: *Malignant Peripheral Nerve Sheath Tumor, Olfactory Neuroblastoma, Paraganglioma, Schwannoma*

Introduction

The neuroendocrine system is made up of neuroendocrine cells that are distributed throughout several organs, including digestive system and lungs. The neuroendocrine cells have characteristics of both nerve and endocrine cells. The neuroendocrine cells are locally aggregated constituting certain endocrine organs, such as adrenal medulla or are scattered throughout all organs with an epithelial lining (disseminated/diffuse neuroendocrine system- DNES). Tumors that arise from DNES, commonly involve the gastrointestinal tract, followed by the lung[1] . In the head and neck region, most tumors involve the larynx followed by salivary glands [2] .

Neuroendocrine cells of the oral mucosa:

Merkel cell, which is a member of the DNES, is the neuroendocrine cell of the oral mucosa. They are distributed in the basal layer of keratinized mucosa of gingiva and hard palate. They appear as scattered clear cells, occurring singly or in clusters[3] . They are not readily identifiable at light microscopic level. Immunohistochemically, they are positive for cytokeratins (CK 8, 18,19, 20)[3], villin, chromogranin A, synaptophysin, neuron specific enolase, vasoactive intestinal polypeptide, pancreastatin, substance P, epithelial and neural cell adhesion molecules and S-100 [4]. Dual expression of both epithelial antigens and neurosecretory substances are characteristic of both normal and neoplastic Merkel cells. But they show variability in expression of the various markers[5] . Merkel cells function as mechanoreceptors and mediate the sense of touch [6]. Ultrastuctural studies reveal the presence of a nuclear rodlet [7] .

Classification of neuroendocrine tumors:

Neuroendocrine tumors at any anatomic site, are classified into two groups [8] :

Group I: Tumors showing epithelial differentiation

Group II: Tumors showing neural features.

Group I

Well-differentiated neuroendocrine carcinoma (carcinoid tumor)

Moderately differentiated neuroendocrine carcinoma (atypical

Corresponding author:
Dr. Sona Baburathinam
Department of Oral Pathology and Microbiology,
Asan Memorial Dental College and Hospital
Chengalpatu, Tamil Nadu, India

carcinoid tumor)

Poorly differentiated neuroendocrine carcinoma, small cell type

Poorly differentiated neuroendocrine carcinoma, large cell type

Pituitary adenoma/carcinoma

Group II

Granular cell tumor

Heterotopic glial tissue

MPNST - Malignant peripheral nerve sheath tumor

Malignant melanoma

Neurofibroma

Olfactory neuroblastoma

Paraganglioma

PNET/Ewing's sarcoma

Schwannoma

(PNET- peripheral neuroectodermal tumor.)

Group I neoplasms:

Majority of lesions in the head and neck region arise from the larynx, while the second most common site is the salivary gland. Majority of lesions in the larynx are moderately differentiated, but those arising in the salivary gland are of poorly differentiated, small cell type. The well-differentiated neuroendocrine carcinoma or the "typical carcinoid tumor" grows in nests and cords, composed of uniform cells having 'salt and pepper' chromatin distribution [9] .

The moderately differentiated neuroendocrine carcinoma or the "atypical carcinoid tumor" grow in nests and cords with peripheral palisading of nuclei. There is mild-moderate nuclear pleomorphism seen [10].

The poorly differentiated neuroendocrine carcinoma, small cell type that occurs in the salivary glands is composed of sheets of spindled to oval cells with little cytoplasm and high mitotic rate. Areas of necrosis are common. Foci of glandular differentiation may be seen[11]. Poorly differentiated neuroendocrine carcinoma, large cell type is composed of intermediate to large cells. The sino-nasal undifferentiated carcinoma is a classic example [12]. The pituitary adenoma may arise in the nasopharynx as an ectopic mass[13].

Group II neoplasms:

Granular cell tumor:

It is a rare, benign, soft tissue tumor that arises from Schwann cells[14]. The lesion could be benign or malignant. Abrikosoff, in 1926 described a tumor of the tongue that was composed of granular cells. The granular cells are large, polygonal, oval or bipolar cells with abundant fine or coarsely granular cytoplasm and an eccentrically located vesicular, pale staining nucleus. The cells occur in ribbons separated by fibrous septa. Pseudoepitheliomatous hyperplasia is characteristic. Of the head and neck lesions, 70% occur intaorally in the tongue, buccal mucosa and hard palate[14]. Granular cells are positive for S 100, neuron specific enolase, laminin and myelin basic protein, confirming their neural origin[15].

Malignant peripheral nerve sheath tumor:

They are rare, highly aggressive soft tissue sarcomas of ectomesenchymal origin that may arise de novo or from a pre-existing neurofibroma. There is a higher incidence in patients with neurofibromatosis I and in those with radiation exposure[16]. Most tumors have spindle cells arranged in fascicles and resemble fibrosarcoma. Mitotic activity is high. Few tumors exhibit variable differentiation. A MPNST with rhabdomyoblastic differentiation exhibits both skeletal muscle and neural differentiation. Other tumors with differentiation include glandular malignant Schwannoma, epithelioid malignant Schwannoma and superficial epithelioid variant[17].

Malignant melanoma:

It is aggressive neoplasm composed of small round cells resembling small cell carcinoma or lymphoma. They may be composed of epithelioid cells, rhabdoid cells or spindle cells[18]. They thus mimick a variety of sarcomas. They exhibit diffuse positive staining for S 100 protein, HMB-45 and anti-tyrosinase [2].

Olfactory neuroblastoma:

Rare tumor that is found in the nasal cavity and nasopharynx. They may also arise from the maxillary sinus or invade it. Microscopically, they are composed

of densely packed masses of small darkly staining cells, with poorly defined eosinophilic cytoplasm and round, vesicular nucleus. Rosette formation with non-ciliated columnar cells and eosinophilic neurofibrils is commonly found. Stroma has a fibrillar neuroid pattern. Few mitotic figures are seen[19].

Paraganglioma:

The tumor is characterized by presence of round or polygonal epithelioid cells that are organized into nests or zellballen. The nests are composed of chief cells, with centrally located vesicular nucleus and a granular, eosinophilic cytoplasm. The tumor is vascular and is surrounded by a thin fibrous capsule [20].

Melanotic neuroectodermal tumor of infancy:

This tumor has a striking predilection for head and neck, frequently involving anterior maxilla. They have a biphasic population of small and large cells forming alveolar or tubular patterns. The small cells resemble neurofibroblasts, while the large cell shave prominent cytoplasmic melanin pigment. The larger cells are positive for cytokeratin, vimentin and HMB-45. Both cell types are positive for neuron specific enolase and may also exhibit positivity for Leu-7 or muscle markers. They may also stain for synaptophysin and GFAP[21].

Conclusion

The basis of classification of neuroendocrine tumors is largely determined by their histologic differentiation. Though they reveal biologic heterogeneity, there should be an awareness of the occurrence of such lesions in the oral cavity to enable them to be detected and treated early.

Does Oral Health Have an Impact on Self Perceptions, Parental Ratings and Photographic Assessments of a Child's Smile?

Suganya.P[1], Prabu. D[2], Sunayana Manipal[3], Rajmohan[3], Bharathwaj[3], Bharathwaj[4,] M.R.Prashanthy[1]

[1](1st Year Post Graduate) [2] (Head Of The Department,[3].Reader, [4]Lecturer, Department Of Public Health Dentistry, SRM Dental College, Ramapuram

Abstract

AIM: To determine whether there is a relationship between the oral health of a child and evaluation of the child's smile by self-perception, their parents perception and through measurements by photographic assessment.

MATERIALS AND METHODS: A Cross sectional study was conducted among 100 children to determine their oral health status. The children and parents were given a questionnaire to assess the child's self-perception of their smile, the parents also responded to questions directed at evaluating the smile of their children. Then the photographs of children were taken at 2 occasions one when they were at rest position and the other photograph was taken when the child was smiling.

RESULTS: The child's self-evaluation correlated significantly with the photographic assessment of the smile and the number of positive responses by the parents. There were significant relationships between oral health indicators and the overall smile evaluation scores. The children with less decayed teeth showed more teeth while smiling and received more positive responses by the parents than children with decay.

CONCLUSIONS: Poor oral health is related to the child's smiling patterns and the way others perceive their smile. Poor oral health may significantly impair a child's smile and may impact the child's social interactions, confidence level and the way they feel about themselves

Key Words-*Oral health, child's smile, photographic assessment*

Introduction

Dental caries though preventable is very common in young children. Especially children from low socioeconomic background are highly vulnerable to dental caries, the dental need is the greatest in this group. Poor oral health in children manifests in various ways later in the course of their life .Dental caries in the primary dentition is an indicator that the individual is highly susceptible to caries in future[1.]

Corresponding Author:
Suganya.P (1st Year Post Graduate) Department Of Public Health Dentistry
SRM Dental College, Ramapuram
Mail Id: Suganyavvk92@Gmail.Com

Dental caries has also been seen as the major reason for emergency dental visits .Toothache was documented as the most frequent complaint at 49% [2]

It is seen that there is a significant relationship between poor oral health and general health status of a chid as well as their height and weight[3]. Caries and its treatment affect children's oral health related quality of life in a significant way there is a social and psychological impact as well[4, 5]

Studies done show that there is a social and psychological impact on the child caused by impaired oral health. A child's smile is very innocent and has certain significance in social interactions .Their own self perceptions are a major indicator of self-confidence and self-esteem. A relaxed natural smile is also an indicative of the comfort level of the child. The smile is the best

way to express our confidence and will power Studies shows that smile plays a great importance to child's social life and their own mood.[6] 'A smile is a curve that sets everything straight' it is a form of greeting and it is very delightful to see a wide beautiful smile. The previous study conducted by Anu Babu et al has showed about the importance of smile[7].

It may even affect the judgement and attractiveness of a person .It shows the welcoming behaviour of a person.[8] Research has shown that children with missing, decayed or stained teeth are very conscious and less confident about smiling.[5]

The objective of this study is to investigate how the oral health of a child is related to their smiling patterns .Taking into account a child's self perception of their smile ,parents proxy evaluation of their child's smile as well as a photographic assessment.

Materials and Method

A cross sectional study was conducted among 100 children of aged 4-12 years in the Department of Public Health and Community Dentistry and Pedodontics ,SRM dental college, Ramapuram, Chennai. The convenience sampling method was used to select the samples.

Inclusion criteria: Children with physical and mental well-being

The parents ranged from age 25 years to 40 years

Exclusion criteria: Children with any systemic diseases

Those who are not willing to participate

Those who didn't fulfil the questionnaire are excluded

Data were obtained from 100 child patients and their parents who consented to participate in the survey. Parents were approached and after receiving their consent the child was examined and asked questions about their smile. Required photographs were taken.

Data consists of three parts

- child's survey

- parents assessment of their child's smile

- photographic assessment of the child's smile

The child survey consists of five easy questions about child's smile which could be answered by the diverse age group from a four year old child to a 12 year old .Questions concerned with the child's smile focussed on their teeth and smiling patterns. Questions included were "Do you like your teeth?", "Are you happy with your teeth and smile?", "do your teeth look nice?", "do you have a nice smile?" and "do you show your teeth when you smile?"

Answers were dichotomous with a simple "yes" or "no"

The total score was the sum of "yes" answers. A higher score indicated that the child was more positive about their smile.

Five parent indices were calculated based on a questionnaire

Index 1 was used as the proxy score which was calculated by averaging scores of two questions. The 5 point Likert scale (1= "disagree strongly" and 5= "agree strongly") was used to answer the questions.

Index 2 was the impact score evaluated by the average response of two questions,(" How much do you think the condition of your child's teeth affects the way your child feels about him/herself?", "How much do you think that the health of your child's teeth affects the way your child smiles?").These responses were based on a 5 point Likert scale ranges from 1= "not at all" and 5= "very much".

Index 3 comprised of the tooth ache score .This score was calculated based on the parent's answer to the question "A tooth ache keeps my child from smiling". The answer was given on a five point scale 1= "Disagree strongly" and 5= "Agree strongly"

Indices 4 and 5 consists of the total number of positive and negative adjectives obtained from the 9 adjectives namely "hides teeth" , "hesitant" , "shy" , "happy", "reserved", "wide smile" ,"shows teeth", "open mouth"," closed mouth" . The positive items number was calculated by adding one point of the adjectives - wide smile, happy, open mouth and shows teeth. The rest were counted as the negative items.

Photographic Assessment

The photographs of the child were taken by a single examiner two photographs were taken for each child one

with the mouth closed indicating when the child's mouth is at the baseline level. The other photograph was taken when the child is smiling. Based on the two photographs three indicators were calculated namely- width of the child's mouth, opening of child's mouth and no. of teeth shown. These indicators were selected based on the assessment of facial expressions.

Child Clinical Examination

The child was clinically examined and the no. of decayed, missing and filled teeth was determined and other details were noted like the number of missing teeth naturally, teeth missing due to caries, the number of restored teeth and the number of extracted teeth.

Results

Children's self-report, the parents proxy assessment and photographic assessment of the children's smile (Table 1)

The children's self-assessment of their smile as measured with number of teeth shown (r=0.736,P=0.05) and mouth width (r=0.436,P=0.05) correlated significantly

Children who were more positive about their smile showed more teeth and had wider smiles.

It also correlated significantly with the parent's assessment of the child's smile proxy score (r=-0.522,P=0.05) and the impact score (r=-0.490,P=0.05)

The most significant variable was the number of positive (r=0.693,P=0.05) and negative(r=-0.712,P=0.05) adjectives chosen.

The more the child liked his smile the parents corresponded with choosing more number of positive and negative adjectives.

Children's self-report, the parents proxy assessment and photographic assessment of the children's smile (Table 1)

The children's self-assessment of their smile as measured with number of teeth shown (r=0.736,P=0.05) and mouth width (r=0.436,P=0.05) correlated significantly

Children who were more positive about their smile showed more teeth and had wider smiles.

It also correlated significantly with the parent's assessment of the child's smile proxy score (r=-0.522,P=0.05) and the impact score (r=-0.490,P=0.05)

The most significant variable was the number of positive (r=0.693,P=0.05) and negative(r=-0.712,P=0.05) adjectives chosen.

The more the child liked his smile the parents corresponded with choosing more number of positive and negative adjectives.

TABLE 2 Correlation between objective oral health indicators and child self-evaluations, parents proxy and own evaluations, and photographic assessment of the children's smile

Correlation between objective oral health indicators and child self-evaluations, parents proxy and own evaluations, and photographic assessment of the children's smile									
	Child assessment	**Proxy score**	**Impact score**	**Tooth_ ache**	**No_ positive_ adj**	**No_neg_ adj**	**width**	**mm_ open**	**No_ teeth**
DMFT	-.711**	.801**	.771**	.199*	-.615**	.616**	-.480**	-.483**	-.639**
Missing (natural)	-.497**	.457**	.394**	0.111	-.468**	.446**	-.201*	-.269**	-.475**
Caries	-.432**	.467**	.667**	.167*	-.216*	.245**	-.229*	-.325**	-.233**
RESTORED	-.454**	.900**	.644**	0.138	-.450**	.486**	-.278**	-.422**	-.451**
EXTRACTED	-.354**	.626**	.890**	0.066	-.250**	.266**	-.235**	-.334**	-.321**

The single star (*) represents the 0.01 level of significance and double stars (**) represents the 0.05 level of significance.

Correlation between objective oral health indicators and child's self-evaluations, parents proxy and own evaluation and photographic assessment of the child's smile (Table 2)

The child's self-assessment correlated significantly with the DMFT (r=-0.711,P=0.05) and number of naturally missing teeth (r=-4.97,P=0.05)

In addition it also correlated with number of decayed teeth (r=-0.432,P=0.05)

Children who felt less positive about their smiles had a higher DMFT index and more number of naturally missing teeth. Their smiling was affected by the change from deciduous to permanent dentition

Table 3: Average child self reports, parent proxy and own assessments, and photographic assessment of smiles of children without versus with decay:

		No Decay (n = 42)	Decay (n = 58)
Children Assessment	Child_assessment	5	2.24
Parent's Assessment	Proxy_score	0	0.59
	Impact_score	0	0.48
	Tooth_ache	3.71	3.98
	No_positive_adj	1.90	0.69
	No_neg_adj	0.19	1.29
Photographic Assessment	Width	0.85	0.40
	mm_open	0.80	0.47
	No_teeth	5.67	2.98

Average child self-reports, parent proxy and own assessments, and photographic assessment of smiles of children without versus with decay(Table 3)

The group comparisons were conducted between the group of children with no decayed, missing, and filled primary teeth due to caries (group 1; n = 42) and the group of children (group 2; n = 58) who had at least one decayed, missing or filled primary tooth due to caries. Children in group 1 (children with no decay) agreed on average with 5 of the five positive statements describing their smiles, while the children in group 2 (with decay) agreed only with 2.24 of the five statements.

The parent's assessments of the smiles of the children in the "no decay" group also differed significantly from the assessments of the smiles in the "decay" group in several ways.

There was a tendency for the children in the "no decay" group to show more teeth than the children in the "decay" group. On average, healthy children showed 5.67 teeth when they smiled, while children with decay showed only 2.98 teeth.

Disscussion

There has been extensive research to assess the implications that poor oral health can have on the quality of life[4,9] and general health there has not been research to indicate whether a child's oral health is reflected on their smiling patterns ,their own perceptions of their smile and the parents perception of the child's smile. Although orthodontists are the ones that primarily deal with perfect smiles[10] but this research shows how poor oral health can also affect the smiling patterns of a child.

Smiling is very essential for communication and elicits a confidence in a child ,smiling faces were evaluated as being more sincere, more sociable and more competent than non smiling faces[7] and were evaluated more positively, Moreover, a smiling person was perceived to be more intelligent and could create in the perceiver a warm feeling more so than a nonsmiling person[11]

This research showed that children were aware about how good their smile was. The children's self-evaluation

correlated significantly with the ratings of their photographed smiles as well as their parents evaluations of how positive the child's smile was. Studies have shown that by using appropriate questionnaire techniques, valid and reliable information can be obtained from children concerning their oral health[12].The research also showed significant similarities between the child's and the parents evaluation of the child's smile indicating that the parents were well aware of their child's smile. Research done on parental ratings of a child's smile shows that parents can be a reliable source of information on a child's smile[12]

Smiling is of great importance in social interaction, communication and confidence hence it is imperative to explore the aspects that affect a child's smile .Poor oral health significantly affected the smiling patterns of a child as shown by the photographic assessments, the child's own perceptions and the parental ratings. Most of these measures are calculated based on questionnaires which are affected by a number of factors like the parents knowledge of their child's smile, their personal style of responding to any survey and the child's knowledge and understanding of the questions. However the results were significant which supported the hypothesis that a child's smiling pattern and their oral health was related.

The results of this study also showed that children with good oral health were more likely to describe their smile more positively, showed more teeth when they smiled and had more positive evaluations by their parents.

These findings stresses even more on the importance of a good oral health care in Children since it has a great impact on the overall development and quality of life of a child.

Limitations

A possible limitation of this study was that the children who participated in this survey had come for a dental check up and it is possible that they would have expressed more positive emotions if this had been done in some other setting. In addition to this the photographs were rated manually and not by complex computer software to measure the smiles.

Conclusions

A child's self evaluations of their smile provide valid information about how they feel about themselves. They significantly correlated with the photographic assessment as well as the parent's description of their children's smile.

There is a clear relationship between a child's oral health status and the evaluations of their smile done by photographic assessment, by the children themselves and their parents. Children with Dental caries as measured with the dmft were less positive about their smile this also correlated with the parent's assessment and the photographic assessment; poor oral health affected the child's quality of life and had an impact on their confidence, social interactions and self-perceptions.

Ethical Clearance: The Ethical approval was obtained from the department of Public Health Dentistry, SRM Dental College, Ramapuram.

Top Most Cited Articles Related to Dental Caries- A Bibliometric Analysis

Suganya.P[1], Prabu. D[2], Sunayana Manipal[3], Rajmohan[3], Bharathwaj[4], M.R.Prashanthy[1]

[1]1st Year Post Graduate ,[2]Head of the Department, [3]Reader,[4]Lecturer, Department Of Public Health Dentistry, SRM Dental College, Ramapuram

Abstract

BACKGROUND: The bibliometric analysis of articles provides more useful information and scientific knowledge about the field of research. This also helps to encourage the scientists to be updated in the research work.

AIM: The aim of this study is to evaluate the bibliometric analysis of top 30 cited dental caries articles from the year 2000- 2019.

MATERIALS AND METHODS: The top 30 cited articles from the year 2000-2019 were hand searched for bibliometric analysis. The Google Scholar and Scopus databases were used to assess the top 30 cited articles. The parameters such as number of citations, geographical distribution, type of articles and patterns of authorship were assessed.

RESULTS: The top 30 cited articles were ranged from 2165- 418. Most of the articles are review articles and are conducted in the United States of America with maximum number of joint authorship patterns.

CONCLUSION: The bibliometric assessment of dental caries articles helps to enlighten the knowledge as well as provides additional information to design a proper treatment protocol.

***Keywords**: Citations, bibliometric analysis, dental caries, research.*

Introduction

Dental caries is most prevalent multi-factorial disease that exists globally which affects the overall health of the individual. The socio- behavioural, environmental and biological factors are the major risk for the occurrence of dental caries [1]. Based on the etiological factors, the dental caries causes rapid destruction of dental structures which produces complications locally and generally and is most common in developing countries especially among children [2].

Dental caries is the most prevalent non-communicable disease and it affects the permanent dentition in the 1st place whereas it ranks 12th place for the deciduous dentition as per the Global Burden of Disease Study in the year 2015 [3].

Bibliometrics deals with the analysis of academic literature quantitatively which includes various parameters such as number of publications, citations, name of the journal, impact factor of the journal, geographical distribution and institutional affliations. The citation is the reference which was used by a researcher during publication of the article. The bibliometric analysis provides most useful information about the articles and journal which provide easy assess to the population [4].

The scientific journal plays a major role in providing knowledge about the research. This also provides more interaction and participation of the authors to develop their skills in research especially in developing countries. The topic of journals related to health provides more

knowledge and awareness in order to maintain health and prevent diseases

This present study aims to evaluate the bibliometric analysis of the top most cited articles related to dental caries.

Materials and Method

The dental caries related articles published from the year 2000-2018 were hand searched using Google scholar and Scopus database. The top most 30 cited articles were ranked based on the citation number provided in the Google Scholar and assessed for bibliometric analysis which includes the no. of citations, journal name, no. of authors, geographical distribution and type of articles.

The inclusion criteria are only the articles published from the year 2000-2018 were selected and those articles published in English language are included. Only the articles with full text are included. The exclusion criteria are the articles published before the year 2000 and the articles published other than the English language are excluded from the study.

Results

Table 1: Ranking of top 30 cited dental caries articles from the year 2000-2018

RANK	ARTICLES	NO. OF CITATIONS

29	Aahola et al, 2002 33	418
30		

In the table 1, top 30 cited articles related to the dental caries were ranked from the year 2000- 2018. The number of citations ranged from 2165- 418.

Table 2: Rank wise arrangement of journal name with geographical distribution

RANK	COUNTRY	JOURNAL NAME
1	USA	The Lancet
2	USA	The Journal of the American Dental Association
3	USA	Community Dentistry and Oral Epidemiology
4	Brazil	Cochrane database of systematic reviews
5	Switzerland	Caries research
6	Denmark	Caries research
7	UK	Cochrane database of systematic reviews
8	UK	Community dental health
9	USA	American journal of dentistry
10	USA	MMWR surveillance summaries
11	Japan	Journal of dental research
12	Norway	Journal of clinical microbiology
13	Finland	Caries research
14	Denmark	Journal of dental research
15	USA	Journal of dental research
16	UK	Cochrane database of systematic reviews
17	USA	Journal of dental research
18	USA	Journal of dental education
19	USA	Journal of clinical nutrition
20	London	British dental journal
21	Switzerland	Community dentistry and oral epidemiology
22	Switzerland	Community dentistry and oral epidemiology
23	USA	Australian dental journal
24	Japan	Caries research
25	Oregon	The official journal of the human biology association
26	IOWA	Paediatrics
27	USA	Critical reviews in oral biology and medicine
28	USA	Journal- Canadian dental association
29	USA	Journal of dental education
30	Finland	Archives of oral biology

In table 2, the geographical distribution and the name of the journal in which the dental caries articles were published were listed. The journal of dental research and caries research were the most published journal. The USA was the most common place where the study was done.

Table 3: Type of articles

Type of article	No. of articles
Original articles	4
Review articles	25

In table 3, the type of the dental caries articles were discussed. The total of original articles was 4 whereas the review articles were 25

Table 4: Geographical distribution of authors

Geographical distribution	No. of articles
Asia	2
Africa	0
Europe	12
America	16
Australia	0
Antartica	0

The table 4 shows about the geographical distribution of the authors of the dental caries articles

Table 5: Patterns of authorship

Authorship pattern	No. of articles
Single authors	9
Joint authors	21

The table 5 shows about the authorship pattern of the dental caries related articles. Out of 25 articles, 21 articles were joint authors whereas 9 articles were joint authors.

Discussion

In this study the top 30 cited dental caries related articles were ranked and their bibliometrics were assessed. This provides more useful information about the articles by providing more details of the number of citation of articles, study design, geographical distribution of authors and the patterns of authorship for easy assessment to the scientists as well to the public.

Selwitz et al, 2007 was the leading article with highest number of citations 2165. It is a review article and the study was conducted in USA. This gives more information about the dental caries which was published in the year 2007 [5].

The second most cited article by Featherstone which was published in the year 2000 in USA and obtained 1195 citations. This article discussed about the prevention and control of dental caries and it was published in the Journal of American Dental Association [6]. The third most cited article was given by Ismail et al which was published in the year 2007 in USA and obtained 997 citations. This article discussed about the International Caries Detection and Assessment System (ICDAS) method of examining dental caries and it was published in the Community Dentistry and Oral Epidemiology [7].

Table 2 shows about the rank wise arrangement of geographical distribution and journal name of the published articles. The maximum number of studies conducted in USA. This shows that authors from the American continent shows more interest in the field of research.

Table 3 shows that among the top 30 cited dental caries articles most of them are review articles and only 4 of them are original articles. These articles provide more information about dental caries such as prevention, diagnostic approach and various treatment modalities.

Featherstone had published more number of articles when compared to others and all of them were review articles. Among these top 30 cited articles most of the articles were published in the Journal of dental research, Caries Research and Community dentistry and oral epidemiology. The table 4 shows that geographical distribution of the authors of top 30 cited dental caries articles of that all the authors were foreigners of that two authors were from Asian continent, 16 authors are from American continent whereas 13 authors were from Europe continent. The table 5, shows about the authorship patterns of top 30 cited dental caries articles among these 9 of them were single authors whereas 21 of them are joint authors. Most of the articles were done in the country of USA.

Limitations:

The limitations of this study are only articles were hand-searched from Google scholar and Scopus database. The inclusion of other databases such as web of science, science direct and Pubmed will provide more additional information.

Conclusion

This study concludes that the bibliometric analysis of highly cited articles provide most interesting and useful information about the dental caries. The citation of the articles ranged from 2165-418. Most of these articles are review articles and these researches were conducted in the American continent followed by Europe continent.

Ethical Clearance: Since it is a review article, the ethical permission taken from the department of public

health dentistry, SRM dental college, Ramapuram.

A Prospective Study of Intestinal Stomas

Sukhnein Singh[1] , P. K. Bhatia[2] , Kapil Sindhu[3.] , Ashutosh Bawa[1], Nischal Shivaprakash[1], Shabool Nafees[1], Jatin Bedi[1]

[1]Junior Resident, [2]Professor, [3]Assistant Professor, Dept. of Surgery, MMIMSR, Mullana Ambala

Abstract

Background and Objectives: Intestinal stomas are commonly constructed in an emergency as well as elective setting for a variety of indications. Historically associated with a high morbidity, evolution of skills on the part of the surgeon has lead to better understanding of the indications, complications and management of a stoma. This study aims to evaluate the above mentioned parameters and hence improve the outcome of patients undergoing a stoma. **Method** 50 patients admitted in MMIMSR, Mullana (Ambala) and later operated and managed with a stoma were closely followed up from the date of admission to the date of discharge and the various parameters were studied. **Results** The indications, technique, complications and its management were studied in detail by following patients in person or through phone and the results were analyzed in detail. **Interpretation and Conclusion** Construction and management of stoma was associated with a few complications. Most patients however tolerated the procedure well and the overall compliance was satisfactory. Loop ileostomy was the commonly constructed stoma and the one associated with most complications. Transverse loop colostomy was associated with no complications and was extremely well tolerated.

Key Words: *Intestinal stoma, complications, end colostomy, loop ileostomy, loop colostomy, Parastomal hernia, stomal prolapse, loop-end ileostomy.*

Introduction

Stoma was introduced in surgical practice more than 200 years ago as a simple and safe procedure[1]. Littre of Paris, made the first colostomy in baby with imperforate anus, in 1710. The mortality rate of 60% with primary repair of colonic injuries, in World War I, dropped down to 30%, with introduction of colostomy in World War II. Though ileostomy was first performed in 1912, it was widely accepted only after Brooke's modification in 1952. Stomas can be made on a temporary or a permanent basis and can be constructed surgically on an emergency or elective basis. The various surgically constructed forms of stomas include gastrostomy, ileostomy and a colostomy. The procedures like ileostomy or colostomy is necessitated in many patients attending tertiary care hospital.

Materials and Method

The present study entitled "A Prospective Study Of Intestinal Stomas" carried out in the Department of Surgery at Maharishi Markandeshwar Institute of Medical Sciences and Research, Mullana, Ambala from December 2017 to July 2019. After submission and clearance of the synopsis from the Institutional Ethical Committee, MMIMSR, MMU, Mullana, a total of 50 patients admitted in department of surgery, MMIMSR, Mullana, Ambala, who underwent surgical procedure and had resultant stoma (ileostomy/colostomy) were carefully selected by applying specific inclusion and exclusion criteria.

Inclusion criteria

All patients 18 years and above in whom ileostomy/ colostomy has been made, whether in emergency or elective surgery.

Exclusion criteria

- Patients less than 18 years of age.
- Patient not fit for surgery
- Patient with bleeding disorders
- Patient with pregnancy

· Patient with immunocompromised state

The demographic profile of each selected patient as per prescribed Performa.

Clinical assessment of each selected patient was carefully done as per the prescribed Performa

Investigations

All selected patients were then subjected to baseline hematological, biochemical and radiological evaluation at the time of admission.

Preoperative evaluation and anesthesia

All selected patients were then explained regarding the need for surgery and a fully explained, well informed, written consent was taken from them, regarding the procedure.

All patients received preoperative antimicrobial prophylaxis before surgery. The antibiotic given was injection ceftriaxone 1000 mg, injection amikacin 500 mg, injection metronidazole 500 mg.

All operations were performed in supine position under general anesthesia.

Procedure and intra operative assessment

For hollow viscus perforations, laparotomy was done, perforation was closed, through wash was given with normal saline and loop ileostomy was constructed.

Post-operative assessment

Post-operative management consisted of standard nursing care and analgesia.

Dressing was removed in the morning. From day 7 to day 10 notes was made of any wound infection, wound dehiscence and burst abdomen.

Compliance was graded as good, average and poor based on patient's acceptance of the procedure.

Results

Table 1 :Nature of presentation among patients undergoing stoma formation

Nature of presentation	Frequency	Percentage	X^2	P Value
Emergency	29	58%	1.28	**0.25**
Elective	21	42%		
Total	**50**	**100%**		

Table 2: Anatomical type of stoma among patients undergoing procedure

Type of stoma	Frequency	Percentage	X2	P value
Loop Ileostomy	28	56.0	60.8	0.0001
Transverse Loop Colostomy	10	20.0		
End Ileostomy	6	12.0		
End Colostomy	4	8.0		
Loop Colostomy (Sigmoid)	2	4.0		
Total	50	100.0		

Table 3: Nature of stoma among patients undergoing stoma formation

Nature of stoma	Frequency	Percentage	X2	P value
Temporary	46	92%	15.48	0.0001
Permanent	4	8%		
Total	50	100%		

Table 4: Complications among patients undergoing stoma formation

Complications	Frequency	Percentage	X^2	P value
Nil	38	76	128.80	**0.0001**
Local sepsis	5	10		
Necrosis	3	6		
Hernia	2	4		
Prolapse	1	2		
Retraction	1	2		
Total	**50**	**100**		

Table 5 :Complications of stoma with respect to nature of stoma

Complication	Elective	Emergency	X2	P value
Nil	6(12%)	32(64%)	15.7	0.008
Hernia	2(4%)	0		
Local sepsis	0	5(10%)		
Necrosis	0	3(6%)		
Prolapse	1(2%)	0		
Retraction	0	1(2%)		
Total	9(18%)	41(82%)		

Table 6: Type of stoma versus compliance

Patient compliance	Good	Average	poor	X^2	P value
End Colostomy	3(6%)	1 (2%)	0	5.270	0.728
End Ileostomy	2(4%)	2 (4%)	1 (2%)		
Loop Colostomy(Sigmoid)	2(4%)	0	0		
Loop Ileostomy	20(40%)	4(8%)	4 (8%		
Transverse Loop Colostomy	10 (20%)	0	0		

Discussion

The findings can be discussed as follows :

I: Indications for surgery In the present study, 17 patients (34%) had stoma constructed for hollow viscus perforation (jejunum, ileum, colon). 8 patients (16%) undergoing stoma formation had intestinal obstruction for malignant conditions while 7 patients (14%). 2 patients (4%) each had blunt abdominal trauma, diverticular disease, inflammatory bowel disease, peri-anal sepsis, and acute mesenteric ischemia as cause for stoma formation.(X^2 = 41.200, p value = 0.0001).

Ahmad Z et al[46], in his study of 85 patients, in 2009, found that 38% patients requiring stoma formation had enteric perforation, which is comparable to the present study. **Chaudhary P et al[60]**, in his study of 630 patients, in 2013 reported a further higher incidence of enteric perforation requiring stoma formation in the range of 63.8%. However, **Ahmad Z et al[46]** and **HussainS et al[61],** in his study of 100 patients and 106 patients respectively, in 2009 and 2013 respectively, reported a lower incidence of enteric perforation in the range of 12.9% and 25.4% respectively.

2 : Nature of the disease

	Benign	**Malignant**
Keerthana DD et al (2019)	24.1%	75.90%
Roshini AP et al (2017)	67.5%	32.5%
Gujar N et al (2016)	43.4%	46.6%
Sumathi P et al (2015)	52.0%	48.0%
Engida A et al (2014)	89.0%	21.0%
Ahmad Z et al (2012)	83.0%	13.0%
ReRedha AG et al (2002)	62.5%	37.5%
Present Study	78.0%	22.0%

In the present study,39 patients (78%) had benign cause where as 11 patients (22%) had malignant cause. In all malignant conditions colostomy was performed i.e 11 patients (22%). Among benign conditions, 31 patients (62%) had ileostomy and 7 patients (14%) had colostomy. The ratio of benign to malignant cause among patients undergoing stoma formation was 3.54:1

1:Nature of stoma

	Temporary	**Permanent**
MessangaA et al. (2017)	94.0%	6.0%
Roshini AP et al. (2017)	57.5%	42.5%
Hussain S et al. (2013)	66.0%	34.0%
Present Study	92.0%	8.0%

In the present study, 46 patients (92%) underwent a stoma construction for temporary period which was closed accordingly, in the range of 3-6 months. Only 4 patients (8%) underwent permanent stoma construction. (x2 =15.48, p value = 0.0001)

3 : Complications of stoma

	Local sepsis	**Necrosis**	**Hernia**	**Stomal prolapse**	**Stoma lretration**
Messanga A et al. (2017)	16%	2%	2%	42%	7%
Gujar N et al. (2016)	25%	4%	1.6%	7%	4%
Sumathi P et al. (2015)	22%	2%	2%	10%	8%
Kurpad V et al (2015)	25%	5%	2.5%	2.5%	10%
Engida A et al. (2014)	23.3%	4.6%	1.4%	2.7%	5.9%
Pipariya PR et al. (2014)	22%	6%	6%	14%	4%
Present study	10%	6%	4%	2%	2%

In the present study, a total number of 12 patients (24%) had stoma related complications while 38 patients (76%) had no stoma related complications throughout their course of treatment. Maximum number of patients i.e. 5 patients (10%) had local sepsis and excoriation around stoma site, while 3 patients (6%) had stoma necrosis. Two patients (4%)

had parastomal herniation while 1 patient (2%) each had stomal prolapse and stomal retraction.(x^2=128.80, p value =0.0001).

Conclusion

Though stoma formation is life saving, it carries significant number of complications, is associated with decreased quality of life and increased economic health burden.

The common complications associated with stoma formation include local sepsis with excoriation, stomal necrosis, herniation, prolapse and retraction. Stomal necrosis, herniation, prolapse andretraction require stomal revision, while local excoriation demands prevention and conservative management.

Patient's compliance may vary with the nature of complications suffered, its duration and intensity. Patients with no complication may rate the procedure good, even if it is cosmetically unfair, while patients with complication may rate a procedure worse, even if it is lifesaving.

Effect of Hand Rehabilitation on Hand Grip Strength and Manual Dexterity in Patients with Diabetic Hand Syndrome

Rasika Panse[1], Ujwal Yeole[2], Nikeeta Aher[3]

[1]Assistant Professor, [2]Principal and Associate Professor, [3]Intern, BPT, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune, Maharashtra, India

Abstract

Background- In patients with diabetes upper extremity impairments are common. Diabetes patient are more prone to diabetic hand. **Aim-** To study the effect of hand exercises on hand grip strength and manual dexterity in patients with Diabetic hand .**Objectives-** To study the effect of hand exercises on hand grip strength in patients with Diabetic hand using Modified sphygmomanometer test. To study the effect of hand exercises dexterity in patients with Diabetic hand using grip ability scale. To study the effect of hand function in patients with Diabetic hand using Michigan hand outcomes questionnaire (MHQ) and Duruoz Hand Index. **Setting and design** – In this study 15 individual participated having diabetic hand which was selected randomly. Modified sphygmomanometer test was performed on patient to check grip strength. Grip ability scale was performed on patient to check manual dexterity. Hand function was check using Michigan hand outcomes questionnaire (MHQ) and Duruoz Hand Index. The effect of hand exercise on hand grip strength and manual dexterity in patients with diabetic hand was analysied. **Result-** Total 15 individual participated with age mean 58±13.519 and duration of diabetes with mean 11±6.448. Modified sphygmomanometer test result improved from 28.13±3.044 to 32.47±2.875(p=0.001). Grip ability test result improved from 23.13±3.523 to 18.67±1.345(p=0.001). Michigan hand outcome questionnaire result improved from 53.29±10.19 to 71.34±5.036(p=0.001). Duruoz Hand Index result improved from 31.67±11.2 to13.47±4.596(0.001).**Conclusion-** There is significant effect of hand exercises on hand grip strength and manual dexterity in patient with diabetic hand.

Keywords*-Diabetic hand, Hand grip strength, dexterity, Duruoz Hand Index, Michigan hand outcomes questionnaire*

Introduction

Diabetes mellitus is a autoimmune systemic disorder in which there is increase in sugar level due to insulin deficiency. In type 1 and type 2 diabetes hyperglycemia that is poor sugar level causes micro- and macrovascular complications primary to pathophysiological and structural changes in musculoskeletal structures causing diabetic hand.(1) Diabetes mellitus is related with musculoskeletal disorders affecting hand, commonly called to as diabetic hand syndrome. These include limited joint mobility (LJM) (also known as diabetic cheiroarthropathy), Dupuytren's contracture, stenosing tenosynovitis (trigger finger), carpal tunnel syndrome (CTS), Charcot neuroarthropathy, reflex sympathetic dystrophy and a variety of hand infections.(2)

Dexterity means ability to use hand skilfully that is during a specific task fine, voluntary movement used to manipulate small objects. Dexterity can be categorized into manual dexterity that is the skill to handle objects with the hand. Grip strength means the measurable ability to apply pressure on objects or force applied by the hand and fingers.(3). Due to hyperglycemia there is adverse effect on connective and nervous tissue which affects hand functions in conditions of dexterity, grip and pinch strength, hand manipulation skills that can be impaired in patients with types 1 and type 2 diabetes. Due to structural changes in connective tissues, in approximately 50% of individuals with diabetes,

musculoskeletal impairments in hand like limited range of motion, tenosynovitis, Dupuytren's contracture, and altered nerve function are noted which affect hand function in terms of strength, dexterity, fine motor skills, and hand performance.(1)

In diabetes, limited joint mobility is considered to be caused by non-inflammatory thickening and increased stiffness in the peri-articular structures. Limited joint mobility may lead severe upper extremity impairments related with pain and disability. The incidence of limited joint mobility and associated impairments at the shoulder and hand can have a important impact on upper extremity function in diabetic patient.(4) Dupuytren's contracture is also called as palmar fibromatosis is thickening of tissue in palmar skin most commonly involving the middle and ring fingers in diabetes.(2) **Carpal tunnel syndrome is a neuropathy that occurs frequently, when the median nerve that passes through the carpal tunnels of the flexor tendons is contracted by the transverse carpal ligament and carpal bones. Diabetes mellitus is the most common metabolic disease that causes Carpal tunnel syndrome.(4)**

Materials and Method

Ethical clearance was taken from institutional ethical committee of Tilak Maharashtra Vidyapeeth, department of physiotherapy. Permission Different centers was approached and permission was obtained prior to study. Explanation of the experiment was given to the patient. A Pre and Post Experimental study was conducted at various diabetic Clinics. Total 15 individual which were medically diagnosed cases of diabetic hand syndrome were selected. Modified sphygmomanometer test, Grip ability scale, Duruoz Hand Index, Michigan hand outcomes questionnaire (MHQ) was used pre and post intervention. Patient with diabetes mellitus both type I and type II, both male and female, patient willing to participate were included in study whereas patient with osteoarthritis, rheumatoid arthritis and fracture of hand were excluded from the study. Intervention protocol was given for 3 weeks 30 minutes 5 min flexor tendon gliding and blocking exercises, 5 min extension gliding exercises, 5 min rest, 10 min strengthening, 5 min rest. Intervention protocol include –Flexor Tendon Gliding Exercises, Flexor Tendon blocking exercises, Extension tendon Gliding exercise, Stretching technique for Intrinsic and multijoint muscles, Technique to strengthen muscles of wrist and hand.

Result

Study showed that out of 15 individual 6 were male and 9 were female (Table 1). Age with mean 58±13.519 and duration of diabetes with mean 11±6.448(Table 2). Modified sphygmomanometer test result improved from 28.13±3.044 to 32.47±2.875 with p value = 0.001(Table 3). Grip ability test result improved from 23.13±3.523 to 18.67±1.34 with p value = 0.001(Table 3). Michigan hand outcome questionnaire result improved from 53.29±10.19 to 71.34±5.036 with p value = 0.001(Table 3). Duruoz Hand Index result improved from 31.67±11.2 to13.47±4.596 with p value = 0.001(Table 3).

Table 1- Pre and post intervention

Outcome measues	Pre Mean±SD	Post Mean±SD	p value
Modified sphygmomanometer test	28.13±3.044	32.47±2.875	0.001
Grip ability test	23.13±3.523	18.67±1.345	0.001
Michigan hand outcome questionnaire	53.29±10.19	71.34±5.036	0.001
Duruoz Hand Index	31.67±11.2	13.47±4.596	0.001

Discussion

Study showed that out of 15 individual 6 were male and 9 were female. For age Mean= 58 SD=13.51 and median=53. For duration of diabetes Mean=11 SD=6.448 and median=10. Pre and post intervention performed noted that for Modified sphygmomanometer test p value= 0.001, Grip ability test p value= 0.001, Michigan hand outcome questionnaire p value= 0.001, Duruoz Hand Index p value= 0.001.

Diabetic hand syndrome is a common but less discussed. Pathologies that were examined in diabetic hand syndrome occur in general population as well. Moreover they are more common in patients with diabetes. These may differ in their Clinical presentation, course and response of treatment in diabetics compared to normal population. This condition has also been called to as diabetic pseudoscleroderma and the term shoulder-hand syndrome is often used when combined with adhesive capsulitis of the glenohumeral joint,.

Research conducted by De Carvalho e Silva et al. on the hand strength and functions in type 2 DM patients, found that hand functions and grip strength impairment are present in patient with type 2 DM . Similarly, Savas et al. And Cetinus et al. found that in patients with type 2 DM grip strength values were reduced than normal individuals. Lewko et al. investigated hand functions and dexirity in patients with DM and found out that poor hand functions are seen in patients with diabetes that leads to reduced quality of life as result of impaired hand function. Hence, it is important to assess hand function and treat it [6]

Muscle weakness is prominently seen in patients with diabetes and is mostly affected in Insulin resistance (Sayer et al, 2005) and, as a result patient exhibit reduce grip strength. researchers conducted by Rantanen et al (1999) an Leveille et al (2004) have reported that patients with type 2 diabetes mellitus showed that there is decreased handgrip strength.[7]

Strength training which employs principles of working at the level of motor neurons can benefit the hand dysfunction. Strength training improves glycemic control and improves grip strength and endurance and it leads to improvement in hand function in patient with diabetic neuropathy. Grip strength training exercises improved hand function in patient with diabetic neuropathy.[7]

Duruöz Hand Index (DHI) is a functional disability scale that can be used to assess the functional disability of hand. The hands are oftenly involved in diabetic patients. The DHI is a practical scale that is efficient in accurate assessment of hand dysfunction in diabetic patients.[8]

The recent study was done to study the effect of strength training on hand function in patient with diabetic neuropathy on 30 patients diagnosed with neuropathy .The patients were assessed and strengthening exercise were given. In Grip strength comparisons of post test values in group A are mean 34.80 and SD 12.23. Group B Mean 35.33 and SD 11.64. These values suggest they are statistically significant. These values suggest they are statistically significant. The study concluded that there was significant effect in giving strength training on hand function in patient with diabetic neuropathy.[9]

Active muscle contraction and specific motions of the digits are used to maintain or develop mobility between the multiple joint musculo-tendinous units and other connective tissue structures of hand. Tendon-gliding exercises and tendon-blocking exercises are used to develop or maintain mobility. These exercises used to develop neuromuscular control of hand musculature. The flexor tendon blocking exercises and extensor tendon-gliding exercise are used to strengthen the musculature by adding resistance manually or mechanically. [10]

Hand-specific exercises have also been emphasised as an efficient way of increasing handgrip

strength and functionality of RA individuals. Hand specific exercise improves hand grip strength and functionality of hand .Muscle strengthening exercises of hand improves functional performance, Quality of Life and muscle force gain. Strength training exercise improves lost function .During Hand movements, Balance between intrinsic and extrinsic muscle is quintessential for correct stabilization of joints in hand. [11]

Hence hand exercises like flexor tendon blocking exercises and extensor tendon-gliding exercise , intrinsic muscle strengthening exercise plays vital role in improving hand grip strength andmanual dexterity in patient with diabetic hand

Conclusion

There is significant effect of hand rehabilitation

exercise, flexor tendon blocking exercises and extensor tendon-gliding exercise , intrinsic muscle strengthening exercise on hand grip strength and manual dexterity in patient with diabetic hand. Hence rehabilitation plays an important role in management of hand dysfunction in patients with Diabetes

Acknowledgement: Thanks to all patients for participating and co-operating in the study. Special thanks to Prof. Tuncay Duruöz who permitted the use of scale Duruoz hand index. Also thanks to all teaching and non- teaching staff of Department of physiotherapy, Pune for giving support, encouragement during research project work.

S. Hegde Medical Academy, Nitte (Deemed to be University), Deralakatte, Mangalore, Karnataka*

Abstract

Background & Objectives: Autism Spectrum Disorder (ASD) being a complex neuro-developmental disorder is found to be associated with Autonomic Nervous System (ANS) dysfunction. The sympatho-vagal continual dynamic excitatory- inhibitory interactions leads to Heart Rate Variability (HRV) which is an index of cardiac autonomic regulation**.** Aim of the study was to evaluate cardiac autonomic regulation in children with ASD at rest using short-term HRV analysis and to correlate it with severity of autism.

Methods: A total of 30 subjects were evaluated in the study comprising of 15 ASD children and 15 healthy controls. A five minutes recording of resting ECG was carried out from which R-R intervals were procured and HRV indices were analysed. Frequency domain analysis of HRV was carried out and the following parameters were evaluated: Spectral powers in low frequency (LF) bands, High frequency (HF) bands, total power (TP), LF/HF ratio and average heart rate (HR) were evaluated. HRV indices between the groups were compared using Student's t test. Severity of autism was correlated with the evaluated HRV indices using Pearson correlation test.

Results: Cardiac sympathetic activity as assessed by low frequency power spectrum ('p' value 0.034) and total power ('p' value 0.023) of the HRV spectrum was significantly higher in autistic children compared to that of normal controls. However, the association between severity of ASDs and HRV indices were not statistically significant.

Conclusion: Study concludes that here was no significant association between HRV indices and severity of autism.

Keywords- *Autonomic nervous system, Autism spectrum disorders, Heart rate variability, High frequency, Low frequency.*

Introduction

Autonomic nervous system (ANS) incorporates two opposing branches, the sympathetic and parasympathetic systems that maintain body homeostasis.[1] Functionally, the sympathetic system is activated during "fight-or- flight" situations and is associated with catabolic processes while the parasympathetic system is concerned with the vegetative functions of routine living and mediates anabolic processes of the body.[2] The parasympathetic division usually opposes or balances the actions of sympathetic division. ANS plays an important role in a wide range of visceral-somatic and mental diseases.

A network of brain areas like prefrontal cortex, amygdala and hypothalamus controls the ANS as

well as socio-emotional and cognitive processes. The central autonomic network has tonic, reflexive and adaptive control over autonomic functions and monitors cognitive, emotional and behavioural responses and its dysregulation is noted in various neuro-psychological ailments.[1] Rising evidence portrays the association of Autism spectrum disorders (ASDs) with the dysfunction of ANS.

ASD is a complex neurological and developmental disorder categorized by impaired social communication, limiting interests, and conventional repetitive behaviors.[1] Differences in development in 3 main areas: communication (verbal and non-verbal), social interactions and imagination. This is stated to as the triad of impairments. It is known as a 'spectrum disorder' because the severity of symptoms may range from a mild learning and social disability, to more complex needs with multiple complications and often very unusual behaviour. The Diagnostic and statistical manual for mental disorders -V (DSM-V) in May 2013 established the use of unique term 'Autism Spectrum Disorders (ASDs)'.[3] At least one comorbid mental disorder is associated with about 70% of ASDs and 40% may have two or more comorbid mental disorders.[4] The incidence of Autism has revealed a swift increase over the last few years. Current international studies show that about 1 in 68 people have autism and its incidence is believed to be steady around the world.[3] Males are more often affected with autism than females, at a ratio of 4:1 (males: females).[5] The onset of symptoms of ASDs are gradual for most children; although they develop before the age of 3 years.

Autonomic imbalance, in which one branch of the ANS dominates over the other, is related to a lack of active flexibility and fitness. Clinical symptoms of these disorders are often non-characteristic and so to identify them it is vital to know the procedures of assessment of ANS function.[6] Autonomic activity dysfunctions may be related to social functioning in individuals with ASD. The mutual regions of the brain that are associated with both autonomic dysfunction and socio-emotional deregulations, make autonomic status a good biomarker for ASD.

Heart rate is complexly modified by the coordination of autonomic, respiratory, circulatory, endocrine and mechanical influences over time. It is an important parameter for the assessment of autonomic function and reflects the autonomic activity of sinoatrial node.[1] The sympatho-vagal continual dynamic excitatory-inhibitory interactions leads to heat rate instantaneous oscillations called Heart rate variability (HRV) which is assessed by computing R-R intervals.[3] HRV pattern variations provide an advanced indicator of health involvements. Higher HRV is a signal of good adaptation and symbolizes a healthy person with well-organized autonomic mechanisms, while lower HRV is frequently an indicator of abnormal and inadequate adaptation of the ANS. HRV is a useful non-invasive tool to study central processes involved in autonomic regulation, thereby emphasizing its relevance in various psychiatric conditions. As per literature, fluctuations in HRV reflects both the sympathetic and parasympathetic responses and the sympathovagal balance can also be assessed.[7] Various HRV indices are widely recognized as useful and powerful indicators of physiological and psychological interaction.[8]

As suggested by literature, the link between ASD symptoms and ANS dysfunction can be related to parasympathetic underactivity, sympathetic over-arousal, or an atypical interaction between these systems.[9-11] Some studies have reported no significant differences in resting autonomic activity in children with ASD compared to controls.[12,13] Both sympathetic and parasympathetic lower resting activity were revealed in studies done by Bujnakova et al. in 2016, indicating autonomic under arousal in ASD children.[14] Studies assessing orthostatic stress in ASD children have shown higher parasympathetic responses with the same sympathetic modulation, suggesting parasympathetic dominance in this population.[15] Thus, the inconsistencies in the existing literature on autonomic function in ASD propose a large heterogeneity in this population.

Many paediatric autonomic disorders occur as a result of developmental abnormalities caused by specific genetic mutations and others as a result of generalized central dysfunction. In addition to traditional neurodevelopmental symptoms, autism also produce symptoms attributable to other organ systems that suggest underlying autonomic dysfunction. Aim of the present study was to evaluate cardiac autonomic regulation in autistic children using HRV as an assessment tool and compare HRV indices between normal and autistic children. The study also correlated the severity of autism with the obtained HRV indices.

Materials and Method

Study population: The study was conducted on Children diagnosed with ASDs and age and gender matched controls. 40 children were recruited for the study including 24 autistic children and 16 controls. Excluding dropouts during ECG recording and HRV analysis reliable statistical data could be obtained only for 15 autistic and 15 normal children. Out of the autistic children 9 were boys and rest 6 were girls whereas normal group comprised of 8 boys and 7 girls. Children aged between 3 and 14 years were recruited for the study.

Selection Method: Children with ASDs were diagnosed by a Psychiatrist or clinical Psychologist using DSM-V criteria (APA, 2013).

Exclusion criteria: Children with diagnosis of disruptive behaviour disorders, severe and profound Intellectual disability, and with autonomic dysfunction were excluded as all these conditions affected HRV parameters evaluated in the study.

Study setting: Study was conducted in the research lab of Department of Physiology of K. S. Hegde Medical Academy, Mangalore. Subjects were recruited from Psychiatric, Paediatric & Speech language pathology departments of K.S Hegde Charitable Hospital.

Ethical clearance: Institutional and Central ethics committee approval was obtained from Nitte University for the study. Study procedure was explained in detail to the parents' of children recruited and written consent was procured from them.

Assessment of severity of autism: Diagnosis of ASD was made by experienced Psychiatrist or Clinical Psychologist according to DSM-5[5] criteria and based on previous psychiatric reports. Medical practitioner confirmed ASD diagnosis in autistic group and normal functioning in control group. Severity of autism was rated using Childhood Autism Rating Scale (CARS-2), which is a behaviour rating scale. It consists of two 15-item rating scales which is completed by a trained clinician and a Parent/Caregiver questionnaire. CARS-2 identifies children 2 years and older with ASD and distinguishes between mild to moderate and severe autism.

Experimental procedure: Subjects suitable for our study criteria were screened. The time required for recording varied from subject to subject depending on their psychological status during the procedure. For normal children the study procedure went for approximately 20-25 minutes, including the initial time taken for subjects to adapt to the study setting. Basal Blood pressure (BP) and anthropometric characteristics like height, weight and body mass index (BMI) were evaluated.

Assessment of HRV: Lead II Electrocardiogram (ECG) was recorded using a computerised 4- channel data acquisition unit (Power lab 26-T, AD instruments, Australia) in sitting position for 5 minutes. From the ECG recording a sequential series of successive R-R intervals were obtained which was validated before analysis using a standardised procedure as recommended by the Task Force of European Society of Cardiology.[7] The data so gathered was then subjected to spectral analysis of HRV using Fast Fourier Transform (FFT) and indices were calculated. Two main spectral components were retained to quantify the power spectral density: low frequency (LF; 0.04 to 0.15 Hz); high frequency (HF; 0.15 to 0.40 Hz) bands and total power (TP: variance of all RR intervals). LF components represent both parasympathetic and sympathetic modulations[16] whereas HF is associated to parasympathetic modulation[7]. Additional calculation included LF/HF ratio which constitutes evaluation of the ANS balance (sympathetic/parasympathetic). If this ratio is <1, there is a parasympathetic predominance, whereas a ratio above 1 reflects a sympathetic predominance.[7,17] These data formed a tachogram and were exported. From the report obtained total power (TP in ms^2), absolute & normalized units of HF and LF HRV indices and LF/HF ratio were considered for statistical analysis.

Statistical Analysis

Statistical analysis was performed using SPSS 20.0. (SPSS- Inc., 233 South Wacker Drive, Chicago) software package.HRV indices recorded were expressed in terms of Mean + Standard error. Comparison of HRV indices between autistic and control group was performed using Student't' test. Probability value $p < 0.05$ was considered as statistically significant. The strength of association of severity of autism with HRV indices was assessed using Pearson correlation for parametric variables.

Results

Subject characteristics

The general subject characteristics are summarized in Table 1. The results suggest that autistic children exhibited a significantly higher weight (p= 0.020) and BMI kg/m^2 (p= 0.041) compared to their non-autistic

counterparts. All other characteristics like age, height, SBP, DBP, and basal heart rate did not show any significant difference between the groups.

Table 1- Subject characteristics

Characteristics	ASD	Control
Age (years)	10.1 ± 1.01	8 ± 1.03
Weight (kg)	32.7 ± 4.36*	20 ± 1.9
Height (m)	1.3 ± 0.07	1.2 ± 0.05
BMI (kg/m2)	18.8 ± 2.07*	13.9 ± 0.46
SBP (mm Hg)	97.7 ± 5.3	98.3 ± 2.84
DBP (mm Hg)	70.7 ± 5.09	67 ± 2.4
Heart rate (bpm)	94.42 ± 3.47	98.02 ± 3.19

Abbreviations: BMI- Body Mass Index, calculated as Weight (kg)/Height (m^2), SBP- Systolic blood pressure, DBP- Diastolic blood pressure, *p < 0.05

Table 2 shows comparison of HRV indices between the study groups. The LF absolute units were found to be significantly higher in the ASD group than the control group ($p = 0.034$); on the contrary, the HF absolute indices, despite exhibiting a lower range in ASD, was not significantly higher ($p = 0.008$) compared to their non-autistic counterparts. The HF and LF nu did not show statistical significance between the groups. . The TP values ($p = 0.023$) on the other side exhibited a significantly higher value in ASD group compared to controls.

Table 2- Heart Rate Variability Indices

HRV INDICES	ASD	Control
HF absolute (ms2)	651.57 ± 123.3	1262.62 ± 295.90
HF normalized	37.47 ± 3.6	43.1 ± 5.09
LF absolute (ms2)	1028.32 ± 138.46*	552.26 ± 59.3
LF normalized	40.55 ± 3.7	36.51 ± 4.32
TP (ms2)	4097.00 ± 877.2*	2180.78 ± 364.8
LF/HF ratio	1.12 ± 0.241	0.85 ± 0.25

Abbreviations: HF- High frequency, LF- Low frequency, TP- Total power, * p< 0.05

Table 3 shows the results of assessment of strength of association of severity of autism with cardiac autonomic parameter using Spearman rank correlation for non-parametric variables and Pearson correlation for parametric variables.

Table 3: Correlation of autonomic indices with severity of ASD.

Autonomic Indices	ASD severity	
	R	P
HF absolute (ms2)	0.034	0.83
HF normalized (nu)	0.06	0.71
LF absolute (ms2)	0.17	0.29
LF normalized (nu)	0.08	0.63
TP (ms2)	0.04	0.81
LF/HF ratio	0.02	0.89

Abbreviations: [R- Pearsons correlation coefficient, P- statistical significance,HF- High frequency, LF- Low frequency, TP- Total power]

Table 3 shows the results of assessment of strength of association of severity of autism with cardiac autonomic parameter using Pearson correlation for parametric variables.

Discussion

Cardiac autonomic regulation has emerged as one of the important psycho-physiological measures of various behavioral features in children and adults. Children with autism spectrum disorder are known to exhibit altered behavioral aspects. Since HRV is a validated indicator of the function of cardiac autonomic regulation, this study attempted to compare the short-term HRV power spectrums between children with and without autism spectrum disorders.

Findings of our study indicate that children with autism spectrum disorders are associated with cardiac autonomic dysfunction. This is reflected by a significantly higher absolute low frequency spectral band, the surrogate of cardiac sympathetic nervous activity, among autistic children compared to that of healthy controls. Further, the total power of HRV was also significantly higher in autistic children indicating that they have an overall greater cardiac autonomic modulation. However, the indices like absolute power of HF band and normalized HF and LF powers did not exhibit any statistical difference between the groups.

Measures of HRV are being increasingly applied in investigations of the central autonomic state and to study the fundamental links between various psychological processes and physiological functions.[8] It has been reported earlier that there is low baseline cardiac vagal tone with elevated sympathetic activity in autistic children.[11] Another study reported that autistic children are associated with lower resting cardiac vagal activity with no significant difference in sympathetic function.[18] Studies also have shown that elevated sympathetic activity is linked with several cardiovascular diseases. LF spectrum is a parameter that includes both sympathetic and parasympathetic activities[16, 19] and the presence of a significant difference of LF values, and TP between our two groups confirms that ASD and control groups have an altered cardiac autonomic function. Studies in children with ASD compared to TD controls under resting conditions as well as during mental stress have frequently reported increased heart rate suggesting an increased sympathetic activity. [20, 9]

Autism severity of the study subjects were evaluated by administering the Childhood Autism Rating Scale (CARS). Based on the obtained scores, we assessed the strength of association of severity of autism with HRV indices using Spearman rank correlation for non-parametric variables and Pearson correlation for parametric variables. However, there was no statistically significant correlation of severity with any of the variables (Table 3). This could be due to the relatively lesser number of autistic children in the severe grade in our study.

Findings of the present study indicate that children with autism are associated with elevated cardiac sympathetic activity with no difference in resting cardiac vagal tone indicating that autistic children have an early risk for cardiovascular disease. Further, higher total power observed in children with autism in this study is

contributed by their greater LF power spectrum of HRV. The behavioral response in ASD could be associated with their impaired sympathetic nervous activity. Our finding is based on relatively smaller sample size; therefore, evaluation including larger study population and using sensitive psycho-physiological measures like sympathetic skin response would help in better understanding of autonomic neural activity in autism spectrum disorders. The study of autonomic regulation in childhood psychiatric disorders may provide a better understanding of the etiology and aids in the prevention of cardiovascular diseases in adults.[21]

Conclusion

Study concludes that severity of autism was not associated with cardiac autonomic indices. ASD children exhibit altered cardiac sympathetic nervous activity. The altered behavioral responses in ASDs could be associated with their impaired sympathetic nervous activity. The core autistic symptoms which include impaired social interaction, repetitive and stereotypical behaviour could be a result of the differences in baseline arousal or stress which may be associated with impaired autonomic nervous activity. Future studies are needed to examine the association of this deregulation of ANS with symptoms and co-morbidity of ASDs.

Source of Funding: The study is a part of project funded by Department of Health Research (DHR), Indian Council of Medical Research (ICMR).

Conflicts of Interest: The authors have no conflict of interest to declare.

Correlation Between Built and Work Ability among Small Scale Industrial Workers at Malkapur, Karad

Rutuja Bhosale[1], G.Varadharajulu[2]

[1]Final Year, Faculty of Physiotherapy, [2]Professor, Department of Neurosciences, Faculty of Physiotherpay, Krishna Institute Of Medical Sciences Deemed To Be University, Karad, Maharashtra, India

ABSTRACT:

Background: The working capability of workers has the effect on productivity of the industry. Work ability has the greater impact on employee's well-being and decrease in the risk of musculoskeletal diseases, sick leave and early retirement. Further, a low work ability affects the company's productivity. There is paucity in the literature regarding field of small scale industrial workers.

Aim and objectives: To find the association between built and work ability among small scale industrial workers.

Materials and Method: The total numbers of 90 workers were examined to assess built. The measurements were taken as per the Heath-Carter anthropometric somatotype method by using weighing scale for weight, stadiometer for height, measuring tape for girth around biceps and calf, small sliding caliper for width of the femur and humerus and skinfold caliper for skinfold thickness. After collecting data it was divided under three categories, Ectomorphic, Mesomorphic and Endomorphic built. Subjects signed the consent form and then work ability score was calculated by the workability questionnaire.

Results: In this study both ectomorphic and mesomorphic showed negative correlation except endomorphic which showed positive correlation nearest to significance. There was no correlation between built and work ability. Study variables in this study such as age, gender and work ability revealed association with built. Thus , the present study concluded that there is no significant correlation between built and work ability

Conclusion: On the basis of the result of the study, it was concluded that there is no correlation between built and work ability among small scale industrial workers working in industrial colony, Malkapur, Karad.. The ectomorphic and mesomorphic built has the very good work ability and there was medium work ability among endomorphic individuals.

Keywords: *small scale industrial workers, Built, Workabilily.*

Introduction

Small scale industries characterize to those small entrepreneurs who are involved in production, manufacturing or service at a micro scale. Small scale industries show a vital role in the economic and social development of India in the post-independence period. Small scale industries construct the backbone of a developing economy with its effective, efficient, flexible and innovative entrepreneurial essence [(1)]. The small scale industry is recognized as an very crucial component of economic development and a critical element in helping to lift countries out of poverty [(2)].

Somatotype is defined as the quantification of the present shape and composition of the human body.

It has three types Endomorphy, Mesomorphy and Ectomorphy[3]**.** According to the American Psychologist W.H. Sheldon, the Endomorph is a human physical type tends towards roundness as per physique classification system. The extreme endomorph usually resemble a round head, a large internal organs relative to his size, rather short arms and legs with fat upper arms and thighs, but slender wrists and ankles . Mesomorph is characterized by greater than average muscular development. Mesomorph has square, massive head; broad, muscular chest and shoulders; a large heart; heavily muscled arms and legs; and minimal body fat. The mesomorphic types tend to develop muscle easily. Where Ectomorph is a type that tends towards linearity as classified by the physique classification system. An extreme ectomorph usually has a thin face with high forehead and receding chin; narrow chest and abdomen; a narrow heart; long ,thin arms and legs; little body fat and little muscle but a large skin surface and large nervous system. On the other hand the somatometry is measured as a fundamental research method in anthropology. It includes the bodily proportions and sizes in living individuals[3].

Anthropometry is the study of the measurement of the human body in terms of the dimensions of bone, muscle and adipose tissue[4]. Weight, stature(standing height), recumbent length, skinfold thickness, circumference (head, waist, limb, etc.), limb lengths and breadths are some of the measures which are included in anthropometric measurements[4].

The obesity has impact on workers capacity [5]. Factors associated with the poor work ability, as defined by Work ability Index were deficiency of leisure time, vigorous physical activity, poor musculoskeletal capacity. Older age, obesity, high mental work demands, lack of autonomy, poor physical work environment and high physical load [5].

Work ability denotes to a worker's job-associated functional capacity, or a worker's ability to continue working in his or her current job, given the challenges or demands of the job and his or her resources. In other words, it is a product of both the individual and the working environment. Prior work ability research from other fields has established practical support for many individual and work-related correlates of work ability, including physical and mental work demands[6]. Work ability affects an employee's well-being and reduces the risk of musculoskeletal diseases, sick leave and early retirement. Further, a low work ability affects the company's output [7]

When the work ability equals the required job demands, a patient is measured to be able to participate in work. Especially in purported high-demand jobs that are categorized by limited opportunities to reduce these demands constructed on the present ergonomics knowledge, the assessment of a patient's work ability needs careful deliberation to support return to work [8].

Methodology:

The study was conducted in the industrial colony , Malkapur , karad , Maharashtra. An observational study was carried out using a cross sectional study design. An approval for the study was obtained from the Protocol committee of the Institutional Ethical Committee of KIMSDU .Study samples of 92($n=4pq/L^2$ were selected ranging from adult of aged 18-50 years and irrespective of caste, religion & sex. Subjects were as per inclusion and exclusion criteria. The study duration was of 6 months. The procedure was explained to the individuals wiling to participate and written informed consent was taken . The materials used in this study includes Stadiometer, Weighing Scale, Measuring Tape, Small Sliding Caliper, Skinfold Caliper, Writing Material. These participants would be further investigated for Weight, Height, Skinfold thickness, Muscle girth measurements, Body mass index and bone width. To ensure the endomorphic built of the individual the measurement of skinfold thickness were taken .The participants were asked remove the clothing. The skinfold thickness then was measured at the triceps, calf , subscapular and supraspinal level by using skinfold thickness calliper. For the confirmation of the mesomorphic built measurements taken were height, calf girth, biceps girth, femur width and humerus width. Inch tape and small sliding caliper was used for muscle girth and bone width measurements respectively. In case of ectomorphic individuals the built was confirmed by the measurement of height and weight. For height and weight measurements Stadiometer and weighing machine was used respectively. Each measurement was taken thrice and the mean was taken out of these three to minimize human error. Then obtained values were plotted on the somatochart for validation of the built. The detailed instructions about workability questionnaire were given to the participants. Then subjects were given the work ability questionnaire. Data was documented and then sent for the statistical analysis.

STATISTICAL ANALYSIS AND INETERPRITATION:

1: Age Wise Distribution In The Study

Age (in Years)	Ectomorphic (n=40)	Mesomorphic (n=38)	Endomorphic (n=14)
18-29	26	22	9
30-45	14	16	5

Interpretation: Above table indicates that , out of 92 individuals the ectomorphic built had 26 and 14 number of subjects under the age group of 18-29 and 30-45 years respectively. Total number of 22 subjects under the age group of 18-29 and 16 under 30-45 years fell in the category of mesomorphic built. The endomorphic built had overall 9 and 5 number of subjects in the age group of 18-29 years and 30-45 years respectively.

Table 2: Gender wise Distribution.

Gender	Ectomorphic (n=40)	Mesomorphic (n=38)	Endomorphic (n=14)
Males	33	33	11
Females	7	5	3

Interpretation: Above table shows that out of 92 industrial workers, in the category of ectomorphic built there were 33 males and 7 were females. While , mesomorphic built had 33 males and 5 females. Total number of 11 male and 3 females under the endomorphic built were documented in this study.

Table 3: Shows that overall association between build and study variables.

Study Variables	Built			Chi-square	p-value
	Ectomorphic n=40	Mesomorphic n=38	Endomorphic n=14		
Age					
≤ 25	22	22	8	0.069	0.97
> 26	18	16	6		
Gender					
Male	33	34	14	3.14	0.21
Female	7	4	0		
Work Ability Score					
≤ 38	6	7	9	14.92	0.0006
> 39	34	31	5		

*significant when $p<0.05$

Interpretation:

The above table revealed that the association between built and study variables such as age, gender and work ability. We had found that the association between built and study variable found no significant $p>0.05$ except work ability where $p<0.05$.

Table 4: Descriptive Statistics among Study.

Study Variables	N	Minimum	Maximum	Mean	Std. Deviation
Ectomorphic	40	32.00	46.00	40.9500	3.73445
Mesomorphic	38	32.00	47.00	40.8684	4.06814
Endomorphic	14	31.00	43.00	35.9286	5.01481

Interpretation:

The above table showed that, for 40 number of ectomorphic individuals the mean was 40.95, standard deviation was 3.7344 with the 32 and 36 minimum and maximum value respectively. The mesomorphic individuals had minimum and maximum value of 32 and 47 respectively with the mean of 40.8684 and standard deviation 4.0681. For endomorphic individuals the mean was 35.928, standard deviation was 5.0148 with 31 and 43 minimum and maximum value respectively.

Table 5: Shows Correlation between Built and Work Ability Score.

Built	Work Ability			Chi-square value	p-value
	Moderate 28-36	Good 37-43	Excellent 44-49		
Ectomorphic n=40	6	26	8	14.995	0.0047
Mesomorphic n=38	7	23	8		
Endomorphic n=14	9	4	1		

Interpretation:

The above table showed that the correlation between built and work ability score and here we found that statistical significant association, where $p<0.05$.

Table 6: Correlation between built and work ability among small scale industrial workers.

Built vs. Work Ability	Correlation Coefficient ®	r2	95% CI	p-value
Ectomorphic	-0.06588	0.00434	-0.3699 to 0.2509	0.6863
Mesomorphic	-0.0938	0.0088	-0.4015 to 0.2329	0.5754
Endomorphic	0.4971	0.2471	-0.04566 to 0.8132	0.0706

Interpretation:

The above table revealed that the correlation between built and work ability, in this study both ectomorphic and mesomorphic shows negative correlation -0.06588 ($p>0.05$) and -0.0938 ($p>0.05$) except endomorphic which shows positive correlation 0.2471 nearest to significance. There was no correlation between built and work ability.

Results

In this study both ectomorphic and mesomorphic showed negative correlation except endomorphic which showed positive correlation nearest to significance. There was no correlation between built and work ability. Study variables in this study such as age, gender and work ability revealed association with built. We had found that the association between built and study variable has no significance except work ability. Thus , the present study concluded that there is no significant correlation between built and work ability.

Discussion

Built is one of the factor which influences the quality of labor. Many studies stated the obesity has effect on workers working capacity. The purpose of this study to find the correlation between built and work ability among small scale industrial workers.The individuals working small scale industries were selected as subjects .Each subject was selected as per inclusion and exclusion criteria. They were instructed about the study. The informed consent was taken from the subjects. The study was taken place at industrial colony Malkapur, Karad.

The Duration of the study was six months with sample size of 92 (females- 11 and males- 81) and age group of 18–60 years. Later, this group was divided into two different groups of age. The groups were from age 18-25 years and 30-45 years. Also the groups were divided in males and females. And the further division were done in accordance to the built for ectomorphic, endomorphic and mesomorphic.

Demographic data including age, gender, working duration, number of working years was collected .The built of the subject was assessed by The Heath-carter anthropometric somatotype method . In which the measurements were taken under three categories.

For Endomorphy individuals, the skinfold thickness of the following was measured in millimeter by skinfold caliper for the triceps, subscapular, supraspinal and calf.

The mesomorphic individuals were assessed by taking the width of the humerus , femur with the small sliding caliper.

The girth was measured by measuring tape for the following – calf , biceps.

The height of the subject was recorded by asking him to stand on the stadiometer.

By the heath carter anthropometric somatotype method ,for the ectomorphic individuals, the weight was taken on the weighing machine. The height was divided by the weight.

Each measurement was taken three times to minimize the human error. After the calculations the data was entered into the equation to derive the co-ordinates. The two dimensional chart was used to plot the somatochart.

The detailed instructions were given to the participants. The subjects were given the work ability questionnaire and they were explained how to mark the questionnaire.

In this study the statistical analysis of the recorded data was done by using the software SPSS version20. Arithmetic mean & standard deviation was calculated for each outcome measure. Arithmetic mean was derived from adding all the values together and dividing the total number of values.MS Excel was used for drawing various graphs with given frequencies and the various percentages that were calculated with the software.

Christiane Wilke*, Philip Ashton, Tobias Elis, Bianca Biallas and IngoFroböse “Analysis of work ability and work-related physical activity of employees in a medium-sized business”

Concluded that there no significance between age and work related physical activity.

In the present study the overall association between built and the study variables such as age and gender found no significance when $p>0.05$except the work ability where $p<0.05$.

The demographic parameters such as age and gender were associated with the ectomorphic built showed no significance with the unpaired t-value=0.66 and p value=0.44 for the age. . The mean for age group 15-

29 was 40.65 and SD was 3.63.For the age group 30-45 the mean was 41.25 and SD of 4.29. For gender it was unpaired t-value=0.59 and 0.56 respectively.

The association between endomorphic built and the demographic parameters showed the statistical significance between age but no statistical significance between gender.

The unpaired t-value and p-value for this association was 6.202 and<0.0001 for age and 1.67 and 0.11 for gender respectively.

Joyce A. Pebrix "Relationship between somatotype and motor fitness" showed that there was significant relationship between mesomorphy and power. They added further about inverse relationship between enomorphy and strength and power.

This study revealed that the correlation between ectomorphic and mesomorphic built with the work ability among small scale industrial workers showed the negative correlation -0.06588 and -05754 with p value 0.6863 and 0.5754 respectively.

The endomorphic built showed the positive correlation 0.2471 which was near to significance with the p value of 0.0706. There was no significant correlation between work ability.

Teodor TÓTH, Monika MICHALÍKOVÁ, Lucia BEDNARČÍKOVÁ, Jozef ŽIVČÁK, Peter KNEPPO "SOMATOTYPES IN SPORT" have mentioned in their studies that mesomorphic built has medium fast energetic expenditure. Re- acts to strength training with rapid accumulation of muscle mass.

This study concluded that in mesomorphs the mean work ability was 40.86 same as the ectomorphic i.e. "very good" with minimum and maximum score of 31 and 43 respectively.

Kuijer PPFM, Gouttebarge V, Wind H, van Duivenbooden C, Sluiter JK, Frings-Dresen MHW "Prognostic value of self-reported work ability and performance-based lifting tests for sustainable return to work among construction workers." This article proved that the lower lifting strength test differs the ability to return to work.

The present study has shown that the endomorphic individuals had the mean work ability score of 35.92 i.e. "medium" with standard deviation 5.0148 and minimum and maximum score was 31 and 43 respectively.

Christiane Wilke*, Philip Ashton, Tobias Elis, Bianca Biallas and IngoFroböse "Analysis of work ability and work-related physical activity of employees in a medium-sized business"

Rated the work ability as good, but according to them there is lack of evidence regarding the work related physical acitivity.

The statistics in the present study shows the ectomorphic individuals had the mean work ability of 40.95 i.e. "very good" on the work ability index and standard deviation 3.73 with minimum work ability of 32 and maximum of 46.

Thus , the present study concluded that there is significant correlation between built and work ability with the p value <0.05. Hence the alternative hypothesis is accepted.

Conclusion

On the basis of the result of the study, it was concluded that there is no correlation between built and work ability among small scale industrial workers. The ectomorphic and mesomorphic built has the very good work ability and there was medium work ability among endomorphic individuals. There was no difference in parameters seen in male and female participants.The endomorphic individuals need to improve their work ability.

Conflicts of Interest: There were no conflicts of interest in this study.

Ethical Clearance: Ethical clearance was taken from institutional committee of Krishna Institute Of Medical Sciences Deemed To Be University, Karad.

Attitude And Utilization of Services Under Rajiv Aarogyasri Scheme in Private Health Care Set-Up At Rajahmundry, Andhra Pradesh

Saptarishi Bose[1], Sushant Kumar Mishra[2] , Sipra Komal Jena[3]

[1]Assistant Professor, [2]Professor & HOD, [3]Professor, Dept. of Community Medicine at GSL Medical College, Rajahmundry, AP.

Abstract

Background: Healthcare services help to keep diseases under control and raise life expectancy. Andhra Pradesh is a state which accounts 9.20% of below poverty line population of its total population. To meet the need of tertiary health care for such people the government of Andhra Pradesh started the Rajiv Aarogyasri Health Insurance Scheme on to improve access of poor to quality medical care and for providing financial protection against high medical expenses. The present study was undertaken to assess the health service delivery to poor population of Rajahmundry and their utilization of these services and to identify any gaps or lacunae in these services provided.

Objectives: 1. To study the socio demographic and the present health condition of the people availing the services under Rajiv Aarogyasri Scheme.2)To assess their behavior & attitude towards the services provided to the patients by private health care providers under guidelines of "Rajiv Aarogyasri scheme". & their utilization & client satisfaction. **Materials And Methods:** A facility based cross sectional study focusing on personal and demographic characteristics, client satisfaction of the service offered to them was designed. The clients, service providers etc. were interviewed with the help of pretested proforma & the results were analyzed. **Results & Conclusions:** Service delivery by private outlets accredited under Rajiv Aarogyasri Scheme is effectively functioning.

Key words*: Age, religion, caste, socioeconomic status, health status, awareness, utilization etc.*

Introduction

Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity according to World Health Organization (WHO).[1] Health is a human right and hence health care should be made available universally[2]. The economic burden are relatively greater for the poor people, who are handicapped by the ill health and who stand to gain the most from the underutilized resources[3]. Tertiary care is often expensive for people with low incomes, so those with conditions requiring tertiary care often go untreated or are left with devastating hospital bills, both of which exacerbate poverty.[4] In 1995-96 an estimated 2.2% of the Indian population fell into poverty because of out-of-pocket spending[5] and it increased to around 3.2% in 1999-2000[6], worsening their poverty. Andhra Pradesh is a state which accounts 9.20% of below poverty line population. Majority being farmers or daily wage earners. To meet the need of tertiary health care for such people the government of Andhra Pradesh started the Rajiv Aarogyasri Health Insurance Scheme on 01.04.2007 to improve access of poor to quality medical care and for providing financial protection against high medical expenses. The scheme provides financial protection to families living below the poverty line up to Rs. 2 lakhs in a year for the treatment of serious ailments requiring hospitalization and surgery. The beneficiaries of the scheme are the members of Below Poverty Line (BPL) families, as enlisted and photographed in BPL Ration Card and available in Civil Supplies Department database.

A beneficiary can avail services for the procedures covered under the scheme. The same is applicable for diagnostics also, if eventually the patient does not

undergo any type of surgery or therapy[8].

Even though, the scheme may look fool proof, well-designed and well- implemented, it may not be successful until & unless the people are aware of the scheme & utilize the services provided.

So the present study was undertaken to assess the awareness, behavior, attitude of poor population of Rajahmundry and their utilization of these services.

Materials and Method

Study design: Hospital based study

Study area: G.S.L General Hospital and Swatantra Hospitals Which provided complete medical care under Rajiv Aarogyasri scheme in Rajahmundry.

Study Subjects: Clients utilizing the services provided by the two hospitals within the study period

Study period: October 2017 – December 2017

Sample size: 400

Study tool: Predesigned and pretested schedule of questions

Study variables: Age, Sex, Income Groups, Residing Areas, Occupation, Disease, Outcome etc

Statistical analysis: All statistical analysis was performed by using SPSS version 20 and MS- EXCEL 2007. The values are presented as mean + or- SD, percentages & proportions

Inclusion criteria:

1. Beneficiaries enrolled under the scheme and admitted in the facility for at least 24 hours.

2. Patients giving consent to participate in the study

Exclusion criteria:

1. Patients who died within 24 hours of receiving treatment

2. Patients who are admitted for less than 24 hours and shifted out.

Methodology

Data was collected from both the selected health facilities for a period of 3 months. All the beneficiaries attending these two hospitals within the study period, satisfying the inclusion criteria were selected for study. After informing them about the complete details of the study and taking their consent, they were interviewed with the help of a pre-designed & pretested proforma & information was noted. The sample size came up to 400. The data collected was analyzed.

Results

Of the 400 study subjects majority 150 (37%) belonged to age group of 30-44 yrs followed by 113 (28%) in the age group of 45-59 yrs. Geriatric age group (above 60 yrs) consisted of 87 (22%)beneficiaries. Among all the study participants, 209 (52%) were males and 191 (48%) were females. Out of 400 study subjects, majority of them i.e.; 385 (96%) were Hindus followed by Muslims and Christians comprising 8(2%) and 7(2%) respectively. Majority of beneficiaries belonged to other backward caste which accounted to 196 (49%) of the study population. Out of 400 beneficiaries, 261 (65%) were illiterate and 83 (21%) had education up to Primary school level. 38 (9%) and 18 (5%) were educated up to Middle school and High school level respectively. [Classification is according to Modified BG Prasad socioeconomic scale (2016)[9]. Of the total 400 Clients, 87 (22%) were unemployed/Housewives 223 (56%) were unskilled workers like labours or domestic servants, 78 (19%) were semiskilled and 12 (3%) were skilled workers. Out of 400, 393(98%) of study subjects belonged to Upper Lower socioeconomic class & rest 7 (2%) belonged to Lower Middle socioeconomic class.

Information Pertaining to Sickness

The time of arrival to RAS (Rajiv Gandhi Aarogyyasri Scheme) accredited hospital after the onset of symptoms or illness was within 24 Hrs. for 80(20%) out of 400. About 138 (35%) subjects came within 1-7 days and 101 (25%) came within 7-15 days whereas 80 (20%) arrived after 15 days. Among 400 subjects, 149 (37%) came with surgical problems, 108(27%) came with cancer, 76(19%) came with fractures. These are followed by stroke, gynaec problems &other medical problems with 8%, 7% & 2% respectively.

Awareness regarding RAS

Out of 400 clients, 360 (90%) were aware of Rajiv Aarogyasri Scheme whereas 40 (10%) were not aware. The source of information for the beneficiaries regarding

RAS was mostly through friends & relatives 183 (51%) out of those aware. Health care workers contributed about 15% (54/360). About 35(10%) were among other source of information like those who availed the services before or their relatives etc. 33(9%) subjects, were informed by doctors. About 30 (8%) were informed through media & 25 (7%) by their experience as they have availed the services before. Of total 400 subjects, 360(90%) were aware of eligibility criteria for availing services under the RAS scheme, whereas 40(10%) were not aware.

Out of 360 study subjects, who were aware regarding the eligibility criteria, only 20(5%) had complete awareness & 340(95%) had partial awareness. All the 400 beneficiaries had some card to avail services. Out of 400, 142(35%) had white card i.e.; the card possessed by people below poverty line. Around 239(60%) had Rajiv Aarogyasri Card. About 12(2%) of them possessed Chief Minister Camp office letter & 7(3%) of them had Temporary Andhra Card.

Reporting Mode to RAS facility

Out of 400 beneficiaries, 116(29%) were accompanied by previous RAS patients or relatives, 107(27%) were direct walk INS, 71(18%) came with referral by doctor from PHC, 54(14%) were accompanied by health workers, 42(10%) were referred by private practitioners, 10(2%) came through emergency services,

First Source of Contact at RAS accredited hospital

Among 400 clients, 339 (85%) first contacted Aarogyamitra, followed by 23(6%) who consulted a doctor at hospital, followed by 22(5%) who contacted Aarogyasri coordinator of hospital, whereas 16(4%) contacted other health workers.

Department Of Admission

Out of 400 Beneficiaries, majority of them 149(37%) were admitted in department of surgery & allied, followed by department of oncology, 108(27%). About 76 subjects (19%) were admitted in department of orthopedics, 39(10%) were admitted in department of medicine &allied, whereas 28(7%) were admitted in department of Obstetrics & Gynecology.

Client Satisfaction

Out of 400 patients, 369(92%) were satisfied with services provided in hospital, whereas 31(8%) were not satisfied.

Reason for dissatisfaction

Out of 31 beneficiaries, who were not satisfied by the services provided, 10(32%) were dissatisfied by nursing care & 3(10%) by services provided by doctors & remaining 18(58%) were unhappy with overall services provided by the hospital.

Satisfaction with the scheme

However, all 400 patients were satisfied by the services provided by the scheme.

Department wise Satisfaction

Out of 400 beneficiaries, 149(37%) were admitted in department of surgery & allied, of which 131(88%) were satisfied with the services, followed by department of oncology i.e 10 104(96%) , 76 (19%) were admitted in department of orthopaedics , of which 73(96%) were satisfied , 39(10%) were admitted in department of medicine & allied , of which 36(92%) were satisfied. Out of the 28(7%) patients admitted to department of OBGY, 25(89%) were satisfied with the services provided.

Out of total 400 beneficiaries, 188(47%) felt the services were very good, 89(22%) felt they were satisfactory, 51(13%) felt they were good, whereas 41(10%) & 31(8%) felt the services provided were excellent & unsatisfactory respectively

Of 400 beneficiaries, 220(55%) liked the overall care, whereas 87(22%) liked the reception, 47(12%) & 46(11%) liked the medical care by doctors & nursing care respectively

Willingness to share information & avail services again:

All the beneficiaries i.e.; 400 (100%) are willing to share information of this scheme & avail services again with others.

Table 1: Awareness Regarding RAS

Knowledge about Aarogyasri	Number(n)	Percentage (%)
Yes	360	90
No	40	10
Total	400	100

Table 2: Source of Information

Source of Information	Number(n)	Percentage (%)
Frnds & Rltvs	183	51
Health Care Worker	54	15
Media	30	8
Doctors	33	9
Prvsly Availed Services for other complaints	25	7
Others	35	10
Total	360	100

Table 3: Whether satisfied by the services provided in hospital

Whether satisfied by the services	Number(n)	Percentage (%)
Yes	369	92
No	31	8
Total	400	100

Table 4: Quality of Services Rated By Beneficiaries

Quality of Services	Number(n)	Percentage (%)
Excellent	41	10
Very Good	188	47
Good	51	13
Satisfactory	89	22
Unsatisfactory	31	8
Total	400	100

Discussion

It was seen in the present study that majority of beneficiaries belonged to age group of 30-44 yrs i.e., 37%. In a study done by Rao et.al[10] also, 29.7% beneficiaries also belonged to 30-44 yrs of age. In another study done by Kadam et.al[11], also, beneficiaries belonging to 30-44 yrs was 28.6% which is similar to the present study..

In the present study, 52% of the beneficiaries were males and 48% were females. In the study done by Rao et.al[10], 53.6% were males and 47.4% were females, which is similar to present study.

In the study done by Dr.D.Shreedevi[12], 38% were illiterates which is similar to the present study. It shows that though majority of the beneficiaries were illiterate they were aware of the existence and functioning of the scheme.

In the present study it was observed that 98% of the beneficiaries belonged to Upper Lower Class and 2% of the beneficiaries belonged to Lower Middle Class.as per Modified BG Prasad Scale[9]. They are very much availing the government schemes better than all the other classes.

About 49% of Backward Caste population were utilizing the health services.

In the present study, it was observed that the majority (37%) of the beneficiaries came with surgical problems & 27% of beneficiaries came for cancer treatment. 19% of beneficiaries suffered from fractures. So people are availing the scheme for diseases which has devastating effect economically on them

The study showed that more than half of the beneficiaries came to RAS accredited centers due to financial problems for free treatment.

In the present study 29% of the beneficiaries reported to study setting with relatives or people who previously availed the services in the same facilities.. It shows that people are aware of the facility and services provided in the facility and they are having good impression about it.

It was seen that, in present study people come from distant places, which shows that people had trust in the services provided by the private health facilities.

In the present study, it was seen that 90% of the enrolled beneficiaries had at least some knowledge regarding eligibility criteria for treatment under the schemes showing that the people are becoming more health conscious & are aware about various government schemes..

In present study, 37% of beneficiaries underwent surgical treatment , 27% came for treatment under Oncology department. 19% underwent surgeries in Orthopedics department which shows that people are availing the scheme for treatment of ailments which was an economic burden for them.

Around 92% were satisfied with the services provided in the hospital. In the study done by Dr. D.Shree Devi et.al[12], 94% of the beneficiaries were satisfied which is almost similar to the present study.

Around 47% of the clients gave rating of very good for the services provided & 22% of the clients gave rating of satisfactory, which shows that majority of the people were satisfied with the services provided in the scheme.

In the study, it was seen that all the beneficiaries were willing to share the information regarding the scheme and the health facility which shows that they are happy with the services

Conclusion and Recommendations

At the end of the study, we hereby conclude that **"The private outlets accredited under Rajiv Aarogyasri Scheme is effectively functioning."**

On the basis of findings from our study, the following aspects related to Rajiv Aarogyasri scheme are recommended:

- Regular auditing by the higher authority can be conducted to check whether hospitals are complying with the protocol guidelines.

- Training the hospital staff regarding the scheme for its effective functioning

- The government needs to review the scope for preventing the diseases currently being treated by the RAS through greater investment in health promotion .The government needs to use a method such as accreditation to improve and standardise high quality care across the system. The government needs to use renewal of empanelment as a lever to stimulate change & to explore how to benefit those individuals who belong to the most marginalized populations.

Abstract

Aim: The aim of this study is to rule out the difference in positional setup errors when using immobilization device such as thermoplastic mould for free breathing and vacloc with ABC gating in ca breast patient treating with 3DCRT technique.

Objective: The study is to compare the patient setup uncertainties using two different immobilization device, one with standard thermoplastic mould and other with vacuum cushion with active breath control gating in our clinical setup.

Methodology: fourteen patients with ca breast are taken for the study. seven patients are undergone immobilization using standard thermoplastic moulding and remaining seven patients undergone, vacuum cushion with active breath control DIBH (deep inspiration breath hold) gating. CT was taken and 3dcrt plan were done according to the standard protocol. Prior to the treatment CBCT was taken, matching was done in XVI with the reference images, to rule out any positional shifts. Positional Shifts on all 3 axes such x, y, z is noted with rotational shift. Comparison were done on systematic error (Σ), random error (σ), mean displacement vector (R), mean setup error (M).

Result: immobilization device used by vacloc with DIBH ABC gating shows very less shifts in all direction, especially longitudinal direction compared with mould one, which we are using routinely in our department.

***Keywords**: ABC, CBCT, xvi, DIBH gating, 3DCRT*

Introduction

Radiotherapy is one of the most effective mode of treatment for all types of carcinoma. There are different techniques in radiotherapy such as 3dcrt, forward planning, imrt, vmat, Tomotherapy etc, present today. Ca breast is a common cancer found in women all over the world with symptoms include lump or mass in the breast, nipple discharge or redness, changes in the skin such as puckering or dimpling, and swelling of part of the breast. Breast conservative therapy is the most common technique in radiotherapy for saving breast. It is done usually after lumpectomy, adding radiation after a surgery lowers the risk of cancer recurrence in the affected breast.

Many women go through radiation therapy for breast cancer, and roughly more than 60 percent of people with early-stage breast cancer will undergo adjuvant radiotherapy followed by surgery. It also helps in reduces the breast cancer death rate. The important and main step in radiotherapy is to immobilize the target, so that the beam can only target the carcinoma and spares the normal tissue. It is a very difficult process especially in thorax and abdomen region to retain the same position on every single day for the treatment, due to the involuntary motion it involves. The nature of breast, supraclavicular nodes, its region of avoidance contours etc. Different means of immobilization devices, are there especially for ca breast to reduce

the positional errors. Thermoplastic mould is one of its kind and commonly used in all radiotherapy center for the radiation treatment, even there are breast board, wedges, etc can also be used. While using this types of immobilization devices the main concern is the errors caused by the involuntary movement such as breathing movement. To limit this types of errors gating's are coming in the picture. By the help of gating technique, we can arrest the breathing motion errors, one of its kind is active breath coordinator device. Respiratory gating is used when there is a need to reduce the anatomical movement in the thorax and abdomen due to breathing and cardiac motion.it is intended for breath hold during simulation and treatment delivery[1].The Active Breathing Coordinator (ABC) allows for temporary and reproducible immobilization of internal thoracic structures by monitoring the patient's breathing cycle and implementing a breath hold at a predefined lung volume level. Active Breathing Coordinator provides non-invasive, internal immobilization of anatomies affected by respiratory motion, such as the breast, lung, liver, pancreatic etc. This is achieved through comfortable, simple and efficient assisted breath-hold techniques. Linked to the digital accelerator through the Response™ gating interface. Respiratory-gated radiotherapy offers a significant potential in improving the irradiation of tumor sites affected by respiratory motion such as lung, breast, and liver tumors [2 ,12].

in this study we were evaluating the impact of controlled breathing using , Active breath coordinator gating with normal free breathing with thermoplastic mould in our radiotherapy setup.

Methodology

There are studies showing reduction in heart dose can be achieved for many left-sided breast and chest wall patients using deep inspiration breath-hold[4].There are studies done in various department in ca breast using different gating methods using infrared, markers or fiducial which are surgically inserted, real time tracking using kv xray beam etc. This study is conducted at Kasturba Hospital using ELEKTA HD versa XVI cbct. Ethical approval was granted by the Institutional Ethics Committee, Kasturba Medical College, Manipal. The study was also registered under CTRI. fourteen breast cancer patients who were planned to treat with 42.5 Gy in 16 fractions were chosen for this study. Age range from 41 to 67 yrs., out of this 8 patients are with T1N2aM0 stage.

Seven patients were immobilized using thermoplastic chest mould (klarity) with four clips and seven by using vacloc with active breath coordinator in deep inspiration breath hold under Standard Operating Procedure in moulding room. Selection for the ABC gating is completely biased. Before the gating, patients are well explained and trained for the procedure. Patients with previous history of lung, heart problem, etc are avoided from ABC gating.

Contours, prescription are done based on ICRU protocol[3]. Standard tangential 3dcrt beam planning was generated using 6 mv or 10 mv photon with wedge. Plans are evaluated by experienced radiation oncologist before sending for verification and treatment. Patients were imaged with CBCT on first consecutive three days and every third day during their course of treatment. CBCT was taken before each fraction. In all, 6 CBCT images were acquired for each patient for 3 weeks. A total of 84 images are obtained. Image registration was done first by automatic and then by manual adjustment by the same person for all the patients. Patients were positioned supine, with both arms raised above their head and immobilized by thermoplastic mould[5]. During the mould making process, three fiducial markers were placed on the patient's body with the support of laser for isocenter reference mark. CT was taken with slice thickness of 5 mm in Philips brilliance 16 big bore and pushed Monaco™ TPS V5.11.02 treatment planning system (TPS) for delineation of the targets and OAR. once plan was done, all plans were approved by a radiation oncologist and transferred from TPS to CBCT system for the treatment delivery along with the corresponding planning CT datasets which will be used as the reference image data sets. The planning CT-scan was imported into the XVI database via DICOM. XVI system consisted of kilo-voltage X-ray source arm and amorphous silicon flat panel imager, is together with Elekta HD versa® (Elekta Ltd, UK) linear accelerator was used as the IGRT system to acquire onboard CBCT images. Patient's 3D-CBCT images are acquired at isocenter after applying the shift from the origin, which we got from the treatment planning station. Rotational shifts such as pitch, yaw and roll are not considered in this study. If the rotational error is more than 3^{o}, patients are repositioned and images are taken once again

Images in cbct were acquired within one-minute time span, 360-degree rotation with the patient immobilized in the treatment position same like during CT acquisition. M20 collimator cassette was used on all patients giving

a nominal irradiated scan length at the isocentre of approximately 26 cm and reconstruction diameter of approximately 40 cm. the acquisition parameters were 120 kV, (with clinical filter F1), maintaining the lower dose to the patient's skin but improving image quality. The image acquisition parameter of xvi is given in table 1 below. Commissioning and calibration of the CBCT isocentre to the linear accelerator isocentre was performed prior to this study according to recommended guidance AAPM TG 58[5].

Table 1: acquisition parameters of xvi CBCT

KV	**120**
MAS	140
Gantry rotation	Clockwise (3600 arc)
Collimator	M20
Filter	F1
Frame	660
Reconstruction filter	wiener
XVI software	Version 5.0.3
Nominal scan dose	3.8 mGy

Image registration was first done automatically by using Clip-box registration (CBR) method, the volume of interest is defined on the CT image in the form of a box drawn around the anatomy of interest[4]. The registration between image sets is limited only to the voxels within the clip box which contains the volume. It is a rigid registration process and does not include any margins during image matching. Once automatic matching was done next step was to do a manual matching to rule out the small mismatch correction in automatic clip box registration. In manual registration we use mouse to move the reference image with translational and rotations. Even though Manual matching is a time taking registration, it is superior than automatic one[4]. Out of automatic matching, the gray value (T + R) registration use grayscale intensity values of the voxels in the registration volume. The algorithm used here is correlation ratio procedure. The bone (T+R) mode of automatic registration use chamfer matching algorithm[9], to calculate the same as bone densities. Since the algorithm is not very sensitive to image noise, this registration can have done very quickly.

The deviation between the actual and intended position in a patient treatment is called the setup errors. Mainly two types of setup errors are present while treating a patient in external beam radiotherapy, such as systematic and random error. Systematic part of an error is one which occur systematically (same direction and magnitude) throughout the delivery[7]. This types of errors may be introduced into the treatment during immobilization preparation, planning, while transferring the data, during delivery etc.so Systematic errors are sometimes called as treatment preparation errors, It can be calculated by standard deviation of the mean error of individual of that population and is represented by the symbol $\sum$. whereas random error which is represented by σ, is one which direction and magnitude of error will vary from each fraction during the treatment. This type error is usually occurring during treatment delivery phase may be due to patient's setup, tumor position, intra-fraction movement and sometimes called as daily execution errors. Which can be calculated by the root mean square of the standard deviation of each patient.

It is easy to reduce the random error to some extent than systematic error[5]. The mean setup error (M) is the average of the setup error in each direction. Whereas mean displacement vector which quantifies the distance and direction of patient setup errors can be calculated using

$$M = \sqrt{(AP)^2+(RL)^2+(SI)^2}$$

Where RL, SI, AP is deviation in three axis of patients respectively[8].

Results and Discussion

It is shown in study done by Mageras GS, Yorke E that Gated treatment offers reduced respiratory motion with less patient effort than DIBH[10].However in this study gating was done in DIBH mode where normal OARS can be saved at the same extend[11]. The result of present study is expressed in tables and chart given below. The mean and standard deviations were calculated. The mean value expressed the systematic error and the standard deviation describes the random error of individuals[7]. The residual population systematic setup errors data are shown in fig 2. The major shifts are

noted in longitudinal direction (SI), the mean of superior inferior (SI), in mould is 4 mm in mould and 1 mm in ABC gating. The random error in RL, SI, AP is 1.6, 4.4, 1.4 mm in ABC gating, where as in mould it is 1.7, 6.1, 2.4 mm respectively. The patient's translational errors of both mould and gating are shown below in fig 1.

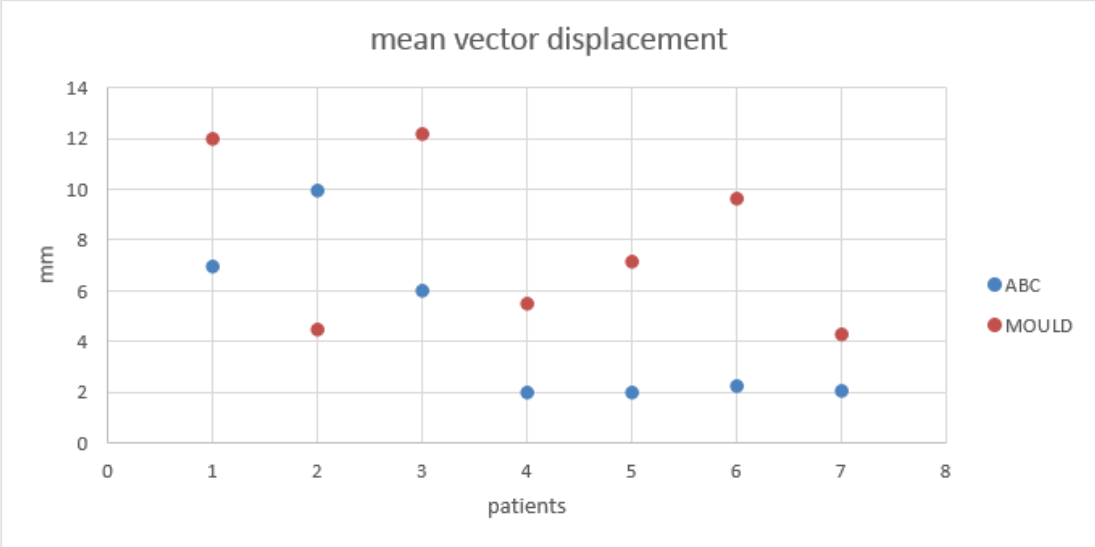

Fig 1: scatter plot distribution of mean vector displacement for each patient in ABC gating and mould immobilization

The vector displacement for mould varies from 3.6 mm to 12 mm, whereas in ABC gating it is from 2.1 to 10 mm. The sample size chosen for this study is very less, more number of samples are needed to know the exact shift difference in all axes. The random error noted for ABC gating is 1.6, 4.5,1.4 mm and 2.0, 6.0, 2.0 mm for mould in RL, SI, AP respectively. The systematic errors of population are given below in fig 2.

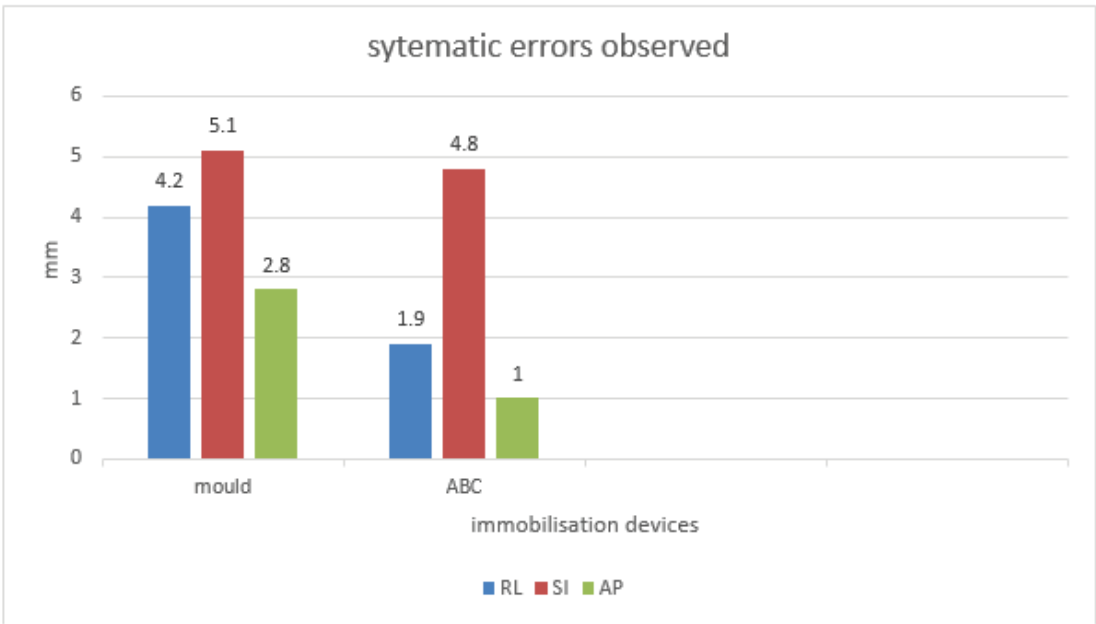

Fig 2: population Systematic (Σ) errors calculated

(X (RL): Medio lateral, Y (SI): Craniocaudal, Z (AP): Anteroposterior) all reading are in mm)

Conclusion

From this study, in our clinic it is found that by using active breath control gating, we can reduce the systematic and random error to a great extended compared with the normal free breathing mould immobilization. One drawback noted in ABC gating is that selection of patient which is a biased one, a complete cooperation of patient is a must for doing all this procedure. Second it is a tedious process compared with the mould technique. A proper training of patient is needed, prior to immobilization simulation and treatment

Effectiveness of Health Intervention on Birth Preparedness on Knowledge and Outcome of Pregnancy among Primi Antenatal Mother in Selected Hospital of Pune

Sofiya Khan[1], Seeta Devi[2], Ranjana Chavan[2], Shitalwaghmare[2]

[1]II year M.Sc (N), [2]Asst. Professor , Symbiosis College of Nursing, Symbiosis International (Deemed University), Pune

Background of the Study: Birth preparedness and complication readiness is a strategy to promote the timely use of skilled maternal and neonatal care, especially during child birth based on the theory that preparing for childbirth and being ready for complication and reduce delay in obtaining care Annual global estimate of 287,000 maternal deaths were recorded in 2010 as a result of complication of pregnancy and childbirth.

Methodology: In the present study Quantitative research approach is applied approach is applied and quasi experimental pre –test post-test design is used sample all primi mother sample size 60 primi mother sampling technique non- probability convenience sampling setting the selection of study setting is on the basis of the feasibility of conducting study and availability of sample. Study will be conducted in Talera and Bhosri hospital, PCMC,Pune

Results: Birth preparedness and complication since all the p-values are large (greater than 0.05), none of the demographic variables was found to have significant association with the mode of delivery Maternal complication during labor.In the present study pretest, 20% of the primi antenatal mothers had poor knowledge (Score 0-3), 66.7% of them had average knowledge (score 4-6) and 13.3% of them had good knowledge (score 7-10) regarding birth preparedness. In post-test, 5% of them had average knowledge (score 4-6) and 95% of them had good knowledge (score 7-10) regarding birth preparedness.

Conclusion: In this study indicates that the knowledge of the women regarding birth preparedness improved remarkably after health intervention Researcher applied paired t-test for the effectiveness of health intervention on Knowledge of woman regarding birth preparedness among antenatal mother

Keywords*: Knowledge, Preparation, Readiness, Pregnancy, Complication*

Introduction and background

Childbirth is a natural and universal phenomenon. Although labour is often thought of as one of the most painful events in human experience, supportive care is intended to ease a woman ‘s anxiety and discomfort. A wide variety of relief measures, pharmacological and non-pharmacological are available for woman in labour pregnant women become more focused about labour and birth of a child as they approach the final phase of pregnancy midwives and maternity nurses play a vital role in helping pregnant woman to overcome their fear and anxieties about labour[1]

Globally, eight hundred women die every day due to pregnancy or child birth related complications. Almost all maternal deaths (99%) occur in developing countries, and more than half of this deaths occur in Sub-Saharan Africa[2]

In India approximately 15% of pregnant women develop life-threatening complications hence need for emergency obstetric care. These complications

Corresponding author:
Ms. Sofiya Khan
Symbiosis College of Nursing, II year M.Sc (N)
Symbiosis International (Deemed University),
Pune 411004

are unpredictable and may progress rapidly to a fatal outcome. Knowledge of danger signs of obstetric emergencies and appreciation of the need for rapid and appropriate response when emergencies occur may reduce delay indecision making and in reaching health facilities. Danger signs in pregnancy are vaginal bleeding, severe headache, severe vomiting, swelling of hands and face, difficulty in breathing fits, fever, reduction or absent fetal movement and drainage of liquor[3].

Mothers who dream of a safe pregnancy and a healthy baby. However, every pregnant woman faces the risk of sudden, unpredictable complications that could and in death or injury to herself or to her infant. Birth preparedness and complication readiness is a strategy that encourages pregnant women, their families, and communities to effectively plan for births and deal with emergencies, as knowledge and practice preparedness and Knowledge of birth preparedness and complication readiness was higher than knowledge of pregnancy danger signs (complication readiness) in many studies, whilst implementation of Birth preparedness and complication readiness interventions was lower than level of knowledge in all studies[4]

Operational Definitions:

Preparation: It is helps ensure that woman can when labour begin and can also reduce the days that that occur experience obstetric complication.

Readiness: It promote active preparation and decision making for delivery by pregnant woman.

Pregnancy: The state of carrying a developing embryo or fetus within the female.

Knowledge: It is important to raise awareness of personal and professional accountability, inform the improve patient care.

Antenatal mother: In this study antenatal mother refers to pregnant mother who are attending antenatal ward checkup.

Objectives:

- To assess the knowledge of woman regarding birth preparedness.
- To assess the effectiveness of health intervention on birth preparedness and complication readiness on outcome of pregnancy among antenatal mother.
- To find the association between outcome of pregnancy and selected demographic variable.

Hypothesis: H_o-There is no significant association between labour preparedness and complication readiness program on outcome of pregnancy.

Methodology

In the present study Quantitative research approach is applied approach is applied and quasi experimental pre –test post-test design is used sample all primi mother sample size 60 Primi mother sampling technique non-probability convenience sampling setting the selection of study setting is on the basis of the feasibility of conducting study and availability of sample. Study will be conducted in Talera and Bhosri hospital, PCMC, Pune In the present study pretest, 20% of the Primi antenatal mothers had poor knowledge (Score 0-3), 66.7% of them had average knowledge (score 4-6) and 13.3% of them had good knowledge (score 7-10) regarding birth preparedness. In post-test, 5% of them had average knowledge (score 4-6) and 95% of them had good knowledge (score 7-10) regarding birth preparedness. This indicates that the knowledge of the women regarding birth preparedness improved remarkably after health intervention Researcher applied paired t-test for the effectiveness of health intervention on Knowledge of woman regarding birth preparedness among antenatal mother

Since all the p-values are large (greater than 0.05), none of the demographic variables was found to have significant association with the Maternal complication during labor.

Discussion and Conclusion

The primary aim of this study is to assess the effectiveness of health intervention on birth preparedness on knowledge and outcome of pregnancy among antenatal mother in selection as in hospital of Pune city. Discussion of the result of data analyzed as based on the objective of the study of birth preparedness and complication readiness among pregnant women in India was found very low as every pregnant woman should be expected to prepare for birth and complication. Specifically, from the key elements of birth preparedness plan very low percent of pregnant women prepared for the emergency situation during pregnancy and childbirth an improve knowledge of women's birth preparedness and complication readiness plan

A self – made variable is used for the present study on the basis of the objective and it was considered to be most appropriate teaching for assessing the effectiveness of health intervention on birth preparedness on knowledge and outcome of pregnancy among Primi antenatal mother. there search design adopted for this study was quasi –experimental group pre test posttest research design. A no probability, purposive sampling technique was used to select 60 Primi antenatal mother.

The obtained data were entered into master sheet for tabulation and statistical processing the finding of the study is discussed in the term of objective

Ethical Clearance – Ethical clearance was obtained from ethical committee of symbiosis college of nursing.

Study to Assess the Knowledge of People About Dengue Fever in Selected Rural Area of Mangalore

Suchithra BS

Asst. Professor, Dept. Of Community Health Nursing , Nitte Usha Institute of Nursing Sciences, Paneer, Deralakatte post , Kotekar beeri road, Mangalore -575018

Abstract

Health is the precious possession of all human beings as it is an asset for an individual and community as well. Like health, disease is a dynamic process and it is just the opposite of health. Effective control of communicable diseases is necessary for national development and economic self dependence. **The aim of the study** is to assess the knowledge of people about dengue fever in selected rural area of Mangalore. M**ethodology :** A quantitative, non-experimental research approach was used for the present study. Research design survey design. 150 subjects between the age 20-60 yrs were collected by using purposive sampling method. The study was conducted in Kalkatta area, under Natekal PHC.**Results:** The majority of in rural people 88(59%) were in the age group of 20-30 years. In rural area 79(53%) people were aware about dengue fever. Source of information showed that majority 59(75%) in rural people got information from paper, TV and media. The present study depict that 64(43%) of rural people have poor knowledge, 85(56%) of rural were having average knowledge and 1(1%) of rural people had good knowledge about dengue fever.

Present study revealed that there is association between level of knowledge and selected demographic variable like age and religion.

Conclusion: The present study depict that 64(43%) of rural people have poor knowledge, 85(56%) of rural were having average knowledge and 1(1%) of rural people had good knowledge about dengue fever.

Key words: *dengue fever, knowledge, rural.*

Introduction

Mosquito-Borne Diseases or mosquito-borne illness is disease caused by bacterial, viruses, parasites transmitted by Mosquitoes. This can transmit disease without being affected themselves.[1] Dengue is a main leading problem to human kind. Some mosquitoes are vectors for some of the diseases. Typically the diseases are caused by viruses or tiny parasites.[2]

Dengue fever is a serious public health problem in terms of its morbidity and mortality. It reports from almost all countries and it is endemic in the tropical countries. Dengue fever is an infectious mosquito-borne disease caused by dengue virus. Its symptoms include fever, head ache, muscle and joint pains and rash resembles measles. The presence of muscle and joint paints gives an alternative name to the dengue fever as ‹break bone fever›. [3]

Dengue is transmitted to humans by the Aedes aegypti or more rarely the Aedes albopictus mosquito. The mosquitoes that spread dengue usually bite at dusk and dawn but may bite at any time during the day, especially indoors, in shady areas, or when the weather is cloudy.[4]

India is one of the seven identified countries by reporting incidence of Dengue Fever/Dengue Haemorrhagic Fever outbreaks and may soon transform into a major niche for dengue infection in the near future. The first confirmed report of dengue infection in India dates back to 1940s, and since then more and more new states have been reporting the disease which mostly strikes in epidemic proportions often inflicting heavy morbidity and mortality, in both urban and rural environments.[5]

Background

Dengue fever usually starts suddenly with a rapidly climbing high fever, that's why the temperature in dengue fever is called a 'saddleback' type temperature, severe headaches, retro-orbital pain behind the eye, nausea & vomiting, loss of appetite, rashes develop on the feet or legs 3 to 4 days after the beginning of the fever, swelling and pain in muscles and joints. The joint pain in the body has given dengue fever the name that is "break bone fever". The common symptoms of dengue fever may go in around 10 days, but complete recovery from dengue fever can take more than a month.[6]

Dengue is currently the most common arboviral infection worldwide. It is endemic in almost all tropical and sub-tropical regions of the world; approximately 40% of the world population is at risk of acquiring a dengue infection. [6]

Dengue is a tropical disease affecting 110 countries throughout the world and placing over 3 billion people at risk of infection. According the World Health Organization 70 to 500 million persons are infected every year including 2 million who develop hemorrhagic form and 20,000 who die. Children are at highest risk for death. [7]The community health nursing experience and the increased incidences of dengue in India, made researcher to assess the awareness among people in rural and urban area about dengue fever so as to prevent dengue in future by administering the self information module.

Methodology

A quantitative, non-experimental research approach was used for the present study with survey design. Total 150 subjects between the age 20-60 yrs including both male and female were enrolled by using purposive sampling method. The study was conducted in Kalkatta area, under Natekal PHC. The institutional ethical permission was obtained. Permission from the medical officer was obtained inorder to carry out the study. Demographic performa and structured knowledge questionnaire to assess the knowledge regarding dengue fever and its control measures was administered. It was on the basis of arbitrary classification. The structured knowledge questionnaire were consist of 20 items and score was classified as good (score 14-20) , Average (score 7-13) and poor (score 0-6) . The tool validity and reliability was assessed. Informed consent was obtained from the subjects; demographic performa and structured knowledge questionnaire were administered.

Results

The present study revealed that out of 150 subjects in rural area majority 88(59%) of them were in the age group of 20-30 years.. Distribution of subjects according to the religion showed that among rural area 33(22%) were Hindu, 117(78%) were Muslims. Percentage distribution of rural people according to the education showed that in the rural area 14(9%) were illetrate, 38(25%) were primary education, 81(54%) were gone up to high school, 17(12%) were graduates. In rural area 79(53%) were aware about dengue. Percentage distribution of samples according to the source of information showed that majority 59(75%) in rural got information from paper, TV.

Table 1: The knowledge of People about Dengue Fever in selected rural area of Mangalore.

n = 150

Level of knowledge	Frequency	Percentage
Poor (0-6)	64	43
Average (7-13)	85	56
Good (14-20)	1	1
Total	150	100

The Present study shows that 64(43%) of rural people have poor knowledge, 85(56%) were having average knowledge and 1(1%) had good knowledge about dengue fever.

Present study revealed that there is association between level of knowledge and selected demographic variable like age and religion. And there is no association between level of knowledge and selected demographic variable like sex, education, occupation, and source of information.

Discussion

The present study revealed that out of 150 samples in rural area 88(59%) of them were in the age group of

20-30 years and mean age group is 29 yrs, this finding is supported by the study conducted in Malaysia the result showed that Mean age of respondents was 34.4 (± 5.7) years, and the age ranged from 18 to 65 years. [8]The study Javed N et all shows that the mean age group is 14.72 ±1.09.[9] Percentage distribution of rural people according to the education showed that in the rural area 14(9%) were illetrate, 38(25%) were primary education, 81(54%) were gone up to high school, 17(12%) were graduates and In rural area 79(53%) were aware about dengue. Similar finding was found in the study by Deepika T, Sharma G,Gupta M, they concluded in the study , 98.6% were literate and majority (99.4%) had heard about dengue fever.[10]

Percentage distribution of samples according to the source of information showed that majority 59(75%) in rural got information from paper, TV this finding was supported by the study by Jevid N et all shows that in their study majority 72.9% received knowledge on Dengue through TV and radio. [9]

The Present study shows that 64(43%) of rural people have poor knowledge, 85(56%) were having average knowledge and 1(1%) had good knowledge about dengue fever. The findings of the study was contradictory to the study by Yboa BC, Leodoro J , the result shows that more than half of the respondents had good knowledge (61.45%) on dengue symptoms and preventive measure. [11]The result of study by Yusuf MA, Ibrahim AN supports the present findings it shows that total 148/49.3% of the participants demonstrated a moderate level of knowledge, 140 (46.7%) a neutral level of attitude and 156 (52%) a low level of practice towards dengue fever prevention. 23A study conducted in Thailand, also showed that out Of the 1650 persons, 67% had good knowledge of dengue. [12]

Present study revealed that there is association between level of knowledge and selected demographic variable like age and religion. This finding was contradictory with study by Haraphan H et all shows that level of education, occupation, marital status, monthly income, socioeconomic status (SES) and living in the city were associated with the knowledge level.[13]

Conclusion

The present study concludes that the majority of the rural people i.e 56% of them had average knowledge on dengue fever and its control measures. Has the study is limited to only rural area and it would have been better to assess the practice of vector control measure.

A Propitous Genetic Impact on Neurodevelopmental Disorders - A Flagstone for Personalized Medicine

Sujitha P.J[1], V. Gomathi[2]

[1]PhD Research Scholar, Department of Pharmacology, Vinayaka Mission College of Pharmacy, Salem, Tamil Nadu, India. [2]Associate Professor, Department of Pharmacology, Vinayaka Mission College of Pharmacy, Salem, Tamil Nadu, India

Abstract

There has been a precipitous advancement of unequivocal technological and methodological upgradings in genetics and genomics, thereby allowing to identify atypical mutations that are involved in complex neurodevelopmental conditions. Neoteric advancements in genomics such as whole – exome or whole genome sequencing have endorsed scientist to identify extensive mutations underlying NDDS. In this review we are recapitating the new-fangled developments in genomic analysis and deciphering it into clinical practice.

Key Words: *genetics, whole – exome sequencing, whole genome sequencing, genomics, neurodevelopmental conditions, NDD*

Introduction

One among the prominent health problems existing in paediatric health care is neurodevelopmental disorder (NDD).[1] About 3 percentage of the general population is to be posed by some form of NDDs.[2] Moreover, the spread of the disease is increasing significantly in people with poor socioeconomic status and health care, especially in the developing countries.[3] NDDs can be defined in a wide term for a multifarious group of conditions symbolized by disability in cognition, communication, behaviour and motor skills, because of abnormal brain development.[4,5] There are no curative pharmacological treatments for cognitive delay.[6] Thus, children with NDDs usually undergo treatment with a collage of rehabilitative therapies and early intervention strategies to optimize their developmental potential. NDDs could be categorized based on defects such as intellectual functioning, speech, language, and fine motor skills, and could coexist with a recognized syndrome. The existence of minor dysmorphism (facial and other superficial physical abnormalities) / multiple congenital anomalies (MCA) may coexist with symptoms of NDD in some instances. In patients with NDDs, the most common clinical features are intellectual disability (ID) or developmental delay (DD), voice delay (VD), linguistic delay (LD) and autism spectrum disorder (ASD). NDDs in children include attention-deficit/hyperactivity disorder (ADHD), autism, learning disabilities, intellectual disability (also called as mental retardation), conduct disorders, cerebral palsy and impairments in vision and hearing. The real dimension of the issue is mainly difficult to evaluate due to disorder definition, sampling processes, tool variations, cultural and environmental differences, training of information collectors and disorder awareness.[7,8] It has been proposed that 85% of children with neurodevelopmental illnesses live in low – and middle income nations, but little information is available to support this. The incidence of neurodevelopmental disorders in India, a study carried out by members of the International Clinical Epidemology Network (INCLEN) disclosed that 10 percent hilly area, 13 percent urban areas and 18 percent rural areas were found to have one or more NDDs in children aged 2 to 9 years. The tribal prevalence was 4.96%, possibly reflecting lower infant

and child survival.[9] A significant interplay between environment and genes is also required to explain complicated NDD etiology associated by abnormality in brain morphology and/or functional activity, including those with a strong genetic element. maternal infection, chemical pollutants, dietary factors, medications, stress, deprivation are the various environmental irritants which may impede with typical brain development pathways, eventually augmenting the chance of either subclinical neuropsychological changes or clinical situations such as learning disabilities, autism spectrum disorders (ASD)[10] and attention deficit / hyperactivity disorder (ADHDs).

Pathology

Astrocyte dysfunction that affects neural circuit development is widely accepted pathomechanism of NDD.[11] Variations in exact timing of the neurogenic to glyogenic switch can lead to death or surplus of astrocytes, which leads to reduction of neuronal survival, synapse formation or limit the available number of neurons to contribute to specific circuits. Discharge of toxic factors or absence of survival or/and synaptogenic signals may precipitate pathogenesis of neural circuits.[12] MRI studies of autistic and normal patients showed brain abnormalities such as hyperplasia of cerebellar white matter, neocortical gray matter and cerebellar white matter in young age which slowed the growth further.

Role of Genetics in NDD

Inch - perfect technological and methodological breakthroughs in genomics have been rapidly evolving, enabling for the detection of mutations engaged in complicated neurodevelopmental disorder. A study exploring gene to phenotype connections for neurodevelopmental disorders classified genes centered on the particular disease were annotated and confirmed that genes connected with various diseases tend to be more multifunctional than specific (mentioned in Table 1). Also genes associated with Fetal Alcohol spectrum Disorder (FASD) were more multifunctional than Autism Spectrum Disorder (ASD) or Cerebral Palsy (CP).

Microarray based technologies for comparative genomic hybrization analysis has permitted the unmasking of submicroscopic microdeletions or microduplications also known by copy number variations (CNVs). Comparative genomic hybridization inquests suggest that rare copy number variations at numerous loci are muddled in the inducement of mental retardation, ASD and schizophrenia. These studies shows that the rearrangements were not disease specific, with possible oddment of maternally derived 15q13 duplication of gene TSPAN7, previously shown in MR and ASDs was spotted in case with schizophrenia.[15]

Animal Models of NDD

Animal models for NDD focus on a four tiered approach such as

i. Scoring for morphological changes in neural cells and in brain regions.

ii. Examination for alterations in brain activity and connectivity.

iii. Neurological behaviours such as sensory alteration, motor abnormalities and seizures.

iv. Higher order behaviour such as learning and memory or social behaviour changes etc.

Traditional models include environmental models such as neonatal brain infection using borna virus, [16] prenatal exposure of valproic acid in rodents, [17] prenatal influenza model, [18] LPS induced model[19] and thyroid models[20] for cerebellar dysfunction which causes NDD.

Genetic Models [21,22,23]

Various models for autism include staggerer mice (mutation of retinoic acid receptor related orphan receptor alpha gene), [24,25] SHANK3 (gene encodes for a post synaptic protein) existing shank3 models have not yet directly inspected on cerebellum, it is expressed in granule cells,[26,27] ENGRAILED2-En2 (involved in development of hind brain and cerebellum, it demonstrate decreased play, social behaviour, increase aggressive behaviour),[28,29] FMR1 (Gene encodes for fragile X mental retardation protein),[30,31,32] $FOXP_2$ (transcription factor, mutation causes excruciating speech and language disorder).[33,34] Tuberous Sclerosis Complex due mutation in TSC_2[35,36] and GABA receptors[37,38] are also studied in autism animal models. Genes studied in schizophrenia model involves G72/G30, [39, 40] Df (16) AKO, [41] DISC1.[42,43]

Although latest improvements in psychiatric genetics and epidemiological research have facilitated development of animal models, very few models have explicitily researched the impacts of mutation or environmental variables in cerebellum. More study

should be conducted in models to gradually regulate concentrations of expression of risk variables in purkinjee cells, as well as concurrent manipulation of genetic risk variables in the cerebellum and frontal cortex to decipher the function of separate brain linkages.[44]

Treatment For NDD

Conspicuous progress has been produced in defining the neurobiological processes of several diseases and the outcome of these diseases are being modified by targeted treatments.[45] A massive collaborative study from a various institutions, department, medical colleges, NGOs throughout India and USA, found the ubiquitousness of NDDs to be nearly 12% in Indian children of age group 2-9 years. Close to 1 in 8 chidren are suffering from not less than one of the NDDs. Recent advances suggest that through manipulations of environment or pharmacotherapy period - like plasticity can be reactivated in the adult brain. These scrutinies explore a tantilizing option that targeted pharmacological treatments in conjunction with training or rehabilitation schemes could relieve or reverse NDD symptoms even after critical department periods have ended. [46]

Personalised Therapeutic Approaches for NDDs:

Exposing various molecular pathways to evaluate novel therapeutic strategies became possible owing to the coalescence of genetics and functional analysis. Genomic sequencing guides the way from patient DNA to personalized medicine. DNA from patients with NDDs are used for sequencing, next generation sequencing which will be used to decipher the genetic code within exons (Whole Exom Sequencing) or entire genome (Whole Genome Sequencing). Mutations are identified in a series of genes with NDDs. The mutations are reinvigorated in various models in order to understand underlying mechanism which reveals targets that endorse the implementation of personalized medicine. Branched chain amino acids (BCAA) and antisense oligonucleotides (ASO) are two examples. The use of same drug for different diseases are used in drug repurposing due to novel mechanisms identified.[47] For example, Angelman syndrome which results from the functional mutations in the maternal allele of the imprinted UB3A gene or paternal allele is silenced by a lengthy noncoding RNA (UBE3A antisense transcript). In an AS mouse model study, reserachers have incorporated antisense oligonucleotides (ASOs) for unsilencing the maternal allele thereby normalizing the UB3A protein concentrations which resulted in the improvement of cognitive functions.[48] Replacing a defective gene may also be carried out by gene therapy using adeno – associated virus (AAV) vectors.[49] The application of antisense oligonucleotides and adeno – associated virus is challenging in clinical trial since safety and pharmacokinetic profile is not well established.[50]

Stem Cell Therapy in NDDS

A common motif among NDDs is a reduced capacity of affected Neural Stem Cells to proliferate, differentiate and migrate. Recent pluripotent methods have effectuated the possibility of modelling neurodevelopmental diseases integrated with genetic impairments. Patient fibroblasts were transformed into pluripotent stem cells to produce adequate neuronal progeny, specifically the cortical neurons which is responsible for higher cognitive skills in humans.[51] Induced pluripotent stem cells (ipsc) has provided new privileges for analysing brain development and the countrecoup of its dysfunctions in NDDs. Also it facilitated the analysis of neuronal phenotypes after the derivation of patients somatic cell into neurons, besides it is used in-vitro in case of syndromic and non-syndromic forms of ASD[52] and shankopathies(mutation of SHANK genes).[53] iPSCs are also used in reconstruction of brain circuitary using neural transplantation of human neurons into mouse brain.[54]

Main limitations of human iPSC cells in vitro: the cell reprogramming rate relies on cell types of the donor and culture conditions.[55] Various models are proposed to analyse the programming processes and transcription factors and epigenetic regulators and their role.[56] These techniques do not come across as sufficiently effective to reprogram human primary fibroblasts accurately.[57] A fresh, optimized technique combining mod mRNA with reprogramming variables and enhanced cell culture[58] environments is encouraging and appears to provide an alternative strategy to human fibroblast reprogramming for ASD and associated syndromes.[59] The low cell reprogramming efficiency observed to date has made it much harder to simultaneously derive separate isogenic cell kinds from the same human iPSC. In vitro systems do not permit the reproduction of globular cellular homeostasis and cell orientation and projections within the separate cortical layers. New movements which include three-dimensional culture systems[60] and brain organoids [61] have been developed for iPSC models. In addition, advances in genome editing technologies allow the genetic manipulations of iPSC in a site-specific way.

Conclusion

At current scenario, the treatments available for NDDs consists of both behavioural therapies and drugs for comorbidities such as irritability and anxiety, while in most cases the mainstay symptoms of NDDs are still unsolved. Numerous molecular pathways being identified in NDD which resulted from the combination of genetics and functional analysis. Genetic findings made personalizing the existing pharmacotherapy or behavioural interventions other than new targets for therapy. Because of the complexity of NDDs, versatile methods that combine genetics, functional genomics, robust biological models and objective reaction measures such as biomarkers,[62] as well as scientists and clinician's potential to work together will be crucial.

Impact of Cancer Related Fatigue on Health Related Quality of Life in Cancer Survivors

Supriya S. Jadhav[1], T. Poovishnu Devi[2]

[1]Final year BPTh Student, [2]Associate Professor, Department of Oncology. Krishna College of Physiotherapy, KIMSDU

Abstract

Background: Cancer related fatigue is multidimensional and has a negative impact on physical, mental, emotional and social health. Most of the time cancer related fatigue is under-reported by patients and under-treated by clinicians, and it may hamper the quality of life in cancer survivors. This study focusses on assessing the impact of fatigue on health related quality of life in cancer survivors.

Objective: To find the impact of cancer related fatigue on health related quality of life in cancer survivors.

Material and Methodology: In this cross sectional study, 66 cancer survivors were enrolled between the age group of 40 and 70, who completed treatment 3 months prior to the study and scoring of fatigue between 3 and 10 in rate of perceived exertion scale. Thus SF-36 questionnaire was used to determine the impact.

Result: According to this study there is a decline of 61.81% in general health, 57.121% in physical functioning, 44.88% in role physical, 41.41% in role emotional, 40.57% in social functioning, 40.75% in mental health, 38.75% in vitality and 37.61% in pain. This indicates an overall decline in the quality of life of the cancer survivors which sums up to 51.46% with P value <0.0001, which considered extremely significant.

Conclusion: Many cancer survivors experienced moderate to severe fatigue which affects their health related quality of life. There is need to develop interventions for effective management of cancer related fatigue to improve quality of life.

Key Words: *Health related quality of life, cancer related fatigue, cancer survivors.*

Introduction

Cancer is the disease that results when cellular changes causes the uncontrolled growth and division of cells. There are many causes of cancer and some are preventable. Smoking is one of the most common cause of cancer. Cancer shows various local and systemic symptoms. Swelling, abnormal bleeding, pain and local skin changes are some local symptoms seen in cancer patients. While the systemic symptoms are fever, excessive fatigue, weight loss and generalized skin changes[12].

Cancer related fatigue is recognized as one of the most common and distressing side effects of cancer and its treatment[1]. Fatigue may also present before treatment onset and typically increases during cancer treatment, including treatment with radiation, chemotherapy, hormonal, and/or biological therapies. Prevalence of fatigue during treatment ranges from 25% to 99%[1]. Fatigue is subjective symptom and is the most bothersome adverse effect of cancer[4].

Cancer-related fatigue is more severe, more persistent, and more debilitating than "normal" fatigue caused by lack of sleep or overexertion and is not relieved by adequate sleep or rest. Studies showed that the intensity and duration of fatigue experienced by cancer patients and survivors is significantly caused greater impairment in quality of life. Cancer-related fatigue is multi-dimensional and may have negative impact on physical, mental, and social health including generalized weakness, diminished concentration, decreased motivation or, and emotional liability. Although

cancer related fatigue shares some characteristics with depression, patients experience fatigue as a central symptom that impairs functional abilities and social functioning[1].

Causes of cancer-related fatigue mainly includes any cardiovascular disease, low platelet count (thrombocytopenia), anaemia, any recent major surgery, fever or active infection. It also includes pain, emotional distress (depression, anxiety), sleep disturbances (insomnia, sleep apnoea), side effects of medications, nutritional disorders (dehydration, malnutrition and electrolyte imbalance), lack of exercise and myopathies, etc[2, 3].

Cancer may cause fatigue due to disturbed circadian rhythms. Circadian rhythms are exogenous or endogenous physiological patterns that run on an approximate 24-hour cycle and modulate several biological functions. It regulates the expression of genes with circadian rhythmicity, resulting in daily oscillations of proteins and is disrupted in cancer patients due to abnormal or uncontrollable cell division and tissue damage. This disruption of clock damages organization of gene and protein expressions, leading to deregulated cell proliferation[13, 14].

Altered circadian also includes changes in endocrine rhythms, metabolic processes, immune system and rest activity patterns. ATP is the major source of energy for contraction of skeletal muscle. Disturbed metabolism processes causes failure to replenish ATP and compromises muscle function[13, 14].

Fatigue in cancer is multifactorial and maybe influenced by a variety of demographic, medical, psychosocial, behavioural and biological factors[1]. Cancer related fatigue clinically presents with reduced physical performance, physical inactivity, avoidance of participation, feeling of helplessness, depressed mood[2].

In the majority of studies, 30% to 60% of patients report moderate to severe fatigue during treatment, which in some cases may lead to treatment discontinuation. Fatigue typically improves in the year after treatment completion. Studies of long-term cancer survivors suggest that approximately one-quarter to one-third experience persistent fatigue for up to 10 years after cancer diagnosis. Fatigue has a negative impact on physical activity, social functioning, emotional health, and activities of daily living and causes significant impairment in overall quality of life during and after treatment. Fatigue may also be a cause for shorter survival[1].

Despite the prevalence and negative impact of cancer-related fatigue, this symptom is under-reported by patients and undertreated by clinicians. One of the barriers to the assessment and management of fatigue is the lack of information about mechanisms underlying this symptom, risk factors, and effective treatments[1].

Quality of life is a major concern in cancer survivors. Cancer survivors experience many symptoms that affect their quality of life. The symptom that most commonly interferes with activity of daily living is fatigue. When compared with other symptoms, fatigue persist in a substantial number of cancer survivors. The different domains of quality of life such as physical and psychological well-being, familial relationship, sexual and personal abilities, economic well-being is hampered[5,10].

Methodology

This cross sectional survey was carried out on 66 subjects which were selected on basis of convenient sampling method. This study was done from Krishna hospital, karad and was completed in 6 months.

Statistical Analysis And Results

Statistical analysis of the recorded data was done. Study design is cross sectional. Arithmetic mean and standard deviation was calculated for each outcome measure. T test was done. The study has p value <0.0001 and is extremely significant.

Table 1- Scoring of the health related quality of life according to the scales

Scales	Mean
General Health	196.909
Physical Functioning	428.79
Role Physical	220.4545
Role Emotional	175.75
Social Functioning	118.86
Mental Health	298.21
Vitality	245.303
Pain	124.77

Interpretation

The graph shows decline in physical functioning, role physical, role emotional, vitality, mental health, social functioning, pain and general health. Thus, there is an overall decline in the quality of life in cancer survivors.

Table 2 – Mean and standard deviation.

Score Name	MEAN±SD
General Health	190.909±86.784
Physical Functioning	428.89±157.89
Role Physical	220.4545±100.38
Role Emotional	175.75±82.389
Social Functioning	118.86±31.142
Mental Health	296.21±41.496
Vitality	245.303±93.648
Pain	124.77±29.462

Discussion

Fatigue is the most commonly experienced in the pre-treatment and post-treatment phase. According to various studies, tumor and treatment methods used can induce fatigue. Fatigue in cancer is multifactorial and may be influenced by a variety of demographic medical, psychological, behavioral and biological factors. Fatigue lasts longer than other treatment side effects and is the symptom reported to interfere most substantially with activities of daily living. The health related quality of life in the cancer survivors shows a significant decline in various aspects of life. The areas where quality of life in cancer survivors is affected are: Physical functioning, Role physical, Role emotional, Vitality, Mental health, social functioning, Pain and General health. These are the components which determine the health related quality of life.

This study aims at finding the impact of cancer related fatigue on health related quality of life in cancer survivors. And the following factors were assed 1, the severity of fatigue and its effect on health related quality of life in cancer survivors 2, to find the type of cancer survivors who perceive more fatigue.

This study was completed with 66 cancer survivors of both the sexes who were between the age group of 40 and 70 years, completed treatment 3 months prior to the study, scoring of fatigue between 3 and 10 in the rate of perceived exertion scale.

This study was completed in 6 months of duration and was conducted in Krishna Institute of Medical Sciences 'Deemed to be' University, Karad. An informed written consent was obtained from the subjects were undergone a test using SF-36 questionnaire and according to the result, conclusion was obtained.

According to the survey the most commonly seen cancers in an around karad is leukemia, carcinoma cervix, oral cancer and lung cancer. Leukemia is a cancer of blood forming tissues including bone marrow and those survivors experienced more fatigue , 8.5 out of 10 according to rate of perceived exertion scale. Carcinoma cervix is another common cancer which had more fatigue. And followed by oral cancer and lung cancer. Most of the population in this geographical area are addicted to tobacco chewing, cigarettes and bidi smoking which results in lung cancer or oral cancer.

After analyzing the data, there is a decline in the different aspects of quality of life in cancer survivors. There is a decline of 61.81% in general health, 57.121% in physical functioning, 44.88% in role physical, 41.41% in role emotional, 40.57% in social functioning, 40.75% in mental health, 38.75% in vitality and 37.61% in pain. This indicates an overall decline in the quality of life of the cancer survivors which sums up to 51.46%.

Conclusion

This study concludes that the health related quality of life is severely affected in cancer survivors with moderate to severe fatigue. The data analysis concluded that there is more decline in general health, physical functioning, role physical and role emotional followed by mental health , social functioning, vitality and pain. According to this study an overall decline in the quality of life of the cancer survivors is up to 51.4%.

Conflict of Interest: The authors declare that there is no conflict of interest.

Ethical Clearance: An ethical clearance certificate was obtained from the Institutional Ethical Committee Krishna Institute of Medical Sciences Deemed to be University, Karad.

Acknowledgement: The authors would like to express their special gratitude towards all the patients that participated in the study. We would also like to thank our families and institution for their everlasting support which enabled us to continue our research activities.

Source of Funding: Self.

‘Health Isn’t Wealth’-An Indian Reality

Swati Soni

Associate Professor, Marketing, Jaipuria Institute of Management, Jaipur,

Abstract

An age old adage suggests that ‘Health is Wealth’, but unfortunately this is not the case in India. Health of an individual and consequently healthcare should ideally be non-negotiable, but health care in India is a relegated reality. There is no equity. There is no access to affordable healthcare. On one hand India is poised to become a medical tourism destination by 2020 while on the other hand the masses have no anchor. Health insurance can salvage the situation but somehow the concept is undersold and there is a very weak conviction even amidst the elite to buy adequate insurance. Most Indian households are either uninsured or underinsured. Out-of –pocket expenses on healthcare are thus on a rise. The authors draw attention on the Indian healthcare industry and suggest that lessons can be drawn from the models prevalent in Japan and Netherlands. The authors build a strong case for a mandatory health insurance for the masses and propose a model for the same.

Keyword(s): *Healthcare, Health Insurance, Healthcare Expenditure*

Background

Healthcare should ideally be non-negotiable, but access to affordable and acceptable healthcare is a privilege for only an esoteric few in India, with 67% of the Indian rural population living in abject denial. For these 67% of masses, healthcare means standing for hours in a queue irrespective of the urgency and immediacy of the situation. Additionally, 60 million people, which approximately equates to the size of the population of UK, go overdrawn while accessing the health care in case of medical exigencies and thus forced below the poverty line. India is infamously renowned to have the world’s lowest public health budgets, which is a little more than 1 % of the country’s Gross Domestic Product (GDP) while out- of- pocket (OOP) expenses are substantial percent of the total cost of health care. Indians spend highest on healthcare in terms of out – of – pocket expenditure in the world. The exorbitant OOP spending on healthcare coupled with a very meagre penetration of health insurance, make health care for all a formidable challenge.

A personal Finance Advisory firm, Big Decisions, in a December 2016 survey revealed that only 18.8% of middle-income urban Indians have a health insurance which is fairly low.[1] The 17.8% insured are also inadequately insured-as the cover is barely enough to meet less than 67% of their medical exigency expenses. Inadequate coverage translates into substantial out of pocket expenses. A review of about 9 lakh claims spanning across a period of five years shows a strong decline in claims received as compared to the actual treatment cost incurred. The gap witnessed a substantial I increase, when the treatment costs was more than Rs 3 lakh per treatment. For instance in the year 2015, for a treatment cost above 10 lakhs close to 30 and claims were received, while almost 85% claims were received for below Rs 3 lakh treatment expenses.

Medical inflationary trends have made healthcare much more unaffordable than ever before. Between 2011-2016, treatment costs of communicable diseases and vascular diseases both have increased by 9.3%, and 2-13% per year respectively. Lifestyle diseases too are at an all-time high. Ironically enough, owning a health insurance has become costlier at a time when it is most needed. The cost of health insurance premiums (for a two member family) post the age of 35 years has soared by the range of 9-16%. The figures indicate that though owning a health insurance at an early age makes a lot of economic prudence, but it’s too less and too late.[2]

Indian Healthcare- At an Intersection

Reports suggest that India is all poised to become a corridor for health with a USD 8 million market for medical tourism by 2020. This is largely attributable to

the emergence of accredited healthcare infrastructure-second largest in the world led by Thailand. This is indeed a glaring paradox because while we are all set to cater to a medical tourist, our own denizens are pushed to an edge for want of an affordable, acceptable, accessible health care. The schism is wide and the two extremes never seem to meet. A little ray of hope in the abyss is a noteworthy improvement in a few health indicators viz. life expectancy, maternal mortality, and infant mortality rate (Refer Table 1) but the health care expenditure indicators still seem to be very disparaging when compared the other countries in the world (Refer Table 2).

Table 1: Comparative Health Indicators

Health Indicators (2014)	**India**	**Indonesia**	**Brazil**	**China**	**Thailand**
Life Expectancy (LE)	68	69	74	76	74
Infant Mortality Rate (IMR)	39	24	14	10	11
Maternal Mortality Ration (MMR)	181	133	46	28	21

Note: LE at birth is in years; IMR is per 1000 live births; MMR is per 1, 00,000 live births

Source: World Bank Data, the World Bank website, https://data.worldbank.org/,accessed in 3 Sept, 2017.

Table 2: Comparative Health Expenditure Indicators

Healthcare Expenditure Indicators (2014)	India	Indonesia	Brazil	China	Thailand
Health Expenditure per capita(Purchasing Power Parity)	75	100	948	420	360
Public Health Expenditure (as a percentage of Total Health Expenditure)	30	38	46	56	86
Private Health Expenditure (percentage of Total Health Expenditure)	70	62	54	44	14
Health Expenditure, Public (percentage of Govt. Expenditure)	5	6	7	10	24
OOP Health Expenditure(percentage of Total Health Expenditure)	62	47	26	32	8
OOP Health Expenditure(percentage of Private Expenditure on Health)	89	75	47	72	57

Note: OOP health expenditure is the percentage of private expenditure on health.

Source: World Bank Data, the World Bank website, https://data.worldbank.org/,accessed in 3 Sept, 2017.

Current Challenges

High out-of-pocket expenditure contributes to 89% of the total private expenditure on health (Refer Table 2). This is an obvious social burden and Universal Health Coverage (UHC) is seemingly the only possible way out. Public spending on healthcare is one of the world's lowest at just 1.3

% of the GDP (Refer Figure 1).

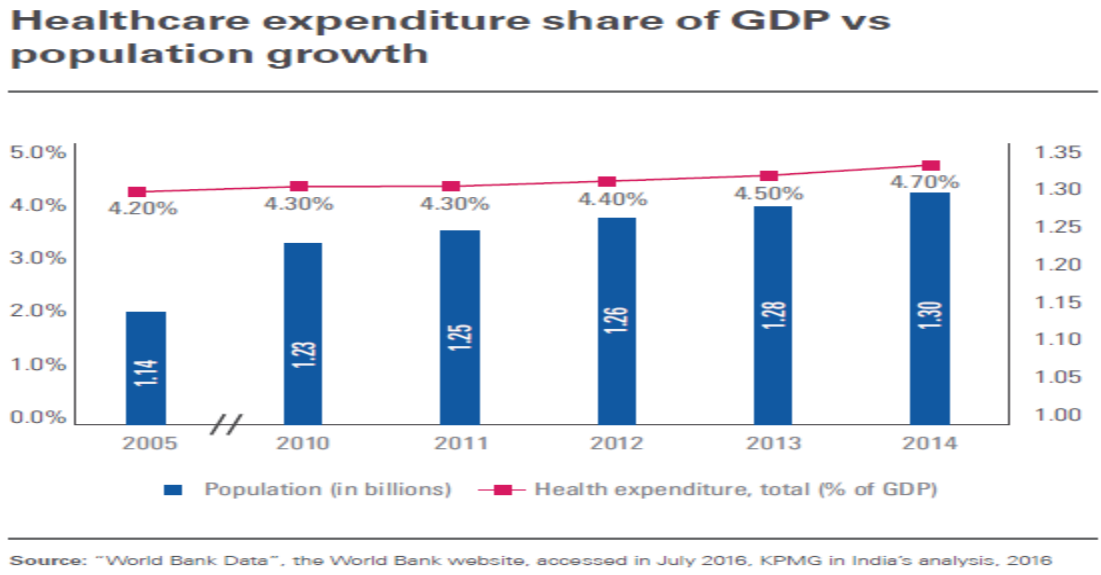

Figure 1: Healthcare Expenditure as a percentage of GDP vs. Population Growth

Source: World Bank Data, the World Bank Website, accessed in Sept, 2017

The last decade has witnessed a population rise of more than 15% while the healthcare expenditure as a percent of GDP has seen a very marginal rise from 1.14% of GDP in 2005 to 1.30% of GDP in 2014. A rise of a meagre 0.16% in a decade- when the country facing the dual burden of an increased incidence of both communicable diseases and lifestyle diseases shall serve little good. (Refer Table 3).

Age Standardized Mortality Rates by Causes (Per 1, 00,000 Population)

Source: NSSO, WHO

Additionally, there is a serious dearth of infrastructure and shortage of skilled professionals. India has only 0.9 beds per 1000 individuals while the same is 2.9/1000 globally and WHO recommended standard is 3/1000. There is a significant inequity in the distribution of this deficient health care ecosystem, which is conspicuous by its very absence in the rural areas. 75% of the available healthcare infrastructure is an urban delight, with those who need it the most being deprived of the most of it.

The Netherland Experience

The Euro Health Consumer Index, 2015 rates the Netherlands as the best healthcare provider in Europe. The Health Insurance Act 2006, mandates every resident and payroll tax payer should enjoy a mandatory health insurance cover.[3] The new act has also terminated the distinction between sickness funds and private health insurance. Now, a single health insurance scheme is in place to cover the entire population. An element of market competition is evident as the health insurers must compete aggressively on type of policy, quality care and premiums. The consumers are empowered to choose the service provider and the policy. No insurer can ever refuse an applicant and deny access, or charge a greater premium or exclude waivers for pre-existing ailments. Insurers are mandated to fix a single and universal premium rate for every type of health policy in order to preempt any unfair competition. Additionally, all insured are required to pay a premium which is related to their income. This premium is fixed by the government as 6 percent for the employed citizens and 4.4 percent for the self-employed citizens. The income level above which an income-related premium has to be paid is Ä30,000. The premiums do not vary with age, gender, past disease history or future risk. This ensures equity and a 30 year old healthy adult pays the same premium as an 80 year old risk prone and disease exposed individual. Children under 18 have a state sponsored premium. Subscribers with relatively low income levels receive a "health insurance subsidy" by the government to facilitate them to purchase a policy.

Learning from Japan

The law mandates every citizen to be covered with health insurance. Those who are employed are covered by a work scheme and the self-employed and the unemployed are mandated by the government to insure themselves under the national health insurance scheme run by the government. The premium is based on a mix of factors-viz. income level, number of dependents to care for and a valuation of the titled property. Subscribers pay only 30% of cost of inpatient and outpatient expenses, including emergencies, whilst a balance of 70% is sponsored by the government. Senior citizens above 70 years are expected to pay only 10% of the expenses, with the balance being borne by the government.

Health for All-The Road Ahead

Health for all is an unfinished agenda in India. There are challenges galore-ranging from lack of finances and infrastructure to lack of awareness. Publicly financed services are thus no panacea to answer the fiscal burden faced by the financially challenged. The government schemes have not been able to work wonders owing to lack of awareness amongst the beneficiaries regarding the provisions, entitlement and the modus operandi involved to avail benefits. India needs an urgent and

immediate revamp of the existing healthcare strategy with a strong focus on newer financing options.[4]

The pertinent questions are:

- How can a country with world's second largest population see a high penetration of health insurance?
- How can every household be reasonably to be able to afford a decent access to health care in case of unforeseen health contingencies?

The answer indeed lies in Mandatory Health Insurance. These is a seemingly brilliant idea to circumvent the likely disaster that is imminent in the absence of health for all. Mandatory health insurance is a kind of system under which cost of healthcare for enrolled members of the population is borne by the government and government mandate for compulsory enrollment for all the members of a population.[5] An innovative micro insurance model needs to be explored to insure those who lie in deprivation at the bottom of the pyramid. A platform that enjoys 'credence' and has a 'wide reach' needs to be identified. A plethora of such public and private platforms are available. For example at a very meagre amount of Rs. 1 per day (Rs. 360 per year) per D2H subscriber base of 56 million household subscribers, a huge corpus can be generated that can provide a health cover to the 200 million deprived households. This is a holistic and inclusive model where all pay for their care.[6]

A Proposed Model

Insurer	**Platform**	**Beneficiaries**
Provides Health Insurance Policies	An interface between insurer and insured and collects premium on a monthly basis	Bottom of the pyramid households
Public Sector Insurance Companies Public-Private-Partnership Based Insurance Companies	Telephone subscribers>one billion D2H Subscribers>56 million	200 million deprived households

If all the members get covered by a mandatory equity instrument, the price of premium shall become affordable to the masses, irrespective of the risk one entails. Buying a health cover is any time a better option than spending all savings on treatment and getting pushed to abject poverty. Not only is this a prudent proposition for the financially disadvantaged, but also for the so called affluent kinds, who have still not voluntarily bought the idea of health insurance. They take pride in buying airline tickets of Rs. 10,000/ but still resist the idea of a health insurance cover. Studies reveal that in next 30 years there shall be an increased incidence of respiratory diseases, thanks to the alarming pollution levels, and also lifestyle diseases owing to the sedentary lifestyles of the masses. Government should make health insurance mandatory for this segment of the population, or else it would see them quietly slipping into lower economic strata owing to unforeseen expenses on health contingencies.

Drawing a Leaf from the Auto Insurance Regulation

The health care industry needs to draw a leaf from the auto insurance regulation. The Motor Vehicles Act 1988 mandates that any vehicle released from the showroom has to be insured before it can venture on the Indian roads. The idea behind the mandate is risk mitigation. The mandatory insurance helps in dispersing the cost of premium and making it affordable to all subscribers. The premium paid by one subscriber helps in providing coverage to another subscriber who has incidentally met with an accident. A palpable and pulsating human life is indeed dearer than any vehicle chugging on the roads! If the government can be so austere about a vehicle

being insured, what stops from making health insurance mandatory for the masses?

Concurrent Strength Training with Yogasana Practices on Power Parameter of Women Hockey Players

T. Priya[1], K. Muralirajan [2], K. Alaguraja[1], K. Selvakumar[1]

[1]Research Scholar, [2]Professor, Alagappa University College of Physical Education, Alagappa University, Karaikudi, Tamilnadu, India

Abstract

The purpose of the present study was to investigate the efficacy of concurrent strength training with yogasana practices on power parameter of women hockey players. To achieve the purpose of the study thirty women hockey players were selected from Karaikudi, Tamilnadu, India during the year 2019. The subject's age ranges from 18 to 25 years. The selected subjects were divided into two equal groups consists of 15 women players each namely experimental group and control group. The experimental group underwent combined concurrent strength training and yogasana practices programme for six weeks. The control group was not taking part in any training during the course of the study. Leg explosive power was taken as criterion variable in this study. The selected subjects were tested on leg explosive power was measured through standing broad jump. Pre-test was taken before the training period and post- test was measured immediately after the six week training period. Statistical technique't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference is found due to combined concurrent strength training and yogasana practices given to the experimental group on leg explosive power when compared to control group.

Keywords: *concurrent strength training, yogasana practices, leg explosive power and 't' ratio.*

Introduction

Explosive strength is essential factor that can be determined the performance of the hockey players during the particular actives. Concurrent strength training made a unique method for promote the strength of an individual. Yoga is a great soul of the Universe. It can promote the social well being through limps of yoga (Asanas, Pranayama, Kriyas, Mudras and Meditations). To practising yoga regularly it can make you into sound body and sound mind. Yoga is the costless permanents treatment for more diseases, alaguraja, k[1]. It is a practical holistic philosophy designed to bring about profound state as well is an integral subject, which takes into Consideration man as a whole, alaguraja, k. et.al[2].

One can start practicing Yoga at any given moment of time and you may start with meditation or directly with pranayama without even doing the asanas (postures), alaguraja, k. et.al,[3]. The science of Yoga Nidra is based on the receptivity of consciousness. When consciousness is operating with the intellect and with all the senses, by making an individual think that he or she is awake and aware, but the mind is actually less receptive and more critical, yoga, p. et. al.,[4]. Training is a chain process that can be able to attain certain needs of the person's goal, alaguraja, k[5]. In the sports world, physical education is the most essential aspect due to the fact physical schooling increases the performance and the effectiveness of the sports, alaguraja, k. et.al.,[6]. Today, sports have become a part and parcel of our culture. It is being influenced and does influence all our social institutions including education, economics, arts, politics, law, mass communication and even international diplomacy, alaguraja, k. et.al,[7]. The sports training can produce some physical fitness, Physiological and psychological benefits to the person and attain performance related task. It's also promoting the individual overall wealth to the sports person, alaguraja, k.[8]. Yoga is a methodical effort towards self-perfection by the development of the potentialities latent in the individual, alaguraja, k. et.al,[9]. Today's there is an escalating emphasis on appearing smarter, feeling better and living longer. In order to

achieve these ideals as, scientific evidence tells us that one of the keys is high fitness and exercises, alaguraja, k. et.al,[10]. Asanas is a limp of Yoga practice it can make some health related gains to the individual who involved in yogasana practice regularly. Asanas can be used upon the needs of the person. It's a scientific process the person must be follow the basic principles yogasana practice, alaguraja, k.[11]. Yoga is a practical aid, not a religion and its techniques may be practiced by Buddhist, Jews, Christians, Muslims, Hindus and Atheist alike. Yoga is union for all, selvakumar, k. et.al,[12]. Yogic action, or inner technique, such as breath control, parthasarathy., s. et.al,[13].

Research Methodology

Selection of subjects

The purpose of the study was to find out the combined effect of concurrent strength training with yogasana practices on power parameter of women hockey players. To achieve this purpose of the study, thirty women hockey players were selected as subjects at random. The age of the subjects were ranged from 18 to 25 years.

Selection of variable

Independent variable

- Combined concurrent strength training and yogasana practices

Dependent variable

- Leg Explosive Power

Experimental Design and Implementation

The selected subjects were divided into two equal groups of fifteen subjects each, such as a concurrent strength training and yogasana practices group (Experimental Group) and control group. The experimental group underwent combined concurrent strength training and yogasana practices for five days per week for six weeks. Control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following power parameter namely leg explosive power was selected as criterion variable. All the subjects of two groups were tested on selected criterion variable leg explosive power was measured through standing broad jump at prior to and immediately after the training programme.

Statistical technique

The't' test was used to analysis the significant differences, if any, difference between the groups respectively.

Level of significance

The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

Analysis Of The Data

The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent 't' test was used with 0.05 levels as confidence.

Table I: Analysis of t-ratio for the pre and post tests of experimental and control group on Leg explosive power (Scores in mm Hg)

Variables	Group	Mean		Degree of freedom	't' ratio
		Pre	Post		
Leg explosive power	Control Group	1.75	1.76	14	0.39
	Experimental Group	1.76	1.82	14	16.99*

**Significance at 0.05 level of confidence.*

The Table-I shows that the mean values of pre-test and post-test of the control group on leg explosive power were 1.75 and 1.76 respectively. The obtained 't' ratio was 0.39, since the obtained 't' ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of the experimental group on leg explosive power were 1.76 and 1.82 respectively. The obtained 't' ratio was 16.99* since the obtained 't' ratio was greater than the required table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant.

Result of the Study

The result of the study showed that there was a significant difference between control group and experimental group in systolic blood pressure. It may be concluded from the result of the study that experimental group improved in leg explosive power due to six weeks of combined concurrent strength training and yogasana practices.

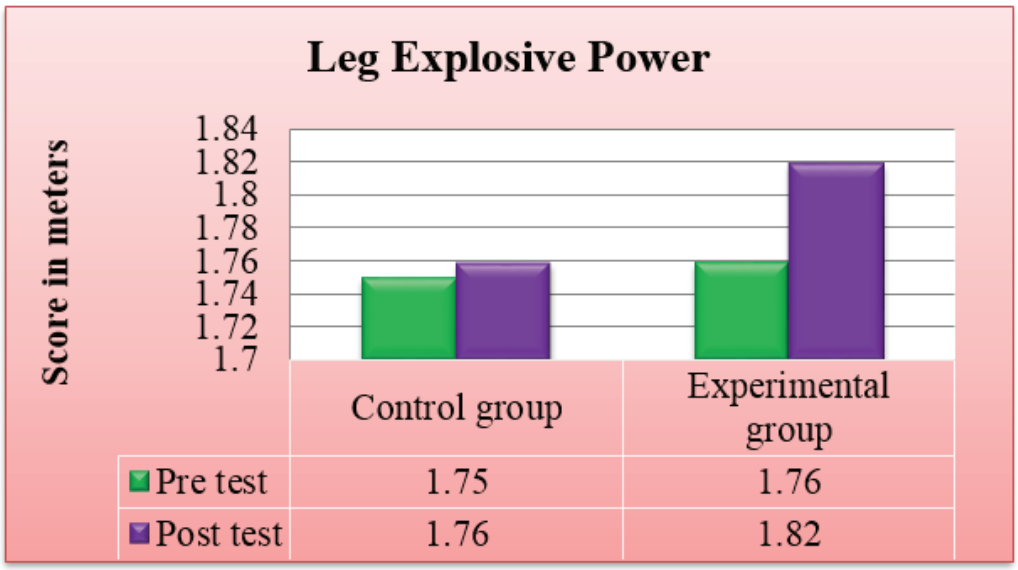

Figure-1: Bar Diagram Showing the Pre and Post Mean Values of Experimental and Control Group on Leg explosive power

Discussions on Findings

The result of the study indicates that the experimental group, namely combined concurrent strength training and yogasana practices group had significantly improved the selected dependent variable, namely Leg explosive power, when compared to the control group. It is also found that the improvement caused by combined concurrent strength training and yogasana practices when compared to the control group.

Conclusion

On the basis of the results obtained the following conclusions are drawn,

1. There was a significant difference between experimental and control group on leg explosive power after the training period.

2. There was a significant improvement in systolic blood pressure. However the improvement was in favor of experimental group due to six weeks of combined concurrent strength training and yogasana practices.

Female Smoking: A Rising Concern in India

Tania Mukherjee[1], Patralika Bhattacharjya[2], Sakhi Roy[2].

[1]Post Graduate Student, Amity School of Economics, Amity University West Bengal, Kolkata

Abstract

Cigarette smoking is the dominant form of tobacco use across the world. There is growing concern about to the increasing trend of female smoking in India. The overall female smoking is growing at a faster rate than male, which is an emerging concern and requires attention of policy makers. A recent WHO report stated that, 'in quickly developing India, female cigarette smoking exists mainly among the urban elite classes of large cosmopolitan cities, which may reflect women's aspiration to 'equal' the social position of men'. Our result suggests smoking cannot be defined with education, and for occupation cigarette smoking is mostly among the higher income groups whereas bidi, gutkha are mostly among the low-income groups.

Keywords: *Female Smoking, India, Trends.*

Introduction

Around 42.4% of men, 14.2% of female and 28.6% (266.8 million) of all adults in India currently use tobacco (smoke and/or smokeless tobacco)[11] .The World Health Organization predicts that India will have fastest rise in death rates for tobacco use in the first two decades of 20th century and most death will be at the productive years of adult life. Tobacco use imposes a significant economic burden on society. The burden caused by tobacco use more than outweighs the economic benefit from their manufacture and sale. India is the second largest consumer of tobacco products and third largest producer of tobacco in world. Each year more than five million deaths are there in the world for consuming any form of tobacco.

Cigarette smoking is the dominant form of tobacco use all across the world. When a person smokes, a dose of nicotine reaches the brain within about ten seconds. At first, nicotine improves mood and concentration, decreases anger and stress, relaxes nerves and reduces amount of food we consume every day. Regular doses of nicotine lead damages to the brain, which then lead to nicotine withdrawal symptoms when the supply of nicotine decreases. Smoking temporarily reduces these withdrawal symptoms and can therefore boost the habit. This cycle is how most smokers become chain smoker. Social and psychological factors play an important part in keeping smokers smoking.

For past two decades female smoking has become rising concern in developing and also developed countries[4,8,9]. The prevalence of female smoking is likely to rise to 20% by 2025 worldwide. It is observed that for females who smoke cigarettes daily, there is increased effect for infertility, still birth and also sudden infant death syndrome (SIDS). Studies showed that the possible risk of fatal breast cancer rises up to 75% for women who smoke two or more packs regularly.[5] Smoking behavior of women differs from that of men[11] . Females are more motivated to smoke and find it hard to quit.

We have focused on this topic because women are the one who gives birth so the entire future generation is dependent on them and if they continue smoking then not only, she suffers but also the new born as smoking significantly damages reproductive organs of females.

The *objectives* of this study is to find out

(i) the trend of female smoking in India,

(ii) Analyze the number of cigarettes smoked on average per day according to age, gender, education and occupation, whether smoking imitation is high among

Corresponding author:

women than men,

(iii) Conduct a correlation and regression analysis to understand the determinants of Smoking in India. We check weather Education and Working status has effect on the cigarettes smoked by females.

Materials and Method

This paper is descriptive and analytical both and is based on secondary data of NSS 50 (1990), NSS 52 (1993), NFHS 2 (1998), NFHS 3 (2005), GATS 1 (2009), GATS 2 (2016) ,where NSS is Nation Sample Survey, NFHS is National Family Health Survey and GATS is Global Adult Tobacco Survey (an initiative of World Health Organization). From that perspective this paper is qualitative and quantitative both. For correlation and regression analysis data is used NFHS 3 (2005), as the latest raw data of NFHS4 (2016) is not available. Here we have used multiple correlations and then multiple regression. To estimate the joint effect of education in single years and females currently working, on cigarettes smoked in last 24 hours. Here regression equation is,

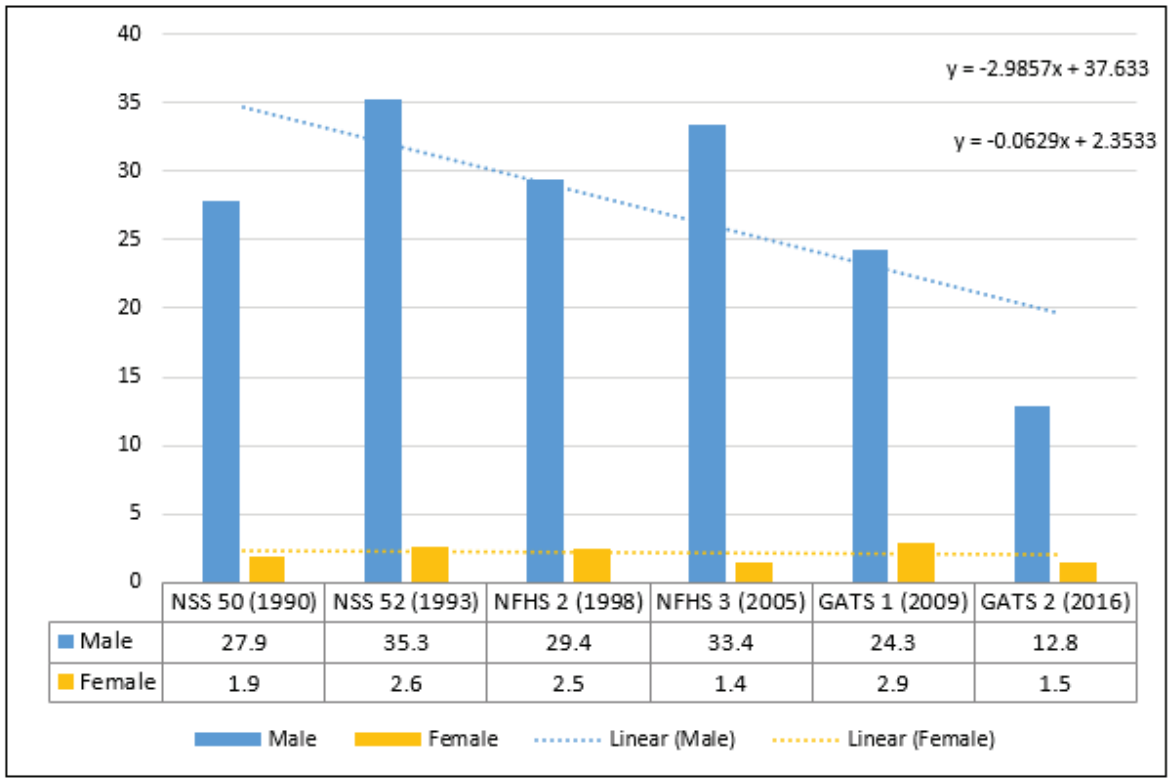
Where, is the dependent variable that is cigarettes smoked in last 24 hours, are the parameters of the model and is the error term,is education in single years, is females currently working. To run the correlation and regression model we have used the software STATA 12.

Findings

I. Smoking Trends among Women:

Figure 1 shows that smoking prevalence (in percentage terms) among male has an overall declining trend. During the period 2009-2016 there is significant decrease (24.3% -12.8%) in smoking trend among male. However, there is rising trend of female smoking during 2005-2009 (1.4-2.9), in 2016 there is a decrease in female smoking but it is greater than in 2005.

We show this data in a comparative bar diagram in Figure1. Here trend line shows the declining trend of male smoking and a steady trend line of female smoking.



Data Source: NSS 50 (1990)[7], NSS 52 (1993)[7], NFHS 2 (1998)[7], NFHS 3 (2005), GATS 1 (2009), GATS 2 (2016)

Figure 1: Smoking Trends according to Gender

Table 1 show that prevalence of female smoking is more among illiterate, which decreased with increasing years of schooling at different time periods. During the period of 2005-2009 smoking trend among illiterate people has risen from 3%-6%, in 2016 it decreased 3.3%, not so much significantly but smoking trend among literate women is fluctuating each year. Table 1 highlight that female illiterates are more prone to smoking, whereas smoking is much less among females who have ten years of educational qualification.

Retired or unemployed	52.2	32	8.2	5.3	2.3	100	5.7

Data Source: GATS 2 (2016)[2]

Table 2 present the percent distribution of daily cigarette smokers classified by number of cigarettes smoked every day. Overall, a typical cigarette smoker in India smokes an average of 6.8 cigarettes every day. The mean number of cigarettes smoked per day by men is 7.0 which is higher than by female (5.2). The frequency of cigarettes per day among rural smokers (7.2) is higher than urban smokers (6.3). Although, prevalence of smoking is less among young adults (aged 15-24 years), mean number of cigarettes smoked by young adults is 5.1. The mean number of cigarettes smoked per day decreases with increase in level of education—from7.3 cigarettes per day among those with no formal education to 6.5-6.6 cigarettes per day among those with primary or more education. The mean number of cigarettes smoked per day is higher among self-employed (7.0) cigarette smokers. The mean of number of cigarettes smoked per day by female is less than male, but 72.5% female smokes less than 5 times per day, which is much higher than male. 4% female smokes more than 25 times per day which is also higher than male. Here we can see that who smokes cigarette 5-9 times on average per day, are students. In extreme case of more than 25 times smokers are somewhat same in every occupation and gender.

III. Initiation of Daily Smoking:

Among 20 to 34 years old smoking initiation is high and associated with greater daily cigarette consumption. For this young people are facing early health hazards especially for women, who facing health hazards which are much more severe than men and also a threat to the society as it affects at the time of the child birth. In Table 3 we can see there that women are making initiation of smoking much more than men

Table 3: Initiation of daily smoking (age 20-34)

	2009-10	2016-17
Overall	17.9	18.9
Gender		
Male	18.1	18.8
Female	14.7	21.2

Data source: GATS (2009-10)[1], GATS (2016-17)[2]

Initiation of daily smoking is higher among female than men. Overall smoking initiation has risen to 18.9% in 2016-17 form 17.9% in 2009-10. According to gender, smoking initiation by men slightly has risen in 2016-17 than 2009-10 whereas female initiation of daily smoking has significantly risen in 2016-17, from 14.7% in 2009-10 to 21.2%.

IV. Smoking and Pregnancy:

Smoking and pregnancy are related to many effects on health and reproduction. This includes preterm birth, low birth weight, birth defects of the mouth and lip. On average smoking during pregnancy doubles the chances that a baby will be born too early or with weight less than 51/2 pounds at birth. GATS 2 data mentions that in India 1.3% pregnant women aged between 25-49 ages are currently smoking. 1.3% is not a big percentage but is not negligible.

Non-smokers who breathe in second hand smoking are affected almost as much as smokers. In day to day life people now are breathing smoke not fresh air. Non-smokers are also now suffering health issues related with lung, heart etc. Second hand smoking is more dangerous when it comes to pregnant women as they have to inhale the smoke and it effects as much as a woman who smokes at the time of pregnancy.

GATS 2 highlights that pregnant women are being exposed to second hand smoke. People are still neglecting the second hand dangers. At home 37.7% pregnant women are exposed to second hand smoke only in one month and at any public place 25.9% pregnant women are exposed.

Table 4: Percentage of pregnant women exposed to second hand smoke

	At home (in one month)	**At any public place**
India	37.7	25.9

Data Source: GATS 2 (2016)

V. Correlation and Regression Analysis

In order to find the association or interdependence, we use Correlation and Regression analysis. Here number of cigarettes smoked in last 24 hours is the dependent variable and education in single years and females currently working are independent variable.

Table 5: Correlation Results

	Number of cigarettes smoked in last 24	**Education in single years**	**Females currently working**
Number of cigarettes smoked in last 24 hours	1.0000		
Education in single years	-0.1484* (0.0000)	1.0000	
Females currently working	0.0309 (0.1928)	-0.1448* (0.0000)	1.0000

Author's own compilation.

From Table 5 we can see a negative correlation between number of cigarettes smoked in last 24 hours and education in single years. This means higher the education, lower the cigarette smoking among women. Higher education means women are aware of the health hazards due to smoking so they avoid it, and women with lesser education, due to lack of awareness- smoking is more among them. On the other hand, correlation between number of cigarettes smoked in last 24 and females currently working is almost insignificant. The correlation between Education in single years and females currently working is negative, but it is not possible and makes no sense, so we can say it is a spurious correlation, i.e., a relationship between two variables that appear to

have interdependence or association with each other but actually do not and often caused by a third unseen factor.

Regression Analysis:

In the regression analysis the dependent variable is number of cigarettes smoked in last 24 hours and independent variables are Education in single years and Females currently working. We find that Education has a statistically negative significant association with smoking.

The R-squared here is 0.023, which is interpreted as the ratio of the sample variation in number of cigarettes that is explained by variations in Education and working status of Females. A value of R square that is nearly equal to zero indicates a poor fit of the OLS line. Low R-squared in regression equations are not uncommon, especially for cross-sectional analysis.

Table 6: Regression Results

	Number of cigarettes smoked in last 24 hours
Education in single years	-0.270***
	(-6.70)
Females currently working	0.363
	(1.17)
Constant	6.896***
	(27.17)
N	1781

Rsme	6.519

t statistics in parentheses
*$p<0.05$, **$p<0.01$, ***$p<0.001$

Here goodness of the fit of the model is low also the data is quite old to interpret the present situation. As the latest raw data of NFHS 4 is not available to us so it is not possible to run a correlation, regression model so, we have used the available raw data of NFHS3 2005.More women are joining workforce and out of stress women are smoking more than before which we can see in the recent data of GATS 2016-17.

It is found that 'Casual and social smoking is on rise amid young working women'[10].The survey also found that only 2% of female are heavy smokers (smoking a pack a day or more), majority of them said that peer pressure and work-related pressure pushed them to increase number of cigarettes they smoked. Smoking for weight loss was also cited as a reason.

Conclusion

The findings of this study show a rising trend of female smoking. Less than 5 cigarettes smoked on average per day, is greater among female which suggests that females are not chain smokers. The study highlights that female illiterates are more prone to smoking, whereas smoking is much less among females who have ten years of educational qualification. Smoking cannot be defined with education or occupation, because most of the female smokers are working, so are aware of the health hazards. Smoking might be to relief their stress or to make an experiment or influenced by someone.

The reasons for smoking are mostly psychological. One might think that smoking among friends is glamorous, it helps to fit with the crowd, it feels sophisticated, and it shows independence of womanhood. Some also smoke out of depression and anxiety. Thus, addiction to nicotine makes it hard to quit smoking, but this addiction can be eliminated once the psychological reasons can be overcome. Females need to fight to have equal access to all opportunities and behaviors, without being judged or stereotyped for them, but that doesn't mean that they should do anything they can. Some addictions are best

avoided, even if they help smash a stereotype. It is time for them to create new "gender-neutral" norms that serve both genders better and help females to be their best version of themselves.

Conflict of Interest: Nil.

Ordinal Birth Order and Behavioural /Emotional Problems: A Study among Dyslexic Children in Kerala

Thomas M.V[1], Vinod Kumar S[2]

[1]Research Scholar, [2]Assistant Professor, School of Behavioural Sciences, Kannur University, Kerala

Abstract

Reading disability or dyslexia is a lifelong condition with an early childhood manifestation of inability to read. About 30% of learning disabled children have behavioural and emotional problems.(12) Birth order among the siblings is one of the important family dynamics which determine the psychological well-being of reading disabled children. **Objectives:** To find out whether any difference in behavioural/emotional problems exist between various birth order positions of dyslexic children. ***Design:*** Exploratory Design. ***Participants:*** Dyslexic Children studying in Malayalam Medium Lower Primary Schools. ***Sample Size:*** 122. ***Sampling Method:*** Purposive Sampling. ***Tools:*** Personal Data Schedule, Dyslexia Screening Checklist (Malayalam), Seguin Form Board, Specific Learning Disorder Diagnostic Tool (2) and CBCL. (1) ***Statistical Tests:*** Means, Standard Deviations and ANOVA. **Results:** The comparison of mean values of CBCL syndrome scales and birth order positions were not significant. **Conclusion:** The study concluded that the ordinal birth positions of dyslexic children could not make any alterations in the behavioural and emotional problems.

Keywords: *Dyslexia, Birth Order, Behavioural Problems, Emotional Problems*

Introduction

There is a biological instinct among many living creatures for a sibling competition to attain parental favour and resources. Human beings also have such behaviours which sometimes shown as sibling rivalry. (17) The early-born children have an adaptive advantage if they build and maintain strong parental & family ties, whereas later-born children will be more successful if they have rebellious tendencies (7).

Birth order among the siblings is one of the important family dynamics which determine the psychological well-being of children in a family. Birth order refers to the ordinal position that a child occupies within the family (7). The 'Ordinal Position' which is actual order of birth of the sibling (15). Children with reading disabilities exhibit many emotional and behavioural symptoms and their ordinal birth order exert variations in its severity and occurrence.

Birth order plays a crucial role in the occurrence and maintenance of psychological problems among reading disabled children. It is directly connected with parental favour and thereby ensures family support by the early born children. The late born children become more aggressive and rebel and revolts within the family to attain parental favour. The secure and insecure positions of siblings within the family due to birth order make them more vulnerable to psychological problems along with the existing disabilities like dyslexia.

Several theories has been put forward regarding the characteristics different birth order positions. Alfred Adler explained birth order through 'Individual Psychology' and used birth order as one of the cornerstones of his theories of personality, and he suggested that, early born-children are more likely to adopt traditional family orientation than later-born children and it is 'Conservation of Traditions' (7). Another proposition was 'Family Resource Theory' which suggested that, each additional child in the family, further stretches to available house hold resources including money, house hold space, and parental attention. It suggest that, the siblings may present a threat to healthy development, because they compete for resources that parents have available to invests in individual offspring. (9)

The Confluence Model was suggested by Zajonc & Sulloway (18) explained that, each new child in a family in a way that inhibits intellectual growth for all children in the family. It also suggested that, there will be a

'tutoring effect' that is intellectually facilitated for the children who have younger siblings to teach [7]. Birth order is a predictor of family dynamics, personality and intellectual capabilities of an individual. It also affects when any of the siblings have a mental or physical disability and when disabilities become challenge among those siblings who show altered psychological roles [4]. The resilience capacity of an individual sometimes depends upon their ordinal birth-order position. Early-born children are more adaptive than later-born children. Adler regarded fisrt-borns as power hungry conservatives, middle-borns as competitive and younger children as spoiled and lazy.[17]

Children with learning disabilities are often associated with several internalizing and externalizing problems. Sahoo, Biswas & Padhy [12] reported that about 30% of learning disabled children have behavioural and emotional problems which range from attention deficit hyperactivity disorder (most common) to depression, anxiety, suicide to substance abuse (least common). Sreedevi, George, Sriveni & Rangaswamy [16] conducted a study which revealed that, children with learning disabilities are exhibiting significant behavioural problems than children without learning disabilities. The mostly reported emotional problem was anxiety. Hyperactivity, opposite defiant conduct disorder and sluggish tempo are the common behavioural problems [8]. Arnold et al., [3] reported that, poor readers exhibit higher levels of depression, trait anxiety and somatic complaints than typical readers.

Behavioural and emotional problems co-existing with dyslexia act as a double edged sword which hurts the individual with long lasting scars. Lack of support from parents and family members makes an individual with dyslexia more vulnerable to psychological issues leading to various behavioural and emotional problems. This 'double disability' makes them hard to be resilient with poor academic performance and behavioural issues.

Method

Design: The study was conducted to explore the behavioural problems of dyslexic children on the basis of ordinal birth order. The study was conducted using exploratory design.

Participants: The participants of the study were dyslexic children studying in Malayalam medium schools with age ranging from 8 years to10 years. The total number of children selected was 122 using simple random sampling method. Only Malayalam medium children studying in 3rd and 4th standards were included in the study.

Tools:

Dyslexia-Screening Checklist (Malayalam). It was used to identify the children with reading problems and consists of 11 items. The checklist was rated by teachers. If any of these items was found with child, he/she was sent for further diagnostic procedures.

Seguin Form Board. It is a non-verbal method for assessing the intellectual abilities of children for 5 years to 15 years. It serves as a quick measure for general intelligence.[10] It is a measure of intelligence using the shortest among the trials considered for calculating mental age and is a most useful measure to test form perception, movement and intelligence.

Specific Learning Disorder Diagnostic Tool-SLDDT (Reading Test). It is diagnostic tool developed by Alex & Kumar.[2] The test was developed in Malayalam and contains five dimensions such as phonological processing, alphabet knowledge, single word reading, oral reading, oral language and motor skill. The reading sub test consists of rapid naming, letter identification, word identification, vocabulary, verbal fluency, semantic fluency, bead threading, reading passage, comprehension and pseudo word reading. The reliability of the tests for classes 3rd and 4th are 0.70 and 0.96 respectively. The criterion-related validity for classes 3rd and 4th are 0.955 and 0.977 respectively. The test is used in the current study was to diagnose the dyslexic children who were screened as having reading problems.

Child Behaviour Check List (CBCL-Malayalam) 6-18 Years. The CBCL is one among the Achenbach System of Empirically Based Assessment (ASEBA) developed by Thomas Achenbach.[1] The CBCL 6-18 years consists of school age forms and hand scored profile. There were 113 items based on DSM oriented nine syndrome scales in the CBCL. These scales were anxious/depressed, withdrawn/depressed, somatic complaints, social problems, thought problems, attention problems, rule breaking behaviour, aggressive behaviour and other problems. The test-retest reliability for problem scale was 0.95. The content validity, criterion related validity and construct validity were well established.[1] The CBCL was used in this study to identify the externalizing and internalizing problems of

dyslexic children.

Procedure: The data collection was done among the primary schools of Kannur, Kozhikode, Wayanad and Malappuram districts of Kerala. The contact number and location of each school was noted from the 'school statistics'. The head teachers were contacted and explained the details of data collection with them. Those who expressed their willingness for data collection arranged an interview with the children and their parents in a convenient time. At school, the class teachers of 3rd and 4th classes screened the children who had problems with reading. The 'informed consent' collected from the parents of screened children and Seguin Form Board administered with them. Children who had IQ above 70 with reading problems were then administered with Specific Learning Disability Diagnostic Test (Reading Disability Test). Those who diagnosed with reading disability then assessed with Child Behaviour Check List (CBCL). The personal information of the children was collected from their parents using Personal Data Schedule.

Statistical Analysis: The data was analyzed using descriptive statistics. The frequencies and means were used for analysis. Analysis of Variance (ANOVA) was used to find out the within group difference of CBCL syndrome scales among the different ordinal birth orders.

RESULTS

The mean and standard deviations of the variables in the syndrome scale of CBCL were given in the Table No.2. The birth order was expressed as first born, second born and later born and above. There were 42 (34.4%) participants as first born, 75 (61.5%) participants as second born and 5 (4.1%) participants as third born and above.

The Table 1. explain the means and standard deviations of different syndrome scales of first order born, second order born and later order born children in the studied population. The total mean and total standard deviations of the syndrome scales were also given.

Table No.1. Mean and Standard Deviations of Syndrome Scales

9	Other Problems	6.516	465.943	3.258	3.915	0.832

Discussion

The study was conducted among dyslexic children with their age ranges from 8 years to 10 years. The children suffering from dyslexia and other disabilities have greater prone to exhibit various forms of behavioural problems. Several factors such age, gender and birth order were reported to influence the onset of behavioural/emotional problems. The data showed that, the participants with third and above ordinal position had higher mean scores on anxious/depressed, withdrawn/depressed, social problems, attention problems and other problems. The participants with second birth order position had higher mean scores on somatic complaints, thought problems and rule breaking behaviour. Aggressive behaviour is high among participants with first birth order positions.

Result of analysis of variance presented in the Table No.2. for the 9 syndrome scales. The F-ratios were not found any significant difference between first order born, second order born and third and above order born children. The study found that, the ordinal birth order positions did not exert any influence on the behavioural and emotional problems of the given sample of participants. There were differences in opinion about the influence of birth order on psychological variables. Some studies accepted the hypothesis that birth order influences psychological variables, while some others reject. Sharma & Smriti [(13)] reported that, there were differences in psychological well-being among various birth orders they studied. Ordinal position the child holds within the sibling ranking of a family is related to intellectual functioning, personality, behaviour and development of psychopathology.[(11)]

While the present study undoubtedly found that, the birth order positions could not influence any psychological variables such as behavioural and emotional problems among dyslexic children. Dyslexia is itself a disability and development of psychopathology is very common among these individuals. Dyslexia and other learning disabilities may lower the self-esteem of the affected individual which may result in the development of behavioural/emotional problems.[(6)(5)(14)] But with the current study, the ordinal birth order could not make any change in behavioural and emotional problems of the given participants.

Conclusion

The children participated in the study were between the ages of 8 years to 10 years old who are suffering from dyslexia. There were three birth order positions described among these children. The second born children were larger in number compared to first born and third born kids. The study concluded that the behavioural/emotional problems of children suffering from dyslexia were left unchanged with various birth order positions.

Awareness of Diabetes Mellitus and Glycemic control amongst patients with Type 2 Diabetes

Ujwal L Yeole[1], Mariya P Jiandani[2], Hashmeet Kaur Bakshi[3], Shailaja Kale[4]

[1]Associate Professor and Principal, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune, [2]Associate Professor, PT School and Center, Seth GS Medical College and KEM Hospital, Parel, Mumbai, [3]Student 4th year BPT, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune, [4]Consultant Diabetologist, Dr. Shailaja Kale's Diabetes and Speciality Clinics, Pune

Abstract

Background: The patient's awareness about diabetes, its complications, role of lifestyle modifications can establish patient specific goals. This study was done to determine the level of awareness regarding Diabetes mellitus, its complications and Glycemic control.

Methods: A survey was carried out on 245 diabetic patients visiting Medicine OPDs at affiliated hospitals in Pune to determine the level of awareness of Diabetes Mellitus and Glycemic control amongst patients with Type 2 Diabetes. A predesigned and validated questionnaire was administered which was further modified post pilot study.

Results: Total 200 patients with mean age of 53±6.66 years (84 males and 116 females), mean duration of diabetes 8.20±8.057 years and mean HbA1C 7.11±0.95 % were interviewed for the level of awareness of Diabetes Mellitus and Glycemic control. Around 62% people perceived diabetes to be a life lasting disorder whereas 24% considered it to be a life threatening and a non-treatable disorder. Almost 77% completely agreed that Glycemic control is important with 71% completely agreed that daily exercise with a particular exercise regime and lifestyle modification proves advantageous. Around 63% completely agreed that a proper diet plan should be followed by diabetics and they should not skip meals.

Conclusion: Majority of diabetes patients had awareness about diabetes, its complications, role of exercises and diet in glycemic control.

Key words: *Awareness, Glycemic control, Type 2 Diabetes, Exercise, Diet, Lifestyle Modification.*

Introduction

Diabetes mellitus is a complex, chronic illness which requires continuous medical care along with multifactorial risk reduction strategies beyond glycemic control.[1] Diabetes mellitus (DM) has emerged as a major public health challenge around the world. The greatest burden of diabetes mellitus has been faced by the low and middle income countries. With rapid economic development, elevated standard of living, dietary shifts, lifestyle alterations, and aging , diabetes mellitus has become an important public health problem worldwide. It is estimated to be the third most challenging disease threatening public health after malignant tumors and cardiocerebral vascular diseases.[2]

In 2011 the Diabetes Atlas of the International Diabetes Federation (IDF) estimated the global DM prevalence in the age group 20–79 years at 8.3%, which translates into 366.2 million people suffering from DM in 2011. By 2030, the number of people living with diabetes mellitus is projected to reach 551.9 million.[3] Recent global study stated that 60% of diabetics worldwide come from Asia because it is the world's most populous region.[4]

Excessive caloric intake and physical inactivity are well recognised environmental factors which predispose type 2 diabetes. Obesity and sedentary lifestyle are risk factors that play important roles in escalating the prevalence of developing Type 2 diabetes mellitus. In

both men and women , increased physical activity is associated with a reduced risk of diabetes and even a moderate activity is protective against Type 2 diabetes mellitus.[3]

By creating awareness amongst patients about diabetes, its complications, medication, lifestyle modification and diet plan patient specific goals like effectiveness of medication and decrease in likelihood of adverse events in diabetic patients can be established.[1] The management of diabetes mellitus largely depends on the affected person's ability to pursue self-care in daily living. The awareness, treatment and control of diabetes mellitus can effectively reflect on the social status of diabetes conditions.[2]

As lack of awareness about diabetes and inadequate control of glycemia are among the major factors for the prevalence of diabetes; this study was carried out with an objective of creating the awareness among the diabetic population to ensure better management , better prognosis and prevention of complications in the diabetic population.

Method

This study was carried out as a part of screening phase of a research project registered under [CTRI/2018/01/011193] approved by institutional ethical committee with the approval number: [IEC II/338/18].

An Exploratory cross sectional survey was carried out on diabetic patients visiting Medicine OPDs at affiliated hospitals in Pune to determine the level of awareness of Diabetes Mellitus and Glycemic control amongst patients with Type 2 Diabetes. Patients visiting diabetic clinics were approached (total 245) amongst which 228 agreed for participation in the survey.

The patients within age of 35-60 years, both male and females and patients diagnosed with Type 2 diabetes since more than one year were included in the study and patients with Type 1 and gestational diabetes were excluded from the study. Total 28 patients did not fit in the criteria so were excluded. A final survey was carried out on 200 diabetic individuals. The patients who agreed for participation in the survey were further interviewed using a predesigned questionnaire by trained interviewer.

Experts in the field were consulted and a predesigned questionnaire was administered which was further modified post pilot study. Prior to participation patients were instructed and explained about the aims, objectives, method of study and informed Consent was obtained from the participants.

The questionnaire was categorized into two components. The first component of the questionnaire included questions evaluating awareness regarding Diabetes Mellitus as a condition and its complications, in which they were given the flexibility to respond more than one option based on their diabetic knowledge about the condition. The second component included questions evaluating awareness regarding Glycemic control where the patients had to choose only one option on Likert scale. The patients were interviewed and the results were formulated.

Data management and statistical analysis:

The collected data was tabulated and analysed using Microsoft Excel 2010 and InStat [DATASET1.ISD] software.

Results

Total 200 patients with mean age of 53±6.66 years (84 males and 116 females) were interviewed for the level of awareness of Diabetes Mellitus and Glycemic control. The average BMI was 26.11±5.66 kg/m^2 in males and 26.6±5.26 kg/m^2 in females. The mean duration of diabetes of the males was 9.88±9.56 years and that of females was 7.077±6.31 years. The mean HbA1C of the male patients was 7.35±1.047 % and those of the female patients was 6.98±1.37%. Table 1 depicts component evaluating awareness regarding Glycemic control.

Discussion

Diabetes mellitus is a metabolic disorder of multiple aetiology characterized by chronic hyperglycemia with disturbances of carbohydrates, fats and protein metabolism resulting from defects in insulin secretion, insulin action or both.[3] The causes of Type 2 diabetes are central adiposity, lack of physical activity and excessive caloric intake, mental stress and genetic susceptibility [3]. In this study around 58% patients said the cause of Type 2 diabetes is mental stress whereas very few said it is due to eating lots of sugar and other factors like excessive bodyweight and genetic inheritance.

There are multiple misconcepts regarding Diabetes as a condition, its causes, the methods for achieving good glycemic control. In this study around 62% of

the diabetic patients perceived diabetes as a life lasting disorder and 24% mentioned it as a non treatable and a life threatening condition. Almost 67% said that insulin helps to control glycemic levels. [3] In this study it was seen that 77% completely agreed that glycemic control is important. Only 29% were aware that no dietary modifications are required with insulin is a misconception. Ali Reza Soltanian et al in their study concluded that lack of awareness can lead to development of diabetes and increase the cost of treatment.[5]

There are various concepts regarding insulin administration, the site of it's administration and also about target blood sugar levels. This study showed hardly 50% of the people were aware about Target BSL for good glycemic control. 51% were aware that insulin should be administrated on the proper body sites but only 30% mentioned that the site should be changed at regular intervals.

While evaluating the knowledge about symptoms of hypoglycaemia and hyperglycaemia it was observed that majority of the patients were aware of symptoms of hypoglycaemia and measures to be adopted for its management. Symptoms of hypoglycaemia include palpitation, sweating, nausea, hunger, headache, fatigue, mental dullness, blurring or clouding of vision and unconsciousness .[3] This study states that 63% were aware that the symptoms of reduced BSL is weakness/ fatigue but only 24% were aware that light headedness is also a symptom of hypoglycaemia and the method of managing it is eating sweets/chocolates was known by 72% of the people but only 18% knew that eating food is also a method of managing it. The clinical features of increased blood sugar levels include polyphagia, polydipsia, polyuria, unexplained weight loss despite of normal appetite, recurrent bacterial infections, recurrent urinary tract infections [6]. In this study , 66% people were aware that the symptom of increased BSL is increased thirst but only 20% were aware that loss of weight despite of normal appetite is also a symptom.

There are studies which stated that the complications of Type 2 diabetes include Ischaemic Heart Disease, Renal failure, Stroke, Heart failure, Peripheral neuropathy, Foot Ulcers, Retinopathy, Myocardial infarction, Major amputations .[2] A study stated that Type 2 diabetes have autonomic symptoms and may further result into autonomic dysfunctions due to damage to autonomic nerve fibres that result in abnormalities in HR control and vascular dynamics that is commonly seen disease like DM.[7] In this study there were only 20% who were aware of the fact that uncontrolled diabetes leads to peripheral neuropathy as a complication whereas more than 50% people were aware that renal failure, cardiovascular problems and retinopathy can also be caused due to uncontrolled diabetes. The major contributory factors for the high prevalence of diabetes and its complications are inadequate control of glycaemia , hypertension , delayed diagnosis of diabetes and lack of awareness about diabetes among the majority of the public.[3]

Physical activity is considered to be an important component of weight management programme. Regular exercise and aerobic fitness improve insulin sensitivity and glycemic control, decrease the risk of developing diabetes and reduces overall mortality in patients with Type 2 Diabetes.

This study states that 63% completely agreed that a proper diet plan should be followed by diabetics and they should not skip meals when busy. Which is in review with the study stated done by Sylria Hhey and Osama Homdy that diet rich in wholegrains, fruits, vegetables, legumes, with moderate in alcohol consumption and low in refined grains, red meat and sugar sweetened beverages have been shown to reduce risk of diabetes and improve glycemic control in patients with diabetes.[8]

A cornerstone of diabetes management is formed by life-style modification which involves giving up of certain pleasures of unhealthy life-styles which include lack of physical activity and irregular eating in order to prevent and / or delay diabetic complications and to achieve a desirable glycemic control.[3] In this study, 71% completely agreed that there are various advantages of daily exercise and lifestyle modification in diabetes. 69% completely agreed that a particular exercise regime should be followed by diabetics 5 days a week for at least 30 minutes. Previous studies that stated the incidence of diabetes is reduced by lifestyle intervention and also that lifestyle interventions are particularly effective to delay or prevent the development of complications substantially reducing the individual and public health burden of diabetes. It also mentioned that lifestyle interventions were more effective than metformin.[8]

Most of participants (65%) completely agreed importance of routine follow up with physician better diabetes management. 79% completely agreed that diabetes medicines should be taken regularly as given by physician. R. Brian Haynes, et al in their study

stated low adherence to prescribed medical regimens is a ubiquitous problem. To reap the benefits of medical therapies, better, more effective, and more efficient interventions for helping people to follow regimens are needed.[9]

Effective diabetes mellitus education, with consequent improvements in knowledge, attitudes and skills, leads to better control of the disease, and is widely accepted to be an integral part of comprehensive diabetes mellitus care and management.[7] During the period of undiagnosed diabetes, risks for micro- and macrovascular complications are elevated and it has been proposed that treating hyperglycemia to prevent complications is more effective than treating these complications after they have developed.[10]

The data collected empirically shows that the level of awareness of patients about diabetes, its complications and management in the diabetic population in Pune in India was good. There are multiple misconcepts regarding Diabetes as a condition, its causes, knowledge about symptoms of hypoglycaemia and hyperglycaemia, the methods for achieving good glycemic control.

This study evaluated the awareness of diabetes knowledge and glycemic control.

The level of literacy of the patients, also may impact the Glycemic control in Diabetic patients. Future studies can be done to evaluate the association of

Further study can be done to compare the awareness between type 1 and type 2 patients and also a comparison study of awareness between patients in rural and urban populations can be done.

Conclusion

Majority of diabetes patients are well aware about diabetes, the possible complications of diabetes and the role of exercises and diet control in glycemic control.

Effect of Dynamic Postural Control Activities on Balance in Amateur Indian Taekwondo Players

Ujwal Yeole[1], Rachna Shah[2]

[1]Associate Professor and Principal, [2]Intern, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune

Abstract

Background: Taekwondo is a technique of unarmed self-defense that involves skillful application of techniques which include punching, jumping, kicks, blocks and dodges. Beside speed, response to the opponent's actions along with good balance appear to be key elements for victory. Hence a good balance is required for excellent performance with minimal injuries

Method: A total of 60 players were selected based on inclusion and exclusion criteria. The aim and objectives of the study were explained to them and their written consent was taken. Balance was assessed using single legged stance test and community balance and mobility scale. The players were divided into two groups of 30 players each. A four week intervention program consisting of dynamic postural control activities was given to the players in group Athrice a week for four consecutive weeks and those in group B received conventional exercises including stretching and drilling. The pre and post values were recorded on 1st and 12th day respectively and the data obtained was statistically analyzed.

Results: The average CBM scale score before intervention were 74/96 in group A and 72/96 in group B. These were improved to an average of 91.2/96 and 80.32/96 in group A and group B respectively after intervention showing a value of $p<0.0001$. Also, significant improvement is seen in single legged stance test scores in group A as compared to group B.

Conclusion: Dynamic postural control activities are effective in improving the balance thereby improving the performance in amateur Indian Taekwondo players.

Introduction

The word "Taekwondo" is derived from the Korean word **"**Tae" means "to Kick" or "Smash with the feet," Kwon" implies "punching" or "destroying with the hand or fist," and "Do" means "way" or "method." Taekwondo thus, is the technique of unarmed combat for self-defense that involves the skillful application of techniques that include punching; jumping kicks, blocks, dodges, parrying actions with hands and feet. Taekwondo is considered to be the oldest of all martial art concepts which translates as 'the ways of hands and feet' consisting of a number of ancient martial arts unified into one sport. Taekwondo is a combative sport that was developed in 1940s and 1950s by Korean martial artists with experience in martial arts such as karate, Chinese martial arts, and indigenous Korean martial arts traditions such as Taekkyon, Subak, and Gwonbeop. However, it was introduced in India in 1974 by Puran Andrew Gurang after studying Taekwondo under Korean Grand Master Lee Pyung Pal[1].

The history of taekwondo dates back over 2,000 years, but the sport has come to light after it made its debut at Sydney Olympics in 2000 and Indian Taekwondo athletes made their debut in 1985 at National Games, New Delhi. Since then Indian Taekwondo players have

Corresponding Author:
Dr. Ujwal Yeole

Tilak Maharashtra Vidyapeeth,
Gultekdi, Pune 37
Email id: drujwalyeole@gmail.com

been participating in various international games like Asian Games, Olympics, and Commonwealth Games. However, India won its first taekwondo gold in 12th South Asian games in 2019.

Technically, taekwondo is a kind of self-defense that involves the skillful application of techniques that include punching; jumping kicks, blocks, dodges, parrying actions with hands and feet. Thus, performance in taekwondo may be determined by a competitor's technical, tactical, psychological, physical and physiological characteristics. From a physical conditioning perspective, the goal of taekwondo training is to prepare competitors to effectively manage both the physical activity and the physiological demands of combat. The physical activity and physiological requirements of taekwondo competition require athletes to be competent in several aspects of fitness, including aerobic and anaerobic power, muscular strength, muscular power, flexibility, speed and agility[2].

Also, balance (static and dynamic) along with flexibility plays an important role in protecting players from injuries and play technically with good tactics. During the last years the type of successful techniques condensed toward direct strait kicks, which can be applied within a shorter time interval compared with more complicated kicks. Therefore, it seems success greatly depends on the execution time of a technique.

Taekwondo training is therefore structured to target these specific performance mediators. From a physical conditioning perspective, the goal of taekwondo training is to prepare competitors to effectively manage both the physical activity and the physiological demands of combat. The physical activity and physiological requirements of taekwondo competition require athletes to be competent in several aspects of fitness, including aerobic and anaerobic power, muscular strength, muscular power, flexibility, speed and agility. Thus, it is important that physical therapist and sports coaches make objective studies about players balance and set a training to target those aspects.

For improving balance, agility, strength and flexibility in players, it is important to assess the present data first. And this can only be achieved using proper outcome measures. Studies suggest use of the single leg stance test is recommended for assessment of static balance in players playing various sports as it has a good reliability for assessing players. Also, the community balance and mobility scale is used for assessing young people with good mobility. It has components that cover both static and dynamic balance assessments[3].

Today, taekwondo is world's most favorable martial arts sports. In India, many school going children are indulged into the sports and many of them consider it as just a recreational activity to keep them fit. However, many students train well and wish to participate in the sports at international levels. Recently, in 2018 Asian Games, 8 Indian athletes participated in Taekwondo whereas in 2014 Asian Games 11 athletes participated in taekwondo where maximum number of players were 12 athletes each from China, South Korea and Nepal. Inspite of such a good participation, Indian players have never won any medals at the Asian Games. This may be due to lack in a proper training protocol. Hence, it is important that the coaches and sports therapists collect objective information about players physical, mental, and physiological status so that better training programs could be established. Moreover, there is very limited study available on the same in Indian taekwondo players. Hence the need.

Method

An experimental study was done on 60 subjects. The study was done by recruiting players from taekwondo clubs across Pune. The study had a duration of 6 months. Both male and female amateur Taekwondo players between 8 – 18 years of age and under 45kg weight were included in the study. Players playing for more than one year[4] were also included. Players using orthotic/ prosthetic devices along with those players who are involved in other sports along with taekwondo and who are not regular with training sessions[5] were excluded. The data was collected primarily by approaching various Taekwondo clubs across Pune and training the players thrice a week for four consecutive weeks. Materials required included data collection sheet, consent forms, notepad, medicine ball (2kg), foam stability pad, measuring tape, Swiss ball (75cm), kettle bell(2kg), stepper, stop watch, whistle, and theraband.

A synopsis was submitted and permission was taken from Institutional Ethical Clearance Committee of Tilak Maharashtra Vidyapeeth, Department of Physiotherapy. Various Taekwondo clubs were approached across Pune and their permission was obtained prior study. The aims and objectives of research were explained to the players and those willing to participate were included in

the study based on inclusion and exclusion criteria after their written consent was obtained. A total of 76 players were assessed, of which 60 were selected according to the inclusion and exclusion criteria. The players were assessed for static and dynamic balance using Single Leg Stance Test (SLST) and Community Balance and Mobility scale. This scale has 13 components like unilateral stance, tandem pivot, lateral foot scooting, hopping forward, lateral dodging, running with controlled stop, etc. and each of these components has its scoring out of 5 each. The players were then divided into two groups of 30 athletes each – group A and group B. Group A was given intervention for dynamic postural control activities while group B was given conventional exercises that included stretching and drilling. The sessions for both the groups were carried out for 30 minutes. The dynamic postural control activities included total 7 forms of exercises using swiss ball, theraband, kettle bell, medicine ball, foam stability pad, and stepper. The participants were instructed to hold particular postures using forone minute each and this cycle was repeated thrice per session. The pre and post intervention values for Single Legged Stance Test and Community Balance and Mobility Scale were recorded on 1st and 12th day respectively and data was collected. Data obtained was statistically analyzed.

Data management and statistical analysis:

The data collected was tabulated and analyzed using Microsoft Excel 2010 and InStat [DATASET1.ISD] software.

Results

The Community Balance & Mobility Scale score of players improved from 74.46 + 9.1 to 91.23 + 4.74 with $p<0.0001$ in group A as compared from Group B which improved from 72.25 + 8.4 to 80.32 + 6.7 with $p=0.01$**(Table 1, Figure 1)**. The Single Legged Stance Time of players improved from 20.77+15.69sec and 23.99+15.79sec to 43.18+3.30sec and 43.04+3.68sec on right and left side respectively with $p<0.001$ in Group A as compared to Group B players whose time improved from 22.74+10.67sec and 21.87+11.12sec to 31.54+10.45sec and 30.72+10.63sec on right and left side respectively with $p<0.01$ with eyes open**(Table 1, Figure 2)**. This score improved from 4.97+3.63sec and 5.21+3.89sec to 13.81+2.21sec and 13.27+2.18sec on right and left sides respectively with $p<0.001$ in Group A as compared to Group B whose time improved from 4.23+3.12sec and 4.33+3.45sec to 8.14+2.14sec and 9.12+4.12sec on right and left side respectively with $p<0.01$ with eyes closed **(Table 1, Figure 2)**.

Also the components of Community Balance and Mobility Scale such as lateral dodging, hopping forward, running with controlled stop, 180 degree tandem pivot and later foot scooting showed improvement from 2.75 to 4.13/5, 2.66 to 4.44/5, 2.34 to 4.75/5, 3.01 to 4.56/5 and 2.45 to 4.87/5 respectively.

Discussion

This study was undertaken to find out effect of dynamic postural control activities on balance in Indian amateur Taekwondo athletes. The players underwent 4 weeks exercise program where a set of dynamic postural control activities were given. Their balance was assessed using Single Legged Stance Test and Community Balance and Mobility Scale. The pre and post intervention values were recorded and the data obtained was statistically analyzed. Overall the dynamic postural control activities showed significant improvement on in both Single Legged Stance Test and Community Balance and Mobility Scale in amateur Indian Taekwondo Athletes.

This study finds that there may be enhancement in ability of sensorimotor system to overcome sensorimotor constraints. Improvement in balance would have been because of these activities cause increase of muscular strength, joints range of motion, neural control of movements. These activities impose overload over the information that is transferred through the three sensory systems of the central nervous mechanism (visual, vestibular and somatosensory). Our findings are supported by a previous study which evaluated the effect of balance training on dynamic postural control in male elderly individuals and concluded that changes in range of motion, muscle strength or length can improve dynamic postural control of individuals[6].

The players showed impaired scores in specific components of Community Balance and Mobility scale those included lateral foot scooting, 180 degree tandem pivot, lateral dodging, running with controlled stop, and hopping forward etc. All these components showed improvement post intervention. This is attributed to increased sensory input that assist in regulation of postural tone and postural muscle activation which is seen with these activities. This finding is supported by an article which states that all sensory inputs contribute to maintenance of posture[7].

The dynamic postural control activities used in this study included squatting, swissball activities, theraband exercises and kettle bell exercise. In our study, the players were told to squat and hold the 2kg medicine ball and maintain the posture for 1min. Squatting is a full body exercise that uses lower limb muscles like quadriceps, hamstrings, and gastro-soleus. Also, this exercise creates an anabolic environment which promotes body-wide muscle building. Since, the posture was held for specific duration, it may have helped to improve upper and lower body muscle strength and also in building and stabilizing the core[8].

In the second activity, the players were told to balance themselves on the swiss ball in half standing position with one hand raised and opposite thigh lifted off the ball. Hence, it must have forced the person to support their own weight and maintain neutral position of spine. Also, maintenance of this posture engages the key stabilizers i.e. abdominal and back muscles, so called core muscles. Swiss ball training used in this study may also target the low – twitched postural muscles[9].

The kettle bell exercise was done by allowing the players to hold the kettle bell in one hand by flexing the spine to 90 degree and extending the hip and knees of one leg and maintaining the entire posture on one leg for 1min. This challenges the COG to be maintained within a small BOS. This activity causes highest activation of the upper erector spinae. The other effect of kettlebell exercise may also be attributed to increased proprioception, increased neuromuscular coordination and improved control of dynamic control and hence reduced risk of falls[10].

Thus, dynamic postural control activities prove to be significantly effective in improving balance in Taekwondo players. Our study could not use large sample size. Further the study could also be done by using advanced equipments to assess static and dynamic balance and also intervention programs to target other performance mediators like strength may be studied.

Conclusion

The study concludes that dynamic postural control activities are effective in improving balance in amateur Taekwondo players.

A Study on the Relationship between Emotional Intelligence and Perception of Home Environment among Adolescents with Respect to Nature of School Management and Gender

Vandana Vijayan[1], K. Govind[2], Ramaa Raju[3]

[1]ResearchScholar, Dept.of Psychology, [2]Associate Professor, Dept. of Psychology, Annamalai University, Annamalai Nagar, TamilNadu, India, [3]Professor & HOD, Dept. of Psychology, Jyoti Nivas College (Autonomous), Bangalore,Karnataka, India

Abstract

In today's world, the life styles of people have totally changed as a result of changes in their physical and socio-cultural environment which in turn is influenced by the advent of information technology. An adolescents life is adversely affected by his/her Emotional Intelligence as it lowers his/her ability to function effectively. The study has been conducted to investigate the relationship between levels of Emotional Intelligence and Perception of Home Environment among Adolescents. It also examines the relationship between the Emotional Intelligence and Home Environment of the Adolescents. The study was made on a random sample of 450Adolescents in Bangalore district of Karnataka State. The tools used in the study were the Mangals emotional intelligence inventory (2000) and Home Environment inventory developed by Dr. Karuna Shanker Mishra (2004). The study reveals the fact that the level of Emotional Intelligenceand Perception of Home Environment are positively correlated.

Key Words: *Emotional, Intelligence, Environment, Adolescents, School Management and Gender.*

Introduction

The modern world, which is said to be a world of achievement, is also a world of intelligence. This though does not signify academic acumen but encompasses within it various forms of intelligence ranging from academic acumen to emotional intelligence. Emotional intelligence is the awareness of a feeling of tension either physical or emotional or both and could be caused as a result of physiological, psychological and environmental demands[1]. It is an established fact that the performance of an adolescents mainly depends upon his psychological state of mind. As emotional intelligence affects the physical and psychological wellbeing of the adolescents, it definitely influences his efficiency and performances.

Emotional Intelligence

Intelligence is a popular word used in day to day life. Different psychologists have tried to define intelligence right from the beginning of this century. Intelligence is an internal component. Human beings cannot neglect the role of emotions in their daily life. According to Cary Cherniss [2] Emotional intelligence has as much to do with knowing when and how to express emotion as it does with controlling it. Emotional Intelligence (EI) refers to the ability to perceive, control and evaluate emotions[3]. Some researchers suggest that emotional intelligence can be learned and strengthened, while others claim it is an inborn characteristic. In modern times, the term Emotional Intelligence has been popularized[4].Since 1990, [5] the leading researchers on emotional intelligence. In their influential article "Emotional Intelligence," they defined emotional intelligence as "the ability to monitor one's own and others' feelings and emotions, to discriminate among them and to use this information to guide one's thinking and actions.". It is also understood as an array of non-cognitive capabilities, competencies and skills that influence one's ability to succeed in

coping with environmental demands and pressure. According to Goleman [4], emotional intelligence has five elements: self-awareness, self-regulation, motivation, empathy, and social skills. Emotional Intelligence is the capabilities, competencies and skills that influence one's ability to succeed in coping with environmental demands and pressures that directly affect a person's overall psychological well-being; a type of social intelligence that involves the ability to monitor one's own and others' emotions, to discriminate among them, and to use the information to guide thoughts and actions.[5]

Home Environment

The new oxford illustrated Dictionary defined home as a "dwelling place, fixed residence of family or household member of family collectively". The Home means the body of people who live in one house or under one roof, including parents, children, domestic help etc. Home is the ground consisting of parents and their children whether living together or not. Webster's New Reference Library (1984) defines environment as the combinations of external or extrinsic conditions that affect the growth and development of an organization. The new Lexican Websters Dictionary the English language (1988) states that "environment means the surroundings especially the material and spiritual influences which affect the growth development and existence of a living being". Environment consists of the sum total of the stimulation that the individual receives from conception until death. It covers all those circumstances which assert their influence on the individual since conception till the end [6,7].

Objectives of the study

- To study the level of Emotional Intelligence among Adolescents.
- To study the level of Perception of Home Environment among Adolescents.
- To study the difference in Emotional Intelligence levels among adolescents studying in government aided and privately run schools.
- To study the difference in Emotional Intelligence levels among adolescents based on their gender.
- To study the difference in Perception of Home Environment among adolescents studying in government aided and privately run schools.
- To study the difference in Perception of Home Environment among adolescents based on their gender.
- To study the relationship between the Emotional Intelligence and Perception of Home Environment among Adolescents

Hypothesis of the study

- The level of Emotional Intelligence of Adolescents is high.
- There is no significant difference in Emotional Intelligence levels among adolescents studying in government aided and privately run schools.
- There is no significant difference in Emotional Intelligence levels among male and female adolescents.
- There is no significant difference in Perception of Home Environment among adolescents studying in government aided and privately run schools.
- There is no significant difference in Perception of Home Environment among male and female adolescents.
- There is no significant relationship between Emotional Intelligence and Perception of Home Environment among Adolescents

Methodology

The investigator, in consultation with her guide, felt that the normative survey method would be the most appropriate method to study the relationship between Emotional Intelligence and Perception of Home Environment.

Sample

In this study, random sampling was used as it was thought to be the most convenient one and is representative of the total sample. A total number of 450 Adolescents participated in the study.

Tool used

Mangal emotional intelligence inventory (2000) and Home Environment inventory developed by Dr. Karuna Shanker Mishra 1983. 8

Statistical Techniques used

For the present study, the following statistical techniques were used:

1. 't' test
2. Pearson product moment correlation.

Result and Discussion

Table-1: Correlation Co-Efficient (r) Emotional Intelligence Scores and Perception of Home Environment

Variables	**'r' value**	**Remarks**
Emotional Intelligence	.112*	S
Home Environment		

S=Significant at 0.05 level.

It is seen from table – 1 that the correlation co -efficient value for Emotional Intelligence and Perception of Home Environment among Adolescents is positive and significant at 0.05 level. The above table shows that Emotional Intelligence and Perception of Home Environment are significant and positively correlated. It indicates that Adolescents who show high levels of Emotional Intelligence also tend to have a more positive Perception of their Home Environment.

Table – 2: Pair – wise comparison of Type of Management and Gender with respect to Emotional Intelligence and Home Environment

Variable		**Sample**	**N**	**Mean**	**S.D.**	**t- value**	**P- value**	**LS**
Emotional Intelligence	Type of management	Government aided	151	66.54	12.02	2.129	<0.05	Significant
		Private	299	69.40	15.51			
	Gender	Male	209	65.54	11.359	2.361	<0.05	Significant
		Female	241	69.58	14.345			
Home Environment	Type of management	Government aided	151	196.54	21.497	2.026	<0.05	Significant
		Private	299	209.39	31.136			
	Gender	Male	209	201.57	25.904	3.303	<0.05	Significant
		Female	241	209.35	26.595			

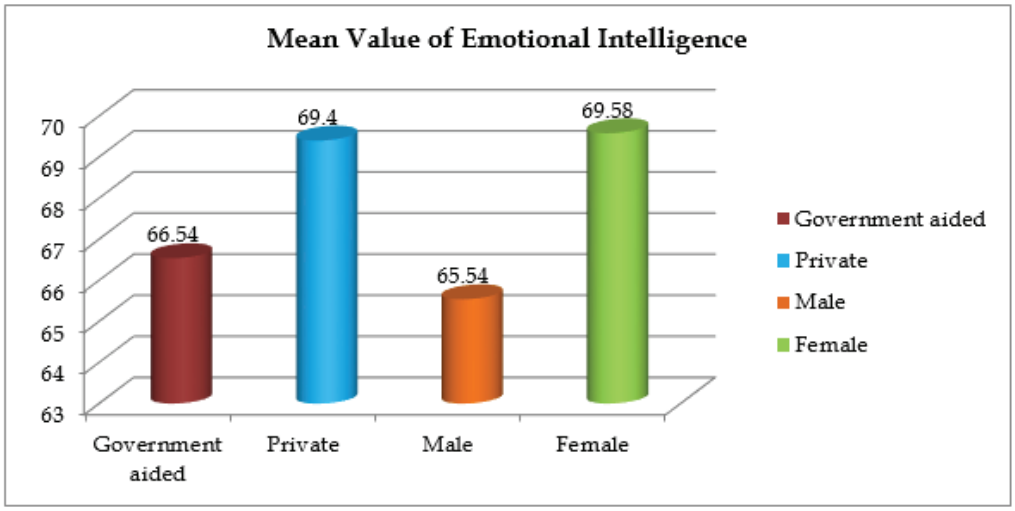

Figure - 1

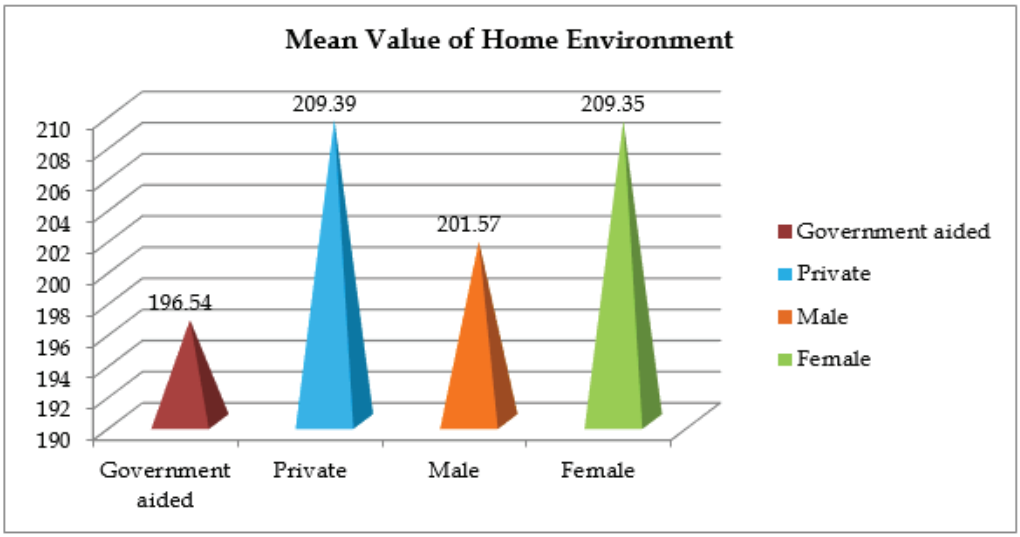

Figure - 2

Major Finding

The calculated ''t' value for emotional intelligence is found to be (2.129 and 2.361), which is significant at 0.05 level. Hence, it is inferred that adolescents studying in government aided and privately run schools as well as male and female Adolescents differ significantly in their levels of Emotional Intelligence. Further the calculated ''t' value for the home environment inventory is found to be (2.026 and 3.303), which is significant at 0.05 level. Hence, it is inferred that adolescents studying in government aided and privately run schools as well as male and female Adolescents differ significantly in their Perception of Home Environment.

Conclusions

On the basis of the results obtained, in the present study, the following conclusions were drawn:

- Adolescents studying in government aided and privately run schools differ significantly in their Emotional Intelligence.
- The male and female Adolescents differ significantly in their levels of Emotional Intelligence.
- Adolescents studying in government aided and privately run schools differ significantly in their Perception of Home Environment.
- The male and female Adolescents differ

significantly in their Perception of Home Environment.

- The results indicate that Emotional Intelligence and Perception of Home Environment are positively correlated and significant.

- The results indicate that if Adolescents show high levels of Emotional Intelligence their Perception of Home Environment too will be positive.

Ethical Clearance – Not required because, data collected through questionnaire.

Source of Funding - Self

Comparative Analysis of Haematinic Effect of Dhatryarista with Standard Ferrous Sulphate in Tannic Acid Induced Iron Deficiency Anaemia in Albino Wistar Rats

Srivastava V[1] , Sarkar S[2], Pattanayak C[3], Mishra M[4], Jena J[3]

[1]Assistant Professor, Department of Pharmacology, Kalinga Institute of Medical Sciences, Bhubaneswar, Odisha, [2]Assistant Professor School of Tropical Medicine, Kolkata, [3]Professor, Department of Pharmacology, Kalinga Institute of Medical Sciences, Bhubaneswar, Odisha, [4]Associate professor, Department of Pharmacology, Kalinga Institute of Medical Sciences, Bhubaneswar, Odisha

Abstract

Background: Iron deficiency anemia affects more than 1.2 billions individuals worldwide.Iron deficiency is caused by physiologically increased iron requirements in children, adolescents, young and pregnant women, by reduced iron intake, or by pathological defective absorption or chronic blood loss.Treatment modalities include both oral and parenteral therapies.**Objectives:**a)To study the improvement in haemoglobin after giving dhatryarista in IDA.b) To compare the effect of Dhatryarista (in different concentrations) with standard oral formulation Ferrous sulphate in terms of haemoglobin.**Materials and methods:**The study was conducted for the period of two months in department of Pharmacology KIMS,bhubaneswar. Total 24 Albino wistar rats were taken and divided into 4 groups containing 6 rats each.Anaemia was induced by adding tannic acid in diet of 24 rats by 21days.After induction of anaemia, Group II, Group III and Group IV rats were given standard drug(Ferrous sulphate),Dhatryarista sample 1 and Dhatryarista sample 2 respectively, alongwith normal diet for next 30 days. Blood samples were taken in day 1, day 21 and day 53.**Results:**All the values are expressed as a Mean±SEM(standard error of mean).Significant decrease in haemoglobin were observed, when compared between day 1 and day 21,while significant increase in haemoglobin was observed after 30 days of administration of test and standard drug.**Conclusion:**The administration of tannic acid to rats caused anaemia characterized by reducing hematological parameters.The oral administration of Dhatryarista in the dose of 4.32ml/kg/day P.O and 8.64ml/kg/day P.O significantly increased haemoglobin level.The results demonstrated that higher doses of the plant extract didnot show any signs of acute toxicity in animals.

Key words- *Iron deficiency anaemia, Dhatryarista, Ferrous sulphate, Amalaki, Haemoglobin*

Introduction

Iron deficiency anaemia or *Panduroga* is defined as *Pitta* dominant *Tridoshaja* disease where *Vivarnata* of *Twaka* (discolouration of skin) is mainly *Pandu* (pallor/yellowish-whitish) due to *Alpa Rakta* (reduced blood) or *Vidushya Rakta* (vitiated blood). Anaemia is defined as qualitative and quantitative reduction of circulating RBC and/or the percentage of haemoglobin concentration in relation to standard age and sex. Iron deficiency anaemia is a common type of anaemia in which blood lacks adequate healthy red blood cells. Red blood cells carry oxygen to the body's tissues. As the name implies, iron deficiency anaemia is due to insufficient iron. In women of childbearing age, the most common cause of iron deficiency anaemia is a loss of iron in the blood due to heavy menstruation or pregnancy. A poor diet or certain intestinal diseases that affect how the body absorbs iron can also cause iron deficiency anaemia.

The state of IDA is being managed with the supplementation of external iron containing drugs for which several types of modern medicines are available in the market. These modern iron formulations contain one or the other types of iron salts such as, ferrous fumarate, ferrous sulfate, ferrous glycine sulfate, ferric ammonium citrate, ferric hydroxide polymaltose complex, iron choline citrate, iron dextran, ferrous calcium citrate, iron sorbitol citrate, colloidal iron hydroxide, ferrous gluconate, ferric hydroxide, and ferrous succinate. It has been further reported that the long-term treatment of IDA with these drugs is associated with constipation, heart burn, nausea, gastric discomfort and diarrhea.

Dhatryarishta, a non iron formulation, is indicated in *Pandu roga* by *Acharya Charaka* . As most of the Ayurvedic formulations are found effective against IDA, their usage should be fostered at all level in addition to modern allopathic medicines. This study focuses about the haematinic effect of Dhatryarista as compared to allopathic medicines available. It contains four major ingredients- amalaki, pippali, honey and sugar. Amalaki (Emblica officinalis Gaertn) has been described in Phalasava and Sarkara as a separate Asava yoni by Acharya Charaka . Asava yoni itself denotes the fermenting base for Asava-Arishta. Dhatryarishta is indicated in the context of Panduroga in Charaka Samhita Chikitsasthan.The same reference is available in Chakradatta, Bhaishajya Ratnavali, and Sahastrayogam in Arishtaprakaran.

Objectives

- To study the improvement in haemoglobin after giving dhatryarista in IDA.
- To compare the effect of Dhatryarista (in different concentrations) with standard oral formulation Ferrous sulphate in terms of haemoglobin.

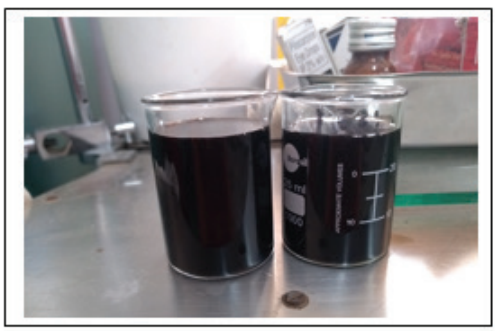
Materials and Method

The study was conducted in the animal house, located in department of pharmacology after getting approval from Institutional Animal ethics committee of KIMS, Bhubaneswar. The study period was two months (60days).

Dhatri Swarasa (Amalaki Juice), Madhu (Honey)-one-eighth of Swarasa, Krishna(Pippali) half Kudava (96 g), and Sarkara (Sugar) are the four ingredients of Dhatryarishta as per classic method.

Amalaki

Pippali



Preparation of Dhatryarista sample

Preparation of Dhatryarista sample

The normal human dose trial compounds i.e Dhatryarista is 48ml/day for an adult (Jyothi et al, RGUHS)[17]. The dose of drug is fixed by extrapolating the human dose to rats on body surface area ratio as per the table of Pagets and Barnes (1969) which will be 4.32 ml/kg body weight.

Rat dose per kg body wt= 0.018× Human dose× 5= 0.018 × 48ml × 5= 4.32 ml/kg

A. Animals required:

a. Species/common name: Wistar albino rats

b. Age/ weight: adult/ 100-200gm

c. Gender- Male

d. Number to be used- 24

e. Source of animal- Institutional Animal house, Kalinga Institute of Medical Sciences, KIIT university, Bhubaneswar, Odisha

Twenty four adult albino rats of either sex weighing 100–200 g were used for this study. The animals were allowed to acclimatize in the research laboratory for 1 week before the commencement of the study. The animals had been maintained under standard conditions (room temperature 25°C±3, humidity 35–60%, and light and dark period 12/12 h). All animals were fed with food and water ad libitum. All the animal testing were done under the approval of Institutional Animal Ethical Committee (IAEC) of KIMS, Bhubanesawar.

B. Induction of anaemia

Induction of anaemia was done was done by adding tannic acid to the basal diet of the rats. The rats were fed on the basal diet containing tannic acid for 3 weeks. 20g tannic acid/kg was added to the basal diet at the expense of the whole diet[18], which was given to all 24 rats belonging to Group I to Group IV. After 21 days, iron deficiency anaemia was induced in those rats. From day 22, Group II rats were started on standard treatment available which is ferrous sulphate, Group III were given Dhatryarista sample 1 (4.32ml/kg P.O) and Group IV were given Dhatryarista sample 2 (8.64ml/kg P.O), alongwith normal diet, for next 30 days. The blood samples were collected on day 1, day 21 and day 53.

C. Grouping of animals

Table 1: shows grouping of the animals with respective treatment group. Ferrous sulphate and two concentrations of Dhatryarista were started from day 22 after induction of anaemia in groups II, III and IV respectively.

Grouping	No of animals	Drug
Group I	6	Control - Basal diet + Tannic acid (normal diet started after day 22)
Group II	6	Ferrous sulphate (Normal diet + FeSo4 40mg/kg P.O)
Group III	6	Test group 1 (Normal diet + Sample 1-4.32ml/kg P.O)
Group IV	6	Test group 2 (Normal diet + sample 2- 8.64 ml/kg P.O)

D. Toxicity Studies

There was no mortality observed with oral administration of Dhatryarista even at the higher dose 8.64ml/kg P.O. Doubling the dose had no toxic effect on the normal behaviour of the rats. Hence, 1ml and 2ml dose per day were selected and administered.

E. Statistical analysis

All the values are expressed as a Mean ± SEM (standard error of mean). The data were analyzed by one way ANOVA and post hoc methods. using socscistatistics.com. A level of $P < 0.05$ was considered as statistically significant. A level of significance was noted and interpreted accordingly.

Observation and Results

The whole study was conducted in 24 healthy albino rats. These rats, divided from Group I to Group IV with six rats in each group, were given basal diet including tannic acid (20g/kg) for next 21 days for the induction of anaemia. From day 22, Group II rats were started on standard treatment available which is ferrous sulphate, Group III were given Dhatryarista sample 1 (4.32ml/kg P.O) and Group IV were given Dhatryarista sample 2 (8.64ml/kg P.O), along with normal diet, for next 30 days.

Blood samples were taken on day 1 and then on day 21 (after induction) and then on day 53 for checking the efficacy of the drugs provided to rats. Blood was withdrawn from retro-orbital vein of rats. Samples were added to a tube containing ethylenediaminetetraacetic acid after 4 weeks of treatment. The haemoglobin was determined at day 53rd , using an automatic blood cell counter.

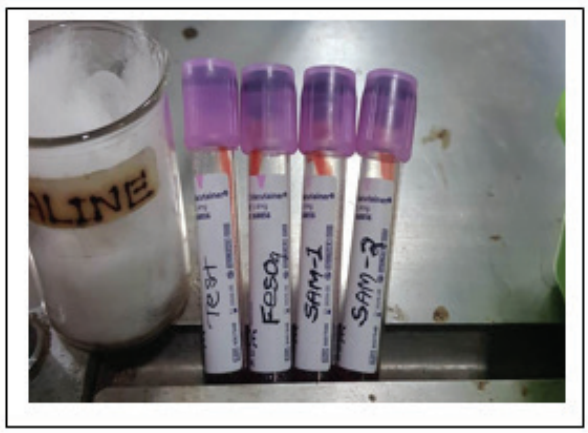


Table 2: Hb level of rats before and after induction and after 30 days of treatment. Values are expressed as mean±SD, one way ANOVA and post hoc was done, * and # shows P<0.05- statistically significant, ** and ## shows P<0.005 - statistically very significant, * indicates increase while # indicates decrease. significant difference between group IV and II.

Grouping	Day 1 Hb%	Day 21 Hb%	Day 53 Hb%
Group I	13.64 ± 0.31	8.78 ± 0.55##	9.22 ± 0.45
Group II	13.23 ± 0.71	9.28 ± 0.43##	12.74 ± 0.28**
Group III	13.44 ± 0.68	8.54 ± 0.52##	13.24 ± 0.43**
Group IV	13.25 ± 0.46	9.13 ± 0.34##	14.92 ± 0.54**^

After adding tannic acid to the diet, there was a significant decrease in haemoglobin on day 21. On applying statistics, it was observed that a significant decrease in haemoglobin were observed, when compared between day 1 and day 21 (#P<0.05- statistically significant, ##P<0.005 - statistically very significant), while significant increase in haemoglobin was observed after 30 days of administration of test and standard drug, when compared between day 21 and day 53(*P<0.05- statistically significant, **P<0.005 - statistically very significant) . The results showed that the rats of the Group II–IV have almost completely recovered at the end of two months. (Table 2). We applied Tukey HSD post hoc analysis and observed that there was significant difference between haemoglobin levels in groups II, III, IV as compared to group I on day 53, while no significant difference was observed within comparison of groups II & III as well as group III and IV. But a significant difference was noted on comparison of Group II and IV , considering that the haemoglobin levels of rats getting higher dose of Dhatryarista were more as compared to the standard drug ferrous sulphate. This implies that doubling the dose of dhatryarista produces beneficial effect instead of toxic effect.

Discussion

Iron deficiency is the most common form of nutritional deficiency. The size and number of red blood cells are reduced. There is a spectrum of iron deficiency ranging from iron depletion, which causes no physiological impairments, to iron-deficiency anemia, which affects the functioning of several organ systems. The terms anemia, iron deficiency, and iron-deficiency anemia are often used interchangeably, but are not equivalent. Anemia can only be diagnosed as irondeficiency anemia when there is additional evidence of iron deficiency. A diagnosis of iron-deficiency anemia can be made if haemoglobin concentration or hematocrit value increases after a course of therapeutic iron supplementation (Centers for Disease Control and Prevention, 1998).

Tannins are a group of compounds belonging to the phenolic class of secondary metabolites in plants. These compounds, in particular tannic acid, exhibit a wide variety of activity and physiological functions[19]. A number of adverse nutritional effects have been attributed to tannins. It has been demonstrated that feeding growing animals diets containing these compounds brings about several physiological and biochemical effects. These effects are reflected by growth inhibition, negative nitrogen balances, reduced intestinal absorption of sugars and amino acids, reduced immune response and increased liver and protein catabolism[20]. Also, foods with high tannin content inhibit iron absorption from meals[21].

Dhatryarista is a derived from amalaki which had been in use as an herbal prepartion for treatment of IDA. Amalaki was taken in 12 kg amount, *Sarkara* was added at 10% of the weight of Amalaki, that is, 1.2 kg, and honey was added one-eighth of the *Swarasa* obtained from *Amalaki*, and 48 g of *Pippali Churna* as *Prakshepa* was added (one-twenty-fifth of *Sarkara*).

Amalaki is an Amla rasa pradhana and can increase Raktha and hence in Rakthalpatha, Amla preeti is seen. It also being a rich source of Vit.C helps in absorption of iron. Hence it is used in anaemia[22] . *Amalaki* is worshipped as an auspicious fruit since ancient time and respected as a symbol of good health. The festival Amala Navami is celebrated at the begining of winter season of Hindu calender, where Amalaki tree is socially and religiously propagated among people and cultivated for promotion of good health. When the fruit is dried, the main ingredient, water, is mostly eliminated, and the remaining constituents are present in considerably larger proportions. The pulpy portion of fruit, dried and freed from the nut contains gallic acid, sugar, albumin, moisture, gum, crude cellulose. The edible fruit tissue contains protein concentration 3-fold and ascorbic acid concentration 160-fold compared to that of the apple.A research showed that 8.75 mg of natural vitamin C complex from *Amalaki* is equivalent to 100mg of the most commonly used synthetic vitamin C. *Amalaki* possesses the highest level of heat and storage stable vitamin C known to man. Phyllembin from fruit pulp is identified as ethyl gallate[23]. It has mild depressant action of CNS and spasmolytic action. The fruit also contains considerably higher concentration of most minerals and amino acids than apples.

Pipali fruits contain 1% volatile oil, resin, a waxy alkaloid, a terpenoid substance and alkaloids piperine and piperlongumine. Two new piperidine alkaloids namely pipermonaline and piperundecalidine were isolated from fruit.Dried spikes are acrid, stomachic, carminative, tonic, laxative, digestive, emollient, mild thermogenic and antiseptic. They are useful in anorexia, dyspepsia, vomiting, flatulence, colic, diarrhea, gastric

disorders and insomnia[24].

Madhu is used as an important dravya in many Ayurvedic formulations, wherein it has its own manifold pharmacological activities. It is also the most commonly used adjuvant as it acts as a suitable vehicle due to its '*Yogavahi'* (catalytic) property. Honey contains dextrose and fructose which are known as invert sugars (50-90%) and water. It also contains 0.1 - 100% of sucrose and small quantities of other carbohydrates, volatile oil, pigments and plant parts especially pollen grains. It also contains vitamin B & C. Acid constituents are Formic, Acetic, Malic, Citric, and Succinic acids. It also contains an enzyme named Invertase.It is laxative, demulcent and emollient. It possesses nutritive properties. The fatty acids present in honey stimulate peristalsis and digestion. It has beneficial effect on the digestion and appetite of those weak stomach and loose bowels. It decreases flatulence and increases general metabolism.

In present study, different doses of dhatryarista were administered in rats along with standard drug ferrous sulphate. Human equivalent dose is 48ml/day. In rats, required dose is 4.32ml/day but in this study , we are giving the higher dose so as to observe any kind of toxicity. We included 30 rats in this experiment which were divided as 6 rats in 5 groups. Blood samples were collected at Day 1 for measuring the baseline parameters. Group I rats were kept on normal basal diet while Groups II, III, IV, and V were put on basal diet including tannic acid for next 21 days. On Day 21, again blood samples were collected. From day 22, ferrous sulphate and Dhatryarista sample 1 & 2 were started in groups III, IV and V respectively for nest 30 days. Blood samples were again collected on day 53. It was seen that the recovery was progressive such that after 4 weeks of continuous treatment, the haemoglobin concentration was higher in the treated groups than in the control groups. It was also observed that the recovery of the treated groups was dose related with the highest dose of 8.64 ml/kg affecting the highest change.

Animals are similar to humans in terms of reduction of haemoglobin, which is indicative of anaemia[25]. In IDA, all the parameters are markedly reduced especially haemoglobin. Dhatryarista has shown to increase the red cell indices in drug sample groups without causing any signs of toxixity.

Conclusion

The administration of tannic acid to rats caused anaemia characterized by reducing hematological parameters. The oral administration of Dhatryarista in the dose of 4.32ml/kg/day P.O and 8.64ml/kg/day P.O significantly increased haemoglobin level. And also, the results demonstrated that higher doses of the plant extract didnot show any signs of acute toxicity in animals. This result supports the traditional use of dhatryarista in the treatment of anemia.

Klippel-Trenaunay Syndrome: A Clinical Case Report

Vikramjot Singh[1], Gauri Chauhan[2], A.K Bhardwaj[3], Gurdeep Singh Dhanja[4]

[1]Junior Resident, [2]Assistant Professor, [3]Professor And Head, [4]Professor, *MAHARISHI Markendeshwar Institute of Medical Sciences, MMDU, Mullana Ambala, Haryana*

Abstract

KTS is a rare congenital disorder. We present a 14 year old boy with the characteristics corresponding to the same i.e. venous varicosities, capillary malformation and limb hypertrophy. The patient also had other bony deformities like pectus carinatum, thoracolumbar scoliosis and campylodactyly. Such lumbar and digit deformities have been reported earlier also in patients with KTS. Patient was managed by a multidisciplinary approach, although a good follow up was not assured by the parents.

Keywords : *KTS, varicosities, limb hypertrophy, scoliosis, campylodactyly, Pectus carinatum.*

Introduction

Klippel-Trenaunay Syndrome (KTS), a syndrome of capillary-lymphatic-venous malformation associated with soft tissue and skeletal hypertrophy. It is a rare congenital disorder with a very low incidence of about 1:100,000. It has no predilection for gender, race, or geographical area and occurs sporadically [(1)]. It manifests as a triad of cutaneous capillary malformations, venous varicosities, and hypertrophy of the osseous and/or soft tissue of the extremities [(2-6)]. Vascular malformations are always present and usually (but not always) affect only one extremity, particularly the lower extremities [(7)].

Case Report

A 14 years old male presented with complaint of intermittent, low-grade fever from past 1 month which was not associated with chills or rigors. History of left lower limb painful swelling which progresses while doing daily activities and regresses while lying down or after elevation of the legs and also abnormal shape of chest which is progressing with age. The developmental growth was normal at each age range. There was no history of similar kind of illness in the family. On examination, the vitals of the patient were stable. The blood pressure of upper limbs and lower limbs were compared which did not show any variation. In anthropometric examination; weight, height and body mass index of the patient were 29.1 kg (-3.53 z), 144 cm (-2.38 z) and 14.0 kg/m^2 (-3.34 z) respectively. The arm span was 163 cm (figure 1) and arm span to height ratio was 1.13 and the upper segment to lower segment ratio was 0.8. The deformities seen were Pectus Carinatum (figure 2), Thoracolumbar scoliosis and Camptodactyly in little finger of both hands (left > right) (figure 3). Also there was increase in size/ diameter/mass of the left lower limb. His right leg was 6 cm longer than the left leg. There were painful venous varicosities on left lower limbs with gross tortousity of veins (figure 4). Visible pulsations were seen over the entire pericardium. However, apex beat was heard in 5ht intercostal space in mid clavicular line. On auscultation, heart sound were normal with no murmur. Neurological examination was intact. There was no respiratory or abdominal abnormalities. On Radiological investigations, thoracolumbar scoliosis with cardiomegaly on anterio-posterior and lateral chest x-rays (figure 5 and 6). Ultrasound of left leg showed extensive varicosities with many of them thrombosed with ectasia of venous channels more so in mid and lower leg with ectasia of superficial femoral vein in distal thigh. A definitive diagnosis with genetic testing and extensive family history and examination was not possible due to financial constrains and a poor follow up by the patient.

Discussion

KTWS is a combination of cutaneous angiomatosis, varicose veins, and enlargement of soft tissue first described in 1900. The KTWS occurs mostly sporadically, affecting males and females in equal numbers in about 1/100,000 people [8].

Limb hypertrophy is often present at birth or during infancy and continues to grow until the child stops growing, although it may continue to progress over time. The hypertrophy is a result of soft tissue and/or bony overgrowth or lymphatic and venous malformations [9, 10]. Although any part of the body can be involved, the most commonly affected sites are the lower extremities [11].

This patient has camptodactyly. Various other limb anomalies including macrodactyly, syndactyly, clinodactyly, ectrodactyly, and congenital hip dislocation have been reported in association with KTS [10].

The exact cause and mechanism of scoliosis in the patient in this study is unknown. It may be secondary to limb length discrepancy (about 6 cm), striking pelvic obliquity and long-term claudication.

A color Doppler ultrasound should be performed for prenatal diagnosis of limb hypertrophy and to assess the underlying cause of any cystic lesion. Most patients present with the complete clinical triad, with port wine stains and vascular malformations first appearing at birth and varicose veins usually appearing during infancy and progressing in adolescence [9]. Although such couldn't be assumed in our case.

KTS can cause significant morbidity from the vascular anomalies including deep venous thrombosis, bleeding, pulmonary embolism, stasis dermatitis, cellulitis, and limb enlargement that may require amputation. Patients also suffer from scoliosis and gait abnormalities related to limb hypertrophy. Therefore, KTS must be suspected, recognized, and appropriately managed in all infants with capillary malformations involving one or more extremity at birth [11].

In an adolescent, vitamin D deficiency and iron-deficiency anemia are quite uncommon. In a study by Jiliang Zhai et al,[12] serum ferritin level were found extremely low in a patient of Klippel-Trenaunay Syndrome and a severe form of iron deficiency anemia was noticed in the patient. Elevated D-Dimer were probably due to extensive venous malformations. Previous studies found that patients with large venous malformations has chronic low-grade consumptive coagulopathy [13]. Mazoyer [14] proposed that the coagulopathy among patients with venous malformations was a result of localized intravascular coagulation.

There is currently no cure or definitive treatment for KTS. However, management should be multidisciplinary and aim to reduce the symptoms and complications of the disease. For instance, compression stockings can be used for varicose veins, and heel inserts can be used and are usually sufficient for leg length discrepancies of 1.5 cm or less, although surgical closure of the growth plate at the knee is sometimes needed to equalize the leg length [15].

Conclusion

Here we present a case of KTS with a unique constellation of signs: unilateral limb involvement and campylodactyly. This case not only serves as a review of the atypical features of the syndrome, but also highlights that patients must be followed up on a regular basis by a multidisciplinary team and more research is required for proper diagnosis and treatment guidelines.

Figure 1: Arm span of the patient was 163 cms.

Figure 2: Pectus Carinatum can be seen in this with protrusion of the sternum.

Figure 3: Camptodactyly can be seen in little fingers bilaterally (Left> Right)

Figure 4: Visible Venous varicosities in lower limbs with grossly tortous veins

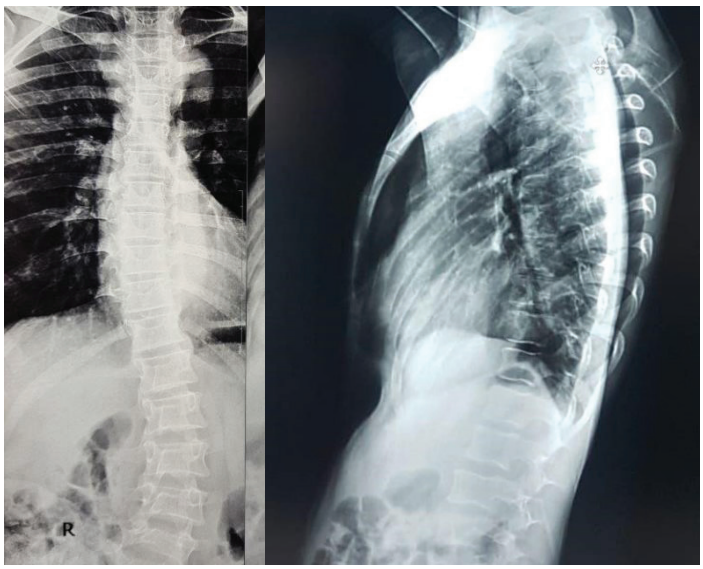

Figure 5&6: Xray chest (Anterioposterior and Lateral view) showing Thoracolumbar scoliosis with cardiomegaly

Abstract

Background: Parkinson's disease is a chronic, progressive and neurodegenerative disorder. A range of motor and non-motor symptoms may cause postural instability and impaired functional mobility often leading to falls and decrease quality of life. Physical therapy with Music therapy may be promising intervention to improve gait and related activities in Parkinson's disease. **Methodology:** Permission was taken from institutional ethical committee. An experimental study was conducted on 30 individual selected on the basis of inclusion and exclusion criteria. Randomized allocation of the participants was done into experimental (Physical therapy with music therapy) and control (Conventional physical therapy) groups. Participants were evaluated pre and post intervention for gait using Dynamic gait index (DGI), balance using Time up and go (TUG) and quality of Life using Parkinson's disease quality of life 39 (PDQ 39) questionnaire. A six weeks intervention program was given to the patients for four times per week. **Result:** Data was analyzed using Shapiro-wilk test accordingly parametric or non- parametric test were performed. Between groups comparisons showed extremely significant ($p<0.001$) improvement on DGI (4±1.363), TUG test (2±0.92) and PDQ 39 questionnaire (45.07±10.62) in experimental group as compare to DGI (2.33±1.496), TUG test (0.933±0.70) and PDQ 39 questionnaire (42.53±10.56) in control group. **Conclusion:** The study concluded that physical therapy with Music therapy is effective in improving gait, balance and quality of Life in patients with Parkinson's disease

Keywords: *Parkinson's disease (PD), Physical therapy with music therapy, Quality of life (QOL), balance, Gait.*

Introduction

Parkinson's disease has been known since biblical times but the symptoms was formally described by James Parkinson and termed 'the shaking palsy.[1] Parkinson's disease is chronic, progressive and degenerative disorder of nervous system characterized by large number of motor and non-motor features. It is characterized by the cardinal features of rigidity, bradykinesia, tremor and postural instability.[2] Parkinson's disease is a second most common neuro degenerative disorder; that affects more than 1.5% of the population above the age group of 60 years and 5% above the age group of 80 years. Based on this in India, approximately 0.32 million individual suffering from PD.[3,4].

The causes of the Parkinson's disease are either genetic or environmental or may be both factors influence the disease.[2] The potential risk factors are age, gender, head injury, area of residence, occupation, pesticide exposure, exposure to metals and genetic predisposition. The term parkinsonism is used to describe a group of disorder with primary disturbance in dopamine system of basal ganglia (BG).[2,5]

Primary motor symptoms of Parkinson's disease are rigidity, bradykinesia, tremor and postural instability. Non motor symptoms include mood disorder, orthostatic hypertension, bowel and bladder problems, integumentary changes, difficulty in speaking & swallowing and

cognitive problems etc.[2] A range of motor and non-motor symptoms have severe consequences may cause postural instability and impaired functional mobility often leading to falls and decrease quality of life.[6]

Modern management of Parkinson's disease aims to obtain symptoms control, to reduce clinical disability and to improve quality of life. Music acts as a specific stimulus to obtain motor and emotional responses by combining movement and stimulation of different sensory pathways.[7] According to research study Music therapy improves the cognitive function, reduce psychological and behavioral disturbances related to neurological disorder that promote functional recovery and quality of life of patients.[3] So we explored Music therapy as a method for inclusion in Parkinson's disease rehabilitation programs and studying their effect on gait, balance and quality of life.

Method

An Experimental study was carried out on 30 Parkinson's disease patients taken from various neuro rehabilitation centers. Patients were selected according to the inclusion and exclusion criteria. Inclusion criteria's were patients diagnosed with idiopathic Parkinson's disease, both male and female, have to be responsive to levodopa therapy or other dopaminergic treatment, Age limit: 40 to 80 years, Modified Hoehn and Yahr stage 2, 2.5 and 3, Berg Balance score

>20. Patient were excluded based on the following criteria such as patient having secondary parkinsonism, severe sensory deficits, disease affecting movement (other than Parkinson's disease), patients having any mental health issue due to which assessment of patient becomes difficult, any recent history of musculoskeletal or cardiac disorder, any recent surgical history. The participants were assessed using DGI, TUG test and PDQ 39 questioner for gait, balance and QOL respectively before the intervention program and were divided into Experimental and Control Group by random allocation using envelope method.

Procedure

Ethical clearance was taken from Institutional Ethical Committee and Participants were selected according to inclusion and exclusion criteria. the aims, objectives and method of study was explained to the participants and written consent was filled. Both of the groups received treatment for duration of 60 minutes with appropriate rest period as required. Number of treatment sessions was 4 times/week for 6 weeks.

Experimental group: Physical therapy with Music therapy.

Each session consist of warm up period, workout session and cool down period. Warm period were included choral singing and bilateral upper extremity movement in sitting. Workout session were included passive stretching of major muscle group and strength training; while these exercises melodic instrumental music was played. Marching music was played during standing and marching activity. During gait training Waltz rhythmic music was played. Modify tap dance music was played during balance training. Cool down period was included breathing exercise with om music and fine motor movement on rocking chair. Exercises were given according to the need of patients. Rest period were also given to the patient if they required.

Control group: Conventional Physical therapy.

Each Session consist of warm up period, workout session and cool down period. Warm period were included active free movements in sitting, and bilateral upper extremity pattern to facilitate trunk rotation in sitting. Workout session were included passive stretching of major muscle group, strength training, active range of motion exercises, and wand exercises. Standing and marching activity, balance and gait training. Cool down period was included breathing exercise and fine motor movement on rocking chair. Exercises were given according to the requirement of patients. Rest period were also given to the patient if they require.

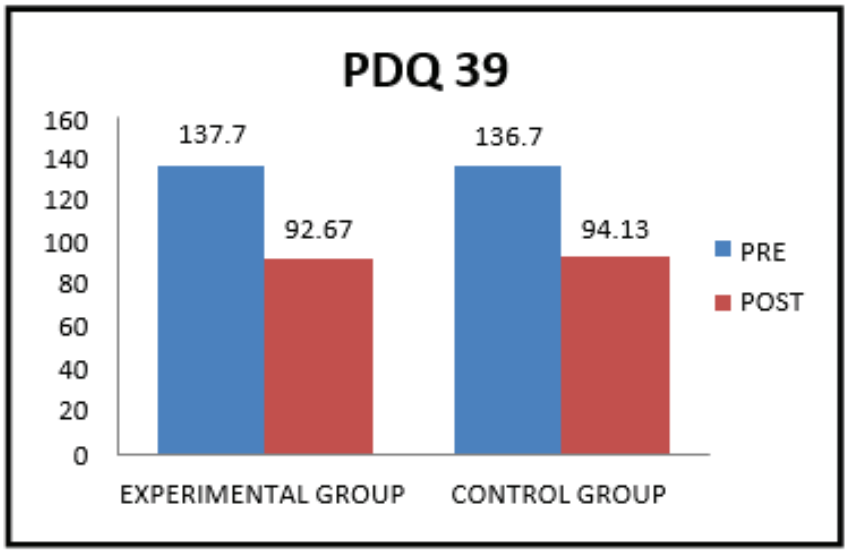

Graph 3: Comparison of pre and posttest values of PDQ 39 questionnaire in experimental and control group

Discussion

The aim of the research was to study the effect Physical therapy with music therapy on gait balance and quality of life in patients with Parkinson's disease. Parkinson's disease (PD) is a second most common degenerative disorder of nervous system characterized by large number of motor and non-motor symptoms may have severe consequences for functioning of patients, affecting their activities of daily living and quality of life.[4]

Graph 1 and 2 show there is more significant improvement on dynamic gait index and time up and go test in individual who were undergoing physical therapy with music therapy as compare to conventional physical therapy. A similar study was carried out by Claudio P. et al in 2000, to study active music therapy in PD on emotional status, gait, balance and QOL, concluded that music improves emotional status, rhythmic limb movements, gait and freezing in patients with PD.[5]

It is difficult to determine the underlying mechanisms for improvements in gait and dynamic balance which reduces risk of fall in PD patients. Musical rhythm acts as template for organization of series of active movements, as well as reduces cognitive issues that affect motor performance and emotional state.[8] It naturally combines cognitive movement strategies, cueing techniques, balance exercises and physical activity while focusing on the enjoyment of moving on music instead of the current mobility limitations of the patient. Motor facilitation in response to music therapy may be based on emotional reactions momentarily activating the cortical basal ganglia motor loop, the circuit which is primarily affected in PD.[7] Music helps in movement facilitation, coordination and synchronization of active movement, improving emotional and mood state, that reduces clinical symptoms and improve their gait and balance.[6]

In our study Graph 3 show there is more significant improvement on PDQ 39 questionnaire in experimental group as compare to control group. It shows more significant improvement in quality of life in individuals who were undergoing Physical therapy with Music with therapy as compare to conventional physical therapy. Another analogous study was performed by M.J. de Dreua et al in 2008, who concluded that Music with movement therapy helps patients to Imagine and engaging in multiple activities which helps in improving motor symptoms in patients with Parkinson's disease. Mindful active ROM exercises program help in improving abilities of individuals and in improving QOL of Parkinson's disease.[6]

A possible explanation for this result may be Physical therapy serve as reinforcement of the

motor program, but this type of intervention is usually lacking in the motivational and emotional spheres.[9] So it has little influence on mood and emotional state. These psychosocial variables such as emotional state or psychosocial stress, strongly influence abnormalities in gait, posture and other motor performance, which affect their functional, emotional and social aspect of patient's life.[10] Music such as rhythm, pitch & timbre has been shown to relax and reduce anxiety, modifying release of stress hormones, improve cardiac function and respiratory pattern. It also promotes socialization, involvement with the environment, expression of feeling, awareness and responsiveness.[7] Hence music act as specific stimuli to increase motivation, reduce psychosocial stress and improve mood state which ultimately improve their QOL.

Conclusion

The study concluded that physical therapy with music therapy is effective in improving Gait, Balance and Quality of Life in patients with Parkinson's disease.

Role of DLCO in differentiation or subtyping of obstructive lung disease beyond spirometry and CT scan.

Vishvdeep Saini[1], Sameer Singhal[2], Sukhjinder Pal Singh[3], Achchhar Singh[4], Aditi Gupta[5]

[1]Junior Resident, [2]Professor, [3]Senior Resident, [4]Associate Professor,[5]Assistant Professor, Department of Respiratory Medicine, MMIMSR, M.M Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Introduction: Spirometry helps us to differentiate between obstructive and restrictive disease, body plethysmography tells about lung volumes and DLCO about diffusion defect. Determining which tests to do depends on the clinical question to be answered i.e. whether test is being done to diagnose a disease or for evaluation for lung surgery or some other reason.

Material & Methods: 46 patients coming to department of respiratory medicine, who were diagnosed with obstructive lung disease by PFT as per GOLD guidelineswere considered for the study. Chest X-ray and CT chest were also done.Then DLCO was performed in every patient. Single breath hold method was used in the study.The report of the DLCO was interpreted according tothe American Thoracic Society/European Respiratory Society statement on PFT interpretation.

Results: Male preponderance was seen in study cases with 65.2% males to 34.8% females. Mean age of the study group was 54.39 years with most cases (18) from 31-50 years of age group. Most common diagnosis was COPD emphysema (22) followed by chronic bronchitis (12), bronchial asthma (10) and bronchiectasis (2). Among obstructive lung diseases, B. asthma had the highest mean DLCO percentage predicted of 102.20 ± 14.36 followed by COPD-Bronchitis (76.33±5.57), COPD–Emphysema (37.80±13.41) and bronchiectasis (62±4.48).

Conclusion: DLCO can be helpful beyond spirometry in classification of obstructive lung diseases. DLCO values in COPD Emphysema variant are decreased, COPD bronchitis variant remains normal or slightly reduced and asthma either normal or increased. So, DLCO can help in differentiation or sub categorization of obstructive disease more than spirometry.

Key Words: *DLCO, Obstructive diseases, Lung function test, COPD, Emphysema, Bronchial Asthma.*

Introduction

Carbon monoxide diffusing capacity is the least understood pulmonary function test in clinical practice worldwide, even among experienced pulmonologists. There are lot of different tests used for evaluation of lung functions. These tests may be performed individually or in combination with other tests.Pulmonary function test report includes spirometry, diffusing capacity, lung volumes and airway resistance(R_{aw}) measurements in a commonly used format. Spirometry help us to differentiate between obstructive and restrictive disease, body plethysmography tells about lung volumes and DLCO about diffusion defect. Determining which tests to do depends on the clinical question to be answered i.e. whether test is being done to diagnose a disease or for evaluation for lung surgery or some other reason. Measuring the diffusing capacity of lungs for carbon monoxide is 2nd most important pulmonary function test that is done after spirometry.

The single breath test of carbon monoxide (CO) uptake has a long history, from its birth (Kroghand Krogh, 1909)[1] to the first publication by Ogilvie et aldescribing a standardized technique for the diffusingcapacity measurement (DLCO) in 1957.[2] The DLCO was devised originally as a physiological tool to test the notion that the lung, like the swim bladder of some deep-sea fish, could secrete oxygen against the normal tension gradient provided by inspired air by Bohr in 1900 although this

notion is now long abandoned.

As a clinical test DLCO was introduced in 1915 by Marie Krogh, but the measurement never caught on because methods of measuring carbon monoxide were so cumbersome.[3]But now a day's single breath technique is in common use. DLCO measures the transfer of a diffusion-limited gas (CO) across the alveolocapillary membranes.

DLCO is increased in the circumstanceswhen pulmonary capillaries are recruited, as occurs during exercise**,** during a Mueller (reverse Valsalva) manoeuvre**,** pulmonary hemorrhage**,** polycythemia,obesity, asthma etc. DLCO is decreased in cases of **l**ung resection, pulmonary emphysema affects capillary or alveolar bed, pulmonary vascular disease including PAH and chronic venous thromboembolism**,** interstitial lung diseases**,** anemia**,** drugs induced fibrosis e.g. bleomycin, amiodarone**,** pulmonary lymphangitic carcinomatosis

Material and Method

23 patients coming to department of respiratory medicine of MMIMSR, who were diagnosed with obstructive lung disease by PFT, Chest X-ray or CT chest, were considered for the study. At baseline, patient's medical history was recorded and thorough physical examination was done. The medical history chiefly included history of symptoms related to respiratory system, namely shortness of breath, cough, weight loss, fatigue, expectoration and any other symptom related to other systems. Obstructive disease was categorized as post-bronchodilator FEV1/FVC <0.70 for COPD and post bronchodilator change in FEV1 by >12% and 200ml in case of Bronchial asthma.Chronic bronchitisis defined clinically as the presence of a chronic productive cough for 3 months during each of 2 consecutive years after excluding other causes of cough. Then DLCO was performed in every patient. Single breath hold method was used in the study.The report of the DLCO was interpreted according tothe American Thoracic Society/European Respiratory Society statement on PFT interpretation and is as follows – normal - >80% predicted DLCO, mild reduction - 79% to 60% of predicted DLCO, moderate reduction - 59% to 40% of predicted DLCO, severe reduction - < 40% of predicted DLCO.

In this present study we aimed to find out the importance of DLCO in differentiation of obstructive disease beyond spirometry and CT evidence as some of the COPD patients may also show post-bronchodilator reversibility.

Results

Male preponderance was seen in study cases with 65.2% males to 34.8% females. Mean age of the study group was 54.39 years with most cases (18) from 31-50 years of age group**.** Most common diagnosis was COPD emphysema (22) followed by chronic bronchitis (12), bronchial asthma (10) and bronchiectasis (2). 14 (30.4%) patients were smokers, 12 (26.1%) were non-smokers and 20 (43.5%) patients were ex-smokers. Among obstructive lung diseases, B. asthma had the highest mean DLCO percentage predicted of 102.20± 14.36 followed by COPD-Bronchitis (76.33±5.57), COPD–Emphysema (37.80±13.41) and bronchiectasis (62±4.48).

Table 1. Distribution of study cases as per Diagnosis

Diagnosis	**N**	**%**
Chronic Obstructive Pulmonary Disease – Emphysema	22	47.82%
Chronic Obstructive Pulmonary Disease – Bronchitis	12	26.08%
Bronchial Asthma	10	21.73%
Bronchiectasis	2	04.34%
TOTAL	46	100%

Table 2– DLCO value in Obstructive lung disease

	N	Mean	SD
B. Asthma	10	102.2	14.32
COPD – E	22	37.80	13.41
COPD – B	12	76.33	5.57
Bronchiectasis	2	62	4.48
Total	46	62.39	29.44

Discussion

DL_{CO} measurement is very reliable and sensitive. DL_{CO} is determined by the amount of blood recruited in thealveolar capillary bed and the alveolo-capillary surfaceavailable for diffusion.

The decrease in DL_{CO} is probably more closely related to the loss of lung volume, alveolar surface area, or capillary bed than to the thickening of the alveolocapillarymembranes. DLCO also decreases when there is loss of lung tissue or replacement of normal parenchyma by space-occupying lesions such as tumours. DLCO may also be decreased in pulmonary oedema as in congestive heart failure. Surgical lung resection for cancer or other reasons also reduce DLCO except in LVRS and bullectomy because the resected areas generally have little to no blood flow.

In acute and chronic obstructive lung disease also DLCO may be decreased. But other obstructive diseases (e.g., chronic bronchitis, asthma) may not reduce DLCO unless they result in markedly abnormal patterns.Some asthmatic patients may have an increased DLCO, but the cause is not completely understood.

Obstructive lung diseases in our study included B. Asthma, Chronic obstructive pulmonary disease-emphysema and bronchitis variants and bronchiectasis. The mean value of DLCO in obstructive lung diseases was 62.39 ± 29.44. In specific diseases, B. asthma had the highest mean DLCO percentage predicted of 102.20 ± 14.36. Saydain G[4] et al did a study on clinical significance of elevated DLCO in 245 patients who had elevated DLCO values. He found that most patients with elevated DLCO had the diagnosis of obesity, asthma or both. Our study also showed COPD- bronchitis patients had the mean DLCO of 76.33 ± 5.57 while COPD-emphysema patients had a mean predicted DLCO value of 37.80 ± 13.41. There were only two bronchiectasis patients in the study and the mean DLCO value was 62±4.48.

To summarize, DLCO is a very good tool for early identification of lung diseases. It can be used to differentiate between COPD and asthma as percentage predicted DLCO is usually decreased in emphysematous patients while it may be normal or increased in asthmatic patients. Bronchitis patients may also show normal or slightly decreased DLCO values.

Conclusion

DLCO can be helpful beyond spirometry in classification of obstructive lung diseases. DLCO values in COPD Emphysema variant are decreased, COPD bronchitis variant remains normal or slightly reduced and asthma either normal or increased. So DLCO can help in differentiation or sub categorization of obstructive disease more than spirometry.

Conflict of Interest- None.

Development and Validation of a Gujarati Questionnaire for Evaluating Levels of Awareness, Acceptance, Socio-Economic Stress & Expectations from Physiotherapy Services in Parents of Children with Cerebral Palsy

Vivek Harsukhbhai Ramanandi[1,2], Mukund Motibhai Prabhakar[3]

[1]Ph. D. Scholar, Faculty of Medicine, Gujarat University, Ahmedabad, [2]Assistant Professor, SPB Physiotherapy College, Veer Narmad South Gujarat University, Surat, [3]Ph. D. Guide, Faculty of Medicine, Gujarat University, Ahmedabad

Abstract

Parents of children with cerebral palsy experience anxiety, depression, guilt and low self-esteem, frustration, low matrimonial and personal satisfaction etc. While planning interventions for the child with cerebral palsy, physiotherapist should consider physical and psychological health of caregivers, influence of social support, family functioning etc. This study gives an overview of the procedure for development and validation of a Gujarati questionnaire to evaluate levels of awareness, acceptance, stress & expectations from physiotherapy services through two-stage process. At the 1st stage domain determination, item generation and instrument formation was done. In the 2nd stage, face and content validation was done using consensus method by a group of 10 experts. As a result, questionnaire having 9 dimensions and 84 items with acceptable levels of validity was developed.

Keywords: *Cerebral palsy, parenting, parents, caregivers, physical therapy, questionnaire.*

Introduction

Parents having a child with cerebral palsy cope with their child's functional limitations along with their specific needs [1]. Parents who have children with CP are faced with many difficulties including issues with the personal relations, social problems, economic problems, personal physical problems, issues involving the sick child's care and education [2]. They frequently experience anxiety, depression, guilt and low self-esteem, frustration, low matrimonial and personal satisfaction due to feelings of inadequacy for not being able to have a normal child, and also have impaired sexual lives [3,4].

While a physiotherapist plans interventions for the child with CP, he should also consider parental awareness about various aspects; acceptance of the situation by parents, family and society; levels of stress due to parenting; experiences and expectations from physiotherapy services. To study such complex constructs, researchers require valid and reliable instrument [5].

CanChild Center for Childhood Disability Research has developed a conceptual framework of family-centered service and has defined it as follows:

"Family-centered service is made up of a set of values, attitudes, and approaches to services for children with special needs and their families. It recognizes that each family is unique; that the family is the constant in the child's life; and that they are the experts on the child's abilities and needs. The family works together with service providers to make informed decisions about the services and supports the child and family receive. In family-centered service, the strengths and needs of all family members are considered [6]". Lack of standard questionnaires or instruments to review and promote family-centeredness in paediatric rehabilitation has lead

to a serious limitation in service provision capacities of country [7].

In the light of previous findings relevant to rehabilitation for CP in India, researchers have recommended that physiotherapists should focus on reviewing the difficulties of parents and provide education, guidance and support to them. This enables parents to cope better with the condition, thereby resulting in improved outcomes associated with treatment[2,4,8-10].

While reviewing available literature, it was found that only few instruments in English can provide comprehensive information about stress, acceptance, beliefs, expectations, utilization etc. [8,11-14]. Studies in India and Gujarat showed that, no valid and comprehensive questionnaire is yet available in Gujarati to help study these aspects.

When a new questionnaire is designed, measurement and report of its content validity have fundamental importance [15].It provides information on the representativeness and clarity of items and help improve a questionnaire through achieving recommendations from an expert panel[16,17]. Therefore, validity evidence should be obtained on each study for which a questionnaire is used [18].

Materials and Method

This exploratory mixed method research (qualitative-quantitative) study was carried out to design and validate the questionnaire measuring levels of awareness, acceptance, socio-economic stress & expectations from physiotherapy services in parents of children with CP.

Stage 1: Questionnaire Design

Process of questionnaire design follows 3 steps, including content domain determination, item generation and questionnaire construction [19,20].

Qualitative data was collected from the interviews with 21 parents of children with CP. Following the guidelines of Tilden et al. (1990) the data from interview was used as a resource to generate questionnaire items [21]. For item generation, Ridenour and Newman's deductive- inductive technique was applied [22]. In third step, questionnaire was constructed by refining and organizing items in a suitable format and sequence so that the finalized items are in a usable form [23].

Stage2: Judgment

This step included confirmation by a panel of experts, indicating that questionnaire items and the entire questionnaire have content validity. For this purpose, a panel with 10 experts having mean research or work experience of 23.1 + 8.47 years was appointed.

Experts were requested to provide their viewpoints on the relevance, clarity and comprehensiveness of the items [15,23]. In first round of judgement, few items were modified whereas some were eliminated based on the opinion of content experts about grammar, appropriate and correct words, correct and proper order of words and appropriate scoring [24]. For quantification purpose Content Validity Ratio (CVR) was used, where the experts were requested to score each item from 1 to 3, with a 3-degree range of "not necessary, useful but not essential, essential", and specify whether an item is necessary in a set of items or not. Values of CVR vary between 1 and -1. For this study 10 experts were included, therefore item with CVR value bigger than 0.62 was accepted [25].

Another widely reported approach for content validity for questionnaire development study is the content validity index (CVI) [23,26,27]. The expert panel members (n=10) were requested for to rate questionnaire items in terms of relevance and clarity on a 4-point ordinal scale [26]. A table like the one shown below (Table 1) was added to the cover letter to guide experts for scoring method. For relevance, CVI was calculated both for item level and the scale-level.

Table 1. The table added to the cover letter to guide experts for scoring method

Relevance	Clarity
1 – Not relevant	1 – Not clear
2 – Item needs some revision	2 – Item needs some revision
3 – Relevant but need minor revision	3 – Clear but need minor revision
4 – Very relevant	4 – Very clear

The I-CVI expresses the proportion of agreement on the relevance of each item, which is between 0 and 1 [18,23]. Minimum 80% agreement among experts was

considered for the items to be appropriate for selection in the questionnaire [26]. Kappa statistic was undertaken to provide adjustment for chance agreement [28].The scale-level content validity index (S-CVI) is defined as "the proportion of items on an questionnaire that achieved a rating of 3 or 4 by the content experts" [29]. S-CVI was calculated using universal agreement method i.e. S-CVI/UA, as well as averages method i.e. S-CVI/Ave.

Determining face validity of a questionnaire

Face validity is related to the appearance and apparent attractiveness of a questionnaire, which may affect the questionnaire acceptability by respondents [19]. To determine face validity 10 parents of children with CP (lay experts) was requested to judge on the importance, simplicity and understandability of items[27]. They were asked to grade importance of all items on a 5-point Likert scale i.e. very important, important, relatively important, slightly important, and unimportant. The items were revised to make them more meaningful and understandable as per the suggestions from respondents.

Final questionnaire was constructed at the end of this designing and validation process. The final version of questionnaire included 9 sections and 84 questions.

Results

Results of Stage 1

Qualitative content analysis of the data collected through semi-structured in-depth interview of 21 parents of children with CP was done. The results led to identification of content domain within 4 dimensions and 16 sub-dimensions (Table 2).

Table 2. The Content Domains identified during qualitative content analysis

Sr. No.	Domain	Sub-domain
1	Awareness in the parents	1. Cerebral palsy: causes & prognosis 2. 2.Available treatment options 3. Role & importance of pt 4. Support & aid
2	Problems experienced by parents	1. Social problems 2. Physical problems 3. Psychological problems 4. Financial problems 5. Other problems
3	Acceptance of the child	1. By parents 2. By family 3. By society
4	Expectations of the parents	1. Availability of rehab services 2. Quality of rehab services 3. Response to rehab measures 4. Other support services

During the process 117 questions were generated from the data derived out of the interviews. 22 questions were added from relevant literature and related questionnaires. 41 questions were removed due to duplication and overlapping of concept. At the end of item generation process, preliminary questionnaire was developed having 98 items within 9 sections. The sections and the variables covered by them are enlisted below:

Section 0: Interview related variables

Section 1: Child related variables

Section 2: Child's difficulties and associated variables

Section 3: Caregiver related variables

Section 4: Child's family related variables

Section 5: Caregiver's awareness and associated variables

Section 6: Child's acceptance and associated variables

Section 7: Parental stress and associated variables

Section 8: Expectations from Physiotherapy and associated variables

Results of stage 2:

Results for estimation of Content Validity

In the second stage the panel of 10 content experts were requested to judge the content of questionnaire qualitatively and quantitatively using prescribed formats in three rounds.

In the first round of judgment, 10 items having CVR lower than 0.62 were eliminated. The remaining items were modified according to the recommendations of panel members.

In the second round, the proportion of agreement among panel members on the relevance and clarity of 88 remaining items of the first round of judgment was calculated. In this round, among the 88 questionnaire items, 5 items with a CVI score lower than 0.70 were eliminated. 7 items with a CVI between 0.70 and 0.79 were modified (according to the recommendation of panel members and research group forums). According to experts' suggestions, an item about advice regarding the neonatal follow up was added in this round. After modification, the questionnaire containing 84 items was sent to the panel members for the third time to judge on the relevance, clarity and comprehensiveness.

The probability of chance agreement was first calculated for each item and then kappa (K) was computed by using the numerical values of Pc and I-CVI. All 84 items had K values >0.74 and were accepted for face validation.

Results for estimation of Face validity

A panel of 10 parents of children with CP (lay experts) was requested to judge face validity of all 84 questions. According to their opinions, to make some items more understandable, objective examples were included. For instance,

"બાળકની ફિઝીયોથેરાપી અને અન્ય સારવાર માટે આશરે કુલ માસિક ખર્ચ કેટલો થાય છે?"

was changed to,

"બાળકની ફિઝીયોથેરાપી અને અન્ય સારવાર માટે આશરે કુલ માસિક ખર્ચ કેટલો થાય છે? (દા.ત. વાહનમાં આવવા-જવાનો, નાસ્તો-પાણી, કેસ ફી, સારવાર ફી, દવાઓ વગેરે.)"

All 84 items were found satisfactory and accepted for the final questionnaire. Finally, at the end of the content validity and face validity process, our questionnaire was prepared with 9 sections and 84 items for the next steps and doing the rest of psychometric testing.

Discussion

Present paper demonstrates quantitative indices for content validity of a new questionnaire and outlines the process of design and psychometric analysis of Gujarati questionnaire for evaluating levels of awareness, acceptance, socio-economic stress & expectations from physiotherapy services in parents of children with CP.

It should be said that validation is a lengthy and complicated process involving many people including experts and subjects from the population of interest. The first-step of validation, the content validity, should be studied in extensive manner. Meanwhile, this study showed that although content validity is a subjective process, it is possible to objectify it through various statistical procedures. The further analyses of psychometrics should be directed towards reliability evaluation (through internal consistency and test-retest), construct validity (through factor analysis) and criterion-related validity [27].

Clinicians and researchers should realize if the questionnaires they use for their studies are suitable for the construct, population under study, and socio-cultural background in which the study is carried out, or there is a need for new or modified questionnaires. Training on content validity study helps students, researchers, and clinical staffs better understand, use and criticize research questionnaires with a more accurate approach.

Main limitation of this study is, as experts' feedback is subjective, the study is subjected to bias that may exist among the experts.

Conclusion

This was a systematic content validity study conducted through two stage process. In the first stage, questionnaire design was carried out and in the second stage; judgment on questionnaire items was performed. Such process should lead the development of a valid and reliable questionnaire in terms of content. In general, this content validity study revealed that this questionnaire enjoys a satisfactory level of content validity.

Comparative Study of Low Pressure Pneumoperitoneum versus Standard Pressure Pneumoperitoneum in Laparoscopic Cholecystectomy

Rashid Murtaza[1], Madhubala Gaur[2], Atul Shishodia[2]

[1]Assistant Professor, [2]Professor, [2]Assistant Professor, Saraswathi Institute of Medical Sciences, Hapur, U.P.

Abstract

Aim: - To evaluate the advantages and disadvantages of low pressure (8mmHg) in comparison to standard pressure pneumoperitoneum (12mmHg) in laparoscopic cholecystectomy.

Setting & Design: - Prospective study from April 2017 to March 2018 in the Department of General Surgery, Saraswathi Institute of Medical Sciences, Hapur.

Methods & Material: - A prospective randomized controlled trial incorporating 80 patients with symptomatic uncomplicated cholelithiasis who underwent laparoscopic cholecystectomy using a four port technique. All patients were divided randomly in two groups: 40 patients underwent LPLC (Low Pressure Laparoscopic Cholecystecomy) and another 40 patients underwent SPLC (Standard Pressure Laparoscopic Cholecystectomy). Factors included in statistical analysis were per-operative pulse, blood pressure, operative time, post-operative pain including shoulder tip pain, complication rate, conversion rate to SPLC, conversion rate to open cholecystectomy, postoperative hospital stay.

Statistical analysis: It was done using Chi-square test & Student t test.

Results: - No statistically significant difference was found in hemodynamic changes, postoperative pain including shoulder tip pain, mean operative time, mean hospital stay in both groups. Conversion from LPLC to SPLC was done in 4 cases. No case was converted to open cholecystectomy.

Conclusions: - Laparoscopic cholecystectomy can be safely performed at low pressure (8 mmHg) pneumoperitoneum.

Key Words: - *Cholelithiasis, pneumoperitoneum, LPLC, SPLC.*

Introduction

Commonest methods to create working space in the abdomen during laparoscopic cholecystectomy is pneumoperitoneum.[1] During laparoscopic surgery the pneumoperitoneum and the patient position induce pathophysiological changes that complicate anesthetic management. Pulmonary & hemodynamic changes are related to pneumoperitoneum pressure which is not a linear relationship. At low pressure (0-10mmHg), relatively few changes occur in a normovolemic healthy adult. Pneumoperitoneum with pressure range 12-14mmHg over prolonged periods is associated with adverse effects such as decreased pulmonary compliance , altered blood gas parameters, impaired functioning of circulatory system, raised liver enzymes, renal dysfunction and increased intraabdominal pressure.[3,4,5,6,7]

Aims & Objective: - To evaluate the advantages and disadvantages of low pressure (8mmHg) in comparison to standard pressure pneumoperitoneum (12mmHg) in laparoscopic cholecystectomy.

Design and Duration: - Prospective study from April 2017 to March 2018.

Setting: - Department of Surgery, Saraswathi Institute of Medical Sciences, Hapur.

Patients: - All patients with symptomatic uncomplicated cholelithiasis undergoing laparoscopic cholecystectomy.

Methodology: - Proper preoperative workup of all symptomatic patients of cholelithiasis of both sexes and age between 18 to 70 years was done. Patients with chronic liver disease, those unfit for surgery, age below 18 years, pregnancy, lactation, coagulopathy, CA Gall Bladder, Empyema Gall Bladder, Acute cholecystitis, previous abdominal surgery were excluded from were excluded from study. Total 80 patients were included in study. Written informed consent was taken from all patients. Approval for this study by local ethical committee was taken. All patients were divided randomly in two groups: A and B, equal in size (n=40).Four port laparoscopic cholecystectomy was performed by experienced laparoscopic surgeon's team. Group A patients underwent low pressure (8 mmHg) pneumoperitoneum laparoscopic cholecystectomy (LPLC). Group B patients underwent standard pressure (12 mmHg) laparoscopic cholecystectomy (SPLC). Intraoperative monitoring of heart rate & blood pressure was done noninvasively. Factors included in statistical analysis were per-operative pulse rate, blood pressure, operative time, post- operative pain including shoulder tip pain, complication rate, conversion rate to SPLC, conversion rate to OC, postoperative hospital stay.

Data Analysis: - Statistical analysis was done using Chi-square test & Student t test (unpaired). P- Value <0.05 was considered statistically significant.

Result

Total 80 patients underwent LC. Age group was 20 to 65 years.

70 patients were females and 10 patients were males. Group A included 40 patients who underwent LPLC. Group B included 40 patients who underwent SPLC. Tachycardia, hypertension after creation of pneumoperitoneum in both group was present but it was not statistically significant. ($P < 0.05$). Mean operative time was longer in LPLC as compared to SPLC but difference was not statistically significant. Conversion from LPLC to SPLC was done in 4 cases. Not a single case was converted in to open cholecystectomy. Postoperative pain including shoulder tip pain was same in both groups. Mean hospital stay was 2.46 days in LPLC vs. 2.26 days in SPLC. Laparoscopic cholecystectomy can be safely performed at low pressure (8 mmHg) pneumoperitoneum. Operative time is more if pressure is kept low.

Table - 1 : Comparative outcome between group A and group B of various parameters

S. No.	Parameters	GROUP A (LPLC) Patients	GROUP B (SPLC) Patients
1.	Mean Pulse Rate (beats per minute)	98	92
2.	Mean Blood Pressure (mmHg)	128.4/74.4	130.4/78.4
3.	Mean Operative Time (minutes)	58	48
4.	Mean Hospital Stay (days)	2.46	2.26
5.	Shoulder Tip Pain	2	2
6.	Gall Bladder Perforation	2	1
7.	Conversion to Open Cholecystectomy	0	0
8.	Conversion to SPLC	4	-
9.	Complication Rate	0	0

Table 1 shows a comparative outcome of different parameters, between two groups, the difference between mean pulse rate (beats per minute) is of 6 beats only. The difference between SBP and DBP between two groups is minimal. The mean operative time difference (in minutes) is of 10 minutes only. Shoulder tip pain in both group is same. The difference between gall bladder perforation is of 1 only. The conversion was not needed in both the groups patients. Conversion of LPLC patient to SPLC was 4. No significant complication were seen in both the groups.

Discussion

The main aim of minimally access surgery is to reduce post- operative pain, post-operative hospital stay and other morbidities. Causes of post-operative pain following laparoscopic cholecystectomy are port site tissue injury, gall bladder bed, peritoneal & diaphragmatic stretch due to pnuemoperitoneum, stimulation of sympathetic nervous system by hypercarbia, Chemical irritation of peritoneum by CO_2 & resultant carbonic acid formation.[6,7] Many studies have reported that the incidence & intensity of postoperative pain including shoulder tip pain was less in low pressure pneumoperitoneum group as compared to standard pressure pneumoperitoneum groups. [8,910,11,12.] Also low pressure pneumoperitoneum results in lesser hemsodynamic changes as compared to standard pressure pneumoperitoneum in many studies.[9,10,11.] In our study there is no statistically significant difference in haemodynamics in both groups. Conversion from SPLC to LPLC was done in four cases in our study. Main reason for this was bleeding & adhesions requiring adequate exposure which was not possible in LPLC as suction of CO_2 along with blood resulting in decreased space demanded intra-abdominal pressure 14 mmHg.

Conclusion

Low pressure pneumoperitoneum with adequate exposure should be recommended in Laparoscopic cholecystectomy in uncomplicated GSD. Operative time is more if pressure is kept low. Advantage of low pressure pneumoperitoneum is decreased post-operative pain including shoulder tip pain.

Prevalence and Risk Factors of Intimate Partner Violence among Indian Women: A Secondary Data Analysis of NFHS-4

Tessy Thomas[1], Vasudeva Guddattu[2], Madhusudan M[3]

[1]Lecturer in Biostatistics, Department of Community Medicine, DM WIMS Medical College, Naseera Nagar, Wayanad, India, [2]Associate Professor, Department of Data Science, Manipal University, Manipal, [3]Assistant Professor, Department of Community Medicine, DM WIMS Medical College, Naseera Nagar, Wayanad, India

Abstract

Background: During the last few decades, violence towards women in general, and intimate partner violence (IPV) in particular, is increasingly being acknowledged as a violation of basic human rights and it is recognized as the consequential barricade of the empowerment of women. **Objectives:** To determine the prevalence and risk factors associated with IPV. **Methodology:** This study used a nationally representative data collected through NFHS-4 (2015-2016). In total 66013 ever married women aged 15-49 were analysed. Multiple logistic regression model was used to quantify the factors associated with IPV. **Result**: The prevalence of women ever confronting IPV in India was 29.5 per cent. It was also found that less severe violence was most prevalent accounting for 27.5% whereas severe violence was 8.2 percent. Prevalence of IPV was higher among women who were uneducated, in the middle age group, who had older partners, from rural background; those with uneducated partners, who themselves and their partners drink alcohol, who are unemployed themselves and have unemployed partners, poorest compared to richest, who justify wife beating compared to who do not, who had witnessed their father beating their mother compared to who did not and all these factors were found to be statistically significant. **Conclusion:** Prevalence of IPV in India is considerably lower compared to other developing countries. Factors like alcohol consumption of partner, education level of respondents as well as partners, past exposure to violence, justified wife beating and wealth index which are linked to IPV which need to be tackled to bring down the prevalence of IPV.

Key-words: *Intimate partner violence, NFHS, India, risk factor, women*

Introduction

Intimate Partner Violence, commonly known as Domestic Violence or Spousal Abuse, knows no geographical, ethnic or cultural boundaries.[1] Intimate partner violence has not only been seen as an infringement of basic human rights, but it also accounts for the health burdens, intergenerational effects, and demographic consequences of such violence.[2] The World Health Organization (WHO) defines Intimate partner violence (IPV) as "behaviours within an intimate relationship that cause physical, psychological or sexual harm to those in the relationship, including acts of physical aggression, sexual coercion, psychological abuse and controlling behaviours".[3] It can also be found in same–sex partnerships even when women can be the perpetrators, but women are the most common victims of such male perpetuated IPV.[4] The Intimate partner violence focused in this study will be on the abuse against women by males, which is common incident nowadays. Gender inequality is another issue existing in the society and violence against women can be considered as a consequence as well as a cause of it.

Worldwide 35% of women have experienced either physical and/or sexual intimate partner violence or non-partner sexual violence.[4] In addition, there may be other forms of violence to which they are vulnerable to. Out of this, intimate partner violence is the most common. Globally, about 1 in 3 women who have been in a relationship have experienced physical and/ or sexual violence by their intimate partner.[4] Across the globe, 34% of all female homicides are committed by male intimate partners. [4] Violence against women has also been recognized as an important health problem publicly, outstanding to its substantial outcome for women's physical, mental and reproductive health. [4- 7, 9, 10] It is also known from the studies that detrimental effects of abuse continue long after violence has stopped. [8] More importantly, it affects country's economy through medical cost, loss of labor hours and increased disability. [2]

There are many risk factors that are consistently identified across many regions for IPV. Factors like young age, low level of education, personality disorders, sexual abuse during childhood, harmful use of alcohol and drug increased the man's likelihood of committing violence against his partner.[3,5,7,12,] On the other hand, there are also many context specific factors; for instance, some of the factors identified in the rural settings may not be factor in the urban settings.[12] Additionally, relationship factors like male dominance in the family, age at marriage, man having multiple partners and spousal education gap are also associated with IPV. [8,11,13] Poverty, low social and economic status of women, lack of legal sanctions against IPV within marriage is also associated with IPV. [6, 7, 14, 15]

Hence, in this background the present study was undertaken to find out the prevalence of Intimate partner violence in India and the socio demographic and lifestyle factors associated with it. By providing an insight about the risk factors associated with IPV, it can help the policy makers, researchers and NGO's in solving the global issue.

Subjects and Method

Secondary analysis of existing data was done in this study using the data obtained from National Family Health Survey (NFHS-4 2015-16). Government of India has proposed the NFHS to maintain a dependable quality data on inhabitants and their well-being. It is a nationwide, multi-round survey conducted in a representative sample of households throughout India. A total of 6,99,686 ever-married women (age group 15 -49) were considered for the interview from 29 states of India.[2] Apart from the demographic and various health related topics, NFHS -4 also addressed the issue of domestic violence against women. As a part of it, a module of questions was included in women's questionnaire related to domestic violence. Information on various forms of violence viz., physical violence, sexual violence was included. Because of security issues only one woman from a household was considered. With all restrictions 66,103 was the resulting sample for the domestic violence module. Domestic violence module obtained information about various forms of violence. [2]

This study focuses only on two forms of violence: physical violence and sexual violence.

Dependent variables

Intimate partner violence: experiencing any form of less severe violence, severe violence or sexual violence from their partner/husband in their lifetime.

Less Severe Violence: being slapped or having something thrown at you that could hurt you, being pushed or shoved, twisted your arm or pulled your hair, being kicked, punched or dragged.

Severe violence: being beaten up, choked or burnt on purpose, or being threatened or having a weapon used against you.

Sexual violence: Physically force you to have sexual intercourse with him even when you did not want to; physically force you to perform any other sexual acts you did not want to; force you with threats or in any other way to perform sexual acts you did not want to.

Independent variables

The questionnaire had questions pertaining to various risk factors of IPV viz., Demographic characteristics, lifestyle factors and variables of economic empowerment. Respondents were asked as to whether violence by husband is justified in each of these cases; she goes out without telling him, she neglects the children, she argues with him, she refuses to have sex with him, she burns the food. The responses for each of these questions were merged and was dichotomized into 'do not justify wife beating' and 'wife beating is

justified'.

Statistical Analysis

Statistical analysis was done by using SPSS version 16.0 and EZR software. Prevalence and 95% Confidence interval was obtained. To identify risk factors associated with intimate partner violence, multiple logistic regression was performed. Enter method was used for variable selection.

Results

Prevalence of Intimate partner violence (IPV):

Table 1: Life time prevalence of IPV

Form of violence	Prevalence n (%)	95% CI for prevalence
Less severe violence	18,434(27.9)	(27.6 ,28.3)
Severe violence	5,386(8.2)	(8.0,8.4)
Sexual violence	4,372(6.0)	(6.4,6.8)
Intimate partner violence	19,459(29.5)	(29.1,29.8)

*More than one form violence is experienced by a person as prevalence of overall IPV is higher

Less severe violence is the most prevalent type of violence among Indian women and sexual violence the least prevalent one (table 1)

It was observed that prevalence of IPV was higher among women who were from rural area (13703, 30.9%) compared to urban (4502, 24.5%),women in the middle age group (11612, 30%) compared to younger age group (6593,27.5%) , women who drink alcohol (776,44.1%) compared to who do not drink (17429,28.6%), women whose partners drink alcohol (9160,47.2%) compared to who do not (9045,20.9%) and all these associations were found to be statistically significant (P<0.001 for all) Also, IPV was highest among women with partner aged between 40-49 years (5363,29.8%) and lowest among partners aged less than 29 years , highest in no education group (7845,38.2%)and lowest in higher education group (>10th standard) (767,12.9%), highest among women with uneducated partners (4587,39.6%) and least among those with highly educated partners (1342,16.1%), highest among women with more number of children(>3) (9146,35.4%) and least among those with no children (1025,19%), highest among Hindus(14444 ,30.7%) and lowest among Christians (1039 ,24.2%) and all these associations were found to be statistically significant (P<0.001 for all) . However, rural area (odds ratio =0.8, P value <0.001), partners age greater than 30 (30-39 years, odds ratio= 0.91, P value <0.001; 40-49 years ,odds ratio =0.82, P value <0.001; above 50years, odds ratio =0.76, P value <0.001)and respondents' age(middle age, odds ratio =0.99, P value <0.001), alcohol consumption (odds ratio=0.93, P value <0.001) turned out to be protective factors in the presence of other regressor variables in multiple logistic regression.

Table 2: Prevalence (95% CI) of IPV by Variables of Economic Empowerment

Variables of Economic Empowerment						
Respondents occupation	Not working	43666	11207(25.7%)	(25.29,26.11)	0.97(0.83,1.13)	<0.001
	Unskilled labor	14253	5711(40.1%)	(39.30,40.90)	1.12(0.97, 1.30)	
	Skilled labor	3001	970(32.3%)	(30.63,33.97)	1.10(0.93, 1.29)	
	White collar	1796	317(17.7%)	(15.93,19.47)	1	
Partners occupation	Not working	3148	932(29.6%)	(28.01,31.19)	1.13(1.01, 1.26)	<0.001
	Unskilled labor	39603	12870(32.5%)	(32.04,32.96)	1.09(1.01, 1.18)	
	Skilled labor	13338	3195(24%)	(23.28,24.72)	1.01(0.93, 1.10)	
	White collar	6627	1208(18.2%)	(17.27,19.13)	1	
Wealth index	Poor and poorest	25314	9607(38%)	(37.40,38.60)	1.45(1.37,1.54)	<0.001
	Middle	13057	3740(28.6%)	(27.82,29.38)	1.18(1.12, 1.25)	
	Rich and Richest	24345	4858(20%)	(19.50,20.50)	1	

*First two quintiles and last two quintiles of wealth index were combined

*First two quintiles and last two quintiles of wealth index were combined

Table 3: Prevalence of IPV by Attitude towards Violence and their Past Exposure of Violence

Attitude Towards Violence and their Past Exposure of Violence						
Wife beating justifies	No	35603	7698(21.6%)	(21.17,22.03)	1	<0.001
	Yes	27113	10507(38.8%)	(38.22,39.38)	1.32(1.267,1.36)	
Did her father ever beat her mother	No	48124	10816 (22.5%)	(22.13,22.87)	1	<0.001
	Yes	14592	7389(50.6%)	(49.79,51.41)	2.79 (2.79, 2.93)	

From table 2 and 3, it was also observed that prevalence of IPV was higher among women who were unemployed themselves and had unemployed partners, poor compared to rich, who justified wife beating compared to who do not, who had witnessed their father beating their mother compared to who do not.

Discussion

The current study, discloses that 29.5% per cent women ever experienced IPV. Chauhan et al. reported prevalence of any form of violence 33.5%. [16] The higher prevalence may be due to the fact that they have included emotional violence also in the definition of IPV, which accounted for 12.5%. The WHO Multi-country study on women's health and domestic violence against women shows that prevalence of IPV between 15% in Japan to approximately 70% in Ethiopia and Peru. [5] It was observed that prevalence of IPV is more in developing countries than developed countries.

The study clearly brings out that education is a protective factor for women. This is consistent with findings of other studies.[11] Education gives women the ability to collect and absorb information, manipulate and control the modern world, secure and protect themselves from any form of violence. [17] The present study shows that Prevalence of IPV was associated with number of children in the family. It may be due to the fact that, families with more number of children experience economic insecurity because of insufficient resources to cater for large family which may increase the stress and frustration leading to violence.

It was found that the poor women were facing greater threat of IPV than rich women. This result supports the findings of WHO that the disproportionality in wealth is a major factor for violence against women.[19] One of the significant factors associated with IPV was found to be the consumption of alcohol by the husband. Several other studies also support this finding. [14, 20-22] It may be due to the fact that excessive alcoholic consumption can reduce the self-control of individuals. From the study it was perceived that women who justified wife beating were more likely to experience IPV than their counterparts who did not. Koenig MA et al., also support this finding. [23] The current study reports that women who reported that their mother had been beaten by their mother's partner are more likely to experience IPV compared to their counterparts who did not have such a history. One of the reasons for this may be that a child witnessing violent behaviour i.e. mother getting beaten by father starts to accept such behaviour and rationalize that it is typical in marital life. This is supported by the study by Makayoto LA et al. [24]. Religion and partners occupation was also found to be significant in the study consistent with result of other studies. [11, 18]

Limitations

Predominantly, the data used is secondary. Moreover, it is large scale demographic survey which may be prone to some kind of biases at the collection base eg., women who are selected for domestic violence may underreport behaviours that are considered to be socially unacceptable. In addition to that, direction of association is also a problem as nature of the study is cross sectional.

Conclusion

India has significantly lower prevalence of IPV compared to other developing countries. Factors like alcohol consumption of partners', education level of respondents' as well as partners', past experience of violence at home, justification of wife beating by respondents and wealth index were found to be associated with IPV. These risk factors need to be tackled to bring down the prevalence of IPV.

Self Reported Experiences of Interns' Regarding Oral Cancer Detection: A Questionnaire Survey

Sahana Maben [1],Audrey Madonna D'Cruz [2], Urvashi Ashwin Shetty[3]

[1]BDS, MHA. Tutor& Clinical Coordinator, [2]MDS. Professor and Head, Department of Public Health Dentistry, [3]MDS. SeniorLecturer, Department of Oral Pathology, A. B. Shetty Memorial Institute of Dental Sciences, NITTE (Deemed to be University), Mangalore

Abstract

Aim: To determine theself-reported knowledge and experiences regarding oral cancer detection among dental interns relatingto the etiology, risk factors and signs of oral cancer.

Materials &Method:A cross-sectional survey was carried out using a questionnaire developed by Carter and Ogden which was modified, among 97 dental interns of a private dental college. The questionnaire was designed to collect information on demography; knowledge of interns in etiology, signs, and symptoms and undergraduate experience in examination and biopsy procedure and management of malignant and premalignant lesions.Descriptive analysis was carried out.Comparison of mean scores between gender using Unpaired t test. Differences were considered significant when $p<0.05$.

Results: The response rate was 97.9%. About 70.6% of the interns examine the oral mucosa routinely during clinical examination. Majority of them (83.7%)were aware of the red and white lesions affecting the oral mucosa and 81.5% have encountered oral cancer patients in their clinics. None of them felt that they have sufficient knowledge regarding detection and prevention of oral cancer and a vast majority (92.4%) were strongly positive and wanted more teaching and information on oral cancer in the form of information packs (32.6%), lectures (21.7%), seminars (25%) and interactive sessions (20.7%).

Conclusion: The level of awareness regarding early detection and prevention of oral cancer was low among the dental interns.

***Key Words**: Oral cancer, knowledge, practice, early diagnosis.*

Introduction

Oral cancer is global public health problem that affects the quality of life of people. It is the sixth most common cancer in the world.[1]Globally, there is a wide disparity in the incidence and intraoral site distribution of oral cancer. The highest incidence of oral cancer is found in India and Sri Lanka which accounts for about 40% of all cancers.It is one of the leading causes of mortality and disability in India.

Several studies have reported general lack of awareness among the public, dentists, dental and medical studentsregarding early detection of oral cancer and premalignant lesions due to which there is a delay in diagnosis and treatment of the lesions.[2,3,4,5,6]About 70% of the oral cancer patients present in the advanced stages.[7]A dental practitioner's negative attitude and low level of knowledge are considered to be factors that contribute to the delayed or inadequate detection of the early stages of oral cancer.[8]Consistently performing thorough oral cancer screening examination for all

patients (including high-risk areas like tongue and floor of mouth), paying careful attention to suspicious red, white and ulcerative mucosal lesions and being aware of patients' high-risk tobacco and alcohol use offer the best potential for dentists to detect oral cancer at an early stage.[9,10]It has been reported that there exists an increasedneed for undergraduate dental students to be educated and trained in the identification of signs andsymptoms of oral malignancy and pre-malignancy aswell as early management of patients with suspiciousoral lesions.[11]

The objective of the present study was to determine theself reportedknowledge and experiences regarding oral cancer detection among dental interns relatingto the etiology, risk factors and signs of oral cancer.

Materials & Method

A cross-sectional survey was carried out using a questionnaire among 97 dental interns of a private dental college in Karnataka, India. Ethical approval to conduct the study was obtained from the Institutional Ethical Committee. Students were informed about the study. Participation was voluntary and interns willing to participate were included in the study.

The questionnaire that was used for the study was originally developed by Carter and Ogden[4]which was modified. The questionnaire consistedof ten close-ended questions divided into two sections, was designed to collect information on demography; knowledge of interns in etiology, signs, and symptoms and undergraduate experience in examination and biopsy procedure and management ofmalignant and premalignant lesions. The questionnaire was pretested on ten interns to check the adequacy of the questions. Modifications were made accordingto the responses before the final questionnaire wasadministered.

Interns were asked to mark the best answer among the options given. Data was entered into Microsoft Excel for Windows and analyzed using SPSS 15.0 version (SPSS Inc., Chicago, IL, USA). Descriptive analysis was carried out (number of correct responses) and presented as number and percentage. A score of '1' was given for each correct answer with 'may be/ Don't know' responses being counted as an incorrect response. Comparison of mean scores between gender using Unpaired t test. Differences were considered significant when $p<0.05$.

Results

Among the 97 dental interns, 5 were absent on the day of survey. Hence, the response rate was 97.9% (n= 92). There were 68 female and 24 male interns. About 70.6% of the interns examine the oral mucosa routinely during clinical examination. Majority of them (83.7%) were aware of the red and white lesions affecting the oral mucosa and 81.5% have encountered oral cancer patients in their clinics. About 47.8% of the participants said that tobacco chewing is the major risk factor for oral cancer, while 21.7% said that UV light exposure is a risk factor for oral cancer. About 12% responded smoking and 15.2% said that alcohol is a risk factor for oral cancer. About 46.7% said that leukoplakia and 31.5% said erythroplakia is associated with oral cancer. Only 68.5% of them were aware that long standing/ non healing scars anywhere in the oral cavity could be a sign for oral cancer and only 51.1% were aware that red or a white patch is a warning sign for oral cancer. None of them felt that they have sufficient knowledge regarding detection and prevention of oral cancer and a vast majority (92.4%) were strongly positive and wanted more teaching and information on oral cancer in the form of information packs (32.6%), lectures (21.7%), seminars (25%) and interactive sessions (20.7%).

Table 1 shows the comparison of mean scores across genders. The mean score among males was5.9 ± 2.4 and among females is 6.1 ± 2.1, the difference of which is insignificant when analysed using Unpaired t test.

Table 1: Comparison of mean scores between gender using Unpaired t test.

		Mean score (SD)	t	df	Standard error of difference	p value
Gender	Male	5.9+2.4	0.3863	90	0.518	0.7, not significant
	Female	6.1+2.1				

Discussion

Dentists need to possess a thorough knowledge of risk factors, clinical signs and symptoms of oral cancer in order to be effective in identifying, referring and counseling high-risk patients. Internship is a phase where most of the theoretical knowledge of dentistry is put into practice under supervision of the faculty. Interns need to possess adequate knowledge regarding of early detection of oral malignant and premalignant lesions as they are just one step away from being fully fledged dental surgeons who have an important role in prevention and control of oral cancer.

The results of the present study showed that the interns lacked sufficientknowledge regarding detection of oral cancer and premalignant lesions. These findings were in accordance to those reported in literature.[12,13,14]Studieshave also shown that dental students have a better knowledge regarding early detection and prevention of oral cancer when compared to medical students.[6,11]

In the present study, majority of the interns felt that they did not have adequate knowledge on early detection of oral cancer and wanted more even information regarding the same.This is a very relevant and important finding and should be viewed seriously. Although theory on epidemiology of oral cancer, etiopathogenesis of premalignant and malignant lesions, early detection, prevention and management of oral cancer in the dental curriculum exists, adequate clinical training under faculty supervision for careful comprehensive intraoral examination for identification of lesions is essential. Dental interns should be also trained to perform clinical diagnostic procedures like toludine blue staining, exfoliative cytology which would help in early detection of premalignant and malignant lesions. Interns should be encouraged to attend seminars/ workshops on oral cancer prevention.Also, it is important that proper and early referral and care is given to the patient diagnosed with oral cancer for a better prognosis.

Conclusion

The present study concluded that the level of awareness regarding early detection and prevention of oral cancer was low among the dental interns. There is a need to strengthen the knowledge and clinical skill of dental interns towards early detection and better management and prognosis of oral cancer.Ageneral lack of awareness among the public, dentists, dental and medical studentsregarding early detection of oral cancer and premalignant lesions results in delay in diagnosis and treatment of the lesions.

Abstract

Objective: The understanding and adherence to postoperative care instructions are factors that influence the healing process of the patients after dental extraction. The aim of this study is to analyse the healing rate of the patients who strictly follow and who do not follow the postoperative instructions after dental extraction. **Study design:** One hundred patients with no medical complications who referred for non-surgical extraction were selected for this study. The patients were evaluated a week after extraction regarding their adherence to postoperative instructions. **Results:** 94 patients completed the study. Smoking, drinking of alcohol/ carbonated beverages are the main influential factors in which patients lack their adherence to post-operative care after dental extraction. **Conclusion:** The result of this study revealed no association of age, gender with the healing of the socket. However habit of smoking, consumption of alcohol associated with male gender highly influence the healing rate of patients after dental extraction.

Keywords: *Extraction, Healing, Instruction, Post-operative, Pain*

Introduction

A dental extraction (also referred to as tooth extraction or exodontia) is the removal of teeth from the dental alveolus in the alveolar bone.[1] It is the most common procedure performed in oral surgery and it is performed for variety of reasons in which teeth have become unrestorable through tooth decay, advanced periodontal disease or dental trauma associated with poor prognosis.[2,3] The other reason for extraction is removal of bicuspids for orthodontic treatment to create space.[3] Surgical removal of impacted or partially erupted third molar which may also cause recurrent infections on the gingiva (pericoronitis).[4]

Though each individual has their own capacity to heal, healing after dental extraction mainly depends on the cause of extraction, extraction procedure, and post-operative care.[5,6] Post operative care is influenced by the understanding of the patient and their subsequent implementation to the guidelines presented by the professional.[8]

The main objective of this study was to determine the percentage of healing rate of patients regarding their adherence to post operative care.[7,9]

Materials and Method

A total of 100 patients underwent dental extraction including surgical removal of impacted tooth were selected for this study. The patients chosen for the study were healthy without any systemic complications. The patients excluded from the study were those who could not attend the scheduled appointments, some psychological disorder and with systemic disorders.

Initially the questionnaire was distributed to the patients after a week of dental extraction. The part of the questionnaire contains the brief detail about the patient and the detail about the tooth which is extracted. The questions in the questionnaire were designed to evaluate patient's adherence to post operative care and their healing process.

Results

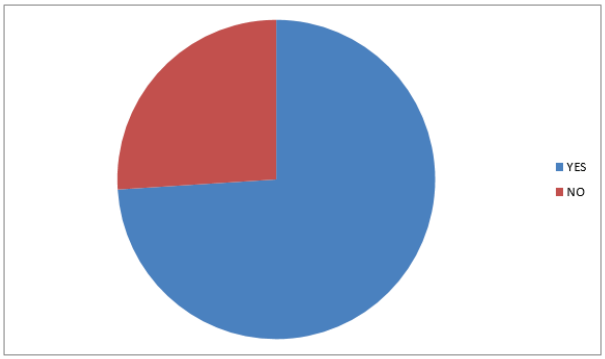

Chart 1: Did you follow the medications prescribed?

74% of patients follow the medications prescribed

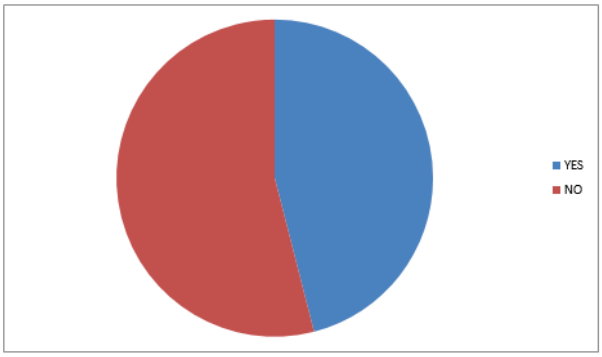

Chart 2: If smoker, did you follow the recommendation of not smoking for a week?

46% of patients follow the recommendation of not smoking for a week

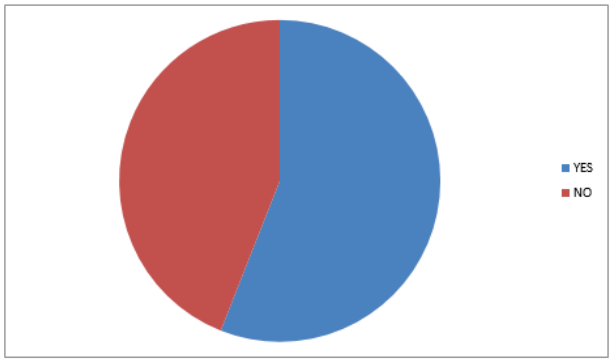

Chart 3: If alcoholic, did you follow the recommendation of not drinking alcohol for a week?

56% of patients follow the recommendation of not drinking alcohol for a week

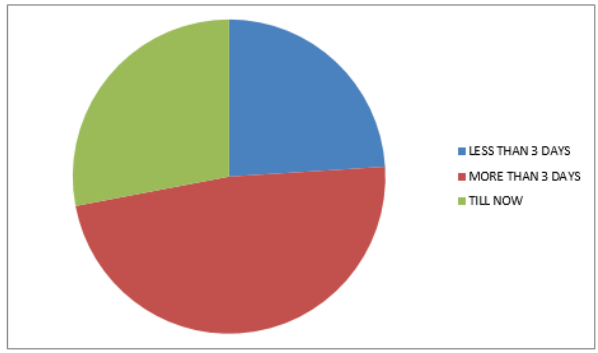

Chart 4: How many days you felt pain in the region of extraction?

24% of patients felt pain for less than 3 days, 48% of patients felt pain for more than 3 days, 28% of patients feel pain till now(after a week)

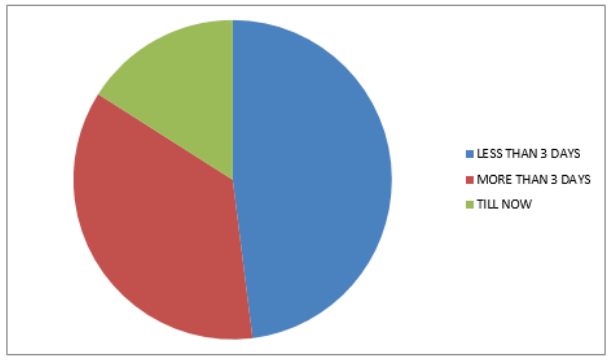

Chart 5: How long does swelling lasts after the extraction?

48% of patients have swelling lasts less than 3 days, 36% of patients have swelling lasts more than 3 days.16% of patients have swelling till now(a week after extraction).

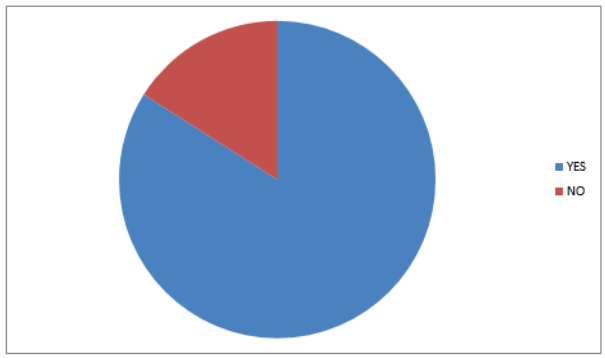

Chart 6: Are you aware that following these instructions influence the healing period?

85% of patients were aware of it

Discussion

The current study was sought to document the perception on healing rate of patients regarding their adherence to post operative care. A detailed survey on patients adherence to their post operative care is

evaluated.[9] Though most of the patients are aware of their post operative care, some of them lack their knowledge and interest on following the instructions told to them.[11]

The understanding and subsequent implementation of the post operative instructions are the factors that influence the healing after the dental extraction.[10] About 74% of patients followed the medicines prescribed, the rest ignored it because of the pain relief.[12] 82% patients followed the instruction of not spitting for next 24 hours, 72% patients followed the instruction of not rinsing with any liquid as all these can dislodge the clot formation after dental extraction which leads to the formation of dry socket. Maximum number of patients (86%) followed the recommendation of maintaining the soft temperature diet since solid and hot foods affect the healing process. Ice pack should be applied on the region of extraction in 15 minutes intervals for the first 36 hours.[6] After 36 hours, moist heat should be used instead.[8] These instructions are followed by 74% of patients.

About 92% patients followed the instruction to brush gently on the region of extraction. Rock salt water gargling is recommended to the patients after extraction, 85% of patients followed the instruction. When the question was asked about the use of carbonated beverages, only 40% of patients followed the recommendation of not drinking the carbonated beverages for a week, the rest were not aware of the instruction. The poor response was obtained when the question was asked to patients about the following of recommendation of not to disturb the region of extraction with tongue, only 36% of patients followed it, the rest were not aware of the instruction and did not follow it.[13,14]

The next question was asked to smokers, that whether they followed the recommendation of not smoking for a week, as it highly affect the healing process after extraction.[16] Smoking after extraction results in dry socket, as the clot moved out of place due to the sucking action used to draw the smoke from the cigarette.[15] Only about 46% of patients followed the recommendation of not smoking for a week. Similarly, the question was asked to alcoholic patients about the recommendation of not drinking alcohol for a week after extraction as it dislodge the blood clot and affects healing.[17] Only 56% of alcoholic patients followed the instruction, the rest ignored it.[18] These poor response has taken into consideration and awareness on effects of smoking and consuming alcohol in healing of tooth socket after extraction should be taught to the patients.[18,19] About 63% of patients follow the recommendation of using mouth washes for a week after extraction.

When question is asked to patients about the pain they felt after extraction, 24% of patients felt pain for less than 3 days, 48% of patients felt pain for more than 3 days, 28% of patients feel pain till the survey (a week after extraction).[19] About 70% of patients experienced normal pain, where 30% of patients felt aggrevating pain. On questions about swelling at the region of extraction 48% of patients have swelling lasts less than 3 days, 36% of patients have swelling lasts more than 3 days, 16% of patients have swelling till the survey (a week after extraction).[18] About 12% of patients encountered other complications after the extraction. About 85% of patients are aware about the instruction given and their influence on healing process after extraction. The overall level of awareness among patients to follow the post operative care is fairly good, it is about 85%.[20,21]

Conclusion

This study is to create the awareness and properly educate the patients about the post-operative instructions and complications and factors affecting, after extraction due to the non-compliance to the post-operative care. The habit of smoking and consumption of alcohol or carbonated beverages for a week after dental extraction influences the healing rate, it is associated with male gender. Hence awareness should be created on effects of smoking and alcohol on healing of socket to patients. It is very important to provide full details of the post-operative instructions to the patients as it promotes healing after tooth extraction. The result of this study revealed no association of age, gender with the healing of the socket. The patients who followed the post-operative instructions healed faster than the people who did not follow the instructions.

Abstract

Background: Prevalence of oral cancer is high in India , other Asian countries, Brazil and France. Micro nutrients like copper and zinc are increasingly recognized for their role during the onset and progression of pre malignant and malignant oral lesions.

Aim -To determine serum levels of copper and zinc among oral cancer patients

Objective -To estimate and compare the serum levels of copper and zinc in healthy and cancer patients and to derive Cu/Zn ratio, to establish a possible relationship between micro nutrients and oral cancer.

Materials and Method - 25 patients clinically diagnosed with oral cancer (study group) and 25 healthy individuals (control group) in the age group of 30-50 years were included in the study. Blood samples were collected and serum copper and zinc values for both cancer and control group were estimated using ERBA CHEM 5 semi auto analyser. Mean and standard deviation of serum copper and zinc values for both the groups were determined and compared. .

Results- Significantly higher values ($p < 0.04$) were noted for serum copper level (mean value 249.39 ± 58.3 µg/dl) for study group compared to control group (123.95 ± 16.2 µg/dl). However there was no significant difference in serum zinc values between both the groups.

Cu /Zn ratio of 1.43 and 2.86 for control and study group respectively was derived from the above estimated value

Conclusion -Mean serum copper value in study group was significantly higher than in the control group mean may be considered as a biological marker for oral cancers.

Keywords : *Zinc , copper , oral cancer , serum levels, micronutrients*

Introduction

Oral cancer is one of the most prevalent and 6th most common type of cancer in the world [1]. Prevalence of oral cancer is higher in, India, Asia Brazil and France compared to other countries globally. Incidence and distribution vary by age, ethnic group, culture and lifestyle associated factors [2]. Alcohol, viruses, genetic mechanisms, candida, and chronic irritation have modifying effects on the etiology of oral cancer .Tobacco can cause genetic damage and can lead to development of oral cancer. Smoking and alcohol consumption are major risk factors. [3]. It mostly affects the tongue, buccal mucosa, gingivae, lips, and palate [4] .It was also found that higher intake of fruits and vegetables had lower risk of oral cancer but an unbalanced diet has been related to an elevated risk. [5]

Clinical and histopathological examination of oral lesions plays a major role in the diagnosis of oral cancer. In addition, it has been reported that levels of trace elements or micro nutrients such as copper, zinc, iron

Corresponding author:
Leya Mathews
Mail – leahmathews23@yahoo.com

and selenium are altered in serum, plasma and tissues of pre malignant oral lesions [2] [6]

Copper, zinc, iron are chemical elements required in minute quantities for vital biochemical reactions such as free radical formation and cellular homeostasis[2]. The enzymes of trace elements are an important part of certain biological and chemical reactions. [7]. Zinc is also an important constituent of biological bio membranes and contributes to membrane stability. It modulates activities of ribonucleic acid and deoxyribonucleic acid polymerase enzymes [8, 9].The need of zinc for a healthy immune system, cell division, skin, hair, and muscle growth cannot be overemphasized.

Copper is involved in the release of energy during cell formation of red blood cells, collagen production, and iron absorption.

However, it was found that there is a potential link between trace elements and carcinogenesis. The ratio of copper to zinc is also believed to be a reliable biomarker in the development and progression towards malignancy [10]. Copper and zinc are often recognized for their possible role in the prevention and modulation of diseases but recent studies have proved increased level of copper and decreased level of zinc in cancer [11].

The present study was undertaken to evaluate and compare the levels of copper and zinc in the blood serum of normal and patients with oral cancer.

Materials and Method

The sample for the present study consisted of 50 individuals. 25 healthy individuals from the outpatient clinic accepted to participate in the study as controls. 25 patients diagnosed with oral cancer were included as the observational study group from the outpatient department, Oral Cancer Institute of Sabetha dental college. The study was approved by the Institutional Ethical Committee and informed consent was obtained from the patients prior to the blood sample collection. The participants were chosen based on the following inclusion and exclusion criteria. Inclusion criteria included patients diagnosed with carcinoma, in the age group 30 – 50 years, and for control group, healthy individuals with no history of systemic disorders were chosen. Exclusion criteria included immuno compromised adults, patients diagnosed with endocrine disorder, coronary artery disease and infectious diseases like tuberculosis or syphilis. Methodology included collection of 5ml of blood sample under absolute asepsis and transferred to acid washed test tubes .The blood collected was centrifuged at 2500rpm for 15 minutes and preserved in a frozen state until analysis. The samples were then analyzed using ERBA CHEM 5 semi auto analyzer. Serum levels of zinc and copper were assessed with the help of reagents provided.

The data obtained, was statistically analyzed using the SPSS software. Range of values of all the samples for serum copper and zinc were evaluated and grouped (Tables Me, II). Mean and standard deviation for serum copper and zinc of both the groups were determined and compared for statistical significance $p<0.05$ (Table III). Cu/Zn ratio was then derived from the above estimated value.

Results

Analysis of the data revealed that serum zinc values ranged from 60 µg/dl to 119 µg/dl in both the groups. (Table I). However a maximum of 8 samples were in the range of 100- 109 µg/dl in controls , and a maximum of 7 samples were in the range of 90 - 100 µg/dl in the study group. The mean value for serum zinc in control group was 86.64±17.4 µg/dl ,while the serum zinc level in the study group was found to be 85.17±14.98µ/dl (Table III). There was no statistically significant difference in the mean serum zinc values between study and control groups.

Table 1 Frequency table and range of serum zinc values

Zinc serum level observed in the study	No. of samples in cancer study group (n=25)	No. of samples in control group (n=25)
60-69 µg/dl	3	3
70-79µg/dl	2	4
80-89µg/dl	4	5
90-100µg/dl	7	5
100-109µg/dl	3	8
110-119µg/dl	6	0

On the contrary, the serum copper level ranged from 180-340ug/dl in study group while in the control group it varied from 110-160ug/dl. (Table II). A maximum of 8 samples were in the range of120-129 µg/dl in the control

and a maximum of 8 were in the range of 300-339 µg/dl in the study group. The mean serum copper values were found to be higher in study group 249.39±58.3 µg/dl, compared to that of healthy control group 123.95±16.2 µg/dl. (Table III). Mean serum zinc levels showed no changes.

Cu /Zn ratio was1.43 and 2.86 for control and study group respectively.

Table II a	
Serum copper level in control group	**No of samples (n=25)**
110-119µg/dl	4
120-129µg/dl	8
130-139 µg/dl	5
140-149 µg/dl	4
150-159 µg/dl	4

Table II b	
Serum copper level in study group	**No of samples (n=25)**
180-219µg/dl	6

Trace metals	**Mean Value ± sd in Control Group**	**Mean Value ± sd in Study Group**	**p value**
Zinc	86.64±17.4µg/dl	85.17±14.98µg/dl	0.67
Copper	123.95±16.2µg/dl	249.39±58.3µg/dl	0.04
Cu/ Zn Ratio	1.43	2.86	

$p < 0.05$value

Discussion

Trace elements Copper (Cu), zinc (Zn), selenium (Se) and molybdenum (Mo) are required in small concentration and have important role in many biochemical reactions. They are essential for proper functioning of life supporting processes and are an essential component of biologically active constituents [13, 14]. Copper is found in plasma (90-95%) as part of oxidative enzyme ceruloplasmin [15]. It is also a part of various enzymes like tyrosinase, cytochrome oxidase etc., and participates in oxidative process in cell metabolism. Zinc another micro nutrient is essential for gene transcription and cell multiplication and critical for activation of RNA and DNA polymerase activity. Decreased zinc levels are associated with increased oxidative stress at cellular level [16].

The normal serum copper and zinc levels are 0.6 - 1.6µg/ml and .6 -1.5µg/ml respectively where atomic absorption spectrometry has been used for analysis [17]. Others [10] have reported 114.20±38.69 mg/dl, 64.57±31.54 mg/dl as copper and zinc values respectively in their control sample by means of calorimeter. The values of these trace elements estimated in the present study were performed with ERBA CHEM 5 semi auto analyzer.

Concentrations of copper when exceeds the optimal level turns toxic. It breaks down the DNA strands or modifies the bases and deoxyribose. [12]. Sliwinski et al observed that zinc did not induce DNA damage in normal cells but exerted a protective effect against DNA damaging agents but increased cytotoxic effect on cancer cells[11] . A number of studies have estimated copper and zinc levels in serum, blood and saliva in various carcinomas especially oral squamous carcinoma and have established a positive correlation with the incidence of malignancy. Significant alteration in serum levels of the trace elements have been reported in head and neck cancer, lung and breast cancer [2, 18]. The increased levels of copper and zinc in cancer reported earlier have been 209.85± 160.28 mg/dl, 113.51± 52.30 mg/dl respectively [10] . In the present study, copper showed a significant increase [249.39±58.3µg/dl] in oral cancer group compared to control group [123.95± 16.23µg/dl]. Similar findings have also been reported by Khanna et al, Amitkumar et al, Yunus et al, Ayinam pudi BK, Jayadeep A et al and Shetty SR et al. [2, 6, 10, 17, 19, 20, and 21] they observed increased copper levels in sera of patients in oral pre malignant and malignant patients.

The increased level of serum copper in OSMF patient was attributed by Khanna et al to high copper content in areca nut, the major physiological factor in the pathogenesis of OSMF [17] it initiates fibrin genesis and inhibit collagen degradation. It has also been explained that increase in serum copper levels in cancer patients is a consequence of increased production of copper containing ceruloplasmin an oxidative enzyme which is precipitated by an inflammatory response to cancer or decrease in catabolism by serum ceruloplasmin [16] . Jayadeep et al also suggested that rise in copper levels might be due to increased turnover of ceruloplasmin, a copper carrying globulin with oxidative activity [19] .

Review of literature indicates low serum zinc level in several forms of cancer like cancer of breast, gallbladder, lung, colon and oral cancer [22, 23] . Serum zinc level in a present study did not reveal a similar finding. The serum zinc level among cancer patient in the present study was marginally lower or similar to control group. Contrary to this finding statistically significant decrease in mean serum zinc levels have been reported by various other studies [18, 20, and 24]

Amit kumar et al [6] suggested that zinc deficiency impair protective mechanism designed to protect against DNA damage, enhance susceptibility to DNA damaging agents and ultimately increased risk of cancer

Increased copper zinc ratio seen in oral sub mucous fibrosis (OSMF) and oral squamous cell carcinoma (OSCC) was also noticed in patients with pancreatic cancer, breast cancer, lymphoma etc. Yunus et al concluded that alterations in serum copper, zinc, copper zinc ratio can be used as potential biomarkers in early detection of oral pre cancerous lesion and their malignant transformation to frank cancer at early stages [2].In the present study the ratio was 1.43 in control, and increased to 2.86 in the study group, probably due to increased copper values. Other reports have shown that Cu/Zn ratio was 0.97 in health and 1.10 in cancer patients, but the diff was not statistically significant [17,25].

This study confirms the earlier reports on the possible relation between serum copper level and oral cancer and can be considered as a biochemical marker for oral cancer, but needs further evaluation on a larger sample including patients with oral premalignant lesions.

Conclusion

Trace element copper level in oral cancer patients did

show a significant increase compared to control group. Serum zinc level however did not show any difference between study and control groups. Alterations in serum copper level are suggestive of its important role in oral carcinogenesis and needs further research on larger population.

Prevalence of Black Stains in School Going Children in age Group 6-12 Years

Leya Meriam Mathews[1], Dhanalakshmi Ravikumar[2]

[1]Graduate Student, Saveetha Dental College, Saveetha University, Chennai, [2]Senior Lecturer, Department of Paedodontics, Saveetha Dental College, Saveetha University

Abstract

Introduction: Black stains are extrinsic discoloration in primary dentition that can also occur along with dental caries. It clinically presents as pigmented, dark lines or as an incomplete coalescence of dark dots rarely extending beyond the cervical third of the crown. This has often been a concern of dental aesthetics and its frequent recurrence, makes it necessary to find the causative factor and the treatment needed.

Materials and Method: In this cross sectional study, 93 children aged between 6-12years were examined clinically for the presence of black stains using mouth mirror and dental probe by one examiner. The DMFS / deft index were recorded in children with and without black stains.

Results: In the limited sample size recorded, it was observed that 11 children had black stains. Black stains were also found along with dental caries in 3 children. The p value was 0.85373, found to be insignificant

Conclusion: The prevalence rate of black stains is estimated to be 10% from the sample size, as per data collected, Black stains can occur along with caries but the incidence is less. In conclusion , the results of our study , indicates the prevalence of caries along with the black stains in children within the age group 6-12 years , highlight the need to do further investigations

Keywords **:** *Stains, intrinsic , extrinsic, iron , children , black stains, caries*

Introduction

Tooth discoloration can be defined as any change in the color, hue or translucency of a tooth due to a cause. It is an altered physical appearance of the tooth which is a common clinical finding and a concern of aesthetics, found more often among the children thereby having significant effects on their personality and self-confidence. There are several causes of tooth discoloration like food, drinks, poor dental hygiene, and medications [1].

Tooth discoloration can vary based on their location, etiology, appearance and composition. Historically, tooth discoloration can be classified, based on their location, to extrinsic, intrinsic and internalized [2]. Intrinsic Discoloration refers to the change that occurs due to the disturbance in the structural composition or thickness of the dental hard tissues. It occurs when the tooth structure is penetrated by pigmented materials, usually during tooth development. Extrinsic discoloration refers to the deposit or stain that occurs on the surface of the tooth or in the acquired pellicle. The origin of the stain might be metallic or non-metallic. Internalized discoloration is the presence of an external stain within the tooth following dental development. It is mostly seen in case of any enamel defects and in the porous surface of dental caries. This stain or discoloration can also be an acquired defect due to tooth wear, gingival recession and restorative materials [3, 4].

A common extrinsic discoloration is the black stain which appears as a dark line or an incomplete

coalescence of dark dots formed on the cervical third of the tooth and following the contour of the gingival margin, firmly attached to the tooth surface. It affects mostly the primary dentition and its prevalence seen in both the sexes [5]. Black stain is a form of dental plaque that covers a great surface of the tooth including the grooves, pits and fissures.

According to Ried et.al, the black pigmentation is considered to be an insoluble ferric compound, most likely a ferric sulfide, which arises from the interaction in the saliva or gingival fluid between hydrogen sulfide produced by the bacteria present in the periodontal environment and iron [6]. The microbiological composition of Black stain is hypothesized to be bacterial strains of Acitnomycetes, Lactobacillus and prevotella melaningenica [7].

The origin of Black stain has been discussed for over a century, since 1890. However, the criteria to diagnose the black stain have still not been established. Shourie used the following criteria for classifying black stain: 1) no line 2) incomplete coalescence of pigmented spots and 3) a continuous line formed by the pigmented spots. Further additional classification by Koch et.al, depending on the size of the spots and the presence of cavitation on the tooth surface, and, depending on the area of the tooth surface have also been used in different studies [8].

Tooth discoloration has been frequently associated with medical problems and sometimes due to certain medications or even restorative treatment. Few of the conditions like malnutrition, rubella, measles, and developmental disorders like gametogenesis imperfect show black stain as one of the manifestation. Another important differential diagnosis is the dental caries. Most of the studies show the occurrence of Black stain with lower caries experience which could imply that caries resistance in children with black stain could be a result of lower caries activity than a localized effect [9].

This study was done to find the prevalence of black stain in school children, aged 6-12 years, among the Chennai population. The children were also asked about their families and their place of residence to help evaluate the risk factors associated with the black stain.

Materials and Method

Sample Selection

A total of 93 children were aged from 6-12 years of age, were examined for black stains from the areas of Old Washermenpet and Perangallthur, Chennai. None of the children had any systemic or infectious diseases and were both physically and mentally well. A written informed consent was obtained from the parents of all the children enrolled in this study. The inclusion criteria and exclusion criteria were as follows;

Inclusion Criteria

- Age group 6-12 years
- Children with black stains

Exclusion Criteria

- Immunocompromised Patients
- Children with any systemic disease
- Enamel hypoplasia

Clinical Examination for Black Stains

The Clinical examination was performed under natural light with plane mouth mirrors and dental probe in the community halls of the respective places. The diagnosis of the black stains was examined based on the criteria given by Shourie and Koch et.al. [8].

A record was maintained for every child with Black stain, where the vestibular and the palatal surface was registered for the maxillary teeth and the vestibular and the lingual surface was registered for the mandibular teeth. In order to record the pigmentation location and extension, every tooth surface illustrated was segmented into three sectors – gingival, middle third and the incisal or occlusal surface.

The DMFS/deft index was recorded in children with and without black stains. The PUFA/pufa index was also recorded to check for any visible pulp, ulceration of oral mucosa, fistula and abscess, if present.

Statistical Analysis

After the examination, the data was processed and a statistical analysis was done using the Social Science Statistics Software for Windows, Version 20.0. Statistical Significance was considered at 5%.

Results

Out of 93 children examined, black stains were

observed in 11 children, 10.23 % of the sample size. 7 children belonged to the age group 6-9 years and 4 of them in the 10 -12 years of age. 82 children did not have any black stains, 76.26% of the sample size. Black stains were found to be more prominent in the lower age group as shown in Table 1

Table 1 - Number of children with Black stains and without

Age group	Black stains (%)	Non - Black stains
6years-12years	7 (6.27)	46 (46.73)
10years-12years	4 (4.73)	36 (35.27)

Dental caries were observed in 3 children black stains. It was observed that in Children without any black stains, dental caries were present in 45 children. (Table 2). The prevalence of caries was found to be insignificant ($p>0.05$)

Table 2 – Prevalence of caries and p value in children with and without black stains

	Black stains	Non - Black Stains	P value
Caries Present	3 (5.68) [1.26]	45 (42.32) [0.17]	0.853
Caries Absent	8 (5.32) [1.35]	37 (39.68) [0.18]	0.853

Discussion

This study was done to estimate the prevalence of black stains in children aged from 6 to 12 years. Additionally, this study helps to show the association between black stains and dental caries in a population based study. Out of 93 children examined, only 11 children were observed with black stains, indicating this type of condition, as a rare disorder, as shown in Table 1. This rare condition observed in this study agrees with other studies which showed similar results [10, 11]. Most of the studies took place in 1970's in different countries. Brazilian studies show a prevalence of 9.3 % of black stains for children aged from 6-13 years of age and 2.5 % for children aged from 3-5 years from different areas of the country [12]. Koch et.al reported a prevalence of 19.9% for school children, aged 7-15 years in Switzerland and 4.6% for children aged 6-10 years in Germany [8]. The different prevalence recorded in different studies could be due to different habitats and lifestyles of different populations, which could be possible etiological factors.

Though etiology behind the formation of black stains still remains unknown, studies show a possible correlation between various risk factors and black stains. Various etiological factors include gender, socioeconomic factors like maternal education, family income, and diet and fluoride level in water consumed. These factors were also commonly associated with the development of caries [13]. With this understanding, Franco et.al found a significant association between black stains and lower income. Children from families with lower income showed a higher prevalence of black stains [14]. Consumption of vegetables, fruits and dairy products also consume black stains development. Certain studies contradict to the fact with the association between sex and black stains prevalence. However, due to insufficient data, the etiology still remains unclear making it difficult to distinguish factors associated with its formation [15, 16].

The association between dental caries and black stains is debatable because of the varying results from different studies. Gallardo et.al stated that there is no association between dental caries and black stains [13]. Contradicting to this, other studies show similar findings demonstrating lower level of caries experience along with black stain Gasparetto et al. Showed a negative correlation between black stains and dental caries, but did not find any association between the presence of black stains and caries prevalence. Similarly, Koch et

al. found a tendency for children with black stains in primary dentition to present less dental caries, but the difference was not statistically significant [8,17] . Other Findings show that both black stains and dental caries had common co-variables, like socioeconomic factors and behavioral which could be reasonable enough to help hypothesize that there could be a possible association [12].

The results of our study suggest that black stains can occur along with dental caries as shown in Table 2. The data revealed that the prevalence of caries in this study was lower among the children with black stains (0.3%) than those of without black stains (36%) ,this finding is in accordance with study done by Gasparetto A et al.10 , Koch et al.8. and Sutcliffe [18] . The mean DMFS values were found to be statistically significant between children with black stains and those without black stains. The mean value of DMFT was 1.5 ± 0.7, which is a bit higher than the mean value observed in another study done in Udaipur for the same age range, which tells us the need for further exploration to find the causative factors responsible [19].

Various hypotheses relating to caries development and black stains have been put forward to understand the biological interaction between microbiota related to the extrinsic pigmentation. Morphological stains reported by Ried et.al and Thaelide et.al confirmed that this kind of stain is a special kind of dental plaque characterized by its flora and its tendency to calcify . The most prominent organisms involved are Actinomyces and Prevotella melaninogenicus. The tendency towards calcification within the black material benefits a high level of calcium and phosphate that gives to a reduction in the enamel dissolution and an increase in the buffering capacity [6, 20]. The saliva of the children with black stains showed a higher content of total calcium, inorganic phosphates, copper, sodium and total protein and less glucose than in controls [21].

With this understanding, and the inverse relationship between dental caries and calculus stated by Duckworth and Hunnigton, Gasperrato et.al proposed that calcium and phosphate are part of the reaction for black stain formation and together with fluoride and pH conditions are the main tooth remineralization components. Because caries development is a demineralization process due to the acids produced by oral bacteria, the presence of a larger amount of minerals in the oral cavity – which could be the case in children with black stains – increases the remineralization process, to keep the oral cavity in a balanced equilibrium and reducing the risk for caries development [12].

Another hypothesis states that low cariogenic oral micro flora is associated with the presence of black stains. The bacteria related to black stains could establish a competitive environment for bacteria related to caries development, impairing the adhesion of these bacteria to dental surfaces or changing the characteristics of the dental biofilm, reducing the potential for caries to develop [22].

The management of extrinsic stains involves proper diet and maintaining oral hygiene. Whitening toothpastes with abrasives help remove extrinsic stains. Other methods include Selective polishing , where polishing is done over a specific tooth using prophylactic angle and rubber cup , with the right toothpaste and use of prophylactic paste , air jet polishing , ultrasonic scaling etc. . However, due to unclear etiology, black stains have a tendency to recur and frequent use of these modalities can lead to enamel removal, which is highly undesirable [23].

In conclusion , the results of our study , indicating the prevalence of caries along with the black stains in children within the age group 6-12 years , highlight the need to do further investigations and statistical analysis with multivariable analysis to help understand the biological mechanism. This in turn will help find a possible solution to help treat this condition.

Complications of Root Canal Irrigation - A Review

Leya Meriam Mathew[1], Jayalakshmi Somasundaram[2]

[1]Graduate Student, [2]Senior Lecturer, Department of Conservative and Endodontics, Saveetha Dental College ,, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Root canal irrigation plays an important role in the debridement and disinfection of the root canal. Most commonly used irrigants have good benefits of tissue dissolving and disinfection capability. However, it also produces toxic effects on the vital tissues resulting in ulcer, necrosis etc. The aim of this review is to analyze the factors causing or affecting the Root canal irrigation during a root canal treatment.

Keywords *: Root canal , irrigants , infection, microbial , complications, toxici*ty .

Introduction

The main aim of a root canal treatment is to ensure complete removal of connective tissue and destruction of residual microorganisms found in the infected root canals[1]. The complexity of root canal system, presence of numerous dentinal tubules in the roots, invasion of the tubules bymicroorganisms and preservation of healthy dentin after achieving the primary objectives of complete shaping and cleaning of root canal systems are done with the help of a proper irrigation [2]. However many mishaps can occur while cleaning and shaping the root canals with irrigating solutions ranging from damage to the patient's clothing, splashing the irrigant into the patients or operators eye, to allergic reactions. The ideal properties of an irrigant [3] include, a potent tissue debris solvent ,low toxicity, low surface tension, lubricant, sterilizing agent, removal of smear layer, low cost and inactive endotoxin

Endodontic Irrigants

Non-bactericidal irrigants

Some general dental practitioners either use saline, local anaesthetics and/or distilled water. These have no antibacterial action and will not lessen bacterial significantly. These irrigants may be used regularly as they are easy to use, readily available and safety. However, irrigants have no role in handling infected root canals..

Bacteriostatic/bactericidal irrigants

These include a collection of solutions which also kill bacteria or enable their death by allowing other irrigants to come into contact with the bacteria.

Sodium Hypochlorite (NaOCl)

Sodium hypochlorite was first recognized as an antibacterial agent in 1843 and used as a hand wash . Its advantages are pulpal dissolution and antimicrobial effect. Studies show that a decrease in microbial numbers is achievable when using NaOCl for endodontic treatment of teeth with apical periodontitis. It was used as an endodontic irrigant ,with low viscosity ,effective antimicrobial properties but low tissue dissolving capabilities acceptable shelf life , easily available and inexpensive [4]. The mechanism of action involvesbreak down of protein by dissolution of amino acid content of vital and necrotic tissue by the available free chlorine in NaOCl

However, certain disadvantages of this irrigant are the toxicity to the vital tissues which includes cytoxicty, foul smell and foul taste, fabric bleach on accidental spillage and corrosive on metals [5].

Hydrogen Peroxide

Hydrogen peroxide (H_2O_2) is a colorless liquid and has been used in dentistry in concentrations varying from 1% to 30% [6]. H_2O_2 degrades to form water and oxygen. It is active against microbes via the production of hydroxyl free radicals which attack proteins and DNA [7]. It has been shown that NaOCl, combined with H_2O_2, is no more effective against E. faecalis than NaOCl alone [8] , however, CHX combined with H2O2 was a better antimicrobial agent than either one on their own.

Chlorhexidine

Chlorhexidine digluconate is widely used in disinfection because of its excellent antimicrobial activity. It is highly antimicrobial especially at pH 5.5-7.0 and is known for its longlasting effectiveness even after the removal of the solution [9] .It is a positively charged hydrophilic and lipophilic molecule which relates with phospholipids and lipopolysaccharides in cell membranes. Consequently, there is disruption of the cell membranes which allows CHX molecules to enter the cell to cause intracellular toxic effects, such as coagulation of the cytoplasm. Other advantages include available in acceptable flavor and not injurious to the surrounding tissues. Chlorhexidine has a persistent residual antimicrobial action.. Commonly, Chlorhexidine is used in conjunction with NaOCl as an irrigant as it raises the effectiveness of the irrigation protocol [10] .

However, in spite of the advantages chlorhexidine cannot be considered as an ideal root canal irrigant because of its inability to dissolve necrotic tissue remnants [11] .But capable of dissolving the smear layer [12] . Additionally studies have revealed the presence of desquamategingivitis, discoloration of teeth and tongue or dysgeusia associated with it .Laboratory findings showed chlorohexidine to be highly cytotoxic to human periodontal cells, fibroblast via inhibition of protein synthesis [13] While it does not appear to cause any long term damage to host tissues, it may still cause an inflammatory response in these tissues if expressed beyond the root canal [14] .

MTAD

MTAD is a mixture of 3% doxycycline, 4.25% citric acid and detergent developed by Torabinejad et.al. The irrigant has a combination of both chelating and antibacterial properties [15] . The citric acid may serve to remove the smear layer, allowing doxycycline to enter the dentinal tubules and exert an antibacterial effect [16] MTAD is considered to be more superior to Cholorhexidine in antimicrobial activity and is also7more biocompatible and enhances bond strength [17] . MTAD was seen to be less toxic than eugenol, 3% H2O2, CA (OH) 2 paste, 5.25% NaOCl, Peridex (a CHX mouthwash with additives) and EDTA, however, was more lethal than NaOCl in absorptions of 2.63%, 1.33% and 0.66%. The procedure for clinical use of MTAD is 20 minutes with 1.3% NaOCl followed by 5 minutes of MTAD . This irrigant is based on a tetracycline isomer; there may be problems with staining, resistance and sensitivity.

EDTA

Ethylenediaminetetraacetic acid (EDTA) is a synthetic amino acid and the sodium salts of EDTA (Na2EDTA) are used in dentistry. It is often used as a chelating agent. EDTA is not bactericidal nor bacteriostatic but inhibits the growth of, and eventually kills, bacteria . EDTA at concentrations of 15–17% removes calcium from dentine leaving a softened matrix of dentine. It also emulsifies soft tissue and removes the smear layer with no deleterious effect to pulpal or periapical tissues. EDTA reacts with the calcium ions in dentine and forms soluble calcium chelates. It is reduces the intracranial microbial flora and also helps to detach biofilms adhering to root canal walls [18] However irrigation with 5%NaOCl or alternated with 17% EDTA, significantly increased the tooth strain .It reduces the chlorine in solution, rendering the sodium hypochlorite irrigant ineffective on bacteria and necrotic tissue [16] . A one minute application of 17% EDTA combined with ultrasonic is efficient for smear layer and debris removal in the apical region of the root canal [19]. EDTA is available in a liquid form for irrigation and a gel form for lubrication .

Other Irrigating Solutions

The other irrigating solutions are sterile water, physiologic saline, iodine compounds, ureaperoxide, etidronic acid, citricacid, maleic acid, tetraclean, chlorine dioxide etc [20]

HEBP is also known as etidronic acid or etidronate and has been proposed as an alternative potential alternative to EDTA or citric acid because it shows no reactivity with NaOCl [19] .It is nontoxic but h owever, the demineralization kinetics was lower than those of 17% EDTA.

Maleic acid is a mild organic acid used as acid conditioner in adhesive dentistry. Ballal et.al reported that the final irrigation with 7%maleic acid for 1minute was more efficient than 17% EDTA in the removal of smear layer [20]

Iodine Compounds are bactericidal, fungicidal, and virucidal. 2% iodine in 4% potassium iodide has been used in endodontics. It shows less toxicity and a

decreased tendency to stain dentine.. However it is not the first choice as an irrigant. Despite its antimicrobial activity, iodine is a very potent allergen thereby causing a risk for allergy [21]

Curcuma longa (Turmeric): Curcumin, possesses anti-inflammatory,anti-oxidant,anti-microbial andanti-canceractivity. In an in vitro study conducted by Prasanna Neelakantan, it has been shown that curcumin has significant anti-bacterial activity against E.faecalis and can be used as an alternative to sodium hypochlorite for root canal irrigation [22, 23] .

Complications during Root Canal Irrigation

Root canal irrigation is an integral part of the rootcanal treatment to ensure proper debridement and disinfection of the root canal system. A review of these complications have been described briefly below, which necessitates the need to carry out effective techniques in order to avoid complications .

Damage to Clothing

Sodium Hypochlorite, a common bleaching agent can cause a concern of damage. Accidental spillage of minute quantities can lead to rapid, irreparable bleaching [24, 25] . When using an ultrasonic device for root canal irrigation the aerosol may also cause damageto the clothing. These mishapsshould be prevented by proper shield of the patients' clothing. When using hand irrigation, oneshould reassure that the irrigation needle and syringe are tightly attached .

Damage to the Eye

Mild burns with the alkali such as sodium hypochlorite can result in significant injury causing blurring of vision and patchy coloration of cornea [26] .Irrigant in contact with patients or operators eyes can result in immediate pain, intense burning and erythema. Immediate ocular irrigation with large amounts of tap water or sterile saline should be performed by the dentist.

Damage to Oral mucosa and Skin

Skin injury with an alkaline substance requires an immediate irrigation with water as alkalis combine with proteins or fats in tissue to form soluble protein complexes or soaps which could further cause irritation to the mucosa. Accidental swallowing of irrigant by patient requires proper monitoring. It is possible that skin injury can result from secondary contamination [27, 28].

Allergic reactions

Various allergic reactions to Chlorhexidine have been described. It is known to elicit allergic contact dermatitis, generally after repeated application. It can also contact urticarial,photosensitivity, fixed drug eruption and occupational asthma [29] .

The allergic potential of sodium hypochlorite was first reported by Sulzberger when a 32 year old female reported a rapid onset of pain, swelling and difficulty in breathing [30] . A subsequent allergy skin scratch test performed two weeks later confirmed a positive result to sodium hypochlorite. Other symptoms include burning sensation, shortness of breath [31] .

Complications arising from the irrigant extrusion beyond root canal apex

Chemical Burns and necrosis

When sodium hypochlorite is extruded beyond the root canal into the periradicular tissues, the effect is a chemical burn leading to localized or extensive tissue necrosis. This can further lead to tissue swelling both intra orally and extra orally. The swelling could later produce a sudden onset of pain, associated bleeding, acute sinusitis, ecchymosis of the mucosa [32].

Neurological Complications

The major complications include parathesia and anesthesia affecting the mental, inferior dental and infraorbital branches of the trigeminal nerve.

Facial nerve damage was first described by Witton et al. in 2005, where the buccal branch of the facial nerve was affected in 2 cases. Both patients exhibited a loss of the naso-labial groove and a down turning of the angle of the mouth. Both patients were reviewed and their motor function, was regained after several months [33].

Upper Airway Obstruction

Without adequate tooth isolation, sodium hypochlorite can lead to the leakage of the solution into the oral cavity and ingestion or inhalation by the patient. This could result in throat irritation and the upper airway could be compromised [34]. Ziegler presented a case of a 15-month-old girl who presented a complication of root canal irrigation with acute laryngotracheal bronchitis, stridor and profuse drooling from the mouth as a result

of ingestion of a high concentration of household sodium hypochlorite.

Air Emphysema

Studies show cases of emphysema which occurs when the root canal is dried with compressed air after injecting hydrogen peroxide into it. Symptoms and signs include a rapid swelling and erythema in the region of the treated tooth, emphysema of the face, the suborbital region, and neck. The mainsymptom is a crepitus of the swelling [35] .

Flare up

An endodontic flare-up is a complication of endodontic treatment which is defined as an acute exacerbation of asymptomatic pulp, after the initiation or continuation of root canal treatment. Excessive pressure during irrigation will cause large amounts of irrigant to come in contact with the periapical tissues, thereby a possible etiological factor for Flare up [36].

Conclusion

Thus, it is important to carry out an effective technique in order to avoid complications. In the event of an accidental extrusion of any solution, treatment guidelines should be applied as may be relevant to each case.

Phytochemical and Antimicrobial Analysis of *Portieria Hornemannii*, A Marine Red Macro Algae

Louis Cojandaraj[1], Gurdyal Singh[2], John Milton[3]

[1]Assistant Professor, Department of Medical Laboratory sciences, Lovely professional University, Phagwara, [2]Plant Head, Affy Parenteral, Baddi, Distt. Solan, H.P. India, [3]Associate Professor, PG & Research Department of Advanced Zoology and Biotechnology, Loyola College, Chennai

Abstract

The present study was designed to evaluate the phytochemical activity of *Portieria hornemannii*. The primary metabolites from *Portieria hornemannii* were obtained by soxhlet extraction using various solvent like acetone, chloroform, ethyl acetate and methanol. The phytochemical analysis determined the presence of flavonoids, terpeniods Saponins, Phenol and Cardiac Glyciosides. The extracts of ethyl acetate exhibited a higher phenolic content of **764.413 ± 22.11 mg/GAE.** The antibacterial activity determined that the extracts of ethyl acetate exhibited a good zone of inhibition of 19mm and 14mm at 20µg against *Klebsiella pneumonia* and *Staphylococcus aureus.* and in the case of antifungal activity no zone of inhibition was obtained in any of the extracts.

Key words: *Portieria hornemannii, Seaweed, Phytochemical Analysis, Red algae, Antibacterial activity, anti-fungal activity.*

Introduction

Seaweeds are able to produce a great variety of secondary metabolites characterized by a broad spectrum of biological activities and because of these properties they are considered to be the most predominant source for bioactive compounds. Seaweeds during metabolic process, infrequently suffer serious photodynamic damage even though they grow in a harsh environment. This fact suggests that seaweed cells possess some protective compounds and mechanisms.[1] Marine algae, like other photosynthesizing plants, are exposed to a combination of light and oxygen that leads to the formation of free radicals and other strong oxidizing agents. However, the absence of oxidative damage in the structural components of macro algae (i.e., polyunsaturated fatty acids) and their stability to oxidation during storage suggest that their cells have protective anti-oxidative defence systems which are similar to vascular plants[1,2].

In developing countries diseases are the major cause of death and accounts to 50% of it. Antimicrobial agents are essentially important in reducing the global burden of infectious diseases. But pathogens with resistance develop and spread, because of which the effect of those antibiotic drugs is reduced. This kind of resistance by bacterial species to the antimicrobial agents invoke a serious threat worldwide[3,4]. Bacterial resistance to antibiotics increases mortality likelihood of hospitalization and also increases the period of hospitalization.[5] Hence, there occurs an urge of antimicrobials with alternate strategies.[6,7] It has been well established by several scientific teams that seaweeds belonging to all three major pigments exhibit inhibitory action against both Gram negative and Gram positive bacteria. Antibacterial activity of nine species of seaweeds belonging to all major pigmentations revealed that brown and red seaweeds had greater antibacterial activity than the green and brown algae.[8] This study reveals the antibacterial and the phytochemical aspects exhibited by the marine red algae. *Portieria hornemannii* is a small red marine algal species which is widely distributed in tropical and subtropical water bodies of the Pacific and Indian Ocean.[9] Portieria belongs to the family Rhizophyllidaceae. The family Rhizophyllidaceae includes 4 genera Contarinia, Ochtodes, Nesophila and Portieria. The geographical distribution of the species belonging to the genera is interesting and exclusive.[10–12]with an evaluation of the ordinal classification of

the Florideophyceae (Rhodophyta The present study was designed to investigate the presence of major phytochemical compounds present in *Portieria hornemannii*.

Materials and Method

The crude metabolites from the sample were extracted using Soxhlet extraction method using solvents like acetone, chloroform, ethyl acetate and methanol. The extracts were subjected to phytochemical analysis to detect the presence of following biomolecules using the standard qualitative and quantitative procedures as described by Trease and Evans[13] and Total phenolic assay was determined by using Folin-Ciocalteu assay.[14]

The screening of anti-bacterial and antifungal activity against fastidious pathogens was performed with extracts of *Portieria hornemannii* by determining the zone of inhibition using disc diffusion method.[15–17]

Result and Discussion

The phytochemical characters of *Portieria hornemannii* were determined for all the crude extracts derived from the solvents after condensation in rotary vacuum evaporator.[13] From the present study, it was observed that Flavonoids, Terpenoids, Phenol and Cardiac glycosides were present in all the four crude extracts derived from acetone, Ethyl Acetate, Chloroform and methanol. However, Saponins were present only in methanol and ethyl acetate extracts (Table 1).

Table 1: Qualitative analysis of Phytochemicals from*Portieria hornemannii.*

Phytochemicals	Solvents			
	Acetone	Methanol	Ethyl Actetate	Chloroform
Tannins	-	-	-	-
Saponins	-	+	+	-
Flavanoids	+	+	+	+
Terpenoids	+	+	+	+
Alkaloids	-	-	-	-
Cardiac Glycosides	+	+	+	+
Phenol	+	+	+	+

The seaweeds are known for their secondary active metabolites which are used in several medical and pharmaceutical industries. Metabolites like Tannins, Saponins, Flavanoids, Terpenoids, Alkaloids and phenolic compounds have a great medicinal value and are extensively used for the manufacturing of new drugs.[13] Saponins are widely used in the treatment of hypercholesterolaemia and hyperglycaemia. It is also used as a mild detergent. Apart from this saponins also possess several medical properties like anti-microbial, cholesterol lowering, anti-oxidant, anti-cancer, anti-carcinogenic, and immune modulatory activities. It also helps in the treatment of congestive heart failure by inhibiting Na^+ and Ca^{2+}antipotal by producing cytosolic Ca^{2+} which reduces congestive heart failure by strengthening heart muscles.[18]

Tannins possess antibacterial anti-cancerous and anti-viral activities, is also used for the inhibition of HIV replication.[19] Flavonoids also possess similar activities like tannins like antioxidant, anti-inflammatory, anti-cancer, antimicrobial and anti-allergic activity.[20]

Determination of Total phenols

Earlier reports have stated that the polyphenols obtained from marine algae possess a good anti-oxidant property [21,22]. Total phenolic content of the extracts was calculated from the regression equation of calibration

curve (Y = 0.001+ 0.25x; R2 = 0.966) and expressed as mg gallic acid equivalents (GE) per gram of sample in dry weight (Figure 1) The Results of the phenolic content of *Portieria hornemannii* determined the ethyl acetate extract has high phenolic content followed by methanol extract comparing to other extracts (Table 2; Figure 2). The differences between the content of phenolic compound between each solvents and extraction methods were statistically significant ($p < 0.05$) (Table 3). The presence of high phenolic compound could be useful for the prevention of oxidative activities of the extract.

Table 2. Mean ± SD of Total Phenolic Content of *Portieria hornemannii*

Solvent	Total Phenolic Content (mgGAE/g)
	Mean ± Std. Deviation
Acetone	486.206 ± 4.84
Methanol	696.146 ± 3.85
Ethyl Acetate	764.413 ± 22.11
Chloroform	449.026 ± 14.43

Table 3. Two way ANOVA Total Phenolic Content of *Portieria hornemannii*

	Sum of Squares	**Degrees of freedom**	**Mean Square**	**F-Value**	**Sig.**
Between Groups	216040.115	3	72013.372	391.723	0.000
Within Groups	1470.699	8	183.837		
Total	217510.814	11			

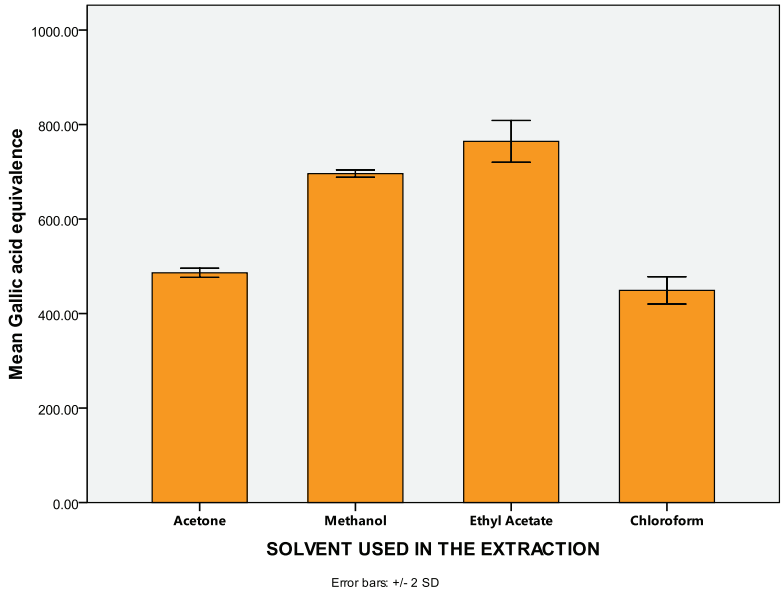

Figure 1. Mean ± SD of Total Phenolic Content of *Portieria hornemannii.*

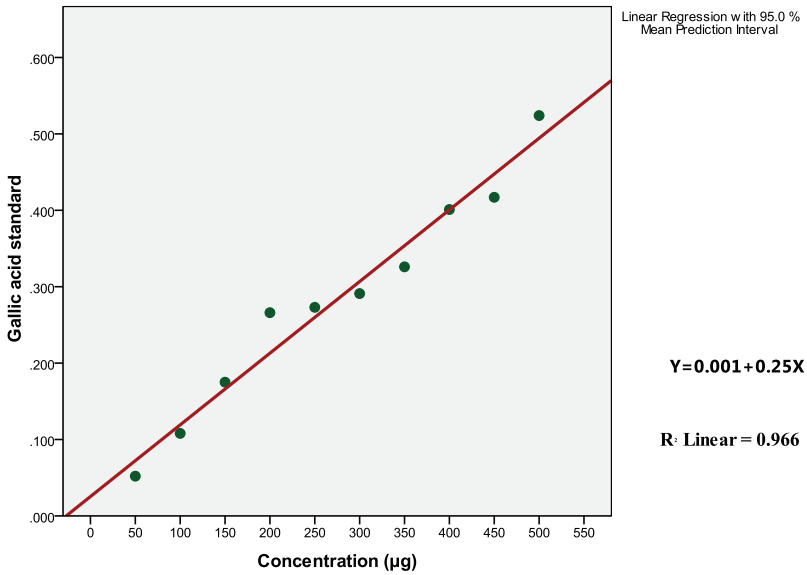

Figure 2. Gallic Acid Equivalence

Phenols are the most significant constituent in seaweed as of for their scavenging activity due to presence of the hydroxyl groups [23]. Pedersen reported that the increase in the phenolic content depends upon two major factors i.e. it increases with the aging of the tissue and also the salinity concentration of its habitat. [24] The bioactive compounds of macro algae is determined by certain aspects like environment, salinity, maturity of the algae and climatic conditions.[25] A lower phenolic content range of 1.5 to 4.1 mg GAE/g, with crude methanolic extracts of red seaweeds which is comparatively very lower with the range obtained with present study [26]. The Phenolic compounds derived from the marine algae play a vital role against the abiotic and biotic stress conditions through cell defense mechanism.[27]8 Phaeophyta and 23 Rhodophyta. In general, the biological activities of the seaweed are reflected by the phenolic compounds present in the seaweed.

Antimicrobial Activity

Antibacterial activity

In this present study the screening of the antibacterial activity was performed against five different bacterial strains *Bacillus subtilis, Staphylococcus aureus, Klebsiella pneumonia, Escherichia coli, Pseudomonas aeruginosa* under various concentration of each crude extracts ranging from 2, 5, 10, and 20µg. From the study, the zone of inhibition of *Bacillus subtilis* was obtained at a concentration range of 20µg only in chloroform extracts (10 mm). Whereas, in *Klebsiella pneumonia*, the zone of inhibition (10 mm and 19 mm) was obtained at a conc. range of 20µg in both the acetone and ethyl acetate extracts. Also, the zone of inhibition against, *Escherichia coli* was observed at a conc. range of 20µg in the extracts of ethyl acetate (11 mm), methanol (10 mm) and chloroform (12 mm). Apparently, the zone of inhibition against *Staphylococcus aureus* was observed at a conc. range of both 10µg and 20µg in the extracts of acetone (10 mm, 11 mm), and ethyl acetate (10 mm, 14 mm). Finally, the zone of inhibition against *Pseudomonas aeruginosa* was observed at a conc. range of 20µg only in the extracts of chloroform (10 mm) (Table 4). Therefore the highest zone of inhibition was seen only in the ethyl acetate extracts comparing with other extracts and also the ethyl acetate extracts inhibited the growth of three bacterial strains followed by acetone and chloroformic extracts which inhibited two bacterial strains and finally methanolic extracts inhibited only a single bacterial strain (Table 4).

Table 4. Antibacterial activity of *Portieria hornemanii*

Bacterial Species	Acetone				Ethyl Acetate				Methanol				Chloroform			
	Concentration in µg															
	2	5	10	20	2	5	10	20	2	5	10	20	2	5	10	20
Bacillus subtilis	-	-	--	--	-	-	--	--	-	-	--	--	-	-	--	10
Klebsiella pneumonia	-	-	--	10	-	-	--	19	-	-	--	--	-	-	--	--
Escherichia coli	-	-	--	--	-	-	--	11	-	-	--	10	-	-	--	12
Staphylococcus aureus	-	-	10	11	--	--	10	14	-	-	--	--	-	-	--	--
Pseudomonas aeruginosa	-	-	--	--	-	-	--	--	-	-	--	--	-	-	--	10

The acetone extract of Caulerpa scalpelliformis showed broad spectrum antibacterial activity when compared to other seaweed extracts.[28,29] But in the present study the maximum zone of inhibition was obtained from the extracts of Ethyl acetate. The maximum antibacterial activity was observed in the methanol extract of Caulerpa scalpelliformis against Salmonella typhi, Micrococcus sp., and Shigella bodii. [30]. Ely *et al*., studied with the methanolic extracts of *Chadophorea profileria* exhibited a moderate antibacterial activity against *Staphylococcus aureus* and *Vibrio cholera* [31].

Anti-fungal activity

In the present study the screening of the antifungal activity was performed by agar disc diffusion method against five different fungal strains *Aspergillus niger, Aspergillus flavus, Aspergillus fumigatius, Fusarium solanum, Exoserohium species* under various concentration of each crude extracts ranging from 2, 5, 10, and 20µg. From the study, the zone of inhibition was not observed in any of the concentrations.

In contradiction to this, the methanolic extracts of *Aspergillus taxiformis* showed inhibitory activity against fungal species like *Fusarium solanum, Aspergillus flavus,* and *trichoderma species*. The organic extracts obtained from *Aspergillus taxiformis* showed low inhibitory zone against *Aspergillus fumigatius* [32]. From the reports of El-Baroty *et al*., it was observed that the hexane and ethyl acetate extracts of *Aspergillus taxiformis* showed a good anti-fungal activity against *Fusarium oxysporees* [33] .

Conclusion

The phytochemical (Flavanoids, Terpenoids, Saponins, Phenols and Cardiac Glycosides) studies were determined for *Portieria hornemannii*. Ethyl acetic extracts showed a significant amount of phenolic content on comparing with other crude extracts. The antibacterial activity for different solvents extracts was measured in range of 10 mm to 19 mm. The extracts of ethyl acetate showed a maximum zone of inhibition against *Staphylococcus aureus, Klebsiella pneumonia, E. coli* at 10µg and 20µg/ml. It was followed by chloroform and acetone extracts. *Portieria hornemannii* was also analyzed for antifungal activity against five ocular pathogens. But, there was no significant zone of inhibition in any of the extracts at any concentration. This algal species possesses a good antibacterial activity which can be used for the drug developmental against various fastidious bacterial strains.

Conflict of Interest: The authors declare no conflict of interest.

Ethical Clearance: Animal study was not involved in this research.

Combination of Walking Practices and Yogic Practices on Low Density Lipoprotein (LDL) among Middle Aged Women

James Rathinaraj. S[1]. P. Yoga [2], K. Alaguraja[1], K. Selvakumar[1]

[1]Research Scholar, [2]Assistant Professor, Alagappa University College of Physical Education, Alagappa University, Karaikudi, Tamilnadu, India

Abstract

The purpose of the present study was to investigate the efficacy of combination of walking practices and yogic practices on low density lipoprotein (LDL) among middle aged women. To achieve the purpose of the study thirty school students were selected from Karaikudi, Tamilnadu, India during the year 2019. The subject's age ranges from 35 to 45 years. The selected subjects were divided into two equal groups consists of 15 middle aged women each namely experimental group and control group. The experimental group underwent a combination of walking practice and yogic practices programme for six weeks. The control group was not taking part in any training during the course of the study. Low density lipoprotein was taken as criterion variable in this study. The selected subjects were tested on low density lipoprotein was measured through heparin precipitation method. Pre-test was taken before the training period and post- test was measured immediately after the six week training period. Statistical technique't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference is found due to combination of walking practice and yogic practices given to the experimental group on low density lipoprotein when compared to control group.

INTRODUCTION

Everyday the human body have received some unwanted food store from the individual habits and its leads to some acute and chronic issues. Yoga is a great soul of the Universe. It can promote the social well being through limps of yoga (Asanas, Pranayama, Kriyas, Mudras and Meditations). To practising yoga regularly it can make you into sound body and sound mind. Yoga is the costless permanents treatment for more diseases, alaguraja, k[1]. It is a practical holistic philosophy designed to bring about profound state as well is an integral subject, which takes into Consideration man as a whole, alaguraja, k. et.al.,[2].

One can start practicing Yoga at any given moment of time and you may start with meditation or directly with pranayama without even doing the asanas (postures), alaguraja, k. et.al,[3]. The science of Yoga Nidra is based on the receptivity of consciousness. When consciousness is operating with the intellect and with all the senses, by making an individual think that he or she is awake and aware, but the mind is actually less receptive and more critical, yoga, p. et. al., 2019[4]. Training is a chain process that can be able to attain certain needs of the person's goal, alaguraja, k.[5]. In the sports world, physical education is the most essential aspect due to the fact physical schooling increases the performance and the effectiveness of the sports, alaguraja, k. et.al.,[6]. Today, sports have become a part and parcel of our culture. It is being influenced and does influence all our social institutions including education, economics, arts, politics, law, mass communication and even international diplomacy, alaguraja, k. et.al,[7]. The sports training can produce some physical fitness, Physiological and psychological benefits to the person and attain performance related task. It's also promoting the individual overall wealth to the sports person, alaguraja, k.[8]. Yoga is a methodical effort towards self-perfection by the development of the potentialities latent in the individual, alaguraja, k. et.al,[9]. Today's there is an escalating emphasis on appearing smarter, feeling etter and living longer. In order to achieve these ideals

as, scientific evidence tells us that one of the keys is high fitness and exercises, alaguraja, k. et.al,[10]. Asanas is a limp of Yoga practice it can make some health related gains to the individual who involved in yogasana practice regularly. Asanas can be used upon the needs of the person. It's a scientific process the person must be follow the basic principles yogasana practice[11]. Yoga is a practical aid, not a religion and its techniques may be practiced by Buddhist, Jews, Christians, Muslims, Hindus and Atheist alike. Yoga is union for all, selvakumar, k. et.al,[12]. Yogic action, or inner technique, such as breath control, parthasarathy., s. et.al,[13].

Research Methodology

Selection of subjects

The purpose of the study was to find out the effect combination of walking practices and yogic practices on low density lipoprotein (LDL) among middle aged women. To achieve this purpose of the study, thirty middle aged women were selected as subjects at random. The age of the subjects were ranged from 35 to 45 years.

Selection of variable

Independent variable

- Combination of walking practice and yogic practices

Dependent variable

- Leg Explosive Power

Experimental Design and Implementation

The selected subjects were divided into two equal groups of fifteen subjects each, such as a combination of walking practice and yogic practices group (Experimental Group) and control group. The experimental group underwent combination of walking practice and yogic practices for five days per week for six weeks. Control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following bio chemical variable namely low density lipoprotein was selected as criterion variable. All the subjects of two groups were tested on selected criterion variable low density lipoprotein was measured through heparin precipitation method at prior to and immediately after the training programme.

Statistical technique

The't' test was used to analysis the significant differences, if any, difference between the groups respectively.

Level of significance

The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

ANALYSIS OF THE DATA

The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent 't' test was used with 0.05 levels as confidence.

TABLE I: Analysis of t-ratio for the pre and post tests of experimental and control group on

Low density lipoprotein (Scores in mg/dl)

Variables	Group	Mean		Degree of freedom	't' ratio
		Pre	Post		
Low density lipoprotein	Control Group	101.11	101.16	14	1.37
	Experimental Group	101.18	100.70	14	**15.87***

**Significance at 0.05 level of confidence.*

The Table-I shows that the mean values of pre-test and post-test of the control group on low density lipoprotein were 101.11 and 101.16 respectively. The obtained 't' ratio was 1.37, since the obtained 't' ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of the experimental group on low density lipoprotein were 101.18 and 100.70 respectively. The obtained 't' ratio was 15.87* since the obtained 't' ratio was greater than the required table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant.

Result of the Study

The result of the study showed that there was a significant difference between control group and experimental group in low density lipoprotein. It may be concluded from the result of the study that experimental group improved in low density lipoprotein due to six weeks of combination of walking practice and yogic practices.

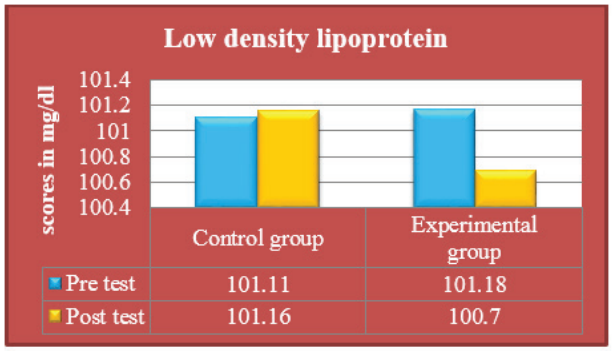

Figure-1: Bar Diagram Showing the Pre and Post Mean Values of Experimental and Control Group on Low density lipoprotein

Discussions on Findings

The result of the study indicates that the experimental group, namely combination of walking practice and yogic practices group had significantly improved the selected dependent variable, namely low density lipoprotein, when compared to the control group. It is also found that the improvement caused by combination of walking practice and yogic practices when compared to the control group.

Conclusion

On the basis of the results obtained the following conclusions are drawn,

1. There was a significant difference between experimental and control group on low density lipoprotein after the training period.

2. There was a significant improvement in low density lipoprotein. However the improvement was in favor of experimental group due to six weeks of combination of walking practice and yogic practices.

Risk Factors Leading to Mental Illness among Patients: A Retrospective Study

Jiji Benny[1], Shivakumara J[2], Thereza Mathias[3]

[1]P G Student -M.Sc Nursing (Psychiatric Nursing), [2]Professor, [3]Professor and HOD, Department of Mental Health Nursing, Laxmi Memorial College of Nursing, Mangaluru

Abstract

Background: Mental disorder is a psychological factor reflected in the behavior, which affect the normal development of a person's culture. The burden of mental health problems is increasing globally. Most mental disorders are result of a combination of several different factors rather than just a single factor. Knowing the risk factors leading to mental illness, may help in future to reduce the incidences of mental illness by taking possible preventive measures.

Aim: The main aim of this study was to determine the risk factors leading to mental illness among patients.

Materials and Method: Case control study design with quantitative non experimental descriptive survey approach was used .Mini mental status examination tool was used to select 100 psychiatric patients based on inclusion criteria and 100 general populations to find the odds ratio. Data was collected using a demographic proforma and risk factors assessment check list.

Results: In biological, socioeconomic, environmental, psychological and personal factors, the highest value of the odds ratio of risk factors for mental illness is sleep disturbance (16.385), financial problems (3.149), slum area (3.162), feeling of loneliness (13.821) and chronic smoking (16.116) respectively; it is higher among patient with mental illness compared to the general population.

Conclusion: Most of the subjects are having one or other risk factors for developing mental illness**.** Hence we need to take care about risk factors and maintain good lifestyle to promote optimal mental health.

Keywords: *Risk factors of mental illness; psychiatric patients; general population; retrospective study.*

Introduction

Mental health as an adjustment of human being to the world and to each other with maximum of effectiveness and happiness.[1] Mental illness is often disorders of the brain that disrupts a person's thinking, feeling, mood, and ability to relate to others. Mental illnesses are of different types and degrees of severity. Some of the major types are depression, anxiety, schizophrenia, bipolar mood disorder, personality disorders, and eating disorders etc. [2]

The causes of mental disorders are complex and interact and vary according to the particular disorder and individual. Genetics, early development, drugs, a loss of a family members, disease or injury, stress, bereavement, relationship breakdown, physical and sexual abuse, unemployment, social isolation, and major physical illness or disability neuro cognitive and psychological mechanisms and life experiences, society and culture can all contribute to the development or progression of different mental disorders.[3] According to WHO, one in every four people develops one or more mental disorders at some stages in life. In India, the reported rate is 73 per 1000 population.[4]

The report of District Health and Family Welfare Office of Dakshina Kannada showed that nearly 238 neurotic and 300 psychotic cases of mental disorder were recorded during the year 2007-2008. Among these only 59 neurotics and 77 psychotic cases had approached for the treatment.[5]

The National Institute of Mental Health and Neuro Science (NIMHANS) report shows that in India 70 million people suffer from mental ailments and yet, 50-90% of them are not able to access corrective services due to less awareness and negative attitude or stigma towards mental illness.[6]

Community- based surveys conducted during the past two decades in India showed that the total prevalence of psychiatric disorder was around 5.8% and depression will be one of the biggest health problems worldwide by the year 2020.[7]

Materials and Method

The study was conducted over a period of two years at selected hospitals, Mangalore, India. Case-control study design with quantitative non experimental descriptive survey approach was used. Formal permission was obtained from the director and administrative department of selected hospitals. The researcher used the Mini Mental Status Examination tool for assessing the level of insight of the patients and followed by the researcher was selected 100 psychiatric patients who has the insight and 100 general populations in a similar background and setting by purposive sampling technique based on sampling criteria to find odds ratio of mental illness. The investigator used demographic proforma and risk factors assessment check list to determine the risk factors leading to mental illness.

Mini Mental Status Examination tool :(Folstein MF, Folstein SE and MC Hugh PR, 1987): It is a standardized tool for assessing the level of insight of psychiatric patients. The reliability of the tool was 0.98. It consisted of five characteristics namely, orientation, registration, attention and calculation, recall, language with total number of score 30 and it is graded as (24-30 no cognitive impairment, 18-23 mild cognitive impairment, 0-17 severe cognitive impairment).

Demographic Proforma: This is for assessing the background information of samples. Which consisted of 11 characteristics namely, age, gender, education, occupation, and marital status, types of family, number of children, number of siblings, birth order, duration of illness and number of previous admission in psychiatric unit.

Risk factors assessment checklist: To determine the risk factors leading to mental illness. Tool was prepared on five aspects of the risk factors such as biological factors (36 items), socio economic factors (9 items), environmental factors (5 items), psychological factors (24 items), and personal factors (15 items) with a total of 89 items in five areas with check responses provided as yes or no answers.

The gathered data was analysed using SPSS software system of version 16. Frequency and percentage distribution was calculated to analyse the sample characteristics and risk factors leading to mental illness. The chi-square test was computed to analyse the association of risk factors leading to mental illness with selected demographic variables. Odds ratio was calculated to compare the magnitude of various risk factors for that outcome.

Results

Section –1: Description of Sample characteristics

The study finding shows that highest percentages (27%) of the psychiatric patients were in the age group of 20-29 years in case group where as in control group, highest percentage (30%) of the samples were in the age group of 30-39 years' old. Majority (57%) of psychiatric patients were female where as in control group, majority (60%) of samples were female. Educational status of the psychiatric patients revealed that highest percentage (26%) of patients had studied up to secondary education where as in control group, highest percentage (27%) of them had studied up to secondary education. Majority (53%) of the patients were unemployed in case group where as in control group, highest percentage (38%) of them was unemployed. Most (69%) of the patients were married where as in control group, most (92%) of the patients were married. Majority (72%) of the patients belonged to nuclear family where as in control group, majority (73%) of them belonged to nuclear family. Majority (34%) of the patients had two children where as in control group, majority (44%) of them had two children. Number of the siblings of the psychiatric patients revealed that majority (52%) of the patients had more than 3 siblings where as in control group, majority (63%) had 3 siblings. Orders of birth in the case group, majority (42%) were first born where as in control group,

majorities (35%) were second child. Majorities (26%) of the patients were having mental illness for less than a year. Number of previous admission in the psychiatric unit revealed that majorities (41%) of the patients were admitted once to the psychiatric ward previously.

Section II: Assessment of Risk Factors Leading To Mental Illness

Table 1: Frequency Percentage Distribution of Risk Factors Leading To Mental Illness

2.2	Epilepsy	9	2	4.714	1	0.030
2.3	Thyroid dysfunction	13	2	8.721	1	0.003
3	**Family history of Paternal**					
	Father	19	9	4.153	1	0.042
	Brother/sister	23	9	7.292	1	0.007
	Maternal					
	Uncle	6	1	3.701	1	0.054
	Cousins	8	2	3.789	1	0.052
	Brother/sister	9	0	0	0	0.003
II	**Socioeconomic factors**					
4	Financial problems	32	13	10.351	1	0.001
5	Joint family	24	11	5.853	1	0.016
6	Family migration	5	0	0	0	0.059
III.	**Environmental factors**					
7	Place of residence					
7.1	Slum area	26	10	8.672	1	0.003
8	Adverse influence of mass media (computer, radio, newspaper)	5	0	0	0	0.059
IV.	**Psychological factors**					
9	Stress full life events					
9.1	Love failure	8	0	0	0	0.007
9.2	Feeling of loneliness	22	2	18.939	1	0.000
10	Loss of a significant person					
	Father	18	3	0	0	0.001
V.	**Personal factors**					
11	Chronic smoking	14	1	12.180	1	0.000
12	Family conflict	13	3	6.793	1	0.009
13	Difficulty at school					
13.1	Fear of punishment	5	0	0	0	0.059

Data depicted in [Table 1] shows that the following risk factors are significantly predisposed to mental illness among cases (psychiatric patients) such as poor nutrition (P=0.014), sleep disturbance (P=0.000), hypertension (P=0.041), epilepsy (P=0.030), thyroid dysfunsction (P=0.003), paternal-father (P=0.042), brother/sister (P=0.007), maternal-uncle (P=0.054), maternal-cousins (P=0.052), maternal-brothers/sisters (P=0.003), financial problems (P=0.016), family migration (P=0.059), slum area (P=0.003), adverse influence of mass media (P=0.059), work related stress (P=0.069), love failure (P=0.007), feeling of loneliness (P=0.000), loss of significant person (father) (P=0.001), chronic smoking (P=0.000), family conflict (P=0.004), and fear of punishment (P=0.054) along with case and control group.

Section III: Determination of Odds ratio of Risk Factors Leading To Mental Illness

Table 2: Odds ratio of risk factors for mental illness among psychiatric patients and general population n=200

SL. No	Risk Factors			Odds Ratio
		Case (100)	Control (100)	
I	Biological factors			
	• Sleep disturbance	71	13	16.385
II	Socioeconomic factors			
	• Financial problems	32	13	3.149
III	Environmental factors			
	Place of residence			
	• Slum area	26	10	3.162
IV	Psychological factors			
	• Feeling of loneliness	22	2	13.821
V	Personal factors			
	• Chronic smoking	14	1	16.116

Data in Table 2 shows that in biological, socioeconomic, environmental, psychological and personal factors, the highest value of the odds ratio of risk factors for mental illness is sleep disturbance (16.385), financial problems (3.149), slum area (3.162), feeling of loneliness (13.821) and chronic smoking (16.116) respectively; it is higher among patient with mental illness compared to the general population.

Section IV. Association of risk factors of mental illness with selected demographic variables.

Table 3: Association of demographic variables with risk factors of mental illness in case and control group n=200

Sl. No.	Demographic factor with Risk Factors	Case(100)		Control (100)	
		Chi-square value	P Value	Chi-square value	P Value
1	Occupation (sleep disturbance)	9.460	0.051*	3.057	0.548
2	Gender (diabetes mellitus)	0.672	0.412	4.001	0.045*
3	Age(hypertension)	9.008	0.016*	0.814	0.937
4	Marital status(hypertension)	15.534	0.004*	1.036	0.309
5	Education(epilepsy)	5.328	0.5036	16.667	0.020*
6	Type of family(epilepsy)	3.846	0.050*	0.548	0.459
7	Marital status(migraine)	9.789	0.048*	0.524	0.469
8	Age (thyroid dysfunction)	17.880	0.001*	2.211	0.697
9	Marital status (joint family)	5.606	0.231	6.238	0.013*
10	Type of family (joint family)	41.009	0.000*	25.612	0.000*
11	Type of family (riot prone area)	3.725	0.054*	1.118	0.290
12	Gender (work related stress)	6.206	0.013*	0.174	0.677
13	Occupation (work related stress)	20.572	0.000*	2.245	0.691

*- significant

Data presented in Tables 3 shows that there is a significant association between the risk factors of mental illness like sleep disturbance, diabetes mellitus (control), hypertension, epilepsy, (both case and control group) migraine, thyroid dysfunction, joint family (both case and control group), riot prone area, work related stress with selected demographic variables. Hence the null hypothesis is rejected and research hypothesis is accepted. There is no significant association found between the rests of the risk factors of mental illness with selected demographic variables.

Discussion

There is a paucity of literature looking to identify the various risk factors leading to mental illness. The present study intended to identify the risk factors leading to mental illness among patients in selected hospitals, Mangalore.

The present study findings are consistent with a longitudinal study conducted on sleep disturbances and depression: risk relationships for subsequent depression and therapeutic implications shows that 90% of patients with depression will have sleep quality complaints. About two third of the patients undergoing a major depressive episode will experience insomnia, with about 40% of patients complaining of problems initiating sleep (sleep onset difficulties), maintaining sleep (frequent awakenings), and/or early-morning awakenings (delayed or terminal insomnia), and many patients reporting all three. Hypersomnia occurs in about 15% of patients. Sleep problems sometimes emerge as a symptom of depression or as a side effect of treatment.[8]

The present study showed that in biological, socioeconomic, environmental, psychological and personal factors, the highest value of the odds ratio of risk factors for mental illness is sleep disturbance (16.385), financial problems (3.149), slum area (3.162), feeling of loneliness (13.821) and chronic smoking (16.116) respectively; it is higher among patient with mental illness compared to the general population.

The study findings are supported by an epidemiologic study of sleep disturbances and psychiatric disorders shows that the risk of developing new major depression was much higher in those who had insomnia at both interviews compared with those without insomnia (odds ratio, 39.8; 95% confidence interval, 19.8 to 80.0).[10]

Study on loneliness in the general population: prevalence, determinants and relations to mental health shows that a total of 10.5% of participants reported

some degree of loneliness (4.9% slight, 3.9% moderate and 1.7% severely distressed by loneliness). Loneliness declined across age groups. Loneliness was stronger in women, in participants without a partner, and in those living alone and without children. Controlling for demographic variables and other sources of distress loneliness was associated with depression (OR=1.91), generalized anxiety (OR=1.21) and suicidal ideation (OR=1.35).[11]

The present study shows that there is a significant association between the risk factors of mental illness like sleep disturbance, diabetes mellitus (control), hypertension, epilepsy, (both case and control group) migraine, thyroid dysfunction, joint family (both case and control group), riot prone area, work related stress with selected demographic variables. Hence the null hypothesis is rejected and research hypothesis is accepted. There is no significant association found between the rests of the risk factors of mental illness with selected demographic variables.

The study findings are supported by a study on relationships of occupational stress to insomnia and short sleep in Japanese workers shows that in men, high occupational stresses were significantly associated with insomnia, especially a high level of Effort Reward Imbalance (defined as the presence of high effort and low reward), had a remarkably higher odds ratio. In women, high occupational stresses were significantly associated with insomnia as well. High occupational stresses were significantly associated with short sleep in men. However, in women, only Effort Reward Imbalance showed a significantly association with short sleep.[12]

Conclusion

Most of the samples are having one or other risk factors for developing mental illness**.** Some of the most relevant risk factors are sleep disturbance, financial problems, slum area, feeling of loneliness, chronic smoking etc. Hence we need to take care about these risk factors and maintain good lifestyle to promote optimal mental health.

Targeted Local Drug Delivery – A Possible Approach in Dentistry

Gummuluri Sriram[1], Kavalipurapu Venkata Teja[2], Kaligotla Apoorva Vasundhara[3]

[1]Undergraduate Student, Bachelor of Pharmacy, SVS Group of Institutions, SVS School of Pharmacy, Bheemaram, Hanumakonda, Warangal, Telangana, India, [2]BDS, Private consultant, Hyderabad, [3]Postgraduate, Sibar Institute of Dental Sciences, Guntur

Abstract

Drug delivery is a method of administering a pharmaceutical compound to achieve a therapeutic effect in humans and animals. Conventional therapy is a classical method of achieving drug delivery. Where, it provides drug release immediately and causes fluctuation of drug level in in blood depending on the dosage forms compared to conventional, which improves the drug potency, controlled drug release to give a sustained therapeutic effect, provide greater safety and target a drug specifically to a desired tissue. It mainly includes targeted, controlled and modulated drug delivery systems. Hence, there is an increased interest towards the application of targeted therapies in medicine and dentistry and has proven to be successful in prevention and treatment of various oro-dental disorders.

Keywords: *Biodegradable; Carrier System; Nanoparticle; Target Drug*

Introduction

Targeted drug delivery is a special form of system, where the medicament is selectively targeted or delivered only to its site of action or absorption and not to the non-target organs or tissues or cells. It improves the efficacy and reduces the side effects [1]. The drug may be delivered, to the capillary bed of the active sites, to the specific type of cell or even an intracellular region, to a specific organ or tissue by complexion with the carrier that recognises the target. The main objective of a targeted therapy, is to mainly achieve a desired pharmacological response at a selected site, thereby the drug has a specific action with minimum side effects and better therapeutic index [1]. The main reason behind the targeting of the drug is in intervention, prevention or treating a disease. Conventional dosage forms have few drawbacks like, pharmaceutical drug instability, low absorption and high membrane bounding, biological instability. The drug delivered through conventional system, has a very low specificity, shorter half life, large volume of distribution and low therapeutic index. These challenges lead to increased interest towards a targeted therapy [2]

Requirements of drug targeting

For a drug to be targeted, it should have certain characteristics or requirements to be satisfied. Mainly it should be nontoxic, biocompatible, biodegradable and physico-chemically stable both invitro and invivo. The drug that has been delivered should be restricted to the targeted area and should have a uniform capillary distribution. It should be controllable and with predictable drug release. Amount of release is therapeutic, with minimal leakage during transit [3]. Carriers used must be bio-degradable or readily eliminated from the body without any problem. Although targeted therapy has several advantages, but still it has many limitations that hinder its application. The main disadvantage of this therapy is difficulty in predicting the exact action of drug at the specified site. Rapid clearance of targeted systems, immune reactions, insufficient localisation of targeted systems, possible toxic reactions in therapeutic dosages and tedious preparation procedures lead to decreased usage for day to day basis [4].

Carriers in targeted drug delivery:

Targeted drug delivery, can be achieved by using carrier system. Carrier is a special molecule or system essentially required for effective transportation of loaded drug to the selected site. Various pharmaceutical carriers used are polymers, microcapsules, microparticles, lipoproteins, liposomes, micelles. The important componential properties that influence drug targeting

are mainly the drug delivered its concentration, particulate location and distribution, molecular weight, physicochemical properties and drug carrier interaction. In case of carrier molecule, its type, number of excipients, surface characteristics, size and density. In vivo electric field [5,6].

Various strategies in drug targeting [5] are, passive, active, ligand mediated, physical, dual, double inverse and combination targeting. Passive targeting utilises, the natural course of bio-distribution of the carrier. The colloids which are taken up by the reticulo-endothelial system can be ideal vectors for passive targeting. Active targeting involves the modification or functionalization of the drug carriers so that the contents are delivered exclusively to the site corresponding to which carrier is architectured. It can be affected at different levels like first order or organ compartmentalization, second order or cellular targeting, third order or intercellular organelles targeting. In first order targeting, there is a restricted distribution of drug carrier system to the capillary bed of a pre-determined target site, organ or tissue. In second order targeting, the drug is selectively delivered to a specific cell type such as tumor cells and to the normal cells. In third order targeting, drug is delivered to the intracellular organelles of the target cells. Inverse targeting is a reverse of passive system which avoids the passive uptake of colloidal carriers by the reticuloendothelial system. It can be achieved, by suppressing the function of reticulo-endothelial system by pre-junction of a large amount of blank colloidal carriers or macromolecules [5]. Ligands are carrier surface groups, which can be selectively direct the carrier to the pre-specified site, housing the appropriate receptor units to serve as homing device to the carrier or drug. The ligands confer recognition and specificity upon drug carrier and endow them with an ability to approach the respective target selectivity and deliver the drug. Physical targeting involves environmental changes like pH, temperature, light intensity, electric field and ionic strength. Dual targeting is an approach where, the carrier molecule itself, have their own therapeutic activity and thus increase the therapeutic effect of the drug. Double targeting is of two types, it can be achieved by spatial and temporal control. In spatial control, drugs are targeted to specific organs, tissues, cells or even subcellular component. In temporal control, the rate of the drug delivery is controlled to the target site. Combination targeting systems are equipped with carriers, polymers and homing devices of molecular specificity that could provide a direct approach to the target site [5,6, 7].

Delivery systems

Drug delivery, is a method or process of administrating a pharmaceutical compound to achieve a therapeutic effect. It is achieved through delivery systems, which help in delivering or carrying the drug to the specified site. The various delivery systems used are nanotubes, nanowires, nano shells, quantum dots, gold nano, dendrimers niosomes virosomes, liposomes, nanocrystals, magnetic nanoparticles, nanorobots [8]. Nano tubes are the hollow cylinder tubes made of carbon atoms, which can be filled and sealed for potential drug delivery they measure about 10 to 100 micrometers [9,10]. Nanowires are the thin wires which are usually microns in size, they localize the pinpoint damaged site. It has its wide applicating in patients with neurological disorders [8]. Nanoshells are the hollow silica spheres, covered with gold. Antibodies can be attached to their surfaces, enabling shells to target a particular cell in the body [8]. Quantum dots are miniscule silica particles, which are mainly the semiconductor particles, which are useful in various diagnostic and therapeutic purposes. Gold nano can be nanoparticles that are coated or made of gold particles. They are helpful in detection of DNA and protein markers. It has its wide applications in cancer treatment and genetic engineering [11]. Dendrimers are precisely defined [10,12]. Synthetic nanoparticles that are approximately 510nm in diameter. They are made up of layers of polymer surrounding a central core. They contain different sites to which the drugs are attaches and delivered. They have wide applications in gene transfection and medical imaging [8,9]. Liposomes are small microscopic vesicles in which an aqueous volume is entirely composed by membrane of lipid molecule. The drug molecules can either be encapsulated in aqueous space or intercalated into the bilayers [13,14,15]. Niosomes are non- ionic surfactant vesicles which can entrap both hydrophilic or lipophilic drugs either in aqueous phase or vesicular membrane made of lipid materials. It seems to have better stability than liposomes. Virosomes are immuno-modulating liposomes consist of glycoprotein of viruses. They helpful in genome grafting and cellular microinjection [16,17,18,19]. Nanocrystals are nanoparticles with lesser than 100nm in diameter. Nanorobots include the technology of creating robots at nanoscale diameters, it is a hypothetical designing principle, which is still in research. It is claimed that they specifically delivered to certain areas and get targeted [8,9].

Applications of targeted drug delivery:

The applications of targeted drug delivery mainly include in treating oral mucosal lesions, in treating endodontic infections, cancer therapy and treating patients with periodontitis [20]. In treating oral mucosal lesions, various drugs are targeted using different strategies like usage of quantum dots, liposomes [13,14,15] which are bio-compatible, biodegradable and nonimmunogenic. Which ultimately reduce the toxicity and side effects of drugs. They have a wider role, with increased therapeutic effect as an antimicrobial, antiviral, antitumoral and also used in gene therapeutics. Folate targeting and sono poration have proven to be useful in treating patients with oral cancer. The major importance of nano particles, compared to the other conventional medicinal drugs is that the targeting of the nanoparticles to the specific tumor tissue. Compared to the microparticulate systems, nanoparticles can easily traverse in the blood vessels and the tumor tissue. In targeting the cancer tissue mainly by active and passive targeting modalities. In passive targeting, the injectable drug carriers have been surface modified to evade the reticule endothelial system. They are lived for longer time they have a greater advantage of reaching the blood vessels surrounding the solid tumors. The nanoparticulate molecules have enhanced permeability and retention. Active targeting is by conjugating a ligand to the surface of the particle, such ligand only target the specific cancerous tissue. Most of the studies till date, have focused on the tissue specific antigen mainly the tissue specific antigen. Liposomal carriers and the polymeric nanoparticles are the major important pathways of the targeted drug delivery [13]. Although other nanomicelle systems and studies are still being undertaken.

Periodontic and endodontic diseases are the conditions which mainly occur due to the inflammatory responses from the teeth and the supporting tissues. Endodontic and periodontal pathologies are both biofilm mediated diseases. Thus suppression of the microorganisms and the bio films is challenging. The recurrence of the infection is more common due to the adaptive nature of the microorganisms, protective extracellular polysaccharide matrix formation and development of resistance to microbial agents. To circumvent these challenges, nanomaterials in the form of nanofibers and nanoparticles have been considered in dental therapies. The micro and nano particles are used for localised delivery of the anti-infective agents for the periodontal and endodontic diseases. The micro particles seem to have a greater potential in improving the strategies in management of the endodontic and periodontal diseases. They are very effective when directed against the periodontal pockets and root canals as they have prolonged antibacterial effect and extremely effective. Among all the natural and synthetic polymers available, copolymers of lactic and glycolide family are the most studied and versatile with reference to its availability, release profile, biodegradation time and biocompatibility [21,22,23,24].

In controlling periodontal pathogens, various antibiotics such as doxycycline, tetracycline and minocycline are used. When these antibiotics, encapsulated with the polylactic glycolic acid blend spheres, it is observed the minimal inhibitory concentration was more than required in the gingival crevicular fluid, with continuous drug release up to a week. There was significant improvement in the plaque and gingival index scorings with relative attachment levels. Calcium hydroxide nanospheres are seen to be more effective in endodontic therapy compared to the conventional calcium hydroxide. The nanoparticles can also be used in dental materials, as nanoparticles, for improving the physicomechanical properties of the dental materials. Polymeric nanoparticles such as chitosan nanoparticles, serve as a prophylactic approaches for prevention of bacterial biofilm formation and possibility of penetration into the already formed biofilms. In addition to chitosan, polylactic glycolic acid and cellulose acetate phthalate nanoparticles have been used optimally as antibacterial agents for endodontic and periodontal disease management [25]. Charged and surface charged nanoparticles have direct interaction with the microorganisms and they are helpful in the selective eradication. It is a process where selectively the bacteria are eradicated by binding to the opposite charged bacteria or pathogens. The concept utilised in both endodontics and periodontics is by usage of the photosensitisers encapsulate with the nanoparticles, in the active photodynamic therapy to eradicate the microorganisms [25]. The principle is that the photosensitiser is preferentially taken by the bacteria and the activation of the light generates free radicals and singlet oxygen which kills the microorganisms. Specific targeting nanoparticles is a strategy where a particular and specific pathogen can be identified and targeted. It is possible via conjugation of the antibodies with the respective nanoparticles. Immunoliposomes have been used to for the precise delivery of these Antimicrobial

agents for specific plaque control. Although there are currently only a limited number of endodontic and periodontal nanodrug delivery systems, there is a future hope of developing and applying these nanoparticles in the endodontic and periodontal perspective [25,26].

Conclusion

Targeted drug delivery is an effective and alternative pathway for the modern dentistry. Although it is beneficial in several ways, the delivery systems still have to be I proved for they effective delivery into the targeted tissues. And there is a hope in near future that nano targeted dentistry will improve the treatment outcomes.

Association of *Viharaja* and *Manasika Hetus* (Behavioural and Mental Factors) with A*mlapitta (*Hyperacidity) amongst Police Professionals in Pune

Babar Smeeta Shivaji[1], Joshi Mrudula Vinayak[2,] Joshi Vinayak Nilkanth[3]

*[1]Ayurveda Practitioner, Pune, Maharashtra, [2]Professor and HOD, P. G. Department of Ayurveda Samhita and Siddhanta, [3]Professor and HOD, Rognidan and Vikruti Vidnyan, Dr. D.Y. Patil Vidyapeeth,, Dr. D.Y. Patil College of Ayurveda and Research centre, Pimpri, Pune, Maharashtra***,** *India*

Abstract

Background-Changing life style in conjunction to unhealthy dietary pattern, mental stress and strain is leading to *Ajeerna* (indigestion), and further *Amlapita* (hyperacidity). **Aim-**To evaluate the association of *Viharaja* and *Manasika Hetus* (behavioural and mental factors) with A*mlapitta (*Hyperacidity) amongst police professionals in Pune.

Settings and Design- This cross sectional study was conducted among Police professionals in Pune region. **Methods and Material: S**tudy included 100 identified patients of *AMLAPITA*; both males and females from the age group of 25-50years. A self administered, structured, pilot tested 9 item questionnaire was used to collect data. **Statistical Analysis:** Descriptive data was analyzed using number and percentages. **Results:** Maximum patients with *Pitta-Vataja Prakruti were* n=47, *Kapha-Pittaja Prakruti* were n = 41 and *Kapha-VatajaPrakruti were* n= 12. 71 (100%) *Amlapitta* Police Professionals did daily ***Ratri-jagarana*** who had night shift and 29 (100%) reported day shifts out of which 21(72.41%) Police Professionals did daily *Ratri-jagarana* yet they had day shift duty. Mental stress was more in Night shift personnel n=52 (73.24%) than stress observed in Day shift participants n=17(58.62%).

Conclusion: Present study help us to estimate association of *Amlapitta* with changed life style pattern. These etiological factors like *Viharaj and Manasika hetus* namely *Ratrijagarana,Vegavidharana,* Mental stress cannot be eradicated totally due to current career progression scenario. But definitely alternative therapies like yoga, meditation and diet plans can be suggested and practiced as and when necessary.

Key Words –*Amlapitta, Etiological factors, Police Professionals, Hyperacidity, Stress, Behavioural causes, mental causes*

Introduction

Amlapitta(Hyperacidity) is a very common disease of this era.30% of the general population is suffering from gastro-oesophageal reflux and gastritis resulting in heartburn.It is very troublesome disease and can give rise to many serious problems if not treated in time. Signs and symptoms of *Amlapiita* are very similar to gastritis [1]. *Amla* means sour and *Pitta* is the functional digestive component of the body. Thus *Amlapitta* (Hyperacidity) is a disease; in which sour blenching is the major symptom. *Avipak*(Indigestion), *Klama*(Exhaustion including normal 8 hr. duty) , *Utklesha* (Nausea) ,*Katu/ Tikta / Amla udgar* (pungent/ bitter/ sour Blenching) , *Hrut / kantha daha*(Heart / Throat burning) , *Aruchi* (Tastelessness), *Chchardi*(vomiting) ,*Shirashoola*(Head ache) are the important signs and symptoms of the disease[2,3].

It has been indicated that *Amlapitta* occurs in the persons having unhealthy food habits[1, 4]. The diet today is governed by social and professional background, has led people to consume unhealthy food and subsequently indigestion. Indigestion caused produces *Annavisha* (toxins) which get mixed up with *Pitta Dosha* and lodges in *Amashaya*(Stomach) and then it produces *Amlapitta* disease[5].

Police officer's job is one such public service profession wherein noxious conjunction due to disturbed life pattern is seen.Policeman has to be on duty for longstanding hours either in a day or night shift, leading to disturbed body clock. *Ratrijagarana* (Night awakening)[6,7,8,9], *Atapa sevana* (exposure to bright Sunlight), *Vega vidharana* (suppression of natural urges like hunger, thirst stool, urine, etc.)[7] is very common in their day to day life. *Ajeernashana*(repeated eating)[1,10,11,12], *Amla / katu / Vidahi/ ViruddhaAhar[12,13,14]sevan*(sour, pungent, spicy food & food having opposite qualities)are mentioned as dietary causes of the disease.This disturbed life pattern also causes, addiction of Paan, tobacco chewing, Gutka, alcohol which in addition contributes to Gastro-Intestinal disorders like *Amlapitta*. Moreover, work pressure causes high stress level especially mental stress, which again contributes to vitiate the *Pitta dosha* leading to *Amlapitta* disease.Therefore it becomes necessary to avoid *Hetus* (etiological factors) to minimize diseases like *Amlapitta* in police professionals.

This study will help us to evaluate the association of *Viharaja* and *Manasika Hetus* (behavioural and mental factors) with A*mlapitta (*Hyperacidity) amongst police professionals in Pune.

This data will help to fetch remedy for different preventive and curative modified dietary and life style changes on the basis of dominant etiological factors.

Materials and Method

This cross sectional study was conducted among 100 pre- diagnosed police professionals from Pune region suffering from *Amlapitta*, who were working on various posts, of both sex and aged between 25 to 50 years, willing to participate in the study were selected. Individuals suffering from *Avipak*, *Klama ,Utklesha ,Katu/ Tikta / Amla udgar ,Hrut / kantha daha ,Aruchi ,Chchardi , Shirashoola* (Head ache) as main symptoms were included; while those who suffered from Hypertension, Cardiac diseases, Diabetes mellitus, Congenital and Immunological disorders were excluded from the study. Approval was obtained from the scientific committee and Institutional Ethics committee (No: AY/PG/130/2014/15/IEC). Every participant signed an informed consent form before starting the study. A structured questionnaire with 9 major questions was administered. All the Police Professionals were asked to complete the questionnaire. Information regarding *Hetus*, *Lakshanas* of *Amlapitta*, Daily schedule and duty shifts and other occupational causes related to stress in Police profession was recorded.The collected data was entered in Microsoft Excel 2007. Descriptive analysis in the form of number and percentages were calculated.

Results

This cross sectional study was completed among 100 police professionals. Important findings regarding demographic variables like Age, *Prakruti* (Physical constitution), *Viharaja hetus namely Ratrijagarana, Vega vidharana* and Mental stress are listed. It was found that according to age, maximum number of patients were n= 39 from the group of 45 -50 years i.e. belonging to higher grade and minimum patients i.e. n= 24 from age group 35-45 years (Table 1).

TABLE 1 - Distribution of 100 patients of *Amlapitta* according to Age

Age Range in years	Number	
25 – 35		37
35 – 45		24
45 – 50		39
Total		100

TABLE 2. Distribution of 100 Amlapitta Police Professionals according to Prakruti

PRAKRUTI	**Number**
PV(Pitta-Vata)	47
KP(Kapha-Pitta)	41
KV(Kapha-Vata)	12

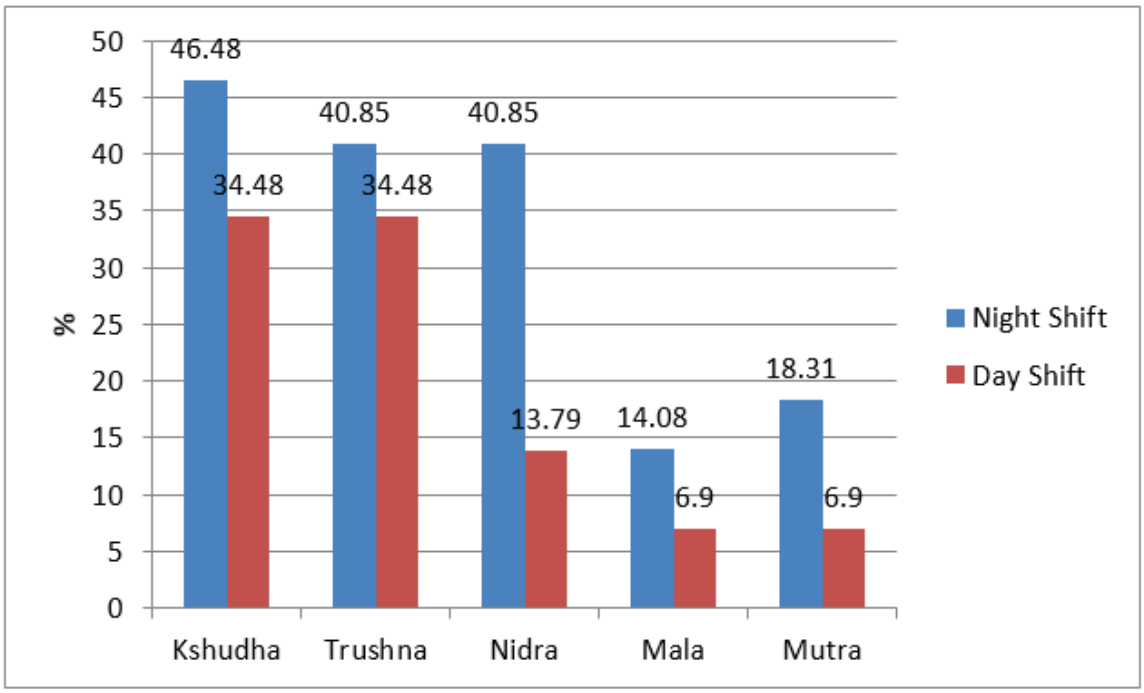

Fig1: Distribution of police professional based on the daily *Vega Vidharana*

Figure 1.***Vegavidharana*** ***(***suppression of natural urges***)*** It was noted in Night shift Participants *-Kshudha (hunger), Trushna(thirst), Nidra(sleep) and Mala(stool),Mutra (urine)Vegavidharana* was prominently noticed in 46.48%, 40.85%, 40.85%, 14.08% and 18.31% respectively.

TABLE 3– Distribution of 100 Police professionals with *ManasikaHetus* of *Amlapitta*

MENTAL STRESS	**Number (%)**
Night duty(n =71)	52(73.24)
Day duty(n =29)	17(58.62)

Prakruti **-**Observations related to Physical constitution denoted maximum patients with *Pitta-Vataja Prakruti* n=47, *Kapha-Pittaja Prakruti* in n = 41 and *Kapha-VatajaPrakruti* n= 12(Table 2).

71 (100%) *Amlapitta* Police Professionals did daily ***Ratri-jagarana*** who had night shift and 29 (100%) reported day shifts out of which 21(72.41%) Police Professionals did daily *Ratri-jagarana* yet they had day shift duty.

It is more in comparison with Day Shift duty Police Professionals where the percentage noted was 34.48%, 34.48%, 13.79%, 6.90%, and 6.90% respectively.

Table 3.*Manasikhetu***-Mental stress was more in Night shift personnel n=52 (73.24%) than stress observed in Day shift participants i.e. n=17(58.62%)**

Discussion

Present survey study executed on 100 Police Professionals, pre-diagnosed with *Amlapitta*; acknowledges prevalence of disease *Amlapitta* in Police Professionals; along with important role of *Viharaja and Manasika Hetus* in disease creation. Age of Police professionals plays vital role in disease progression mainly due to continuous change in life style for longer duration. Working in shift duty is trigger factor for uneven sleep pattern, unpunctual and unhealthy food habits.

Present study reveals that Police Professionals with Night Shift were found to be more exposed to *Hetus* of *Amlapitta* and were suffering from classical symptoms of *Amlapitta* as compared to Day shift Police Professionals. According to this study *Hetu* – **Age** between 45-50 years in participants indicates the middle age group which is *Pitta* dominant phase of life. Further, the increasing load of responsibilities is also a characteristic of this age group which can be an etiological factor. ***Sharirprakruti(***Physical constitution***)*** adds on to susceptibility to disorders. *Pitta Vataj prakruti* dominates with n=47. These type of constitutions in persons make them physically weak and more sensitive to external factors.

Working in Night shift exposes them to *hetus* like *Ratrijagarana, Vegavidharana of Kshudha, Trushna, Nidra, Mala and Mutra vega.* These *hetus* are *Viharaj hetus* and cause *Annavaha and Rasavaha srotas dushti*(disturbed digestion and assimilation). This leads to *ajeerna*(indigestion), *agnimandya(weak capacity of digestion)* and finally results in *Amlapitta*.

In *Manasika hetus*[15]; *Krodha* (Anger) causes *Pitta prakopa(increase in Pitta), Chinta* (Stress)causes *rasa dhatu dushti, Bhaya(Fear)* causes *Trasa (*pain) and *Shoka(*Grief *)* causes *vataprakopa(Increase in Vata)*[16]. *Vata pitta anubandha* is there in *Manasika hetus* which causes indigestion[15] which again leads to *Agnimandya* and creates *Vidhaha(burning), Shuktata(sour blenching) and Amlapitta* symptoms appear.

Apart from above *hetus* if person takes *Pitta prakopak (spicy ,pungent food items) Ahara, Vihara, Adhyashana(excessive eating), Viruddha-ahara(*opposite property in food*) ,Pishtanna (*Bakery products*), katu-lavan Rasa sevana (food with pungent and salty taste)*, it leads to *vidagdhata (incomplete digestion)* of *Ahar(food)* and then leads to *Amlapitta.*

Conclusion

Present study help us to estimate association of *Amlapitta* with changed life style pattern. These etiological factors like *Viharaj and Manasika hetus* namely *Ratrijagarana,Vegavidharana,* Mental stress cannot be eradicated totally due to current career progression scenario. But definitely alternative therapies like yoga, meditation, diet plans etc. can be suggested and practiced as and when necessary. This may help in lowering the rate of incidence, symptomatic relief and act as preventive measure in young Police professionals.

Salivary Selenium Levels in Dental Caries

Nireeksha[1], Mithra N Hegde[2], Suchetha Kumari N[3], Sharmila[4], Roopa[5]

[1]Lecturer, [2]Vice principal, Head of the Department, Department of Conservative Dentistry and Endodontics, A.B.Shetty Memorial Institute Of Dental Sciences, Nitte University(deemed to be), , Deralakatte Mangalore, [3]Professor, Department of Biochemistry, Principal Scientific Officer, [4]Research Assistant, [5]Junior Research Fellow Central Research Laboratory, K.S.hegde medical academy, Nitte university(deemed to be), Deralakatte , Magalore

Abstract

Background: Selenium , an essential trace element performs various biological functions through different -containing proteins[7].Selenium has over 25 different proteins named as selenoproteins. These trace elements play a major role in remineralisation and demineralization cycle of tooth surface. Therefore, this study is aimed at evaluating the salivary selenium levels in caries free and caries active individuals.

Methods and Materials: After obtaining the ethical clearance the study was conducted among the 60 individuals reporting to the department of conservative dentistry and Endodontics A.B.Shetty memorial institute of dental sciences , Nitte University, Deralakatte Mangalore who can be included into the study based on the inclusion and exclusion criteria. Salivary samples were collected and assessed by Micowave Plasma Atomic Emission Spectrometer (MP-AES) for selenium levels in caries free and caries active group .

Results: The values obtained where statistically analyzed using SPSS version 2.0 software. Caries free group showed a mean selenium levels of 116.9863 microgram/L with a standard deviation of 9.60601. Whereas caries active group showed a mean selenium levels of 63.7547 microgram/L and standard deviation of 12.06005 . Levene's Test for Equality of Variances was done to test the significance. The values shows significant difference between the two group.

Keywords: *Saliva, dental caries, trace elements, selenium*

Introduction

Saliva due to its unique properties and constituents plays a protective role against occurrence of dental caries. Dental caries is a multi-factorial disease which occurs due to various etiological factors[1]. Presence of an ocean of anions ,minerals,electrolytes,proteins and enzymes in different degrees of intensity contributes to various important functions of the saliva namely buffering capacity, cleansing ability, anti-bacterial action and maintaining of supersaturated state. Presence of trace elements which are required in minute quantities for the physiology and proper growth development of organisms are present in approximately 0.2 % concentration of saliva[2].

A trace element is an element in a sample that has an average concentration of less than 100 parts per million measured in atomic count or less than 100 micrograms per gram[3].These trace elements play a major role in remineralisation and demineralization cycle of tooth surface. Various levels trace elements like phosphorous, Zinc, copper, molybdenum, calcium, magnesium, barium, strontium ,iron, ,selenium, lead and potassium are associated with increased or decreased occurrence of caries[4].Even though microorganisms play a major role in occurrence of dental caries ,the components of saliva which are in very minute concentration play a part in caries incidence and progression[5,6].

Selenium , an essential trace element performs various biological functions through different -containing proteins[7].Selenium has over 25 different proteins named as selenoproteins[8].It is a part of several metabolically active enzymes thioredoxin reductases and glutathione peroxidises. These selenoproteins play a major role in anti-oxidant defences, redox regulation of homeostasis and thyroid hormone metabolism. Various pathogens and pathogenic conditions are influenced by the presence of selenium.

Low levels of selenium leads to decline of tissue selenium-dependent glutathione peroxidase activity. One among the various sites selenium concentrations are evaluated is saliva[9].Selenium concentration varies according to different geographical locations. Their content in soil, plant also their bioavailability and retention also varies[10].

Therefore, this study is aimed at evaluating the salivary selenium levels in caries free and caries active individuals .

Methods and Materials

After obtaining ethical clearance the study was conducted among the 60 individuals reporting to the department of conservative dentistry and Endodontics A.B.Shetty memorial institute of dental sciences , Nitte university(deemed to be), Deralakatte Mangalore who can be included into the study based on the inclusion and exclusion criteria.

Inclusion Criteria:

- Age group of 18-40 Y.
- Free from systemic and local illness that affects the salivary flow.

Exclusion Criteria:

- Individuals with systemic illness like diabetes, Rheumatoid arthritis, undergoing radiotherapy affecting oral health.
- Individuals with chronic generalized gingivitis and periodontitis.
- Long-term medication and intake of other nutritional supplements.
- Individuals under a restricted diet will be excluded from the study.

Oral examination:

Mouth mirror and straight probe was used to perform clinical evaluation ,patients seated on the dental chair.

Dental caries evaluation:

"D" in DMFT index determines the no. of a decayed tooth, But PUFA index detects the depth, severity of this decayed tooth.

DMFT:

The patient will be seated in the dental chair, under ideal illumination mouth mirror and the straight probe will be used to evaluate caries and recorded in WHO oral survey2013 format. Any probe, catch or caries involving to any extent will be coded as "D"

Individuals were further divided in caries active and caries free group based on the no.of decayed tooth present. Individuals with caries; **caries active group(D=more than 4)** and absence of caries; **caries free group(D=0).**

Biochemical analysis:

Unstimulated saliva samples will be collected by NavazeshProtocol[22]. Subjects will be asked to abstain from smoking brushing of teeth, use of mouthwash, eat/ drink for 2 hour prior to the sample collection. Sample will be collected between 10.00 am – 11.00 am.

During sample collection subject will be seated in a normal chair instead of dental chair to maintain stress free environment. Once saliva is pooled in the floor of the mouth 5 ml will be collected in a Tarson's saliva collection tube. Five millilitres of saliva will be collected from the patient, centrifuged, and the supernatant obtained will be stored at 4°C for subsequent analysis.

Evaluation of Trace element Selenium in saliva was performed by Micowave Plasma Atomic Emission Spectrometer (MP-AES):

Image courtesy: ICAR-Directorate of Cashew Research

MP-AES is a high sensitive instrument for detection of wide range of elements down to sub ppb levels and is faster compared to conventional atomic absorption based instruments. Instead of flammable gases, MP-AES uses micro wave energy to produce plasma for ionisation of elements, using nitrogen extracted from ambient air. The excited electrons while returning to ground state emits radiation characteristics to each element and the intensity of emission being proportional to the concentration of element in solution.

Results

The values obtained where statistically analyzed using SPSS version 2.0 software. Caries free group showed a mean selenium levels of 116.9863 microgram/L with a standard deviation of 9.60601.Whereas caries active group showed a mean selenium levels of 63.7547 microgram/L and standard deviation of 12.06005 . Levene's Test for Equality of Variances was done to test the significance. The values shows significant difference between the two group.

TABLE 1: DEPICTS THE MEAN LEVELS OF SALIVARY SELENIUM

	Carries	**N**	**Mean**	**Std. Deviation**	**Std. Error Mean**
Selenium level (microgram/L)	FREE	30	116.9863	9.60601	2.20377
	ACTIVE	30	63.7547	12.06005	2.76677

TABLE 2: STATISTICAL ANALYSIS DEPICTING THE LEVEL OF SIGIFICANCE

		Levene's Test for Equality of Variances		t-test for Equality of Means						
		F	Sig.	t	Df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	95% Confidence Interval of the Difference	
									Lower	Upper
Selenium level	Equal variances assumed	1.273	.267	15.04	36	.000	53.2315	3.53717	46.058	60.405
	Equal variances not assumed			15.05	34.29	.000	53.2315	3.53717	46.045	60.418

*There is significant difference in selenium level among the subjects with and without carries with p<.001

Discussion

Presence of trace elements in the saliva and its accumulation on the tooth surface may affect the susceptibility of tooth to caries or may prevent occurrence of caries. The minute elements may attach to the apatite structure thereby decreasing the solubility and increasing the crystalline nature of enamel decreasing dissolution of tooth surface .The tooth surface turns more rigid there by making it more resistant to acid attack[11,12].The role of fluoride and tooth surface in the demineralization and remineralisation cycle itself explains that trace elements do play a role in occurrence of dental caries[13].

In the present study salivary selenium levels where significant higher in caries free group which can be attributed to the protective role of selenium element on tooth surface. A study conducted by Sekhri P et al did not show any significant changes in selenium and potassium levels among caries active and caries free individuals ,whereas caries free group showed significant levels of calcium and fluoride levels in childrens[14].Various other authors mentioned in their studies that selenium was associated with increased occurrence of dental caries and few others reported there was no relationship between selenium levels and dental caries. Selenium molecules serve has generator of superoxide radicals produced from thiols thereby helping in free radical scavenging and also are toxic to the bacteria's like staphylococcus aureus, E.coli[16].In a study conducted by Hegde MN copper and zinc were significantly high in caries active childrens[16].

Therefore the above study can be concluded as the concentration of salivary selenium estimated and showed a significantly increased salivary selenium levels in caries free group, a study with larger sample size could define the association better.

Automated Glaucoma Detection Using Variational Mode Decomposition from Fundus Images

Bhupendra Singh Kirar[1], Dheeraj Kumar Agrawal[2], Seema Kirar[3]

[1]Ph.D. Research Scholar, [2]Assistant Professor, Department of Electronics and Communication Engineering, Maulana Azad National Institute of Technology, Bhopal, India, [3]Assistant Professor, Department of Electronics and Communication Engineering, Bansal Institute of Science and Technology, Bhopal, India

Abstract

Glaucoma is a chronic eye disorder and one of the major causes of vision loss. Increased intraocular pressure damaged the optic nurves and hence blindness. Available methods on glaucoma image classification are expensive and slow. Therefore fast and low cost methods are needed. In this paper, glaucoma image classification using two dimensional variational mode decomposition and support vector machine from fundus images is proposed. The variational mode decomposition is used to decompose the glaucoma and normal images. Features are extracted from decomposed sub band images. Selected and reduced features are used to classify images in glaucoma or normal by support vector machine. The obtained accuracy, sensitivity, specificity are 94.17 %, 95 %, and 95 %, respectively for tenfold cross validation technique. Obtained results confirm that proposed method is adequate and improved over the state-of-the-art methods.

Keywords: *Glaucoma, pre-processing, variational mode decomposition, feature extraction and normalization, singular value decomposition, support vector machine*.

Introduction

Glaucoma is a dangerous disorder within the eye and has become a second main reason of vision loss over the world.(1) About 64.3 million glaucoma cases reported in the year of 2013 and it may reach to 111.8 million by the year 2040.(2) Glaucoma is of two kind, open angle and angle closure.(3) Generally, former type of glaucoma is mainly responsible for vision loss due to increase intraocular pressure within the eye. Open angle glaucoma is also known as silent destroyer of the optic nerves of the eye because it grows gradually with continuing destroyed the optic nerves.(4) There is no heal for glaucoma, it can be stop to further damage of optic nerves if it is detected at early stage .(5)

At present computer aided diagnosis is increasing research area in glaucoma detection. (6) There are several research papers on glaucoma detection. Kolar(7) extracted fractal dimensions (FD) and power spectral features. The support vector machine (SVM) yielded an accuracy of 74%. Bock(1) extracted features from fast Fourier transform (FFT) and B-spline coefficients and fed to SVM which yielded accuracy, specificity and sensitivity of 80%, 85% and 73% respectively. Acharya(8) extracted texture and higher order spectra (HOS) features and classified by SVM. They reported an accuracy of 91%. Dua(9) extracted energy features using discrete wavelet transform (DWT) and classified by SVM. They reported an accuracy of 93%. Yadav(10) extracted texture feature with artificial neural network (ANN) and reported an accuracy of 72%. Raja(11) used wavelet packet decomposition (WPD). They extracted entropy and energy features and fed to ANN which yielded accuracy of 85%. Gajbhiye(12) proposed a method for glaucoma detection using WPD and moment features. Extracted features were normalized and fed to SVM. They reported an accuracy of 86.57%. Ghosh(13) extracted grid colour moment features and BPNN. The reported accuracy, sensitivity and specificity are 87.47 %, 88 % and 87.45 % respectively for tenfold cross validation. Maheshwari(14) proposed glaucoma diagnosis method. They extracted correntropy features using two dimensional empirical wavelet transform (2DEWT). The features are classified using SVM. They reported an accuracy of 80.66 %. Kirar(15) proposed a new glaucoma diagnosis approach using third level 2dimensional discrete wavelet transform (2D DWT). Six histogram features namely mean, variance, skewness, kurtosis,

energy and entropy were extracted and fed to LS-SVM. They reported an accuracy of 88.3 %.

State of the art methods explained above are less accurate because these methods are limited to dyadic scale and required predefined basis function. In higher level of decomposition only low frequency sub band is used for next level of decomposition. It creates interference from other nearby frequencies in every sub band. All the above explained methods are not adaptive. 2DEWT is adaptive but it suffered from interference and redundancy due to improper segmentation of image spectrum and design of wavelet filter bank. In this adaptive filter bank sub band images varies. Hence the conventional methods are less accurate.

This paper presents an automated glaucoma detection using variational mode decomposition from fundus images. 2dimensional variational mode decomposition (2DVMD) decomposes the input images in to sub band images. Concatenated sub band images (SBI) are used to extracted features. The proposed method also uses singular value decomposition (SVD) and SVM classifier to classify images in glaucoma and normal. The obtained accuracy is more than the existing methods. Hence the proposed method is better than the state of art methods. The obtained performances are validated and compared with the existing methods for tenfold cross validation. The proposed method is better because it decomposes images in to sub band images which are centered around a specific frequency and with no interference, no boundary distortion and mod mixing problem.

The remaining part of the article is organized as follows: Section materials and method explains the glaucoma image data and presents the proposed method. At last results and their discussion are presented followed by conclusion and references.

Materials and Method

In this paper 15 normal and 15 glaucoma fundus images have been used from publically available image database RIM-1 Medical Image Analysis Group (MIAG).[16] The proposed methodology contains a number of stages, which are presented in the Fig. 1.

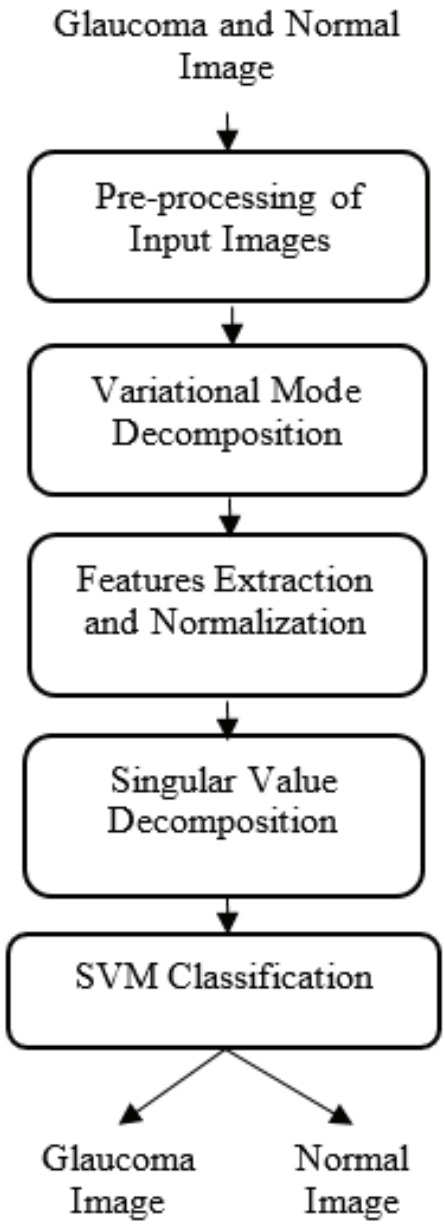

Fig.1. Block diagram of proposed method

Preprocessing: It is used to remove irrelevant variations. In this, images are resized to make all input images of same dimensions. Only green channel image is used because it contains more amount of information [1]. Contrast limited adaptive histogram equalization (CLAHE) is applied on green channel to improve the image quality.[17] The noise is reduced using median filter (MF).[18]

Variational Mode Decomposition: In this paper 2dimensional variational mode decomposition (2DVMD) is used. 2DVMD[19] is non-recursive, non stationary and fully adaptive decomposition technique for analysis of images. It overcomes the limitations of

conventional methods. In this paper decomposed sub band images are band limited and centered around a specific frequency. The bandwidth of a band limited sub band images are calculated as follows.[19]

Constrained variational problem for VMD is expressed as follows:

$$\min_{\psi_p \omega_p} \left\{ \sum_p \left\| dt \left[\left(\delta(t) + \frac{i}{\pi t} \right) * \psi_p(t) \right] e^{-i\omega_t} \right\|^2 \right\} \quad (1)$$

Such that $\sum_p \psi_p = S$

where S is a signal. ψ_p and ω_p are the p^{th} VMD component and centre frequency respectively. The above equation can be written as:

$$\mathcal{L}(\psi_p, \omega_p, \beta) = \alpha \sum_p \left\| dt \left[\left(\delta(t) + \frac{i}{\pi t} \right) * \psi_p(t) \right] e^{-i\omega_p t} \right\|_2^2 + \left\| s(t) - \sum_p \psi_p(t) \right\|_2^2 + \langle \beta(t), s(t) - \sum_p u_p(t) \rangle \quad (2)$$

The estimate of the p^{th} mode is given as follow:

$$\hat{\psi}_p^{m+1}(\omega) = \frac{\hat{S}(\omega) - \sum_{f \neq p} \hat{\psi}_f(\omega) + \frac{\hat{\beta}(\omega)}{2}}{1 + 2\alpha(\omega - \omega_p)^2} \quad (3)$$

where α is balancing parameter. The center frequency can be expressed as:

$$\omega_p^{m+1} = \frac{\int_0^\infty \omega |\hat{\psi}_p(\omega)|^2 d\omega}{\int_0^\infty |\hat{\psi}_p(\omega)|^2 d\omega} \quad (4)$$

[19,20]well explained the complete algorithm of 2DVMD. The 2DVMD sub band images for normal and glaucoma images are used to extract features.

Feature Extraction Normalization and Reduction: After decomposition, sub band images are concatenated and 77[21-29] features are extracted. Extracted features are normalized using z- score and selected using reliefF method.[30] 45 features have been selected and fed to singular value decomposition (SVD) [31] which reduces the dimensionality (r) of the dataset from 45 to 9. This part removes the redundant features while retaining important features.

Support Vector Machine: This paper used least squares support vector machine (LS-SVM) [32] with RBF kernel.[33] It is a supervised widely used method to classify two or more classes in the field of medical image classification.

The performance parameters (in %), namely accuracy, sensitivity, specificity are calculated as: [34]

$$\text{Accuracy (ACC)} = \frac{TP + TN}{TP + FP + TN + FN} \times 100 \quad (5)$$

$$\text{Sensitivity (SEN)} = \frac{TP}{FN + TP} \times 100 \quad (6)$$

$$\text{Specificity (SPE)} = \frac{TN}{FP + TN} \times 100 \quad (7)$$

where, FP, FN, TP and TN represents false positive, false negative, true positive and true negative.

Results and Discussion

Results: This paper represents a new method for glaucoma detection using 2DVMD from fundus images. The performances of proposed method using LS-SVM with RBF kernel and tenfold cross validation are listed in Table 1. The obtained specificity, sensitivity and accuracy are 95%, 95% and 94.17% respectively for tenfold cross validation.

Table 1: Performance of proposed method

(CV) Cross Validation	ACC (%)	SEN (%)	SPE (%)
3 folds	93.33	93.33	93.33
5 folds	93.33	86.67	100
10 folds	94.17	95.00	95.00

The radial basis function (RBF) kernel parameter is taken from one to ten with a uniform step size of one. Fig.2 shows performance versus cross validations

The highest accuracy is achieved for kernel parameter value = 3 and tenfold cross validation. Therefore kernel parameter = 3 and tenfold cross validation has been chosen. Fig. 2(d) has the highest value.

The cross validation technique is taken from two to eleven with a uniform step size of one. The plot of performance versus cross validation for kernel parameter = 3 and 9 features is depicted in Fig. 3. Tenfold cross validation technique yielded highest glaucoma detection accuracy. Therefore tenfold cross validation is better and selected for the proposed method.

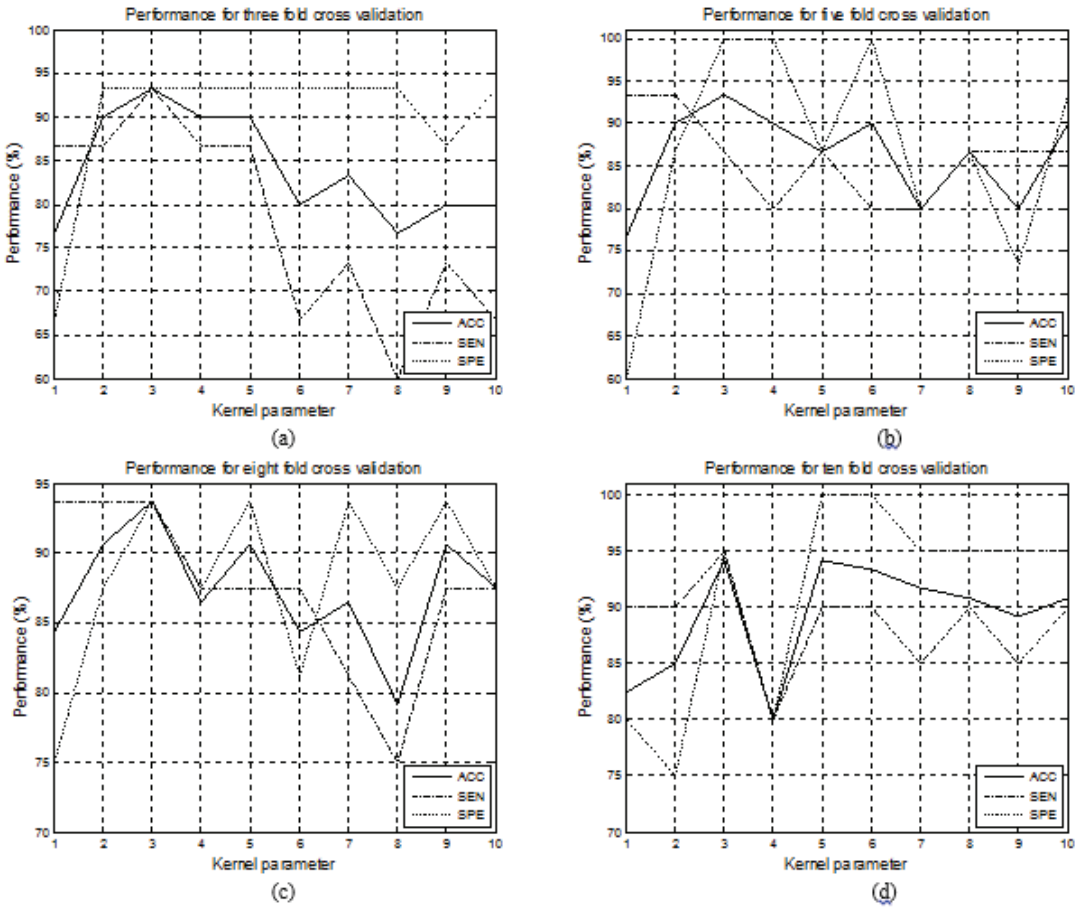

Fig.2: Plot of performance versus kernel parameter for cross validation (a) Three, (b) Five, (c) Eight and (d) Ten

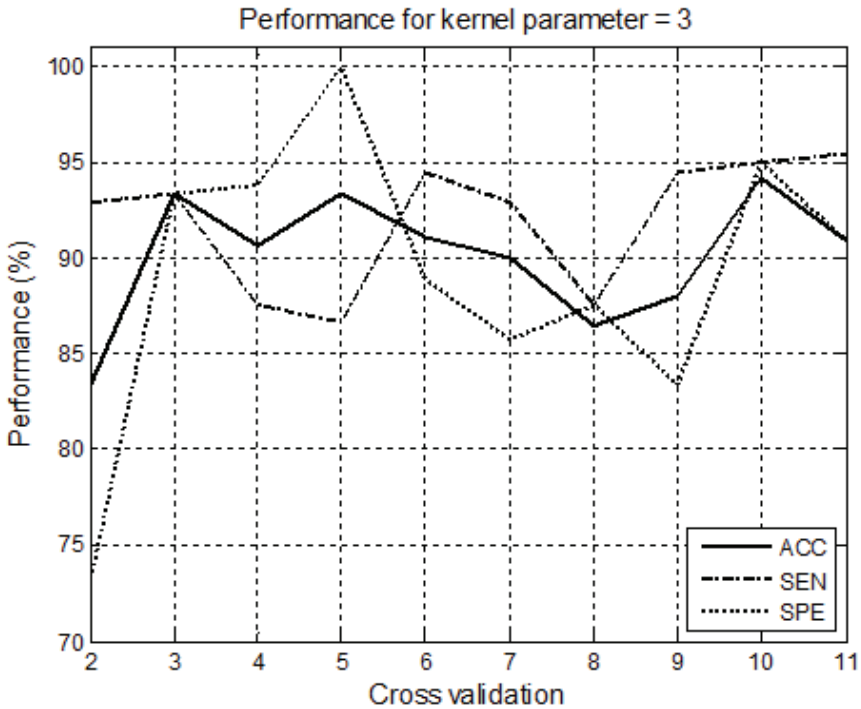

Fig.3: Plot of performance versus cross validation using proposed methodology

The extracted features also fed to different types of classifiers using weka soft-ware to compare the performance of the proposed methodology. It is clear from the Table 2 that the selected SVM classifier for the proposed methodology is found suitable.

Table 2: Performance using different classifiers

Comparison	**Accuracy (%)**		
Classifiers	3 FCV	5 FCV	10 FCV
Naive Bayes	73.33	76.67	76.67
Random Forest	76.67	80	80

OneR	73.33	73.33	83
Multilayer Perceptron	66.66	83,33	90
Support Vector Machine	93.33	93.33	94.17

FCV-Folds cross validation

Discussion

Glaucoma detection using 2DVMD from fundus images is presented in this paper. The obtained performances have been validated and compared with the existing methods for tenfold cross validation using public image database.[16] A comparison has been given in Table 3.

Kolar[7] extracted FD and power spectral features with SVM and obtained an accuracy of 74%. Bock[1] extracted features from FFT and B-spline coefficients and fed to SVM obtained accuracy, specificity and sensitivity of 80%, 85% and 73% respectively. Acharya[8] extracted new types of texture and HOS features and classified by SVM. They reported an accuracy of 91%. It was a good accuracy. Dua[9] extracted energy features using DWT and classified by SVM. They reported an accuracy of 93%. Yadav[10] extracted texture feature with ANN and reported an accuracy of 72%. Raja[11] used WPD. They extracted entropy and energy features and fed to ANN which yielded accuracy of 85%. Gajbhiye[12] proposed a method for glaucoma detection using WPD and moment features. Extracted features were normalized and fed to SVM. They reported an accuracy of 86.57%. Ghosh[13] extracted grid colour moment features and BPNN. The reported accuracy, sensitivity and specificity are 87.47 %, 88 % and 87.45 % respectively for tenfold cross validation. Maheshwari[14] proposed glaucoma diagnosis method. They extracted correntropy features using 2DEWT. The features are classified using SVM. They reported an accuracy of 80.66 % form 505 images. Kirar[15] proposed a new glaucoma diagnosis approach using third level 2D DWT. Six histogram features namely mean, variance, skewness, kurtosis, energy and entropy were extracted and fed to LS-SVM. They reported an accuracy of 88.3 %.

State of the art methods explained and listed in Table 3 are less accurate due to interference, distortion and redundancy.

Table 3: Comparison of methods based on accuracy (%) for tenfold cross validation

Authors / Ref.	Methods description	ACC
Yadav,[10]	Texture feature & ANN	72
Kolar,[7]	Power spectral features & SVM	74.00
Bock,[1]	FFT, PCA & SVM	80.00
Maheshwari,[14]	2DEWT, correntropy & LS-SVM	80.66
Raja,[11]	WPD, entropy, energy & ANN	85
Gajbhiye,[12]	WPD, moment feature & SVM	86.57
Gosh,[13]	Color moment features & BPNN	87.47
Kirar,[15]	2D-DWT & histogram features	88.30
Acharya,[8]	HOS features & RF	91.00
Dua,[9]	DWT, texture features & SVM	93.00
Proposed method	2DVMD, hybrid features, SVD and LS-SVM	94.17

This paper presented a novel variational computer based glaucoma detection using 2DVMD from fundus images.

Our proposed method yielded accuracies of 93.33%, 93.33%, and 94.17% for 3, 5 and 10 fold cross validation respectively.

The obtained results found better than the existing and compared methods as depicted in Table 3. This shows that our method detects glaucoma more accurately and hence it out performed over state of art methods.

Conclusion

This paper presented a novel approach of glaucoma detection using 2DVMD from fundus images. The green channel image is extracted from the fundus images and decomposed using 2DVMD. LS-SVM classifier with RBF kernel used to classify images. The obtained accuracies are 93.33%, 93.33%, and 94.17% for 3, 5 and 10 fold cross validation respectively. The obtained glaucoma detection accuracy is better for tenfold cross validation with kernel parameter = 3 and 9 features.

Glaucoma, serious eye disorder worldwide may be treated if detected at an early stage. The presented method is effective for glaucoma detection. Obtained results have been listed in Table 1 and Table 3 confirmed that this approach is better than state of-the-art methods.

The proposed methodology requires testing for huge image database. In upcoming research it is planned to implement it on other disease like diabetes and retinopathy with deep learning.

Conflict of Interest: Nil

Influence of Deciduous Molar Hypomineralization on Molar Incisor Hypomineralization – A Systematic Review

Himali P Solanki[1], Aditi Mathur[2], Ananth Kamath[3], Vishwas Patil[4]

[1]Pediatric and Preventive Dentist, [2]Reader, Department of Pediatric and Preventive Dentistry, Dr.D.Y.Patil Vidyapeeth, Pimpri, Pune, Maharashtra, India, [3]Pediatric and preventive dentist, Private Practitioner, [4]Professor, Department of Pediatric and Preventive Dentistry, Dr.D.Y.Patil Vidyapeeth, Pimpri, Pune, Maharashtra, India

Abstract

Aim & Background: Developmental anomalies of enamel like Molar Incisor Hypomineralization(MIH) and Deciduous molar hypomineralization(DMH) affect first permanent molars and the second primary molars respectively. The aim of this systematic review is to determine the probability of developing MIH in children with DMH.

Results: From 271 studies, 9 were included in this systematic review and the mean of the co-occurrence of DMH and MIH ranges from 2.4 % to 77%.

Conclusion: According to the present systematic review, the presence of DMH is indicative of MIH. The identification of demarcated opacities of the enamel on the primary molars is predictive of an increased risk of MIH.

Keywords: *Deciduous molar hypomineralization, Molar incisor hypomineralization , Hypomineralized second primary molar, Dental enamel hypoplasia*

Introduction

Along with decline in caries prevalence, there still persists a subgroup of children in whom an accelerated caries progression is seen, particularly affecting the first permanent molars (FPM). These children present with large developmental defects during or soon after the eruption of the affected teeth. Developmental defects of dental enamel are classified into hypomineralization and hypoplasia. The qualitative defect is known as enamel hypomineralization [(1)] and those molars have been referred in literature as non-fluoride hypomineralization, non-endemic mottling of enamel or cheese molars.[(2)]

The phenomenon, known as molar incisor hypomineralization (MIH) was first recognized in 2001 and defined as hypomineralization of one to four FPM often in combination with affected permanent incisors.[(3)] Subsequently, MIH-like lesions have been recognized in second primary molars leading to the description of hypomineralized second primary molars (HSPM)[(4)] also called deciduous molar hypomineralization (DMH).[(5)]

The prevalence of MIH varies considerably throughout the world ranging from 2.5 – 40.2 % [(6,7)] and that of DMH ranges from 4.9% - 6.9%.[(8,9)] The reported prevalence of MIH in India ranges from 6.3% to 9.46%.

The severity of MIH and DMH varies between patients, but also within a patient. Opacities being the mildest form of MIH and DMH, and atypical extractions the most severe manifestation.[(3)] MIH can cause serious pain due to post-eruptive enamel loss, and rapid caries progression. Other challenges in patients with MIH are hypersensitivity, anxiety, difficulties with anesthesia, poor aesthetics, fast progressing carious lesions and pain during restorative treatment.[(10,11)] It is essential to diagnose MIH at the earliest to reduce the vulnerability of the MIH-affected molars by focusing on their restorative and preventive needs.[(12)]

Currently as there is no particular identified cause and no risk prevention actions are adopted. The development of the second primary molars starts at around the same time as the development of the FPM and permanent incisors, but the maturation of the permanent teeth occurs more slowly. If a risk factor occurs during this overlapping period, hypomineralization might occur in the primary as well as in the permanent dentition. [13] Some authors hypothesized that HSPM could be predictive for MIH.[9,12] Therefore as DMH/HSPM can serve as a useful risk marker for MIH. As there is lack of concrete evidence regarding the relationship between DMH and MIH, the purpose of this study was to evaluate clinically if DMH can be used as a predictor for MIH.

Material and Method

A detailed search of literature published from 2000 to May 2018 was conducted. This systematic review was conducted and reported following the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA Statement) checklist.

Selection criteria:

Based on the following inclusion and exclusion criteria articles were selected for this systematic review.

Inclusion criteria

- Articles in English.
- Studies pertaining to co-existence or influence of DMH or HSPM and MIH.

Exclusion criteria

- Review, case reports, abstracts, letters to editors, editorials and in vitro studies were excluded.
- Studies with other developmental or environmental enamel defect.

Information source:

Dental literature on risk of MIH associated with DMH/HSPM was reviewed. The Databases used for the search were PubMed and Google scholar. The terms (hypomineralized AND second AND primary AND molars) OR (deciduous AND molar AND hypomineralization) OR HSPM) OR (molar AND incisor AND hypomineralization) OR (demarcated AND opacities) OR (MIH) were entered into the search fields. Hand search of dissertations and journals related to the topic of interest was performed. All cross reference lists of the selected studies were also screened.

Data collection process:

The data was collected and analyzed from each article by the same investigators that selected them and a standard data extraction sheet was prepared using spreadsheet (Excel 2010, Microsoft).

Result

Selection of studies was done initially by reading the title and abstracts of the articles obtained from each database. From 271 potentially eligible studies, 231 studies were selected on the basis of title. Twelve out of 231 studies were selected on the basis of the abstract. Out of which nine articles were selected for full text analysis and all nine were included in the systematic review. Cross-sectional, cohort studies and questionnaire surveys were included. The selection process involved two independent investigators and a consensus decision was made with a third evaluator to shortlist the articles for the systematic review. The sample size of the included studies ranged from 134 to 6161 participants, a total of 12627 included children from all the studies. Descriptive characteristics of the nine studies are shown in Table 1.

Table 1: Description of included studies.

Author	Design	Sample size	Age of Participants	Diagnostic criteria	Prevalence analysis		Co-occurrence of MIH and HSPM
					HSPM / DMH	MIH	
Elfrink et al.,2012 (14)	Prospective cohort study	6161	5- 6yrs	EAPD	9.00%	8.70%	27%
Ghanim et al.,2012 (10)	Cross sectional study	809	7- 9 yrs	EAPD	6.60%	18.60%	39.60%
Costa-Silva et al.,2013 (20)	Cohort study	134	4- 6 yrs	EAPD	20.14%	15.67%	30.40%
N. Mittal , B. B. Sharma ,2015 (18)	Cross sectional survey	978	6- 8 yrs	EAPD	5.60%	7.40%	32.73%
Temilola et al, 2015 (16)	Questionnaire survey	563	3- 5 yrs (327), 8-10 yrs(236)	Kemoli et al's Criteria	4.60%	9.70%	34.80%
Mittal et al., 2016 (19)	Cross sectional study	1109	3-5yrs (223), 6-12yrs (886)	EAPD	4.88%	7.11%	48%
Oyedele et al.2016 (21)	Cross sectional study	496	8-10 yrs	EAPD	5.80%	-	77%
Negre-barber et al., 2016 (22)	Cross sectional study	414	8-9 yrs	EAPD	14.50%	24.20%	11.10%
da Silva FS et al., 2017 (23)	Cross-sectional study	1963	6-11yrs	EAPD	6.48%	14.69%	2.43%

Discussion

This review focuses on the co-relationship between MIH and DMH. In the past years various studies have been performed to analyze the related risk factors and conceivable determinants of MIH.[14] This helps early diagnosis and prompt management of MIH. Because the second primary molars erupt four years earlier than the FPM, DMH might be a clinically useful predictor for MIH and hence the need for more research into the relationship between DMH and MIH. The present study summarized the prevalence of co-occurrence of MIH and DMH/HSPM globally.

In 2003, European Academy of Pediatric Dentistry (EAPD), proposed a criteria for epidemiological studies of MIH.[4] It also considered the potential of development of MIH- like hypomineralized defects to occur on primary molars.[4] Later in 2009 EAPD updated the diagnostic criteria of MIH so as to add demarcated opacities, PEB, atypical restorations and extractions of permanent molars and /or incisors. Whereas for HSPM similar criteria was used with the inclusion of "atypical caries" along with atypical restorations.[8] The criteria developed for MIH and HSPM are currently considered to be a standard and validated criteria for diagnosing and recording MIH and HSPM.

Ghamin et al pointed out that the rationale behind adapting the EAPD evaluation criteria was to allow demarcated lesions to be recorded in their different clinical presentations and hence gain a better understanding of the association between primary and permanent teeth lesions.[9] All studies included in this review except one [15] employed the EAPD criteria with some variations with respect to HSPM scoring. Study done by Temilola et. al in 2015 used the criteria suggested by Kemoli et. al[16] Out of nine, in four studies [9,15,17,18] teeth were viewed as sound when the lesion were less than two mm in diameter and in the other four studies [19,20,21,22] teeth were considered sound when the defect was one mm or less whereas one study [12] did not specify the same.

In the study done by Elfrink and his colleagues[12],Temilola et. al.[15] and Mittal R. et. al[18] photographs were used for identification of the defects, while the other researchers directly examined the oral cavity for the defects using the mouth mirror and the probe. The use of intraoral photographs for scoring HSPM has been presumed to be substantial for epidemiological studies.[6] It ought to be contemplated that varying examination conditions impact the reported prevalence. There may be underestimation of defects when natural light intensity is low. In most studies, the teeth were cleaned before examination and were moist while examination.

Elfrink and colleagues recently recommended standardization of studies on HSPM and MIH as there was a lot of discrepancy in recording of restorations or carious lesions.[23] All studies except one [12] reported that mild HSPM (opacities without PEB, caries, atypical restorations or crown) were more frequent than severe forms. However, Elfrink and colleagues reported higher prevalence of severe HSPM than mild HSPM.[12] A study done by Rakesh Mittal et. al. [18] concluded that mandibular molars were more affected than maxillary molars while all the other studies reported a greater prevalence of DMH/HSPM in maxillary arch.

The most favourable age for examination of HSPM would be five years, owing to greater cooperation of the child and complete eruption of second primary molars. [23] And that for MIH, as suggested by EAPD experts it is around eight years pertaining to the presence of FPM as well as the permanent incisors.[23] On the other hand, there is a risk of camouflaging hypomineralization with other defects like dental caries if the examination occurs too late. Even exposure to masticatory forces there is a greater possibility of increasing the severity rating of defects due to PEB. In this systematic review the included studies have a wide age range from five – twelve years.

Risk of developing MIH was more likely in the case of mild HSPM (without PEB) than severe HSPM. The present study summarized the prevalence estimations of co-occurrence of MIH and HSPM globally ranging from 2.4 % to 77%.Whereas the individual prevalence of MIH is ranging from 7.11% to 24.20% and that of DMH/ HSPM the range is 4.60% to 20.4%. Cross-sectional studies done by Mittal et al. [18] and Oyedele et al. [20] have estimated the co-relationship between MIH and DMH was > 40 %. Two Indian studies included in this review done by N. Mittal , B. B. Sharma (2015) [18] and Mittal et al. (2016) [17] showed a co-occurrence percentage of 32.73% and 48% respectively. The results of this review are in agreement with another systematic review by Elsa Garota which stated that the weighted mean of the co-occurrence of HSPM and MIH prevalence was 19.94% globally.[23]

As we know that the calcification of the second primary molar starts earlier than the first permanent molar, at four months in-utero and at birth, respectively. [25] The second primary molar and first permanent molar have a shared period of development and mineralization. Hence if a risk factor occurred during this overlapping period, hypomineralization might occur concurrently in the primary and permanent dentition.[12] Mittal and colleagues have hypothesized that the etiological insult causing milder hypomineralization defects on second primary molars must have occurred during latter stages of mineralization/maturation, overlapping with earlier phases of active mineralization of FPM when the ameloblasts are most active.[16] As the number of primary molars affected by hypomineralization increases the greater the risk for developing MIH.[12] It was found that the presence of single hypomineralized primary molar was not associated with MIH while subjects with more than two hypomineralized second primary molars had significantly higher MIH.

Limitations:

1. All articles indexed and published only in PubMed & Google scholar were selected other search engines were not selected like Cochran, Medlilne, Embase.

2. Subjective clinical indices are used for the diagnosis of enamel defects. Hence to strengthen the investigations of MIH and HSPM there should be development of quantitative methods for precise determination of the such deformities.

Future goals:

It is essential to improve the recognition of this particular dental enamel defect. Data from round the world and from different birth cohorts are important not only for future dental planning but also in helping the search for understanding the etiological factors involved in MIH and HSPM.

Conclusion

According to the present systematic review, the presence of DMH/HSPM is predictive for MIH. The association between these defects appears even more important in the presence of mild HSPM. Thus, the identification of demarcated opacities of the enamel on the primary molars is predictive of an increased risk of MIH, allowing anticipation of the risks of tissue damage caused by the MIH and establishment of an early preventive regimen for PEB and sensitivity, if necessary. Indeed, by targeting patients likely to develop MIH and providing them with the information needed to manage this anomaly at an early age, one could perceive a marked reduction in the problems caused by these enamel defects.

Junk Food is the Danger of Future Generation – Review for a Decade

V.Surya[1], M. Arul[2], A.Arockiaraj[3]

[1]Ph.D. Research Scholar (Part Time) (External), Department of Business Administration, Annamalai University, Chidambaram, [2]Director, Directorate of Distance Education, Annamalai University, [3]Assistant Professor and Head, Department of Business Administration, Jawahar Science College, Neyveli, Tamilnadu, India

Abstract

The present paper is emphasizing the revealed aspects of junk food dangers to the future generation. The present paper will help future researchers in the field of junk food markets. The suggestion and the core problems of junk food will help the consumers and the general public. This article will create awareness among the public to avoid the junk food eating habits and educate the diseases are creating through the high amount of consuming sugar, fates, and salts inherent on junk foods. The junk foods are commonly taking foods unusually with high sugar, fats, and salts in any form of solid, semi-solid, liquid and dry food, even vegetarian or non-vegetarian foods. The junk foods are most common in a few types of foods like carbonated sugar beverages, salty preserved foods, oily food, fast food, and dry fishes. These are creating certain diseases like obesity, cardiovascular disease, uncontrollable adolescent growth, stomach cancer, and infertility.

Keywords*: Carbonated Sugar Beverages; Salty Preserved Foods; Oily Food; Fast Food; Obesity; uncontrollable adolescence growth; Stomach Cancer;and infertility.*

Introduction

The world health organization is responsible to control all the diseases created from the mass production of junk foods in the international market. The developed countries are much interested to produce junk foods and fetching the rural and village markets throughout the world. The continuous research on junk food stringencies has not been helped to society. The producers and belonging countries are looking the same as their business motives. The restrictions of junk food are the need of the hour due to increasing the diseases day by day is uncontrollable. It requires separate insurance to the people while consuming junk foods or a caution statement (along with pictures) "consuming junk foods are harmful to health" is required like Tobacco, Alcoholic and Drugs products consumptions. The present paper is emphasizing the revealed aspects of junk food dangers to the future generation. The present paper will help future researchers in the field of junk food markets. The suggestion and the core problems of junk food will help the consumers and the general public. This article will create awareness among the public to avoid the junk food eating habits and educate the diseases are creating through the high amount of consuming sugar, fates, and salts inherent on junk foods. The junk foods are commonly taking foods unusually with high sugar, fats, and salts in any form of solid, semi-solid, liquid and dry food, even vegetarian or non-vegetarian foods.

Junk Food Definition

Junk food defined as "pre-prepared or packaged food that has low nutritional value". It is a noun. The word junk food has been used after 1952. It has many of definitions such as "food that is high in calories but low in nutritional content", and "something that is appealing or enjoyable but of little or no real value"[1]. "Junk food is unhealthful food that is high in calories from sugar or fat, with little dietary fiber, protein, vitamins, minerals, or other important forms of nutritional value.[2]Precise definitions vary by purpose and over time. Some high-protein foods, like meat prepared with saturated fat, may be considered junk food.[3] The term HFSS food (high in fat, salt and sugar) is used synonymously.[4] Fast food and fast food restaurants are often equated with junk food,

although fast foods cannot be categorically described as junk food.[5] Most junk food is highly processed food. Concerns about the negative health effects resulting from a junk food-heavy diet, especially obesity, have resulted in public health awareness campaigns, and restrictions on advertising and sale in several countries."[6]

CAUTION OF JUNK FOOD AND EFFECTS

Continuous of taking junk food will store the excess fatcarbohydrates, and processed sugar contents to increase the risk of obesity, cardiovascular disease, and many other chronic health conditions.[7] "A case study on consumption of fast foods in Ghana suggested a direct correlation between consumption of junk food and obesity rates. The report asserts that obesity resulted in related complex health concerns such upsurge of heart attack rates.[8] Studies reveal that as early as the age of 30, arteries could begin clogging and lay the groundwork for future heart attacks.[9] Consumers also tend to eat too much in one sitting, and those who have satisfied their appetite with junk food are less likely to eat healthy foods like fruit or vegetables.[10]Testing on rats has indicated negative effects of junk food that may manifest likewise in people. A Scripps Research Institute study in 2008 suggested that junk food consumption alters brain activity in a manner similar to addictive drugs like cocaine and heroin. After many weeks with unlimited access to junk food, the pleasure centers of rat brains became desensitized, requiring more food for pleasure; after the junk food was taken away and replaced with a healthy diet, the rats starved for two weeks instead of eating nutritious fare.[11] A 2007 study in the British Journal of Nutrition found that female rats that eat junk food during pregnancy increased the likelihood of unhealthy eating habits in their offspring.[12]"

REVIEW OF LITERATURE A SYSTEMATIC META-ANALYSIS

Review Table

(Revealed after 2011 to 2020)

Year	Name of the Author(s)	Findings/Conclusion	Problem Identified
2020	Michael Stark1	About 10% of people who have diabetes have type1 diabetes, or insulin-dependent diabetes. Type 1 diabetes has also been called juvenile diabetes because it usually develops in children and teenagers. But people of all ages can develop type 1 diabetes. Diabetes is a serious condition that causes higher than normal blood sugar levels. Diabetes occurs when your body cannot make or effectively use its own insulin, a hormone made by special cells in the pancreas called islets (eye-lets). Insulin serves as a "key" to open your cells, to allow the sugar (glucose) from the food you eat to enter. Then, your body uses that glucose for energy. But with diabetes, several major things can go wrong to cause diabetes.	Health issues to children
2019	Piyush Gupta et al2	Harmful effects of juncs food are given Overweight/Obesity, Cardiometabolic Risk, High Blood Pressure, Behavioral Symptoms, Dental Caries, Adverse effects from Caffeinated Energy Drinks, and the like.	Health Issues
2018	Christopher Thomas et al3	participants with obesity did, on average, report seeing one extra HFSS broadcast advert per week - a further indication that broadcast marketing could be nudging young people towards harmful long-term weight increases	Advertisement (Health Issues)

	Muthukumar E and Bhuvaneswari R11	Eating junk food causes many ill effects to the health to the customers but the consumer eats the food for change and not because of their nutritional value. Based on the culture adopt the change in eating habits. Today both the parents are working so they give packet money for her children because they have no time to prepare snacks it becomes convenient to purchase for junk food and sometimes the taste impressed by the customer it becomes the intention to buy the junk food. But health wise it is not safe by eating a lot. Traditional way of eating food is good for health and also people accept that is the fact also.	Working parents, Convenient Purchase (Health Issues)
	British Heart Foundation12	An unhealthy diet high in sugar also increases the risk of developing tooth decay. Children are also eating too much salt which increases the risk of high blood pressure, which in turn increases the risk of heart disease and stroke later in life.	Children (Health Issues)
2012	Ashakiran and Deepthi R13	Unfortunately, today's world has been adapted to a system of consumption of foods which has several adverse effects on health. Lifestyle changes has compelled us so much that one has so little time to really think what we are eating is right! Globalisation and urbanisation have greatly affected one's eating habits and forced many people to consume fancy and high calorie fast foods, popularly known as 'Junk foods'.	(Globalisation and urbanisation have greatly affected one's eating habits and forced many people to consume fancy and high calorie fast foods, popularly known as 'Junk foods')

From the above reviews, author has revealed most of the studies are involved in the advertisement, awareness, brand, celebrity, children attitude, consumer satisfaction, taste, and quality, health awareness, marital and gender difference, Socio-cultural Impact, Television Advertisement and taste, production methods, environmental impact, quality, price, health safety, attractiveness of packing, curiosity, and prestige. Hence, the future generation will affect based on the side effects of junk foods. The habitual of the younger generation seldom accept the consequences of junk food effects while they are younger. The elder people pieces of advice to the younger, they won't accept the benefits of avoiding junk foods. It is noticed by the developed countries, they are (65 countries) prohibited the manufacturing and sales of Snicker brand of chocolate. Kukure, lays, bingo, cheetos, jelly, boomer, kinder joy, cream biscuits, 5 star, dairy milk, kit kat, perks, perks, munch, snickers. These are very harmful due to they contain large MSG (MonoSodium Glutamate) that will cause bone and teeth damages.

Affecting Factors of Future Generation's Health

"Other research has been done on the impact of sugary foods on emotional health in humans and has suggested that consumption of junk food can negatively impact energy levels and emotional well-being.[13]In a study published in the European Journal of Clinical Nutrition, the frequency of consumption of 57 foods/ drinks of 4000 children at the age of four and a half were collected by maternal report. At age seven, the 4000 children were given the Strengths and Difficulties Questionnaire (SDQ), with five scales: hyperactivity, conduct problems, peer problems, emotional symptoms, and pro-social behavior. A one standard deviation increase in junk food was then linked to excessive hyperactivity in 33% of the subjects, leading to the conclusion that children consuming excess junk food at the age of seven are more likely to be in the top third of the hyperactivity scale. There was no significant correlation between junk food and the other scales."[14]

Findings

1.There is a need for the advertisement for awareness about junk food effects and health impacts particularly children who affect more through media promotions.

2.The schools and colleges should conduct the campaign against junk foods, which will help and save the student community from various diseases.

3.In India, the health conscious nesses are decreased even in the rural and village, the migration level of urbanization is taking into consideration of cultural changes and unpracticed rural culture will affect the future generation.

4.Most of the studies are given fruitful findings to beware of the health-conscious.

5.The present article is also giving health-conscious to the future generation.

Conclusion

From the above discussion, authors have concluded that junk foods will harmful to the health of human being, it is not necessarily taking in the leisure time. The natural food and customary practices of homemade snacks will save our health and do the physically fit conditions as well. The future generation is the asset of every nation. Their fertile capability is a must for developing the nation's future achievement. The parents, government, and WHO should not favour the junk food manufacturer. The health should be kept in safe mode and the prevention of diseases is the responsibility of the nation. The consequences of taking junk food will give a more adverse impact on future society. The research reviews about the study will help the decision-maker in the field of conscientiousness to human life.

Morphological Study of Placenta in Low Birth weight Infants

Shekhar Sharma[1], Sangita Singhal[2], Yogesh Kumar Goel[3], Shivani Bansal[4]

[1]PG student III year Department of Paediatrics, Muzaffarnagar Medical College, Muzaffarnagar, U.P [2]Professor and Head Department of Paediatrics, Muzaffarnagar Medical College, Muzaffarnagar, U.P , [3]Professor Saraswati Institute of Medical Sciences, Hapur,U.P [4]Senior Resident Department of paediatrics, Muzaffarnagar Medical College, Muzaffarnagar, U.P

Abstract

Objective: To study placental morphological changes in low birth weight neonates

Material and Methods : This prospective case-control study was carried out on 100 cases at Muzaffarnagar Medical College, Muzaffarnagar. Placentas of Low Birth Weight term babies were collected from department of gynaecology and obstetrics during the period from March 2016 to May 2017.Placental morphological changes were studied.

Conclusion: The mean placental weight, thickness and diameter for the case group was lower than the control group.Also the mean placental thickness and diameter of case group was found to be lower than in control group.Highest placental weight in both cases and control was found in 18-22 years age group mothers.However highest neonatal weight in both cases and control was found in 28-32 years age group mothers

Keywords:*PET and eclampsia, APH, Idiopathic IUGR*

Introduction

Low birth weight is defined by W.H.O as birth weight < 2500 grams. This is based on epidemiological observations that neonatal mortality in infants weighing less than 2500 g was 20 times more than in heavier babies.[1]

Perinatal mortality and morbidity is highest among LBW babies and babies who have survived are at increased risk of long term physical and intellectual impairment. In developed countries, the incidence is 4-8% and in developing countries it is about 6-30%.[2] It was estimated that 20 million infants worldwide (15.5%) were LBW and 95.6% of these infants were born in developing countries.[3]

IUGR or small for gestational age (SGA) is defined as birth weight below tenth percentile of estimated gestational age. In India 15-30% of babies born at term are ‘’small for date’’, under nutrition and toxaemia of pregnancy are considered to be important maternal causes. In India, about 6-8% of the pregnancies belong to the high risk category.[4]

Since 19th century, basic understanding of the cell biology, molecular biology, biochemistry, physiology, pharmacology and immunology of the placenta has increased almost exponentially. There are later studies to suggest that placental volume in the second trimester can predict birth weight and newborn anthropometry and identify the fetus in danger of being LBW.[5]

Asian Indian newborns may be classified as SGA because of ethnic, physiological factors more so than pathological factors; thus, we hypothesized that infants of Asian Indian origin classified as SGA would be less likely to have increased morbidity compared with SGA White infants and less likely to be admitted to a special care nursery setting. Previous studies have shown that despite the increased incidence of LBW and SGA in Asian Indian infants, no corresponding increased risk of neonatal mortality was reported compared with White infants.[6,7]

Factors for low birth infants can be divided in to maternal and placental.

Maternal Factors are: Pregnancy with medical diseases, Diseases related to pregnancy, Obstetrical conditions & miscellaneous factor[8]

Placental Causes: Infarction, Premature separation of placenta, haemangiomas, thrombosis of fetal vessels, presence of single umbilical artery and vascular terminal villi. Human placenta is hemochorial and it is the only organ in the body which contains maternal and fetal tissues. The study of placenta is an opportunity to obtain information about the two individuals, the mother and fetus. [8]

Medical diseases are hypertension, chronic renal diseases, heart diseases, diabetes, venereal diseases, infections like rubella, herpes simplex, toxoplasmosis. The diseases related to pregnancy include Toxaemia, Eclampsia, Anaemia, Rh incompatibility and obstetrical conditions like Placenta praevia, Abruptio placentae, multiple pregnancy and post maturity. Miscellaneous factors- smoking, alcoholism, inadequate maternal nutrition, teratogenic drugs, radiation, genetic defects and chromosomal disorders. [8]

. **Objectives**

- To study the spectrum of placental changes associated with LBW infants.
- To enumerate possible etiological factors responsible for low birth weight in view of placental abnormalities.

Material & Method

This prospective case-control study was carried out on 100 cases at Muzaffarnagar Medical College, Muzaffarnagar.Placentas of Low Birth Weight term babies were collected from department of gynae and obstetrics College name during the period from March 2016 to May 2017 .

Study Design: Prospective case-control Study

Study Location: This is a tertiary care teaching hospital based study done in Department of gynae and obstetrics at Muzaffarnagar Medical College, Muzaffarnagar College name , India.

Study Duration: March 2016 to May 2017

Sample size: 100 patients (75 cases & 25 controls)

Statistical analysis

Data was analyzed using Statistical Package for Social Sciences, version 23 (SPSS Inc., Chicago, IL). Results for continuous variables are presented as mean ± standard deviation, whereas results for categorical variables are presented as number (percentage). Student test (two tailed, independent) or Chi-square/Fisher's exact test has been used to find the significance of study parameters on categorical scale between groups. The level $P < 0.05$ was considered as the cutoff value or significance.

Inclusion criteria:

- Gestational age ≥ 37 weeks & Appropriate for gestational age.
- All placentas delivered to mothers with Low birth weight infants (birthweight<2500 grams)

Exclusion criteria:

- Multiple pregnancy (twins, triplets etc.)
- Not consenting to participate in the study

Observations

Mothers of 13 (17.3%) infants were the patient of PET &Eclampsia, 11 (14.7%) were the patient of Essential Hypertension, 11 (14.7%) were Anaemia patient, 8 (10.7%) were the patient of APH and 32 (42.7%) suffered due to Idiopathic IUGR.

Table I -Distribution of patients on the basis of various etiological factors

Various factors (n=75)	Frequency (%)
PET &Eclampsia	13 (17.3)
Essential Hypertension	11 (14.7)
Anaemia	11 (14.7)
APH	8 (10.7)
Idiopathic IUGR	32 (42.7)

Gross placental parameters in control group as well as in cases group was recorded in the table. While mean Placental Weight (grams) in cases was 386.4±24.06 grams. the same was 503.7±16.5 grams. in control group. Likewise the mean Placental Thickness (cm) in cases was 1.76±0.19 cm. the same was 2.47±0.22 cm. in control group. Further the mean Placental Diameter (cm) in cases was16.73±0.63 cm. the same was19.3±0.65 cm. in control group.

- **Table II-Gross morphology of placenta in case group and control group**

Placental Parameters	Case(n=75)(mean±SD)	Control (n=25) (mean±SD)	P value
Weight (grams)	386.4±24.06	503.7±16.5	<0.001
Thickness (cm)	1.76±0.19	2.47±0.22	<0.001
Diameter (cm)	16.73±0.63	19.3±0.65	<0.001

Comparison of Placental weight of both cases as well as control groups on the basis of mother's age was made and mentioned in the table. Whereas for mothers under cases in the age group of 18-22years, Placental weight (gram) was 401.2±19.9, the same was502±9.4 gram for mothers under control group. For mothers under cases in the age group23-27years, Placental weight was 403.9±6.8 (gram), & the same was 520.7±13.1 gram for mothers under control group. For mothers under cases in the age group 28-32years, Placental weight was 377.58±19.9(gram), & the same was 498.1±18.1 gram for mothers under control group and for mothers under cases in the age group of >32years, Placental weight was 363.03±21.1(gram),& the same was 491.25±13.2 gram for mothers under control group.

Table III-Comparison of Placental weight (gram) of both groups on the basis of mother's age

Mother's Age (in years)	Case (n=75) (%)	Mean Placental weight (gram)	Control (n=25) (%)	Mean Placental weight (gram)	P value*
18-22	20 (26.7)	401.2±19.9	8 (32.0)	502±9.4	<0.001
23-27	16 (21.3)	403.9±6.8	6 (24.0)	520.7±13.1	<0.001
28-32	24 (32.0)	377.58±19.9	7 (28.0)	498.1±18.1	<0.001
>32	15 (20.0)	363.03±21.1	4 (16.0)	491.25±13.2	<0.001

P value*= Mean placental weight (case & control)

Comparison of neonatal weight (gram) between both cases as well as control groups on the basis of mother's age was made and mentioned in the table. Whereas for mothers under cases in the age group of 18-22years, neonatal weight (gram) was 1945±336.4, the same was 3025±291.5 gram for mothers under control group. For mothers under cases in the age group 23-27years, neonatal weight was 1893±276.8(gram),& the same was 2833±355.9 gram for mothers under control group. For mothers under cases in the age group 28-32years, neonatal weight was 2042±224.4(gram), & the same was 3157±257.3 gram for mothers under control group and for mothers under cases in the age group of >32years, neonatal weight was 1953±247.5(gram), & the same was 2975±359.4 gram for mothers

under control group.

Table IV-Comparison of neonatal weight (gram) of both groups on the basis of mother's age

Mother's Age (in years)	Case (n=75) (%)	Mean neonatal weight±SD (gram)	Control (n=25) (%)	Mean neonatal weight (gram)	P value*
18-22	20 (26.7)	1945±336.4	8 (32.0)	3025±291.5	<0.001
23-27	16 (21.3)	1893±276.8	6 (24.0)	2833±355.9	<0.001
28-32	24 (32.0)	2042±224.4	7 (28.0)	3157±257.3	<0.001
>32	15 (20.0)	1953±247.5	4 (16.0)	2975±359.4	<0.001

P value*= Mean neonatal weight (case & control)

Result and discussion

• In our study, out of 75 cases, there were maximum 32 (42.7%) cases of Idiopathic IUGR followed by 13 (17.3%) of PET & Eclampsia while 11 (14.7%) of Essential Hypertension & Anaemia each and least patients was 8 (10.7%) of APH.Maximum number of cases i.e. 32% were between 28-32 years age group, 26.7% were in 18-22 years, 21.3 % were in 23-27 years & 20.0% were in >32 years group as compared to maximum ie 32% in 18-22 years & 28 % in age group of 28-32 years & 24% were in 23-27 years and only 16% of cases were in >32 years age group among controls**.** Mean placental weight in every age group of case group was less than mean placental weight in control group i.e. 401.2 gms, 403.9 gms, 377.58 gms and 363.03 gms in case group in comparison to 502.0 gms, 502.7gms, 498.1 gms and 491.25 gms in control group. In these entire group P values were statiscally significant (P value <0.05).Mean foetal weights in every age group was less than mean foetal weight in control group i.e. 1945 gms, 1893 gms, 2042 gms and 1953 gms in Case group in comparison to 3025 gms, 2833 gms, 3157 gms, 2975 gms in control group, P values were statistically significant in all age group.(P value <0.05).Similar findings was reported by Acharya V[4]et al i.e maximum number of cases i.e. 72% were between 21-30 years age group, 20% were in 15-20 years & 8% were between 31-35 years in IUGR group as compared to maximum cases ie 58% in 21-25 years & number of cases in age group of 15-20 years & 26-30 years were almost equal i.e. 18% & 20% and only 4% of cases were between 31-35 years. Mean placental weight in every age group was less than mean placental weight in control group i.e. 422.5gms, 405gms, 411.11gms and 350gms in IUGR group in comparison to 496.11gms, 501.03gms, 502gms and 525gms in control group. In these entire group P values were statistically significant (P value <0.05).Mean foetal weights in every age group was less than mean foetal weight in control group i.e. 2090gms, 2120gms, 2150gms and 2000gms in IUGR group in comparison to 2930gms, 2870gms, 2980gms, 3150gms in control group, except in age group 15-20 years, P values were statistically significant (P<0.01)

• Findings in our study were similar to that of Dawson L et al[9] and according to them there in an adverse-effect on the new born at both extremes of child bearing age. Highest incidence of low birth weight has been found among mothers under age of 20 years and incidence falls, as the age of mother increases and incidence of LBW increases after the age of 30-35 years. Placenta is said to be affected by ageing process, because as the age advances pregnant women are more prone to develop hypertensive disease, chronic vascular diseases, PET, Eclampsia and anaemia and these affect placenta in their turn causing IUGR. Various diseases like hypertension,

• Diabetes, PET and Eclampsia, which are related to advanced maternal age may cause placental ischemia and cause reduced placental blood flow leading to chronic hypoxia and chronic subnutrition to fetus, Donald[10]

• In our study, the mean placental weight ± standard deviation (SD) for case group was 386.4±24.06 in grams while for controls was 503.7±16.5 in grams and the difference between them was statistically significant. ($p<0.05$), placental thickness ± standard deviation (SD) of case group was 1.76±0.19 in cms while in control group it was 2.47±0.22 in cms.Placental diameter ± standard deviation (SD) of case group was 16.73±0.63 in cms while in control groups 19.3±0.65 in cms.The difference between case & control was statistically significant. ($p<0.05$). Similarly, these placental findings were similar to findings of Londhe P S et al[11], they reported that mean placental weight ± standard deviation (SD) was 321.2 ± 63.7 g in SFA group (case group) and 388.9 ± 54.1 g in normal weight/ control group. The mean placental surface area ± SD was also lower in SFA group (cases) (184.0 ± 61.6 sq.cm) than control group (219.7± 41.6 sq.cm) and the difference was statistically significant. Londhe P S et al study shows that placental diameter and thickness measurements are valuable parameters for predicting low birth weight infants.

• In this study, neonatal weight ± standard deviation (SD) was observed 1966±273.8 in grams for case group while 3008±313.5 in grams of control group**.** Londhe P S et al[11] it was reported 2833±234 in grams of control group while 2131±293 in grams of case group. This was statistical different from both groups. In another study, Ranga SS[12] et al reported the mean birth weight of neonates of case group (hypertensive group) was 2.5 ± 0.7 kg while the mean birth weight of babies of control (non-hypertensive) group was 2.9±0.4 kg.Udainia et al[13], Majumdar S et al[14], Rosana R.M. et al[15] and Abdul HafeezBaloch et al[16]observed similar finding in the birth weight of neonates.

Awareness on Tuberculosis and Factors Determining it among Migrant Brick Kiln Workers in a Rural Area in South India

Vanishree Shriraam[1], Srihari. R[2], Gayathri.K[3], Lakshmi Murali[4]

[1]Associate Professor, Department of Community Medicine, [2]Demonstrator, Department of Physiology, [3]Senior Lecturer in Statistics, Dept. of Community Medicine, Sri Ramachandra Medical College & Research Institute, Chennai, [4]Deputy Director of Medical Services (TB) District TB Centre, Poonamallee, Tiruvallur District

Abstract

Background: Awareness of the subjects on Tuberculosis is an important factor in early reporting by symptomatics as well as early case finding by the program.

Aim: The current study was done to find out the awareness of migrant brick kiln workers, a key population as per RNTCP, on various parameters of Tuberculosis.

Method: This was a cross sectional study conducted among all migrant brick kiln workers working in the brick kilns in the field practice area of the Rural Health Centre of a medical college hospital. A pretested structured questionnaire was used for the interview. SPSS version 16.0 was used for analysis.

Results: Among 580 brick kiln workers, the mean age was 36.47. The awareness on TB was as follows – germs as cause -8.3%, cough and sputum as main symptoms – 21%, that TB spreads – 28%, availability of free treatment for TB – 19% and TB is preventable – 16%. Their educational status was directly associated with their knowledge. ($p<0.05$)

Conclusion: The awareness on TB is very low among this population. Targeted health education will have a positive impact on the migrants' health as well as overall public health by reducing transmission.

Keywords: *Brick kiln workers; migrant; awareness; Tuberculosis*

Introduction

According to International Organization for Migration (IOM), "Tuberculosis is not simply an infectious disease – it is also a disease of poverty, social vulnerability and marginalization".(1) The Revised National Tuberculosis Control Programme (RNTCP) in its "National Strategic Plan for Tuberculosis 2017-2025"(NSP) for the control and elimination of TB in India by 2025, has emphasised on reaching undiagnosed TB cases in high-risk migrant workers.(2) Migrant Brick kiln workers are one such population who are not only a key population who are at a high risk for development of TB, but also a frequently missed out one by the health sector and programs for treatment, surveillance and prevention services.

The Advocacy, Communication and Social Mobilisation document of RNTCP, stresses on performing a situational analysis of priority population, reasons for low case detection and identifying the target audience for implementation. Lack of information and awareness, cultural beliefs, stigma associated with TB, poor service availability are quoted as reasons for low performance of the program.(3)

Awareness on the symptoms, modes of transmission and availability of free treatment to cure TB in

Government hospitals is very important in early reporting by symptomatics as well as early case finding by the program. This will decrease morbidity and mortality due to TB in any population. A systematic review on health seeking for Tuberculosis shows that awareness of the subjects on Tuberculosis is an important factor in early care seeking. (4) In this context, the current study was done to find out the awareness of migrant brick kiln workers on various parameters of Tuberculosis.

Method

This was a population based cross sectional study conducted among migrant brick kiln workers working in the brick kilns in the field practice area of the Rural Health and Training Centre of a medical college hospital in South India. A study by National Institute of Research in Tuberculosis (NIRT) among brick kiln workers has shown that 66% of them were not aware of the mode of spread of Tuberculosis.(5) Thus taking the awareness as 34%, a relative precision of 15% of prevalence, a sample size of 332 was arrived at.

Study Population:

Brick kiln workers both males and females who were more than 18 years of age were included in the study. There were 12 brick kilns, with 30-50 workers in each and all were contacted for for participation in the study.

Ethical Considerations:

The study was approved by the Institutional Ethics Committee of Sri Ramachandra University. (IEC-NI/16/AUG/55/66). Permission was obtained from Brick kiln Association of Thiruvallur district as well as the owners of the brick kilns. Written informed consent was obtained from all the participants after explaining the purpose of study and before administering the questionnaire.

Data Collection:

Information on background demographic characteristics, their living conditions, type and duration of work and their awareness on various aspects of Tuberculosis namely the cause, mode of spread, common symptoms, treatment, prevention were collected using a pretested structured questionnaire. Awareness on the three questions - cough as a symptom of TB, that TB spreads through air and treatment can cure TB was taken as Sufficient Knowledge on TB and the results cross tabulated.

Statistical Analysis

Descriptive statistics namely proportion, mean, standard deviation, range etc. were calculated for the quantitative variables. Test of significance for difference in proportion among groups was found using Chi-square test and p value < 0.05 was considered as statistically significant. SPSS Inc. 16.0 was the statistical software used for analysis.

Results

There were 580 brick kiln workers included in this study. The mean age of the participants was 36.47 (SD 11.45). Nearly 40% were <30 years of age, whereas there were 30% each in the 31-40 years and >40 years group respectively. There was an almost equal distribution of males and females (52% vs 48%).

More than half of the brick kiln workers were illiterates (52%) and only a small proportion (4%) had studied more than 10th standard. A higher proportion of females (57%) were illiterate compared to males (46%). The duration of work was 5-15 years in 46.5% of subjects. Two-thirds (66%) of them were in the moulding job. Table 1 gives the details of background characteristics of the study population.

Table no.1: Background Characteristics of the Study Population:

Background Characteristics		**N (%)**
Age	Upto 30 Years	222 (38.3)
	31-40 Years	186(32.1)
	>40 Years	172(29.7)

Cont... **Table no.1: Background Characteristics of the Study Population:**

Sex	Male	284(49)
	Female	296(51)
Educational Status	Illiterate	299(51.6)
	Primary	99(17.1)
	High School	158(27.2)
	HSC/ Diploma/ Graduate	24(4.1)
Duration Of Work (N=577)	<5 Years	201(35.6)
	6-15 Years	262(46.5)
	>15 Years	101(17.9)
Nature Of Work	Carriage And Placement	144(24.8)
	Moulding	381(65.7)
	Baking	35(6.0)
	Others Specify	20(3.4)

Awareness on TB among brick kiln workers:

The disease by name Tuberculosis was familiar among less than a third (31.7%) of the study population. (Table no.2)

Table no.2: Awareness on various aspects of TB among migrant brick kiln workers (n=580)

Awareness on various aspects of TB	**No. (%)**
Cause of TB	
Germs	48(8.3)
TB spreads from one person to another	161(27.8)
By cough/sneeze	123(21.2)
Diagnosis of TB	
Sputum test	93(15.9)
Blood test	41(7)
X ray	8(1.4)
Treatment for TB	
6 months or more	28(4.8)
As long as symptoms persist	71(12.2)
Free treatment is available for TB	109(18.7)
TB is curable	108(18.5)

Germs as cause for TB was known by 48 (8.3%) of the workers. The commonest misconceptions on causation were smoking, 55 (9.5%) and exposure to dust, 37(6.4%).

Even though 161(27.8%) people felt that TB spreads from one person to another, only 123 (21.2%) knew coughing or sneezing by a patient to spread the disease. Here again there were misconceptions like TB spreads by touching, sharing things, water etc though the numbers were limited. A majority of the study population felt that TB spreads by stamping on someone's sputum 152(26.2%).

Around 16% of the workers were aware of sputum test for diagnosis of TB. But only 5% of them knew the duration of the treatment as 6 months or more. The awareness on availability of free treatment in Government hospitals for TB was present in less than a fifth of the people (19%).

Among the workers, 131 (22.6%) were aware of one of the symptoms of TB athough cough and sputum were the ones known by majority of them. (Figure 1) The other symptoms that were known were breathlessness 7(1.2%), weakness 6(1%), wheeze 4(0.7%), vomiting 3(0.5%), headache 2(0.4%), chest pain, loss of appetite, giddiness, sleeplessness, increased sweating, death by 1 each (0.2%).

Figure 1: Awareness of the brick kiln workers on common symptoms of TB

TB is preventable was known by 93 (16%) workers. The modes of prevention commonly mentioned were closing mouth while coughing (14%) and proper disposal of sputum (12%). (Figure 2)

Figure 2: Awareness of brick kiln workers on prevention of TB

Knowledge on all the three namely - Cough is a symptom of TB , TB spreads by airborne route and TB is curable with treatment was considered as sufficient knowledge and was present among 69 (11.9%) brick kiln workers. Its association with background characteristics is given in table no.3.

Table no.3: Association of background characteristics with knowledge on TB

Background Characteristics		**N**	**No. of workers who were aware (%)**	**P value**
Age	upto 30 years	222	29(13.1)	.369
	31-40 years	186	17(9.1)	
	>40 years	172	23(13.4)	
Sex	Male	284	31(10.9)	0.475
	Female	296	38(12.8)	
Educational Status	Illiterate	299	30(10)	0.009*
	Primary	99	11(11.1)	
	High school	158	20(12.7)	
	HSC/ Diploma/ Graduate	24	8(33.3)	

Cont... **Table no.3: Association of background characteristics with knowledge on TB**

Duration of work	Less than 5 years	201	21(10.4)	0.125
	6-15 years	262	28(10.7)	
	16 and above years	101	18(17.8)	
Nature of work	Carriage and placement	144	19(13.2)	0.045*

	Baking	35	2(5.7)	
	Others	20	6(30)	

*P < 0.05 – statistically significant

There was no difference in the awareness level on TB between different age groups as well as between males and females. But the level of awareness increased as the educational level increased.. ($p<0.01$)

The duration of work in brick kiln did not affect the level of awareness of TB. But the nature of work did and this difference was statistically significant ($p<0.05$).

Discussion

Current study is a Cross-Sectional study to assess the level of awareness on Tuberculosis among 580 migrant brick kiln workers in South India. The key findings are just 31.7% of the respondents had heard of TB and a meagre 12% had sufficient knowledge on TB. The knowledge on TB increased as the educational status increased. Those involved in core work such as moulding, baking, carriage had lesser knowledge compared to others such as drivers, managers etc.

India being the country with the highest TB burden and mortality in the world,(6) it was really tragic that only a third of the study population have heard of Tuberculosis. This is much lower in comparison to that of studies done in urban slums in Puduchery (94%), as well as school and university students. (7,8,9)male and female were 68.2 % and 31.8 % respectively. Most of the students (94.4 %

The knowledge on how TB spreads (28%) was much lower than the finding (66%) among brick kiln workers in a study by NIRT. (5) However the misconceptions that TB spreads by touching, sharing and through water was similar to other populations.(7,10) But many of the respondents in this study 26% believed that TB spreads by stamping on one's sputum which is not reported much in literature.

More people thought TB to be caused by smoking or dust than germs (8.3%). Studies found that most people in urban and rural areas and students knew it to be due to germs(7,10,8) but in few others done among backward population a similar pattern was observed (11,5,12)

Cough as a symptom of TB was known among 21% respondents and that TB is curable with treatment and free treatment is available in all government facilities was known among 19% of the study population only. This is an important factor determining the health seeking behaviour and choice of facility. Studies show that the awareness on these aspects are better among students, general population, TB symptomatics as well as patients who are admitted for other illnesses.(8, 9male and female were 68.2 % and 31.8 % respectively. Most of the students (94.4 %, 7, 10, 13). In-spite of the great efforts taken by RNTCP towards advocacy and communication, awareness on these has not percolated to the people in the difficult to reach areas such as the brick kilns.

There was no difference in knowledge between males and females unlike in few studies where males had better knowledge. (14,15) But the finding that higher the educational status, better the awareness was similar to other study findings. (12,16,17,18,19Jijiga y Harar. DISEÑO: Entre julio y noviembre de 2008,

382 pacientes sospechosos de tuberculosis y fueron entrevistados mediante un cuestionario estructurado. Los datos se analizaron mediante estadística descriptiva y regresión logística ordinal. RESULTADOS: Sólo seis (1,6%,20)

The low level of awareness among the brick kiln workers might be attributed to their low level of literacy (less than 50% were literates compared to general population where it is 80% as per census 2011 in Tamilnadu),(21) social isolation for six to eight months in a year while working in brick kilns and also less targeted interventions by the people of the health sector.

Poor knowledge of TB symptoms, diagnostic tests, duration of treatment, misconceptions of costs have been identified as barriers for effective TB control. (3) So it is high time we reach these migrant brick kiln population at regular intervals and empower them by raising their overall health consciousness as well as improve their disease specific knowledge. This is expected to improve TB case finding as well as when initiated on treatment, treatment completion.

Conclusion

The awareness of the migrant brick kiln workers on various parameters of TB was very low. Efforts focussed on health promotion and disease prevention among these internal migrants will not only impact their health positively but also the overall public health by reducing the transmission among surrounding communities and the communities of origin.(22)

A Study on the Prevalence of Diarrhoeal Disease among The Under 5 Age Children In Urban Area of Sangareddy, Telangana

Humera Abida[1], Batchu Naga Gayathri[2]

[1]Assistant Professor, [2]Assistant Professo, Department of Community Medicine, Mahavir Institute of Medical Sciences, Vikarabad, Telangana, India

Abstract

Background: Diarrhoea is defined as the passage of three or more loose or liquid stools per day (or more frequent passage than is normal for the individual) [1]. Diarrhoea can last several days, and can leave the body without water and salts that are necessary for survival. In urban setting, diarrhoea is more common in the slum dwelling children who live in an environment with poor sanitary facilities and polluted water [2]

Aim and Objective: To estimate the prevalence of acute diarrhoeal diseases among the children below 5 years of age.

Material and Methodology: Cross sectional type of study conducted in children of 0-5 years of age using pre designed, pretested structured questionnaire. 402 children were selected for the study using convenient sampling technique. Study area was 5 Urban slum pockets in Urban Health and Training Centre(UHTC), Sangareddy, Department of Community Medicine, MNR Medical College, Telangana.

Results: Prevalence of acute diarrhoeal diseases was 15.7% among 402 under-fives children from the urban slum, over a recall period of 2 weeks. Among them 207 children were males and 195 were females, of which prevalence of diarrhea was observed more in females 33 (16.9%) when compared to males 30 (14.5%). About 90% of study participants belonged to nuclear family of which most of them belonged to class IV (upper lower) according to Modified Kuppuswamy scale[3]. Socio environmental conditions of these families were poor.

Conclusions: The study brought light on the unmet needs regarding poverty, sanitation, proper disposal of waste water and daily supply of safe potable drinking water and health care delivery.

Keywords: *Prevalence, diarrhoea, under 5 age children, environment.*

Introduction

Globally, four billion episodes of diarrhea were estimated to occur each year, with > 90% occurring in developing countries. Diarrhoeal disease is an important public health problem among children in developing countries.

According to WHO[4], 'Human faeces remains one of the most dangerous pollutant, spreading microbes causing various diseases like enteric fevers, diarrhoea etc. Rotavirus and Escherichia coli, are the two most common etiological agents of moderate-to-severe diarrhoea in low-income countries. Infection is more common when there is a shortage of adequate sanitation and hygiene and safe water for drinking, cooking and cleaning.

Diarrheoea can also spread from person-to-person, aggravated by poor personal hygiene. Food is another major cause of diarrhoea when it is prepared or stored in unhygienic conditions .Unsafe domestic water storage and handling is also an important risk factor.

In India especially poor sanitary conditions was the most important cause for most of ADD episodes. Health education on the etiology, prevention and management

of the diarrhoea has the potential to establish productive contact between the health services and the community, to increase the capability of the families to recognize the danger signs of diarrhoea in children and to encourage appropriate and early care seeking.

There is an imperative need to know about prevalence of diarrhoea and to assess the existing gap between knowledge and practice such as hand washing and use of sanitary toilet. There is also a need for supply of safe drinking water and maintenance of clean environment through provision of sanitary latrine and proper disposal of refuse. This is more important in case of mothers with under five children, in whom the morbidity and mortality to diarrhoea is very high.

Method

A community based cross sectional type of study conducted for a period of 12 months(January 2016-December 2016) . Study area is Urban slum area by name Marxnagar selected randomly from urban field practice area of Sangareddy. Out of 5245 population in urban slum, 681 under 5 age children are expected to be available to draw the adequate number of study population.

Out of 681 children only 402 children were taken for the study as per the calculations by using the formula for fixing the sample size as mentioned below n = (Z)2pq/ d2.

Where **Z**= percentage point corresponding to significance level. For significance level 5%, Z is1.96. **p** prevalence of diarrhea among under 5 children is 30%[5] q=100-p=70%

d is corresponding maximum error and is 15%. Hence n=1.96x1.96x30x70/4.5x4.5=398 i.e. rounded to 402 children < 5 yrs.

Data Collection:

Informed written consent was taken from the study participants prior to the start of the study. A pre designed, pre tested questionnaire was made as per guidelines given in basic biostatistics by A. Indrayen and L. Sathyanarayana . Pretesting of questionnaire was done in 40 samples selected randomly in 4 streets in the respective area of Sangareddy.

Data Analysis:

Statistical analysis was done using SPSS version 17.0 and the details regarding mother's knowledge and attitude regarding diarrhoea prevention was obtained. Data was summarized in percentages and proportions. Statistical associations was done using Chi square test wherever necessary with $p<0.05$ and considered statistically significant.

Results

Table 1: Distribution according to age & sex of under 5 age children

Demographic Characteristics		**No. of children**	**Percentage (%)**
Age Group	0-12 months	75	18.66
	13-24 months	108	26.86
	25-36 months	90	22.39
	37-48 months	71	17.66
	49-60 months	58	14.43
Sex	Males	207	51
	Females	195	49
Prevalence of Diarrhoea	Males	30	14.5
	Females	33	16.9

From the table 1, it was observed that, out of 402 under 5 aged children 108 (26.86%) children were from the age group of 13-24 months followed by 90 (22.39%). In the above table, majority of children were males 207 (51%) while females were 195 (49%).It was observed that prevalence of acute diarrhoeal diseases was more in females 33 (16.9%) when compared to males 30 (14.5%).

Table 2: Distribution according to Socio Environmental conditions of the families (n=255) of under 5 age children

Socio Environmental Characteristics		**No. of families(n=255)**	**Percentage (%)**
Type of family	Nuclear	235	92.3
	Joint	14	5.7
	Three generation	6	2
Socio Economic status	Class I (Upper)	5	1.96
	Class II (Upper middle)	31	12.15
	Class III (Lower middle)	56	21.96
	Class IV (Upper lower)	136	53.33
	Class V (Lower)	27	10.58
Source of drinking water	Municipal tap water	178	70
	Borewell water	77	30
Type of house	Kutcha	145	57
	Semi pucca	76	30
	Pucca	34	13
Sanitary facility	Present	41	16
	Absent	214	84
Garbage Disposal	Garbage pit	158	62
	House to house collection	18	7
	No facilities	79	31
Fly breeding	Yes	226	89
	No	29	11

From the table 2, it was observed that, majority of the families belonged to nuclear family 235(92.3%) and then followed by joint families (14%). Modified Kuppuswamy scale[6] was used to determine the socio economic status of the study population .Based on that majority of the families belonged to class IV (53.33%) followed by class III (21.96%).

Out of 255 families surveyed 178(70%) houses were receiving municipal tap water whereas 77(30%) houses were still receiving borewell water. Majority of the houses were kutcha type145(57%) followed by semipucca houses76(30%). Only a handful of houses 41(16%) had the sanitary facilities available.

Garbage pit was the major source of Garbage Disposal(62%) in the present study. Fly breeding was seen in approximately 90% of the houses.

Discussion

The present study was conducted in the urban field practice area of department of community medicine of MNR Medical College, Sangareddy, Telangana. For the purpose of study total 255 families were taken which had 402 under five age group children, who were enrolled in the study. The findings in this study document the prevalence of Diarrhoea among the under-five population of urban slum of Sangareddy.

Prevalence of diarrhoea in under five children in this study was found to be 15.7% .Similar findings were seen in studies conducted by Mishra CP[6] and Sudipta Basa[7].The study done in Aligarh of Uttar Pradesh by Ansari et al[8] has reported a prevalence of 16% which is comparable to our study.

In the present study it was observed that, males belonging to 13-24months age group was higher(30.9%) in number. Females belonging to 37-48months age group were higher (25.6%) in proportion than other age groups A cross-sectional study conducted to assess the prevalence of under-five diarrhea and socioeconomic factors by A.M. Elizabeth and Sherin Raj[9], the percentage of children suffering from diarrhea was highest among children aged 6-23 months (20.2%-20.6%) and lowest in the age group of 48-59 months (3.6%).

It was observed that sex ratio of the under five children in this study was 955 females /1000 males and it is slightly higher than the national average of 940/1000(NHFS-4).Prevalence of diarrhoea among under-five females was higher i.e. 33(15.9%) when compared to under-five males 30(14.5%) which is similar to study done by Sudipta Basa[10]

Majority of the under five children were from nuclear family 235(92.3%) and from joint family 14(5.7%). The majority of population was from urban areas and nuclear family culture was mainly followed in such part of country. It may be due to higher number of nuclear families in our study. A similar study done in Rural Community in the Jordan Valley by Abdelhakeem Okour, Ziad Al-Ghazawi, Muntaha Gharaibeh[11] showed no differences in diarrhoea due to type of family.

Source of drinking water in majority of houses 178(70%) was by municipal tap water followed by bore water i.e 77(30%). Among the 70% of water supplied by Corporation 75% were through corporation Lorries to the respective slums in the corporation council wards. Only 25% of the houses were supplied with regular water supply through taps. In a study done by Katharina Diouf[12], public taps were the most common source of drinking water (29.4%; n=162), which is similar to our study.

Out of 255 study families,136 (53.3%)families were belonging to class IV of Modified Kuppuswamy socioeconomic classification followed by 27(10.5%)%) families were of class V. Majority of children with diarrhea were from lower socioeconomic class with 35 children being affected from diarrhoea from class IV . Diarrhoea was higher in lower socio economic groups. It was found that there is a significant relation between socio economic status and prevalence of diarrhoea. ($p<0.05$) Similar findings were also reported by Sudipta Basa[10] in their study, with maximum number of study subjects 312 (44.8%) belongs to socio-economic class IV followed by class V 203(29.2%) which is statistically significant.

From Table no.2 which shows the environment of study area, the types of houses are mostly Kutcha houses(57%) and about 30% were Semi pucca. Only 13% were pucca houses . The environment around the Kutcha houses was poor with inadequate drainage facilities and the housing floor was in surface with street. About 84% of houses have no sanitary latrines and they are using either sulabh public toilet complexes or open air defecation. 40% of mothers said their family members use the near by play ground for open air defecation. Among 16% of houses having sanitary toilets, only 6% has latrine with adequate water supply. Refuse disposal by most of households 62% were into garbage pits or cabin .About 88.81% of mothers complained about fly nuisance in their houses and they accepted it was due to improper refuse disposal. In a study done in Turkey[13] it was found that the association between family environment and diarrhoea is statistically significant (median 1.48+-0.12). The association between key health care practices and

family environment in prevention of diarrhea .Village-level and township-level care were sought for childhood diarrhea by 67.02% of the caretakers[14].

Conclusion

Diarrhea is still the major killer of children under 5 years of age group, although its toll has dropped by a third over the past decade. It killed more than 1600 children under 5 years of age every day in 2012[15]. Hence, along with creating awareness regarding prevention and control of diarrhoeal episodes there is also a need for supply of safe drinking water and maintenance of clean environment through provision of sanitary latrine and proper disposal of refuse.

Ethical Clearance- Proposal presented in SRM College of Occupational therapy, SRMIST.

Evaluvation of Sensory Responsiveness in Children with Autism Spectrum Disorder

U.Ganapathy Sankar[1], Monisha.R[1], Christopher Amalraj Vallaba Doss[2], R.M. Palanivel[3]

[1]Dean & Professor, SRM College of Occupational therapy, SRMIST, Kattankulathur, Chennai, [2]College of Medicine, Imam Abdulrahman Bin Faisal University, P. O. Box 1982, Dammam, Saudi Arabia, [3]Deanship of Quality and Academic Accreditation, Imam Abdulrahman Bin Faisal University, P. O. Box 1982, Dammam, Saudi Arabia

Abstract

Objective: To identify the sensory responsiveness pattern using Dunn's Sensory Profile and severity of social impairment using Social Responsiveness Scale in children with Autism Spectrum Disorder.

Methodology: Cross sectional quantitative study design with convenient sampling was used. This study involved 20 children diagnosed with Autism Spectrum Disorder aged 5-6 from special School in and around Chennai. Caregiver's Sensory profile and social Responsiveness Scale was administered in order to quantify the severity and pattern of sensory responsiveness.

Result: Significant relation were found between social responsiveness scores and each of the six sensory system profile scores for children with Autism Spectrum Disorder

Conclusion: Atypical sensory responsiveness pattern is predominant in children with Autism Spectrum Disorder.

***Key Words**: Sensory responsiveness, Autism Spectrum Disorder, Primary schools, special schools*

Introduction

Autism spectrum disorders (ASD) are complex neuro-developmental disorders that can cause problems with thinking, feeling, language and the ability to relate to others. The core feature includes persistent deficits in social communication and social interaction across multiple contexts, Restricted, repetitive patterns of behavior, interests, or activities which cannot be explained by intellectual disability and significantly impairs the functioning (DSM-5™ Diagnostic Criteria). Autism is known as a "spectrum" disorder because there is wide variation in the type and severity of symptoms people experience. ASD occurs in all ethnic, racial, and economic groups. Although ASD can be a lifelong disorder, treatments and services can improve a person's symptoms and ability to function[1].

Abnormalities at the level of synapses, including newly described genetic perturbations and autism susceptibility genes, have been implicated in the pathogenesis of autism (Simone Khaliifeh et al 2016). Non-invasive modalities like Diffusion Tensor Magnetic Resonance Imaging have identified white matter tract involvement in the brains of autistic individuals and socio-emotional processing[2].

Early and intensive intervention impact prognosis. Though no known medication relieves core symptoms of social and communication impairment, but fluoxetine is used to decrease anxiety and risperidone and aripiprazole are approved for irritability in autistic patient. Early identification and intervention with ABA(applied Behavior Analysis, speech, psychomotor and occupational therapies are crucial as is social integration .Early diagnosis and intervention with therapies remains the mainstay of insuring an improved outcomes and a better chance at full integration into society [3].

The sensory systems are the sources for a living being to acquire information about the world, which support that being in successfully responding and

adapting to the environmental demands(Claudia L. Hilton et al 2010).Sensory processing (SP) refers to the way that sensory information e.g. visual, auditory, vestibular or stimuli is processed and managed in the brain to generate adaptive responses to the environment and engagement in meaningful daily life activities (Johnson- Ecker &Parham 2000).SP theory suggests that optimal functioning in daily environments requires efficient reception and integration of incoming sensory stimuli and when this fails the individuals is unable to respond to sensory information with behavior that is regulated relative to the intensity of the input (Miller et al. 2007). Studies show that between 69% and 95% of individuals with an autism diagnosis experience sensory processing that is atypical (Ausderau, Baranek et al 2016). Sensory symptoms were first included as part of the ASD diagnosis in the most recent (2013) edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) and atypical sensory processing is now considered to be a core feature of Autism.

Dunn (1997) proposed a model for classifying patterns of dysfunction in SP according to individuals' behavioral response to stimuli and neurological thresholds, describing four patterns of SP dysfunction: Low Registration, Sensation Seeking, Sensory Sensitivity and Sensation Avoiding[4]. The most common atypical sensory processing that observed and studied in people on the autism spectrum are challenges with sensory modulation, where atypical responses to sensory stimuli make it difficult for the individual to function effectively within a particular environment(Hazen, Stornell et al 2014).

There are three types of atypical sensory modulation: (1).Sensory over- responsivity describes when an individual has an exaggerated negative response to sensory input, often leading to avoidance and hyper vigilance of the stimulus. (2). Sensory under-responsivity describes when an individual may seem to be unaware of, or slow to respond to, a stimulus that would typically be expected to elicit a response. (3). Sensory-seeking behavior describes when an individual has an unusual craving for, or preoccupation with, certain sensory experiences. Many people on the autism spectrum experience a combination of sensory under- and over-responsivity (Baranek 2002). In addition, their sensory-seeking behaviors are associated with both under- and over- reactivity[6,7]. (Lane, Baker et al. 2010.). Abnormalities occurs across all sensory domains, including tactile, vestibular, auditory and visual (Harrison and Hare 2004, Rogers 1998) and in the absence of known peripheral dysfunction such as a visual or hearing loss (Baranek 2002).

Methodology

Children diagnosed with Autism Spectrum Disorder aged 5-6 was selected from Child Therapy Service and special schools around Chennai. Twenty children diagnosed with ASD were recruited through the convenient sampling from the rehabilitation centers, hospitals and special schools in Chennai. All the participants were selected following physician diagnosis confirmed by the DSM-IV-TR criteria and Children with Intellectual Disability and other neurodevelopment disorder, visual and hearing impairment were excluded. The purpose of the study was explained to the caregivers of the children with ASD. Written consent form was obtained from the caregivers and duly filled and signed demographic details were obtained. After obtaining the written consent the participants were administered sensory profile in order to quantify the severity of sensory issues

Result

The Spearman rank correlation coefficient was used to compare the SP sensory raw scores with the SRS raw scores raw scores were also used to quantify the sensory responsiveness for each of the senses.

Table 1 Demographic DATA.

S. No.	Demographic Variables	Class	No. of Children	Percentage
1	Age	5 Years	9	20.7%
		6 Years	11	79.3%
2	Gender	Male	15	76.7%
		Female	5	23.3%

Table 2 : Sensory profile score for children with Autism Spectrum Disorder based on gender

S. No.	Domains of Sensory profile	Gender	Mean	SD
1	Auditory Processing	Male	20.11	5.122
		Female	35.13	5.555
2	Visual Processing	Male	32.40	4.233
		Female	34.15	4.532
3	Vestibular Processing	Male	40.12	3.747
		Female	43.11	3.847
4	Touch Processing	Male	72.21	18.748
		Female	70.22	14.384
5	Multi-Sensory	Male	22.35	4.648
		Female	25.34	4.748
6	Oral/Olfactory Sensory	Male	45.31	6.748
		Female	42.24	6.433

Discussion

Table 1 shows the characteristics of the participants based on the age and gender distribution. Most of the children were between the age of 5-6. Table 2 shows the mean scores of the following component of the sensory profile based on gender: auditory processing, visual processing, vestibular processing, and touch processing, multisensory and oral/olfactory processing. It displays the pattern of distribution of atypical sensory processing in various domains and shows very less difference in the scores between male and female children therefore indicating similar atypical sensory pattern in both the genders. Atypical sensory modulation is an important consideration in diagnosis and treatment of ASD. Difficulties in sensory responsiveness are often among the first indicators of autism noticed by parents, and therefore, may be useful to facilitate early diagnosis and intervention (Baker et al. 2008). The earlier a disorder

is recognized, the earlier a child is able to receive help, and the more effective outcomes of treatment can be achieved.

Additionally, the relationship between sensory modulation and other autistic traits seems more important than previously recognized and addressing sensory responsiveness issues in children with ASD may be more critical than previously understood. atypical scores from multisensory responsiveness, and responsiveness of the proximal senses of oral sensory/ olfactory and touch as the strongest predictors of greater social impairment in the participants. This study would increase the understanding of OT practitioner on differential associations of sensory responsiveness with autism and could contribute to development of intervention linking sensory processing with social, communication, and language functioning in children with autism. It would help OT practitioner in assessing sensory processing patterns in young children with autism for earlier identification of children with a poor prognosis for later social and/or communicative competence. This may offer sensory implications for diagnosis and intervention addressing social issues in children with ASD for OTs.

Conclusion

Atypical sensory responsiveness is often one of the first signs that parents notice in their children with autism, and therefore, may facilitate early diagnosis and intervention. Atypical responses to multi-sensory, touch, and oral sensory/olfactory stimuli were identified as possible predictors of social severity.

Factors Associated with Work Fatigue in the Fuel Truck Drivers at Oil Company Padalarang

Aditiyana Eka Saputra[1], Budi Hartono[2], Dyan Nugrahaeni[3], Novie Mauliku[3]

[1]Postgraduate student of Public Health Sciences, Department of Environmental Health, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia, [2]Department of Environmental Health, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia, [3]Public Health Study Program, Health Science College of Jenderal Achmad Yani Cimahi

Abstract

Fatigue can affect work productivity. Based on data obtained from Oil Company Padalarang in 2013 had 16 fuel truck accidents, work fatigue factor ranks 4th (25%). This study aims to determine the factors associated with work fatigue in fuel truck drivers Oil Company in 2015. The research design used was analytic survey study with Cross Sectional research design. With the number of cases 60 respondents, sampling techniques using Quota Sampling. Data collection using reaction timer, questionnaires and interviews. Data analysis using univariate and bivariate (Chi-Square) analysis. The results showed a description of work fatigue 61.7%, age at risk (≥40 years) 65.0%, abnormal nutritional status 45.0%, work period (≥5 years) 63.3% and heavy workload 38.3 %. It is known that there is a relationship between fatigue and age with P Value (0.002), work period with P Value (0.001), workload with P Value (0.018) and there is no relationship between work fatigue and nutritional status with P Value (0.936). It is recommended to provide a resting place for fuel truck drivers, making a policy to regulate the distance of fuel delivery between drivers who are old and young, do a health check before and after sending fuel and maintain a pattern of rest or sleep for fuel truck drivers.

Keywords: *Work Fatigue, Fuel Truck Drivers, Oil Company, Reaction Timer.*

Introduction

Fatigue is a condition that is often found in every worker, fatigue is one of the causes most often felt or experienced by each worker. Fatigue can occur anywhere and anytime, and in various kinds of work. Work exhaustion cannot be clearly defined but can be felt by workers [1]. Fatigue also has significant consequences for society. Several studies have showed that fatigue sustained for a long time can predict future morbidity and mortality [2]. Fatigue also can result in declines in worker productivity due to the debilitating nature of fatigue [3].

Corresponding author:

E-mail: aditiyanaputra@gmail.com

Based on the International Labor Organization (ILO) in 2013, every year as many as two million workers die from workplace accidents caused by fatigue. The study stated that of the 58,115 samples, 32.8% of them or about 18,828 samples suffered from fatigue. Data from the Ministry of Manpower and Transmigration of Indonesia (DEPNAKERTRANS) about workplace accidents in 2004, in Indonesia every day there were 414 workplace accidents, 27.8% due to high fatigue, 9.5% or 39 people experiencing disabilities. Data from the Indonesian Central Bureau of Statistics (BPS) in 2012 has occurred 117,949 cases of workplace accidents with a total death of 25% and it is predicted that this number does not include the types of work accidents that are not reported (http://bps.go.id, obtained on April 5, 2015).

Fatigue experienced by workers is caused by a variety of factors, both internal self-factors (age, nutritional status) and external factors (work period, workload). Factors that affect work fatigue are internal factors and external factors. Which includes internal

factors include: somatic factors or physical factors, nutrition, gender, age, knowledge and lifestyle. Whereas external factors are physical conditions of the work environment, including: noise, temperature, lighting, chemical factors, biological factors, ergonomic factors, occupational categories, nature of work, company discipline or regulations, wages, social relations and work position or position [4]

A number of previous studies have indicated that fatigue is one of the most significant factors that contribute to accidents on the job: people who are tired often fail to take safety precautions [5]. A comprehensive study of accidents showed that 58 percent of commercial vehicle crash were caused by fatigued workers in the workplace.[6]

Data obtained from Oil Company Padalarang (2013) that there have been 105 truck accidents in the working area of Oil Company Padalarang 2010-2013. The data shows that the number of truck accidents at Oil Company Padalarang ranks third (11%) of 22 Fuels terminals managed by Oil Company throughout Indonesia. Reports in 2013 showed that there had been 16 oil truck accidents which caused 6 people to be injured and 2 people died from fatigue factors ranked 4th (15%) after human error, vehicle conditions, and road factors as well as temporary cost losses of Rp. 73,089,750.

The results of a preliminary study of work fatigue using Lakassidaya's L77 Reaction Timer were carried out on 10 fuel truck drivers Oil Company Padalarang in 2015, of which 10 drivers were carrying out work fatigue with an average score above 300,0 milliseconds and 3 others did not experience work fatigue.

Method

This study uses a cross-sectional design and was conducted in May 2015 at Oil Company in the Padalarang. The respondents in this study were fuel truck drivers. The population was 152 drivers and in this study 60 drivers were used as research samples. The cross sectional design used in this study aims to link work fatigue associated with internal factors (age, nutritional status) and external factors (work period, workload) on fuel trucks drivers at Oil Company Padalarang in 2015. In sampling the researcher used quota sampling technique that is sampling technique by setting a certain amount as a target that must be met in sampling from the population [7].

This study uses the Chi-Square test and uses the significance limit of α (alpha) = 0.05 and 95% convidence interval. The primary data of work fatigue is measured by the Reaction Timer, which is to measure fatigue in BBM truck drivers by looking at the driver's excitement towards sound and light stimuli from the Reaction Timer tool. Age by asking the respondent directly and by looking at his identity card (KTP). To measure the nutritional status of the fuel truck drivers based on Body Weight and Height using set of scales and microtoa. To measure the workload of fuel truck drivers by calculating the driver's heart rate/pulse in one minute or by using a digital tensimeter that directly displays the driver's heart rate.

Result

The results of the research are the relationship of internal factors (age, nutritional status) and external factors (work period, workload) with work fatigue on fuel trucks drivers at Oil Company Padalarang using univariate analysis to see an overview of frequency distribution and percentage, and bivariate to see the relationship between independent variables and dependent variables using Chi-Square analysis.

Table 1. Frequency Distribution of Factors Associated with Work Fatigue in The Fuel Truck Drivers at Oil Company Padalarang

Variable	Frequency (N)	Percentage (%)
1. Work Fatigue • Fatigue • Not fatigue	 37 23	 61,7 38,3
Total	60	100

Cont... **Table 1. Frequency Distribution of Factors Associated with Work Fatigue in The Fuel Truck Drivers at Oil Company Padalarang**

2. Age • At risk (≥40) • Not at risk (<40)	39 21	65,0 35,0
Total	60	100
3. Nutritional Status • Abnormal • Normal	27 33	45,0 55,0

Total	60	100
5. Workload • Heavy • Thin	23 37	38,3 61,7
Total	60	100

Based on table 1. It was found that fuel truk drivers who experienced fatigue were 37 people (61.7%). Drivers of trucks over 40 years old were 39 people (65.0%), while overcrowded fuel truck drivers (overweight) were 27 people (45.0%). Fuel truk drivers who worked more than 5 years were 38 people (63.3%), while the Fuel truk drivers whose workload was heavy were 23 people (38.3%).

Workload									
1.	Heavy	19	82,6	4	17,4	23	100	1,698 (1,161-2,484)	0,018
2.	Light	18	48,6	14	51,4	37	100		
Total		37	61,7	23	38,3	60	100		

Based on table 2 the relationship between the age of fuel truck drivers and the work fatigue occurs was found that as many as 30 fuel truck drivers (76.9%) over the age of 40 experienced work fatigue, based on the results of statistical analysis, the OR value = 2,308 (95% CI: 1,231-4,328) means that the fuel truck drivers aged over 40 years have a risk of 2.3 times experiencing work fatigue compared to fuel truck drivers aged under 40 years.

The relationship between nutritional status of fuel truck drivers and work fatigue was obtained by 16 fuel truck drivers (59.3%) who were abnormally weight, the results of statistical tests show no relationship (P = 0.936) between fuel truck drivers with the nutritional status.

The relationship between work period of fuel truck drivers and the work fatigue was found that as many as 30 fuel truck drivers (78.9%) who worked more than 5 years and above experienced work fatigue, based on the results of statistical analysis, the OR value = 2.481 (95% CI: 1,317-4,674) means that fuel truck drivers who work more than 5 years and above risk 2.4 times experiencing work fatigue compared to fuel truck drivers who work under 5 years.

The relationship between workload of fuel truck drivers and work fatigue was obtained that as many as 19 fuel truck drivers (82.6%) who had a heavy workload experienced work fatigue, based on the results of statistical analysis, the value of OR = 1,698 (95% CI: 1,161-2,484) means that fuel truck drivers with heavy workloads have a risk of 1,6 times experiencing work fatigue compared to fuel truck drivers with light workloads.

Discussion

Based on the results showed fuel truck drivers who experienced fatigue were obtained as many as 37 drivers and 23 drivers did not experience fatigue in work. Fuel truck drivers who experience fatigue in work are caused

by several factors including age, nutritional status, work period and workload, besides that there are other factors that influence it also to cause the occurrence of work fatigue as a condition of poor drivers caused by lack of rest, suffer from certain diseases, the distance of sending BBM/Fuel is far enough to be delivered plus road conditions that allow to increase driving fatigue (quite long congestion, damaged road conditions, etc.), weather conditions. Drivers often do not realize the fatigue they experience and the longer they are left to have a negative impact, namely the occurrence of chronic fatigue, this is possible because of their minimal level of knowledge about occupational safety and health and allows for accidents to occur at work. Tiredness, although a synonym for fatigue, may not encompass all aspects of fatigue (e.g. weakness or cognitive fatigue).[8]

Age has a significant relationship with work fatigue. The results of the analysis of the relationship between the age of fuel truck drivers and work fatigue on 60 respondents found that, as many as 30 drivers over the age of 40 experienced work fatigue. The results of the analysis prove that the driver of a fuel tank truck with an age of more than 40 years is very risky for the occurrence of work fatigue, because the more a person's age increases, the ability of his organs will also decrease. The results of this study are in line with age directly influences strength muscle which then affects physical ability labor to work. Muscle strength in men and women around the age of 25-35 [9]. Also, Study found that almost 30% of the participants in Chinese study population had experienced fatigue, and fatigue is associated with age, marital status, employment status, regular exercise, number of self-reported chronic diseases, number of individual's children and hospitalization in the last year in middle-aged and elderly males [10].

Nutritional status does not have a meaningful relationship with work fatigue. The result of the analysis of the relationship between the nutritional status of fuel truck drivers and work fatigue was found that as many as 16 drivers who were abnormally heavy experienced work fatigue. The researcher argues that nutritional status is not related to the occurrence of fatigue due to the results of BMI which shows that the majority of respondents were normal nutritional status and experienced fatigue. Another factor, which is when the driver starts shipping, looks tired and most of the driver does not rest properly when finished sending. This research is in line with the research conducted by [11] on factors related to work fatigue in sewing workers in the sewing section at CV. Aneka Garment Gunungpati Semarang, the results showed that nutritional status was not related to work fatigue, normal nutritional status was 25 (80.6%). Also, Nutritional status may influence fatigue levels [12]Korea. Fatigue was measured using Piper's Fatigue Scale (PFS, but The high level of work fatigue is only experienced by workers with energy intake in the less category [13]it will affect of the worker's health condition. Work fatigue can be affected by several factors, some of which are energy intake and nutritional status. Objective: The aim of this research was to analyze the correlation between the adequacy of energy intake and nutritional status with the level of work fatigue. Methods: This study was an analytic observational, used cross sectional study with 33 sample from 48 workers of cocoa powder production PT. Multi Aneka Pangan Nusantara Surabaya selected by simple random sampling. Data were collected by food recall 2X24 hours for energy intake, measuring weight and height for nutritional stastus and Industrial Fatigue Research Committee (IFRC. And in other studies explained older adults with undernourishment in the present study were not experiencing tiredness in activities of daily living [14]the information regarding the association between nutritional status and physical performance does not provide a complete picture. Most studies used limited or self-reported measures to evaluate physical performance. The objective of this study was to examine the correlation between nutritional status and comprehensive physical performance measures among undernourished older adults who reside in residential institutions.\\n\\nMETHODS: Forty-seven older adults (26 males, 21 females.

The work period has a significant relationship with work fatigue. The results of the analysis of the relationship between the working period of fuel truck drivers and work fatigue obtained that as many as 30 drivers who worked more than 5 years and over experienced work fatigue. The results of the analysis prove that fuel truck drivers with long working periods will easily experience work fatigue, although many argue that the longer a person's work is, the better their skills will be, but according to the researchers it shows the influence of the length of work of workers with fuel truck driving that are carried out tend to be monotonous so that they will affect the physical and muscle conditions that work statically. The results of this study are in line with working period has a significant effect on work fatigue, which means that the working period increases it will increase work fatigue. Work period is the accumulation of time the worker has

held the job [9]. Also, work period may affect workers both positively and negativel. A longer work period could have a positive impact through the greater amount of experience the worker gains, while conversely it could have a negative impact through causing increased fatigue and boredom [15].

Workload has a meaningful relationship with work fatigue. The results of the analysis of the relationship between the workload of fuel truck drivers and work fatigue was found that as many as 19 drivers who had a heavy workload experienced work fatigue. The analysis proves that fuel truck drivers with heavy workloads will be more susceptible to work fatigue, according to researchers, this is influenced by physical environmental conditions that tend to be hot and also affected by road / traffic conditions such as congestion and others that can cause work fatigue. The results of this study are in line with the physical workload is significantly related to general, physical and mental fatigue but the association was weakest with mental fatigue. This suggests that physical workload primarily affects the physical experience of tiredness and fatigue [16]9.05 (SD 3.36. And Also, workload increased over the working week and the rating of workload was associated with fatigue which in turn was associated with higher risk of an incident as indicated by the HSE risk Index [17].

Conclusion

Based on the results of research and discussion about factors related to work fatigue in fuel truck drivers at Oil Company Padalarang 2015, conclusions were obtained that there was a significant relationship between age, work period and workload with work fatigue and in this study nutritional status had no effect on work fatigue.

Acknowledment: In this study I was assisted to be loaned by the Reaction Timer tool by Ms. Dr. Gurdani Yogisutanti, SKM., M.Sc. This Study uses personal funds and there are no sponsors from any party.

Ethics Approval: The study protocol was approved by the Ethics Committee of Public Health Faculty, Universitas Indonesia, Depok, Indonesia.

Conflict of Interest: No conflict interests.

Health and Safety Risk Analysis in the Fertilizer Industry

Ana Islamiyah Syamila

Lecturer, Department of Public Health, University of Jember, Indonesia

Abstract

Background: There are high risks and potential hazards in the process of making Zwavelzuur Kalium (ZK) fertilizer. The risk varies according to the chemical used in the process. Identification of potential hazards and risks is required periodically to control the risks

Objectives: To identify the potential hazards and risks in the process of making ZK fertilizer and to control the risk

Methodology: This study is an observational study to observe the process of making ZK fertilizer and to conduct occupational health and safety risk management

Results: There are various hazards can occur in ZK production including chemical hazards such as hazardous, toxic, reactive, irritant, and corrosive as well as physical or mechanical hazards which include altitude, machinery, equipment, noise, and temperature

Conclusion: The highest risk assessment results on ZK production are in the reactor unit, which causes the risk of explosion. Risk control refers to the principle of the control hierarchy

***Keyword**: fertilizer, risk, potential hazard, safety, and health risk management*

Introduction

The production of ZK fertilizer is through several stages, which are quite long: raw material preparation, reaction process, cooling and neutralization, bagging, scrubber, or absorber.

ZK fertilizer produces with raw material is 98% liquid Sulfuric acid (H_2SO_4) and Potassium chloride (KCl) powders. The raw material is mixed in a reactor and heated in a furnace that operates at 500^0C. The reaction from mixing the two raw materials is $2KCl + H_2S0_4 \rightarrow K_2S0_4 + 2\ HCl$. So the product from the mixing of raw materials is K_2SO_4 or ZK fertilizer, and the by-product is liquid hydrochloric acid (HCl).

The Globally Harmonized System of Classification and Labeling of Chemical (GHS) and the Department of Transportation (DOT) classify sulfuric acid in transport pictograms as class 8 hazardous substances, corrosive. The definition of corrosive is where the chemical causes damage to the wound to the skin tissue with an exposure time of fewer than 4 hours, or the chemical can cause corrosion in equipment either steel or aluminum with an area of more than 6.25 mm per year at 55^0C.

The International Agency for Research on Cancer (IARC), the International Agency for Research on Cancer, has concluded that there is sufficient evidence that fog-containing sulfuric acid exposure is carcinogenic in humans[1].

Another raw material in making ZK fertilizer is Potassium chloride (KCl) in the form of white powder. These chemicals are classified as health hazards with code number 1 by NFPA 704, which means that KCl can irritate, even with minor injuries. In the process, KCl move through a bucket elevator and conveyor belt to the reactor mixing between raw materials.

ZK fertilizer that comes out of the furnace with a temperature of 300^0C will be cooled by jet ejector cooler to 50^0C by contacting ZK with water. ZK fertilizer is then transported by bucket elevator and entered in the sieving stage (screener) separate between oversize and on size products. Oversized products will be included in the crusher to be mash into products that are on size. K_2SO_4 or ZK fertilizer has the same danger as Potassium

chloride (KCl), which irritates.

ZK products which are on size will be neutralized to produce ZK, which is free acid with the supporting material, namely Sodium carbonate (Na_2CO_3). Na_2CO_3 has the same danger as KCl and K_2SO_4 that is irritating. NFPA 704 classifies it into health hazards with code number 2, prolonged and repeated exposure can cause residual injury.

Furthermore, the finished ZK fertilizer will store in a silo before being packaged in a bagging unit. Semi-automatic packaging equipment is used where workers simply place the bag under the scales and handle the bag during sewing. Surely there are dangers in the packaging area where workers can be exposed to ZK dust or expose to the worker's body parts.

The side product of the ZK Plant is Hydrochloric acid (HCl), which is liquid and colorless and has a pungent odor typical of hydrochloric acid. Chloride acid has the same classification as sulfuric acid, according to GHS, which include in Transport Information Class 8 (corrosive). NFPA 704 also classifies the same health hazard between hydrochloric acid and sulfuric acid, plus the special code for hydrochloric acid, corrosive.

HCl coming out of the furnace will be cool by graphite cooler, which will change the original temperature of 400^0C to 50^0C by contacting HCl with water before the HCl enters the scrubber. Scrubber sulfuric trace removal has the function of capturing a mixture of HCl gas and SO_3 exhaust gas from the reactor. After that, the HCl that enters the absorber will be absorbed again by the gas to get HCl liquid. Pumps are used to pump water into the scrubber, which will be used to absorb HCl vapor. HCl scrubber reabsorbs the HCl gas fume before releasing it into the atmosphere. The absorber reabsorbs HCl, which still escapes. HCl concentrations of 33-40% are collected in HCl containers before the product pump into a distribution vehicle.

The chemical properties of the raw materials and the products produced have each hazard characteristics that can threaten the safety and health of the workforce, so it needs to consider properly. Appropriate identification and control with the existing hazards will give good results too.

Risk management is a coordinated activity to direct and control an organization in managing risks[2]. OHS risk management is an effort to manage OHS risk to prevent unwanted accidents in a comprehensive, planned, and structured manner in a good system. OHS risk management is related to hazards and risks that exist in the workplace that can cause losses for companies[3].

According to AS/NZS 4360 Risk Management Standard, risk management is the culture, process, and structures direct towards the effective management of potential opportunities and adverse effects [4].

The first step in the risk management process is to identify workplace hazards or places that are likely to suffer damage[5].

Hazards identification is a process that can be done to recognize all situations or events that have the potential to cause workplace accidents and diseases that may arise in the workplace[6].

Risk is a possibility of an accident or loss at a certain period of time or a certain operating cycle while the level of risk is a multiplication between the frequency and frequency (consequence) of an event that can cause loss, accident, or injury and illness that may arise from exposure to a hazard in the workplace[7].

Risk assessment is part of the activities of the risk management process, which includes the entire process of analyzing risks in the form of activities using information that is available systematically to determine the level of frequency an event might occur and the impact or influence that will arise, while risk evaluation is a process that used to determine the priorities used by risk management by comparing the level of a risk with standards, targets or other criteria predetermined by management[8].

The steps for conducting a risk assessment are[6]: estimates of the frequency or frequency of accidents or occupational illnesses, estimate the severity of the accident, determining the level of risk using a risk matrix. After determining the level of risk, the risk priority scale must make for each potential hazard identified to prepare a risk control plan.

Risk control must be implemented to reduce risk to acceptable limits based on applicable rules, regulations, and standards. In introducing a risk control tool, one must consider whether the risk control tool is applicable and can provide benefits to each workplace

The hierarchy of risk control sequentially starts from elimination, substitution, engineering control,

administrative control, and personal protective equipment.

Material and Method

Data collection at the time of this research was carried out by two methods, namely primary data and secondary data. Primary data such are preliminary observations about the general condition of the company, observation regarding hazard identification, risk assessment and risk control in the production area, and interviews with relevant workforce such as employees in the safety department and safety officer in the production area

Secondary data collection is a general description of the company and data on Occupational Safety and Health. A literature study was also carried out to complete the standard implementation of the identification of potential risk hazards.

Findings

Health and Safety Risk Management start from the identification of potential hazards and risks, which are then assessed to determine the control plan that is appropriate to the level of risk that has been obtaining. The author divides the dangerous areas in making ZK fertilizer into six areas which are discussed in detail one by one as follows

Reactor Unit

Risks that occur from natural gas and diesel fuel are burning or exploding. The risk of explosion certainly has a greater impact than burning. Determining the scale of the measurement of the impact of the risk of explosion is 5 (catastrophic), that is, the impact is very significant or very large on labor or humans (death). But for the opportunity is determined by a scale of 1 (rare) because the possibility of occurrence is very slight or rare (0-1 times occur every year).

The risk level is high, which means that control must be carried out to the ALARP stage or as low as possible. Control that can do is to regularly check the vacuum of the burner chamber or hallway, check line leakage, and administratively perform safety permits correctly.

Determining the scale of the measurement of the impact of fire is 3 (moderate), the moderate impact on labor or humans (injury and unable to work). The probability of a fire occurring in this unit is impossible (2), which is the likelihood that it will be small or occasional The level of risk is the medium and efforts that make at Petrochemicals in addition to equipment maintenance efforts are the availability of fire hydrants, and fire extinguisher is also carried out to cope if a fire occurs.

The risk of inhalation of H_2SO_4 vapor occurs in workers who clean or repair H_2SO_4 tanks. The danger from these chemical vapors is corrosive to the respiratory tract, which is characterized by coughing and shortness of breath. Corrosive effects can also occur in the nasal passages with epistaxis or nosebleeds if workers expose for prolonged, repeated or high concentrations.

Workers can also be inhaled H_2SO_4 vapor when opening the storage tanks, and the worker does not use the mask correctly. Petrochemical has provided masks to every worker, which is a chemical cartridge that can clean gases or vapors by flowing air containing toxic gases or vapors through the cartridge.

Control efforts that can do are the availability of exhaust ventilation to keep the concentration of exposure below the threshold. The provision of eyewash and safety shower in the work area contained H_2SO_4. Other efforts are the use of masks that are correct and appropriate and training of employees for the first countermeasures if there is a risk in the area.

The risk of splashing or splashing of H_2SO_4 can occur in workers working in the area around the tank and leaking piping. This risk has a more immediate effect because it hits the limb directly and can cause burns. For this reason, the first control effort is to carry out routine maintenance of all equipment used to avoid leakage. If a spill occurs, the spill can neutral with a solution of soda or lime before being doused with water.

The process of transporting KCl using bucket elevators and conveyor belts has the risk that workers can be inhaled by KCl dust, exposed to the skin, and exposed to the eye. The control effort that can do is to make engineering efforts by closing the belt conveyor area and providing local exhaust ventilation to keep KCl dust exposure below the threshold. The area must also equip with an eyewash or safety shower. Besides that, another effort is the use of dust counter correctly and correctly. Other risks related to safety are also present in this process including being sandwiched into a conveyor belt. Control efforts that can do are the installation of safety on the tool.

The next process is the reaction between raw materials in the reactor that has the risk of heat, burning, or explosion. Controlling efforts that can do is to check the burner chamber or hall routinely, pre-start a safety review must be carried out, and check the feed ingredients to avoid the inclusion of flammable materials into the reactor. Also, fire protection systems, such as fire hydrants and fire extinguishers, must provide. Related to drinking water also must be considered for workers in the furnace area to avoid destruction and heat stroke.

Ejector Refrigerator

The risk that can occur in this unit is the temperature of heat produced by K_2SO_4 coming out of the furnace with a temperature of 500^0C. Transporting that must do is routine maintenance of ships or pipelines that transport K_2SO_4 before entering the refrigeration unit. The risk of noise can also occur due to engine noise. Repairing with a personal protection device such as earmuffs must be done besides caring for the engine to reduce approval. Petrochemical has implemented this regulation in which every area with more than 25 dB approval is given a safety sign for mandatory use of earmuffs, and every worker equips with the PPE.

Screening and Crusher

At this stage, the most visible risk is the presence of ZK dust due to machines that are not completely closed. Potassium sulfate has the same dangerous properties as potassium chloride, which causes minor irritation. The control is including the availability of exhaust ventilation in the area to keep the air concentration below the threshold value. So, workers must give dust masks, and their use must be appropriate and correct.

Neutralizer

At this stage, there is a process that produces a supporting material, namely sodium carbonate or potassium carbonate, to produce acid-free ZK products. The addition of this product also has advantages caused by dust due to its powder form. The dust of these two chemicals contains properties with potassium chloride or potassium chloride, which cause health effects in the form of minor irritations. Although the impact caused is quite small, of course, repairs must be made to protect workers from dust.

Silo and Bagging Units

ZK fertilizer that has become a finished product is then stored in a silo or temporary tank before the packaging process is carried out. The danger in this area is due to using opened tanks or ZK products coming out of the tank for the packaging process. The packaging process uses a semi-automatic packaging unit that still uses workers to install the machine sewing process. The main danger that arises is that workers can be sewn at any time if the worker is too slow or not concentrating on the work. The control that can do is shift work and rest 10 minutes every 1 hour to work for freelancers

Graphite Cooler, Scrubbing System and HCl Tank

Hydrochloric acid has special properties with sulfuric acid, which functions as a corrosive, so controlling what to do is the same as controlling sulfuric acid chemicals. Workers can be inhaled HCL vapor, which will release into the air in a scrubbing system. Workers can also get the splash or splash hydrochloric acid during the process of loading and unloading into the transport truck. Work at heights that are at risk Workers above if they do not use appropriate protective equipment that is utilizing the entire body.

Providing education related to the hazards that exist in each production process is needed so that workers know the dangers and that there are. If the worker understands, there will be more vigilance from the worker. Training against the use of personal protective equipment must also carry out so workers can use it properly and appropriately.

Conclusion

Based on the identification of hazards that have been carried out, then a risk analysis is carried out using the risk matrix. Petrochemical refers to the Australian Standards / New Zealand Standards 4360 qualitative risk analysis techniques. The risk assessment determines by determining the risk impact criteria and risk opportunities on a scale of 1-5. The highest risk assessment results on ZK production are in the reactor unit, which causes the risk of explosion.

Risk control refers to the principle of the control hierarchy, starting from elimination, substitution, engineering, administration, and personal protective equipment.

Maternal Behavior of Child Malocclusion Dental Treatment in Gayungan Health Center Surabaya

Ananda Firman Putranto, Thalca Hamid[2], Gilang R. Sabdho Wening[3], Dinna Fitria Greisya[4], Amalia Wimarizky[4], Aisyah Marwah[4], Muhammad Faisal[5]

[1]Lecturer, [2]Professor, Department of Orthodontic, Faculty of Dental Medicine Universitas Airlangga Surabaya-Indonesia, [3]Lecturer, [4]Post Graduate Dental Student, [5]Dental Student, Departement of Public Health, Faculty of Dental Medicine Universitas Airlangga, Surabaya-Indonesia

Abstract

Context: based on Gayungan Health Center Surabaya's patient visit data obtained from April-June 2018 primary teeth persistence is the most common dental case, with percentage 42.6% in April, 20.8% in May and 48.6% in June. The most common cause of primary teeth persistence is the absence of successor permanent teeth. It has connection with the physiological process of primary tooth shed and change to permanent teeth, which occurs to the school-age children, and requires more attention from parents to take care of their children's dental health.

Aims: To determine the effect of maternal behavior and sociodemographic factors on child malocclusion dental treatment in area of Gayungan Health Center Surabaya.

Methods and Material: This research is an analytic-observational study. Using instruments in the form of questionnaire that developed from the Theory of Planned Behavior. Results: poor maternal knowledge of dental health may results to not to bring the child to get malocclusion treatment.

Results: poor maternal knowledge of dental health may results to not to bring the child to get malocclusion treatment

Conclusions: perceived control of orthodontic treatment history (perceived control that characterized by history of orthodontic treatment?), maternal's level of knowledge, usage of health insurance, and maternal's perceptions of the child's dental condition have the opportunity to influence the maternal behavior to make dental visit to get malocclusion treatment.

Key-words: *maternal behavior, child malocclusion, Gayungan Health Center, Theory of Planned Behavior*

Introduction

The results of the 2013 Basic Health Research (RISKESDAS), the percentage of people who have dental and mouth problems according to Riskesdas in 2007 and 2013 increased from 23.2% to 25.9%. This can be caused by several factors, one of which is the lack of public knowledge and awareness of the importance of maintaining oral and dental hygiene.[1]

Based on data from the Gayungan Surabaya Health Center, monthly patient visits were obtained from April to June 2018. From these data it can be seen that persistence is the most frequently encountered case at the Puskesmas, with a percentage of 42.6% in April, 30 , 8% in May and 48.6% in June. Based on preliminary survey data conducted on 151 children at SDN Gayungan 1 Surabaya, the highest percentage of persistence was found to be 37%. The second most common problem encountered is caries which is 69.58%. The last problem most frequently encountered was pulp disease and periapical tissue by 28.22%.

Corresponding Author:

E-mail: anandafirman2019@gmail.com

Persistence of deciduous teeth is a condition where deciduous teeth are not has the ability to exfoliate when it's time to exfoliate, but the permanent teeth that will replace the deciduous teeth have erupted[1]. In some cases persistence can cause clinical problems such as periodontitis, deep caries, ankylosis and even malocclusion.[1]

In connection with the physiological process of turning primary teeth into permanent teeth that takes place during school-age children, it requires more attention from parents in the dental and oral health care of their children. Until now, the knowledge that parents have about oral health is still relatively low. Parents do not apply the maintenance of children's dental and oral health properly, a reason that is often cited is because of the lack of access to information about dental and oral health maintenance, parents' busy work, high costs and so forth. Even though the behavior of parents who maintain good dental and oral health of children can affect the growth and development of permanent teeth and children's quality of life.[3]

One model used to predict behavior, including malocclusion treatment behavior is Theory of Planned Behavior , theories of attitude that is widely used in behavior. The Planned Behavior Theory is a prediction of good behavior because it is balanced by the intention to carry out the behavior[4]. In Planned Behavior Theory, the behavior displayed by individuals arises because of the intention to behave. The emergence of intention to behave is determined by three determinants, namely: (1) attitude towards behavior; (2) subjective norms; and (3) perceived perception control.[5]

Based on the survey results and background above, the author's interest arises to examine the influence of maternal sociodemographic and behavioral factors on the behavior of child malocclusion treatment to dentists in the Gayungan Public Health Center in Surabaya. Hypothesis of this research is there are influences on maternal sociodemographic and behavioral factors on the behavior of child malocclusion treatment to dentists in the Gayungan Health Center

Subjects and Methods

This research is an analytic-observational study with a cross sectional study design. The population in this study was the mother of Gayungan I Elementary School students in the Gayungan region, Surabaya city as many as 151 people. Sampling using simple random sampling method. Research subjects were asked questions by questionnaire method to find out the factors that influence the behavior of mothers bringing children to dental and oral health services in the Keputih area, Surabaya City. The questionnaire was developed based on the Theory of Planned Behavior which contains questions that contain closed ended questions. As supporting data, a check on the prevalence of malocclusion in children. Then the data obtained is processed data and results.

Findings

The research data were obtained from epidemiological studies on 18 and 20 August 2018 at SDN Gayungan 1 Surabaya. Data was collected by dental examination and questionnaires for students in grades 1-4 with an age range of 7-12 years at SDN Gayungan 1 Surabaya. The sample of this study was 151 students selected by simple random sampling.

Based on data, there is information that there is no tendency for a relationship between risk factors in academic level with orthodontic visit experience. This is indicated by the p value of $p = 0.078$. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with higher education and the lowest is the risk factor group with primary education

Based on data, there is information that there is no tendency for a relationship between risk factors in job status with orthodontic visit experience. This is indicated by the p value of $p = 0.091$. In the table illustrated, both of risk factor has the same percentage of orthodontic visit experience.

Based on data, there is information that there is tendency for a relationship between risk factors in daily working hour with orthodontic visit experience. This is indicated by the p value of $p = 0.007$. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with scheduled working hour and the lowest is the risk factor group with unscheduled working hour.

Based on data, there is information that there is tendency for a relationship between risk factors in shift working hour with orthodontic visit experience. This is indicated by the p value of $p = 0.003$. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with morning

shift working hour and the lowest is the risk factor group with afternoon shift working hour.

Based on data, there is information that there is tendency for a relationship between risk factors in salaries with orthodontic visit experience. This is indicated by the p value of p = 0.005. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with well paid salaries and the lowest is the risk factor group with under paid salaries.

Based on data, there is information that there is no tendency for a relationship between risk factors in residential with orthodontic visit experience. This is indicated by the p value of p = 0.076. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group in sub-urban residential and the lowest is the risk factor group in urban residential.

Based on data, there is information that there is no tendency for a relationship between risk factors in insurance with orthodontic visit experience. This is indicated by the p value of p = 0.098. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with covered by insurance and the lowest is the risk factor group with uncovered by insurance.

Based on data, there is information that there is tendency for a relationship between risk factors in mother orthodontic treatment experience with orthodontic visit experience. This is indicated by the p value of p = 0.000. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with mother with orthodontic treatment experience and the lowest is the risk factor group with mother wih no orthodontic treatment experience.

Based on data, there is information that there is tendency for a relationship between risk factors in family orthodontic treatment experience with orthodontic visit experience. This is indicated by the p value of p = 0.001. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with family with orthodontic treatment experience and the lowest is the risk factor group with family with no orthodontic treatment experience.

Based on data, there is information that there is tendency for a relationship between risk factors in children orthodontic treatment experience with orthodontic visit experience. This is indicated by the p value of p = 0.000. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with children with no orthodontic treatment experience and the lowest is the risk factor group with children with orthodontic treatment experience.

Based on data, there is information that there is tendency for a relationship between risk factors in dental alignment with orthodontic visit experience. This is indicated by the p value of p = 0.002. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with bad dental alignment and the lowest is the risk factor group with good dental alignment.

Based on data, there is information that there is no tendency for a relationship between risk factors in total children in family with orthodontic visit experience. This is indicated by the p value of p = 0.076. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with total children in family is 1 and the lowest is the risk factor group with total children in family more than 1.

Based on data, there is information that there is tendency for a relationship between risk factors in orthodontic treatment need basic knowledge with orthodontic visit experience. This is indicated by the p value of p = 0.004. In the table illustrated from the results of the highest orthodontic visit experience in the risk factor group with family with good orthodontic treatment need basic knowledge and the lowest is the risk factor group with bad orthodontic treatment need basic knowledge.

Discussion

The Planned Behavior Theory is a prediction of good behavior because it is balanced by the intention to carry out the behavior. In this theory, a behavior is influenced by several variables, namely attitudes that are influenced by the strength of beliefs about the behavior, subjective norms that are influenced by social pressures that motivate individuals to behave, and perceptual controls that take into account ease and difficulty factors in carrying out the behaviour [10]. In this research, it is known that actions are not influenced by intention but are directly influenced by perception control. Based on Theory of Reasoned Action (TRA) that connects beliefs, attitudes, intentions and behavior. Intention is the best predictor of behavior, meaning that if you want to know

what someone will do, the best way is to know that person's intentions. However, one can make judgments based on completely different reasons (not always based on intention).[2]

An important concept in this theory is the focus of attention (salience), which is to consider something that is considered important, namely control of perception. More simply, this theory says that a person will take an action if he views the action positively and if he believes that he can do the action. Knowledge has a direct influence on perceptual control and on behavior. The characteristics that have an influence on perception are the condition of the child's teeth, insurance, history of child stirrup, history of maternal stirrup and family stirrup history.

In this epidemiological study begins with a preliminary study to determine the severity of malocclusion in Gayungan I Public Elementary School Surabaya in the Gayungan Surabaya Public Health Center area by using the Angle classification. The number of research subjects was 151 students from classes I to IV at SDN Gayungan I Surabaya. The severity of malocclusion can be influenced by many things such as parental income, ability to buy services and participation in health insurance.

Based on the results of research and data analysis found that mothers who have insurance and do not have insurance do not visit the dentist. This is because orthodontic treatment is not included in the BPJS dependents and therefore mothers have or do not have insurance must continue to pay orthodontic treatment costs so that there is no difference with mothers who don't have insurance. History is an event that someone has experienced in interacting with their environment. An unfavorable history is soon forgotten, if it is pleasant it will become an imprint in mental emotions and eventually form a positive attitude in his life[9]. Based on the results of research and data analysis, it was found that mothers who had no history of orthodontic treatment did not visit the dentist to treat their malocclusion teeth. That is because there is no encouragement from the nearest party, namely the family to take care because of the low level of knowledge about the dentist.

Based on the results of research and data analysis, it was found that mothers who had children with poor dental conditions as much as 58.3% did not come to the dentist, while mothers who had children with good dental conditions as many as 100% did not visit the dentist. This is caused by the perception of parents who assess the child's dental condition is good, and does not require a visit to the dentist. Based on the results of research and analysis obtained results that mothers with poor knowledge of 73.3% did not visit the dentist while mothers with good knowledge of 53.8% did not visit the dentist. If parents have good knowledge, it will be directly proportional to their behavior. Parents who have high knowledge will show positive behavior in performing dental care, including treatment of malocclusion. A theory revealed that before having a behavior, a person must pass through the stages of awareness, interest, evaluation, trial and adoption[10]. Malocclusion care behavior of children by mothers to dentists based on theory of planned behavior is associated with attitudes, subjective norms, perception control perceptions, intentions and actions of mothers towards pediatric malocclusion treatment to dentists. Attitudes, subjective norms, perception control perception, positive intention will produce positive behavior.

Conclusion

From this study it can be concluded that the perception of perception control with the characteristics of the mother's orthodontic treatment history, the level of maternal knowledge, the use of health insurance, and the mother's perception of the condition of the child's teeth have a chance of influencing the behavior of the mother's visit to perform treatment of children's malocclusion in the dentist.

Analysis of Platelet Counts and Platelet-Derived Growth Factor-Bb Levels in Platelet Rich Plasma Produced with Edta as Anticoagulant in Three Different Centrifugation Methods

Andi Munawirah[1], Tenri Esa[2,3], Uleng bahrun[1,2,4]

[1]Clinical Pathology laboratory, Hasanuddin University Hospital, Makassar, Indonesia, [2]Department of Clinical Pathology, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia, [3]Clinical Pathology laboratory, Siloam Hospital, Makassar, Indonesia, [4]Clinical Pathology laboratory, Wahidin Sudirohusodo Hospital, Makassar, Indonesia

Abstract

Background: *Platelet rich plasma* (PRP) is an autologous product made of whole blood through centrifugation process producing high platelet concentrate in a small volume of plasma. This high platelet concentrate can lead to high growth factor levels that play important roles in the nature of thrombosis, hemostasis and wound healing. PRP has been widely used in clinical setting, however standardized procedure of PRP production has been lacking, mainly the procedure related to duration and speed of centrifugation, and also anticoagulant used.

Aim: To analyze the difference between platelet counts and PDGF-BB levels in PRP produced from various preparation methods (centrifugation speed and duration), using *Ethylenediaminetetraacetic Acid* /EDTA as anticoagulant.

Method: This study used experimental laboratory design, involving 34 healthy volunteers that met inclusion criteria. These subjects were divided into three groups with different centrifugation methods that adopted from previous study.

Results: The platelet counts was found in group 1, 2, and 3 with an increase of, 2,69, 3,69, and 2,53 times from the initial platelet counts respectively and there was significant difference between platelet counts before and after treatment on three groups that used EDTA (p=0,000, p=0,003, and p=0,002 for group 1, 2 and 3 respectively). PDGF-BB levels in this group was also higher than the remaining groups.

Conclusion: The highest platelet counts and PDGF-BB levels was found in PRP with EDTA produced from first spin at 2800 RPM in five minutes, and second spin at 3800 RPM in seven minutes. This study suggests further research on qualitative assessments of platelets and PDGF-BB resulted from various preparation methods (centrifugation and anticoagulant usage).

Keywords: *Platelet, Platelet Derived Growth Factor-BB, Platelet Rich Plasma, centrifugation, Ethylenediaminetetraacetic Acid*

Introduction

Platelets are megakaryocyte cytoplasmic fragments that are formed in the bone marrow and have a diameter of about 1-4 µm. Platelets play an important role in the process of hemostasis and thrombosis.[1] Another function of platelets is to help the wound healing process. Growth factors on platelets can affect chemotaxis, differentiation, proliferation, and synthetic activity of cells, which regulate physiological remodeling and healing. The more growth factors that can reach the wound site, the greater the potential for improving the healing process.[2]

Platelet rich plasma (PRP) is an autologous product that is produced from whole blood through a process of centrifugation to produce high platelet concentrations in low plasma volumes. The number of growth factors contained in PRP can accelerate endothelial, epithelial and epidermal regeneration, stimulates angiogenesis, stimulates collagen synthesis, accelerates soft tissue healing, decreases scar tissue in the skin, accelerates the response of homeostasis to injury, thereby stimulating wound healing.[3]

Until now the process of making PRP has not been standardized. A systematic review by Chahla, Cinque, and Piuzzi[4] involving published research in 2006-2016 found that the existing PRP preparation protocols and PRP compositions used in clinical trials were inconsistent and were not standardized so that they produced different effects. Araki et al.[5] also mentioned that the non-standardization of PRP-making protocols for clinical trials makes the efficacy of PRP still debatable. Therefore, standardization of the PRP manufacturing process is needed to obtain platelet counts and levels of growth factors with certainty.[4,6] This standardization must consider factors that influence the quantity and quality of the PRP, including the number of centrifugation cycles (single or double), speed and length of centrifugation, temperature during the manufacturing process, anticoagulants used, and sampling techniques.[3, 4, 6]

The speed and duration of centrifugation is one of the very varied factors used in the preparation of PRP. The study by Nugraha et al. used 30 treatments employing a range of intervention (speeds and duration) of centrifugation. The study results found that the highest platelet increase was obtained at a speed of 1300 RCF for 5 minutes at the first centrifugation and a speed of 2300 for 7 minutes with a platelet increase of 4.11 times.[7]

The use of anticoagulants is also a very important factor in maintaining the function, integrity, and morphology of platelets. Some researchers argue that the use of Ethylenediaminetetraacetic Acid (EDTA) anticoagulants can damage platelet membranes, and recommend the use of Acid Citrate Dextrose (ACD). However, the study of Araki et al.[5] in 2012 showed that the use of EDTA anticoagulants increased platelet counts and PDGF levels showed higher results compared to the use of ACD anticoagulants. This is because the use of EDTA shows better effectiveness in preventing platelet aggregation compared to the use of ACD.[5] Based on the abovementioned phenomenon, this study aimed to identify the difference between platelet counts and PDGF-BB levels in PRP with different treatments (speed and length of centrifugation) using EDTA as the anticoagulant.

Methodology

(*Research Design, Ethical Aspect, Data Collection and Data Analysis*)

This study used an experimental laboratory research design. The study was conducted from August to September at the Clinical Pathology Laboratory of Hasanuddin University Hospital and at The Research Center of Faculty of Medicine of Hasanuddin University, which both were located in Makassar, South Sulawesi Province, Indonesia. The sample size of this study was determined by employing *Frederer Formula* of experimental laboratory study and it was obtain that the minimum sample per group of intervention was seven (7) subjects. The inclusion criteria for the research were: healthy individuals aged 18-40 years; individuals who had not taken any drugs that can affect platelets such as thrombolytic or Non-Steroid Anti-Inflammatory Drug (NSAID) at least 7 days before blood collection. The study included sample with initial platelet examination results of platelets in between 150,000 / µl and 400,000/ µl, while serum/plasma sample which were indicated jaundice, lipemic or hemolysis were excluded.

Regarding ethical aspects, this study had obtained permission by The Ethical Committee of Health Research, Faculty of Medicine of Hasanuddin University, which issued the Ethical Agreement No. UH19060359. Every volunteer filled and signed an informed consent sheet, and was allocated to each of experimental groups by using *simple random sampling*. After volunteer blood was collected, the blood would be assessed for initial hematology examination. Platelet count from this assessment is the number of platelet cells in blood cells, measured using the Sysmex XE800i® Hematology Analyzer expressed in units of µU/mL. The reference value for platelet counts is 150-400 x 103 / µL. From this initial assessment, platelet counts were obtained and were considered as the platelet counts *pre-intervention*. Subsequently, the blood was processed to produce PRP through different interventions. In details, there are three groups of intervention, any of which was different in speed and time of centrifugation as seen in table 1.

Table 1. Type of interventions included in the study

Intervention groups	1st Centrifugation	2nd Centrifugation	Anticoagulant
I	Speed of 1200 RCF (2700 RPM) in 5 minutes.	Speed of 2000 RCF (3500 RPM) in 6 minutes	EDTA
II	Speed of 1300 RCF (2800 RPM) in 5 minutes	Speed of 2300 RCF (3800 RPM) in 7 minutes	EDTA
III	Speed of 600 RCF (1900 RPM) in 10 minutes	Speed of 2000 RCF (3500 RPM) in selama 5 minutes	EDTA

After the second centrifugation, PRP was obtained and the platelet counts were also examined by using similar hematology examiner. The platelet counts obtained from this examination were considered platelet counts of *post-intervention*. In terms of growth factors measurement, PDGF-BB levels was measured by the Enzyme-Linked Immunosorbent Assay (ELISA) method using the human PDGF-BB ELISA kit (LifeSpan BioScience, Inc., China) and the units expressed in pg/mL. The detection range was 31.25-2000 pg/mL.

Results

The study involved 33 volunteers who met the inclusion criteria. The subjects aged 26-40 years old with an average of 32,88 years old with more female subjects than men, accounting for 24 people (72.7%) as seen in table 2.

Table 2. Sample characteristics

Characteristics	n	Mean±SD	Median (Min-Max)	p value	Ratio
Age (years)	33	32,88±3,69			
Gender Male Female	 9 24				
Platelet Counts (103/µL)					
Group 1 (pre)	11	323,18±51,46		0,000*	2,69
Group 1 (post)	11	868,90±257,84			
Group 2 (pre)	11	313,82±62,28		0,000*	3,69
Group 2 (post)	11	1277,36±835,39			

Cont... **Table 2. Sample characteristics**

Group 3 (pre)	11	346,27±76,57		0,000*	2,53
Group 3 (post)	11	877,09±423,00			
PDGF-BB Levels (pg/mL) Group 1	11	6905,68±3696,58	8271,63 (168,62-12189,67)		
Group 2	11	8330,86±6115,52	6238,44 (676,80-25691,57)		
Group 3	11	5206,75±1574,97	5362,00 (1609,41-7216,84)		

**paired t-test*

Table 2 shows the mean difference in the number of platelets counts (pre and post-treatment) of each group. Using *the paired t-test* it was found that platelet counts were significantly higher in all groups of PRP, compared to the baseline (group 1 (p=0,000), group 2 (p=0.000), and group 3 (p=0.000) respectively). Interestingly, the highest platelet counts was found in group 2, with an increase of 3.69 times from the initial platelet counts.

Table 3 depicts the mean difference of PDGF-BB levels in PRP from all groups of intervention. It is shown that there was no significant difference between PDGF-BB levels in all of the intervention groups. However, the highest PDGF-BB levels was found in group 2.

Table 3. PDGF-BB levels in all groups of intervention

	PDGF-BB Levels (pg/mL)			**p***
	Mean	**SD**	**Median (Min-Max)**	
Group 1	6905,68	3696,58	8271,63 (168,62-12189,67)	0.14
Group 2	8330,86	6115,52	6238,44 (3676,80-25691,57)	
Group 3	5206,75	1574,97	5362,00 (1609,41-7216,84)	

**Kruskal Wallis test*

Discussion

Among PRP produced from three different groups of intervention (centrifugation speed and duration of centrifugation), the highest platelet rise was found in group 2, with an increase in platelets counts as of 3.69 times compared to the baseline. This is in line with the studies of Hans et al. as cited Nugraha et al.,[7] showing the highest increase in platelets with speed and duration similar to the intervention conducted in this study, namely 1300 RCF for the first 5 minutes of centrifugation and 2300 RCF for 7 minutes in the second

centrifugation. Platelet increase in the studies of Hans et al was 4.11 times higher that the initial platelets.[7] The increase in platelet counts in group 2 was also in line with the research by Perez et al.[8] who found that PRP produced from double centrifugation can reach platelet counts three times more even up to five times if 2/3 of the plasma volume is removed.[8]

The benefit of PRP lies in the number of platelets it contains, but more than that can be seen from the level of growth factors released when activated.[9] These growth factors have the highest concentration in platelets and play a very important role in the process of wound healing.[2,10] Among many growth factors, PDGF-BB is one of the most important in the regeneration and healing of wounds or damaged tissue.[9,10]

PDGF-BB levels in the three groups showed no significant difference. The interesting fact from this study is that the mean of platelet counts found in such platelet rich plasma products was not directly proportional to the levels of PDGF-BB after platelet activation. This finding is supported by Sonker and Dubey[11] research that there is no correlation between platelet counts with PDGF-BB levels found, as well as correlations with other growth factors. This is supported by the results of the study of Singh et al who analyzed qualitatively differences in the morphology of platelets in some PRP products. The study found that platelets in EDTA tubes had the worst morphology so that the effect on PRP resulting from EDTA tubes had a low growth factor compared to other tubes.[12]

Platelet activation during the PRP preparation process can occur, which results in the early release of alpha granules which results in the loss of growth factors needed, depending on the preparation method.[11]. In terms of platelet Activation, when platelets are exposed to EDTA, platelets lose their discoid shape to "spiny-spheres" resulting in changes in the membrane surface structure and OCS (Open Canalicular System).[13] This change can cause early activation of PRP platelets in tubes that use EDTA anticoagulants and may result in early PDGF-BB growth factor release. Measurement of PDGF-BB levels is also strongly influenced by its half-life. Some studies report that the half-life of PDGF-BB is around 1.8 hours, [14] while Saik et al.[15] reported that the half-life of PDGF-BB is only about 30 minutes after activation.

Conclusion and Suggestion

This study concluded that there was a significant mean difference between platelet counts of PRP in all groups of intervention compared to the number of platelets in the baseline. The significance was as follow: group 1 (p = 0,000), group 2 (p = 0.000), group 3 (p = 0.000), and the highest platelet counts was found in group 2 in which PRP produced in a method of centrifugation as follow: speed of 1300 RCF (2800 RPM) in 5 minutes for the first centrifugation and speed of 2300 RCF (3800 RPM) in 7 minutes for the second centrifugation, resulting 3.69 times platelets compared to the initial platelets. This study also found that there was no significant difference in terms of PDGF-BB levels between the three groups, but PDGF-BB levels in group two (2) was higher than the other groups regardless. This study suggest further research that can identify qualitatively the function and morphology of platelets contained in PRP that are produced various method of preparation (speed and time of centrifugation). Further research that employ a variety of anticoagulants will also be needed to best understanding the best outcome of PRP products.

Abstract

Introduction: Poor nutritional status is a major nutritional problem in infants and has an impact on growth disorders and is a problem that needs to be addressed seriously, age 6-18 months is a very important period as well as a critical period in the process of growth and development both physically and intellectually. Therefore, every baby at this time must obtain nutritional intake according to their needs. Aim; to prove the relationship between enabling factors and infant nutritional status. **Methods:** type of research used analytical survey with a cross-sectional study approach. This research was carried out in Maccini Sawah Sub-District, Makassar Sub-District, Makassar City. The sample of this study was infants with exhaustive sampling with 62 samples. **Results:** The study found that the age of starting complementary food for breast milk was related to the nutritional status of the baby with a p-value (0,000), the type of complementary foods for breast milk related to the nutritional status of the baby with a p-value (0,015), the frequency of complementary foods for breast milk related to nutritional status with p-value 0.004), and the variation of complementary foods for breast milk administration is related to nutritional status with p-value (0.001).

Conclusion: It was found that there was a strong relationship between age, starting, giving, type, frequency, and variation of complementary feeding with infant nutritional status.

Keywords: *Nutritional Status, Complementary Food*

Introduction

Nutritional status in children is very important for their lives(1), growing and developing into healthy, productive adults who benefit the community, this is an international priority to improve children's nutritional status (2). The World Child Association (UNICEF) and the World Health Organization (WHO) state that good nutrition practices in children include the initiation of early breastfeeding, exclusive breastfeeding ages 0-6 months, the addition of adequate, safe nutrition, and complementary foods according to the breastfeeding period for 1 year (3,4). The prevalence of malnutrition in Indonesia is still high. One potential factor that contributes to the high prevalence of malnutrition is the inappropriate complementary diet and practice of breastfeeding (5).

Malnutrition during breastfeeding, especially the practice of exclusive breast milk for 6 months after birth is a risk factor for infant and child morbidity and mortality that can be corrected by providing complementary food (6). One intervention to prevent a more effective way to reduce 13-15% of child deaths is to apply exclusive breastfeeding supplemented with complementary foods that will prevent 19% of children's deaths (7). The impact during the child learning process is inactivity, intellectual disruption, decreased productivity, and development of social behavior (6).

Improvement of maternal nutrition carried out before and during exclusive breastfeeding is one of the efforts to improve infant nutrition 0-6 months. This problem is very important and needs to be addressed seriously. The age of 6-18 months is a critical period due to malnutrition at the age of under two years, has an impact on decreasing brain development, physical growth, intellectual, and productivity, the impact of malnutrition is largely irreversible. Malnutrition in infants and children occur because of the food given is low in nutrition or energy. Additional food for babies in developing countries generally made of cereals or tubers tends to be powdery. At the age of one year, the proper administration of complementary foods for breast milk is expected to meet the nutritional needs of the baby, but it can also stimulate the baby's eating behavior which is usually liquid and then adapt to the types of porridge and biscuits [8].Premature babies are at high risk and really need adequate nutrition to increase proper growth [9]. The complimentary food program of breast milk is very important to give to babies in overcoming high nutrient deficiencies, based on the description above the authors feel interested in conducting research on the relationship of enabling factors for complementary food for breast milk with the nutritional status of infants. Aim; to prove the relationship between enabling factors and infant nutritional status.

Method

This research was conducted in 2017 with samples in the study, namely infants aged 6-11 months, using exhaustive sampling techniques as many as 62 infants. The type of research used is an analytical survey with the approach cross sectional study. The source of complementary food data is derived from the results of interviews with mothers and caregivers using questionnaires, nutritional status data obtained from weighing the baby's weight using Baby Scale the GEA brand with measurement accuracy of 0.05 Kg to 0.1 Kg followed by calculation of standard deviation using anthropometric methods (WHO Anthro Plus) and referring to the NCHS table. Data analysis using univariate, bivariate and multivariate analysis.

Results

Sample Characteristics:

Table 1 shows a description of the sex of the baby, the age of the baby, the level of education and the type of work the mother has on the case of infant nutritional status. The homogeneity test results between cases of abnormal nutritional status and normal nutritional status in the baby sex obtained a value of p = 0.77, the average age of the baby obtained a value of p = 0.87, the maternal education level obtained a value of p = 0.44 and work mother obtained p value = 0.73.

Factors Enabling Complementary Foods : relationship between enabling factors and infant nutritional status is presented in Table 2. Based on table 2, age suitability in supplementary feeding does not have a significant relationship with infant nutritional status, age suitability in the process of providing complementary food for breast milk in cases of abnormal nutritional status is more 37.5 ± 22.7 compared with age suitability in the case of normal nutritional status 62.5 ± 77.3. Chi-square test between the two variables obtained p value = 0.23. There is a significant relationship between the consistency of the type of complementary food given with the nutritional status of the baby, where the consistency in the case of abnormal nutritional status is more 55.6 ± 14.3 compared to the consistency of food types in the case of normal nutritional status 44.3 ± 85.7 . The chi-square test between the two variables obtained p = 0.001. there is a significant relationship between the frequency of complementary feeding and the nutritional status of infants, where the frequency in cases of abnormal nutritional status is more 45.2 ± 19.4 compared to the frequency in cases of normal nutritional status 54.8 ± 80.6. The chi-square test between the two variables obtained a value of p = 0.03.

Table 2. Correlation Factors Enabling Food Complementary foods for breast milk with Infant Nutritional Status

Multivariate Analysis: Requirements fulfilled in multivariate analysis, namely all variables related to p value <0.05 entered which are then analyzed include variable consistency the type of complementary food, the frequency of supplementary feeding, using the statistical ratio method to see the riskier and most related variables. It is indicated that the consistency of food types and frequency can improve nutritional status (Table 3).

Table 3. Multiple Logistic Regression

Variable	B	Sig (p-value)	Exp (B)	OR	95% CI

Discussion

Giving Age Suitability: Provision of complementary foods for breast milk should be started at the age of 6 months because the digestive system of the body has started to be perfect and ready to receive food other than breast milk. When babies enter the age of 6 months and above, some nutritional elements such as protein, carbohydrates and some vitamins and minerals contained in breast milk are no longer sufficient. Based on the results of this study that the suitability of the age of the first time giving is not related to nutritional status. Important findings in this study, supplementary feeding was first given in the first 6 months, but more were given formula milk at the age of under 6 months. Similarly, Lakshman's research is more focused and specific in the provision of bottled milk and obesogenic foods [10].

The results of this study are in contrast to Alzaheb's research in Saudi Arabia (2015) stating that the practice of giving is very useful as a complement to infant malnutrition obtained from breast milk [11]. The introduction of earlier complementary foods before a six-month-old baby has a negative effect as a substitute for breast milk and can stop breastfeeding practices at an early stage [12,13]. Baby's nutritional needs increase along with increasing age and reduced breast milk production and duration of breastfeeding [11]. In the first year of life, the method of feeding babies on time is one way of intervention carried out in the community to support optimal baby growth and development [14].

Consistency of Food Types: important finding in this research is that the type of complementary food has an influence on the nutritional status of infants and children. Research found and explained more specifically the age conformity with the type of quality food consumed has an influence on the absorption of nutrients that have an impact on nutritional status. Various kinds of complementary foods for breast milk are given to each day according to age development. Complementary foods cannot match breast milk in its nutritional content, enzymes, hormones, and immunological substances and antibodies. Modified food ingredients or mixtures of various types of food ingredients that are specially made as complementary foods for breast milk so that these foods contain complete nutrients needed by babies because this period includes the period of growth.

This study is not in line with stating that the average food supplement studied cannot meet the needs of calcium, iron and zinc every day as a nutritional source of complementary foods for infants in developing countries [15]. This study is in line with that conducted in Tanzania in the 6-23 month age group (2010) which states that the main determinant that can affect a baby's health, development and growth is the proper consumption of complementary foods [16]. Giving baby food is a modification factor that can reduce mortality and disability caused by preterm birth [17]. The growth and development of premature babies is in accordance with types of food such as breast milk or fortified formula [18].

Giving Frequency: Quantity of complementary food is very important for brain growth and intelligence development. The fulfillment of infant and family nutrition is closely related to the frequency of food provided. The frequency of breastfeeding must be adjusted to the age and ability to produce breast milk. Increasing age needs are also increasing and the ability to produce breast milk decreases so that the frequency of supplementary food supply is increasing and added some types of snack foods.

The frequency of eating children is also influenced by several factors such as the family's socio-economic status and the number of family members. According to

the theory, the proportion of adults more than children in the family can result in less food availability for children. Low-income communities increase the attention and focus on breastfeeding and supplementary food for babies [2].The results of this study are similar to research conducted in Krakow and Silesia (2014) stating that regular feeding is very important, adequate daily nutrient intake is useful for physical development and and it is necessary to introduce healthy eating patterns for health during the growth period [19]. Perceptions about breast milk and feeding given complementary breast milk can be improved by health education [14].

Conclusion

Provision of complementary breast milk food is related to the nutritional status of the baby. The consistency of food types has a greater relationship with nutritional status compared to frequency. The age match for starting complementary foods performed by mothers starts at 6 months of age. The practice of giving complementary foods for breast milk is influenced by the mother's knowledge which has an impact on the mother's skills in serving complementary foods.

Significant Statement

Results of this study found that babies need complementary food as they age to cover malnutrition from the intake of breast milk for growth and development. The practice of providing good complementary foods can be seen from the suitability and consistency in providing complementary foods caused by knowledge of maternal nutrition.

Funding Sources: Used during this study were sourced from personal funds.

Determinant of Premature Rupture of Membrane in Indonesia (Secondary Data Analysis of Idhs 2017)

Chintya Elittasari[1], Sudijanto Kamso[2]

[1]Magister Program of Public Health, Faculty of Public Health, [2]Biostatistics and Population Studies Department, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Premature rupture of membranes (PRoM) constitutes 5-10% of the causes of complications in full-term pregnancy and 30% of preterm pregnancy. In Indonesia, according to Riskesdas data in 2018, ProM is the biggest delivery complication of 5.6% in women aged 10 - 54 years. Based on IDHS 2017 data, it is the third biggest complication during labor with a percentage of 16.1%, which increased from 14.9% in 2012. Premature rupture of membranes risks troubled mothers and fetuses that potentially cause maternal and perinatal morbidity and mortality. Little is known about the determinants of PRoM in Indonesia. Therefore, this study was conducted to identify the determinants of the ProM in Indonesia. This research method using logistic regression analysis to individual data IDHS 2017 by enclosing 4 independent variables: age, parity, amount of iron tablet consumption, and smoking habit to predict the incidence of PRoM. Sample of this study counted 12,340 people. Based on multivariate analysis found that consumption of Fe tablets is significantly related to PRoM by Odds Ratio (OR) 0.7 (95% CI: 0.631 - 0.777) controled by maternal age. The conclusion of this study is mothers who consume ≥ 90 iron tablets during pregnancy are 0.7 times low risk of experiencing PRoM than mothers who consume iron tablets < 90 tablets during pregnancy.

Keywords : *PRoM ; Amount of Iron Tablet Consumption; Indonesia*

Introduction

Premature rupture of membranes (PRoM) is a condition of membranes rupture before the beginning of labour, where cervical dilatation of less than 3 cm in primipara and less than 5 cm in multiparas. PRoM which occurs before 37 weeks pregnancy is called premature PRoM, whereas occurs after 37 weeks PRoM itself[(1)]. PRoM constitutes 5-10% of the causes of complications in full-term pregnancy and 30% of preterm pregnancy[(2)]. According to Riskesdas 2018, PRoM is the biggest delivery complication of 5,6%[(3)]. Based on IDHS data 2017, ProM is the third biggest complication during labour of 16.1%[(4)]. PRoM is risked causing maternal and perinatal morbidity and mortality. A serious complication of ProM includes retained placenta and haemorrhage requiring dilatation and curettage (12%), maternal sepsis (0,8%), and maternal death (0,14%). So that, ProM is a high risk of caesarean deliveries [(1)]. Based on IDHS data 2017 the number of caesarean deliveries caused by PRoM decreased to 18.8% from 22.8% in 2012. Meanwhile, cases of within a month old infant mortality increased to 19% from the previous 14%[(4,5)].

The risk factors associated with PRoM include maternal age, parity, infection, anemia, multiple pregnancies, increased intrauterine pressure, and genetic factor[(6)]. According to a case-control study conducted at Tugurejo Regional General Hospital mentioning the relationship between fetal malposition, maternal age, parity, history of PRoM, maternal employment status, anemia status, and active-passive smoking with the incidence of PRoM and there was no association between multiple pregnancies, genetic factor, previous recurrent miscarriage with PRoM[(7).] Another case-control study where conducted in Mekele City Tigray about risk factors of PRoM in public hospital mention abortion histories, caesarean delivery histories, previous PRoM, and abnormal vaginal discharge significantly associated with KPD, and previous PRoM to be the strongest risk factor for PRoM[(1)].

Determinants identification of PRoM is needed to predict and prevent the occurrence of PRoM to prevent complications. Previous PRoM determinant researches have been conducted in various regions and different times of health services, yet secondary data utilization thoroughly in Indonesia still less in amount. Therefore, this study aims to fill those gap by identifying the determinants of PRoM using Indonesian Demographic and Health Survey (IDHS) data.

Method

This study used secondary data from IDHS 2017 and designed in cross-sectional. Populations of this study are all interviewed women who had live births in the 5 years before the survey. The total sample of this study were 12,340 people. Univariate, bivariate (crosstabs), and multivariate analysis (logistic regression) were performed in this study. Statistical analyses were performed using SPSS version 21.0; p <0.05 indicated statistical significance. Inclusion criteria of this study were women who gave birth to the last child within 5 years before the survey and experienced complications at the time of delivery. The dependent variable of this study was PRoM and the independent variables were maternal age, parity, amount of iron tablet consumption and smoking.

Tabel 1. Bivariate Analysis result for significant variables (ρ ≤ 0,25) of determinant PRoM in Indonesia, 2017

Variable	PRoM				OR	P Value
	No		Yes			
	n = 8400	%	n = 3940	%		
Age (years)						
No risk (20 – 35)	6051	49	2956	24	0,857	0,006
High Risk (< 20 & > 35)	2349	19	984	8		
Parity						
< 2	2822	22,9	1341	10,9	0,980	0,686
≥ 2	5578	45,2	2599	20		
Amount of iron tablets consumption						
≥ 90	4253	34,5	2342	18,9	0,700	0,000
< 90	4147	33,6	1598	13		
Smoking						
No	8275	67,1	3885	31,5	0,936	0,729
Yes	125	1	55	0,4		

**Bivariat analysis was using crosstabs*

The bivariate analysis showed that maternal age (*p-value*: 0.006) and total consumption of iron tablets (*p-value*: 0,000) are related to PRoM. Meanwhile, parity (*p-value*: 0.686), and smoking (*p-value*: 0.729) were not related to PRoM. Based on the table above there are 2 variables that have *p-value* <0.25, there are age and amount of consumption of iron tablets. So both of them required to enter multivariate modelling.

Tabel 2. Multivariate analysis Determinant of PRoM in Indonesia, 2017

Variable	Model 1	Model 2
	cOR (95% CI)	aOR (95% CI)
Age	0,851 (0,761, 0,952)**	0,858 (0,769 - 0,958)**
Parity	1,032 (0,933, 1,120)	-
Amount of iron tablets consumption	0,700 (0,631, 0,777)***	0,700 (0,631 - 0,777)***
Smoking	0,940 (0,645, 1,370)	-

OR, odds ratio; CI, confidence interval.
*p<0,05, **p<0,01, ***p<0,001

The multivariate analysis showed that iron tablet consumption was the dominant factor causing PRoM, with OR 0.7 (95% CI: 0.631 - 0.777) after controlled by maternal age variable. This study in line with the case-control study conducted at Wates Regional Hospital in 2015 that stated there is an association of anemia in pregnancy with ProM with *p-value* = 0.036 and OR 2,524 (95% CI: 1.042 - 6.113) pregnant women with anemia have a risk 2, 524 times higher experiencing PRoM[8].

Discussion

Study Limitation

This study used secondary data of IDHS 2017, because of limitation the research data, anemia variable which in theory is related to PRoM incidences in this study was replaced by the amount of iron tablet consumption during pregnancy. Researchers also could not control results from interviews with respondents due to the possibility of recall bias that caused by respondents memories related to research variables.

Relationship Between Maternal Age and ProM

The results of this study showed that there is a relationship between maternal age and PRoM incidences. Similarly with past research conducted by Berkowits (in Hussain, 2012) which found that mothers with 30 years old or older significantly increased occurrence of preterm rupture of membrane (pPROM)[9]. Larger studies by retrospective cohort study conducted by Lucke and Brown (2007) show that increasing maternal age is significantly associated with a high risk of pPROM occurrence after being controlled by variables of race, parity, diabetes, chronic hypertension and maternal smoking status[10]. However, in contradiction with past research conducted at Yogyakarta Hospital by Rahayu (2018) which states that there is no relationship between maternal age, parity, gestational age, uterine over distance with PRoM occurence[11].

Based on literature optimal maternal reproduction age is between 20-35 years old. Under or above those ages will increase pregnancy and deliveries risked. Maternal age will affect the reproductive organs by decreasing their ability and elasticity in pregnancies. The older maternal ages, both of environmental stress and oxidative stress are increased that induce biological damage of cell at molecular level[12], which affects decreasing of vitamin C level on blood circulation[13] so that inhibit collagen formation and stability of collagen cross-link[12]. Structure alteration, amount of cells and collagen catabolism cause rupture of membranes[14].

Relationship Between Parity and ProM

This study showed that there is no significant relationship between parity and occurrence of PRoM. In line with research conducted in Gowa, suggesting that the amount of parity is not a risk factor of premature rupture of membranes even though both of ≤ 1 and> 3 parity are 1.5 times higher risked than maternal parity of 2-3 (OR = 1.5 95%CI: 0, 91 - 2.48)[15]. Contradiction with results research was conducted at Bahteramas Hospital which states that maternal parity is a risk factor of PRoM occurrence (OR = 9.94 95%CI: 4.44 - 22.24) [16]. This may be due to more respondents with ≥ 2 parity who didn't experience PRoM compared to those who experienced it.

In multiparous and grand multiparous women the risk of PRoM occurrence will increase. Multiparous women have intrinsic weakness of the uterus caused by cervical trauma due to previous deliveries that caused increasing of uterine motility, hanging bellies and decreasing of cervical flexibility that causes premature cervical dilatation and ends with PRoM. Furthermore, in multiparous and grand multiparous women occurred cervical damage tissue which consists more of nerve fibres than connective tissue that allows the basic muscles of the uterus to stretch[17].

Relationship Between Amount Of Maternal Iron Tablet and ProM

Overall, 50% of anemia was caused by iron deficiency[18]. 75 - 95% of anemia during pregnancy were caused by iron deficiency[19]. A study conducted in Singapore in 2019 mentioned that almost three-quarters of pregnant women in Singapore experienced an iron deficiency in the early third trimester of pregnancy[20]. During pregnancy, women lose 680 mg iron. Iron necessity enhances 3 times higher during pregnancy (> 4 mg per day). Pregnant women are fragile to iron deficiency due to an increased need for iron during pregnancy for the expansion of erythrocytes, plasma volume, fetal, and placental growth. Based on research at Karang Asem primary health services in Samarinda 2015-2017, it was found that there was a significant relationship between the distribution of Fe tablets and anemia. Pregnant women who are not compliant with consuming Fe tablets are 1.3 times more likely to develop anemia than pregnant women who are compliant in consuming Fe tablets[21].

This study showed that mother who consumes ≥ 90 iron tablets during pregnancy is 0.7 times low risk of experiencing PRoM than mothers who consume iron tablets < 90 tablets during pregnancy. Same with the retrospective cohort study conducted in Purworejo Regency stated that anemia in the second trimester has been shown to increase of PRoM occurrence. Mothers with anemia are at risk of PRoM 2.11 (RR = 2.11; 95% CI: 1.06 - 3.44) times higher than mothers without anemia after controlled by iron tablet consumption[22]. Another case-control study in Singaraja Bali found, mothers with anemia at risk of experiencing PRoM 3.59 (OR = 3.59; 95% CI = 1.82-7.09) times higher than mothers who were not anemic after controlled by parity variable[23].

Anemia during pregnancy causes weakness of amnion membranes due to lack of tissue oxygenation caused by reduction of haemoglobin mass[6]. So that mother with anemia during pregnancy is risky to PRoM occurrences

Relationship Between Smoking and ProM

This study showed that smoking is not associated with PRoM. Same with a case-control study at General Hospital of Mekele Tigray City, December 2015 - June 2016 that Stated there was no significant relationship between smoking and PRoM(1). Contradiction with research was conducted in Southern Ethiopia, that smoking is a positive predictor of premature rupture of membranes, women with a history of smoking during pregnancy are at risk of experiencing PRoM of 17 times higher than non-smoking mothers (AOR; 17,053, 95% CI [2,145, 135,6])[24]. The differences might be due to the low prevalence of smoking respondents.

Based on the literature, smoking lead to decrease of collagen and protein in membranes by increasing cadmium levels and decreasing the ability of CU2 + to synthesize collagen in mesenchymal cells of aminion[25]. Also, nicotine causes arteriolar constriction leading to uterine decidua ischemia[26] so affecting the integrity of the membrane that leads PRoM.

Conclussion

Amount of iron tablets consumption is a dominant factor of PRoM occurrence after controlled by maternal age variables. Based on these results, the researcher recommends consumption of ≥ 90 iron tablets to all pregnant women during pregnancy to prevent the occurrence of PRoM, that can cause maternal and perinatal morbidity and mortality. The results of this study are expected to encourage the effectiveness of distribution and compliance of the iron tablets consumption for pregnant women.

Abstract

The performance of midwives in Balangan District in neonatal health services from 2016 to 2018 did not reach the Minimum Service Standard target for newborn services based on Ministry of Health Decree of the Republic of Indonesia No 43 in 2016. The low performance of midwives in neonatal health services in Balangan District has an important position on the performance of the Balangan District Health Office to reduce IMR. This research aim to analyze the factors that influence the performance of midwives in neonatal health services in Balangan District. The research using an observational analytic study with a cross sectional study design. Sample of 70 midwives took using a purposive sampling method. The results of this research showed that there was no influence between education (p=0.230) and compensation (p=0.193) on the performance of midwives in neonatal health services, while the length of service could not be analyzed. The most dominant factor influencing was training (p=0.000) with Exp (B) of 23.33 with a confidence level of 95%.

***Keywords**: education, compensation, training, tenure, performance*

Introduction

Neonatal health service by midwife is one way to reduce infant mortality in the neonatal period. Neonatal visits that do not meet the standards or behavior of non-neonatal visits statistically have a large risk of neonatal death. Neonatal visits are conducted to reduce the risk of neonates who are vulnerable to health problems.

Based on maternal and child health reports of Balangan District Health Office, neonatal health services in 2016 amounted to 78.77% consisting of coverage of the first neonate visit at 6-48 hours after birth according to the standard of only 87.83%, complete neonatal visits according to the standard only amounted to 84.42% and handling neonatal complications was only 64.05%. In 2017 neonatal health services only amounted to 69% consisting of coverage of first neonate visits according to the standard of only 84.45%, complete neonatal visits according to the standard was only 79.66% and handling neonatal complications was only 42.5%, whereas in 2018 neonatal health services by 75.57% consisting of coverage of first neonate visits according to the standard of only 83.2%, complete neonatal visits according to the standard of only 79.3% and handling of neonatal complications only by 64.2% .[1] The performance of midwives in neonatal health services from 2016 to 2018 did not reach the Minimum Service Standard (SPM) target for newborn services based on the Ministry of Health Decree of the Republic of Indonesia Number 43 of 2016. The low performance of midwives in neonatal health services in Balangan District has an important position on the performance of the Balangan District Health Office to reduce IMR. Neonatal health services have a statistically significant relationship with neonatal deaths in Indonesia. The low performance of midwives in neonatal health services is influenced by various

factors.[2] Individual factors influence performance consisting of abilities and skills, cultural background and demographics. Demographic factors can influence performance.[3] Factors that affect employee performance are influenced by a number of factors including motivation, ability, knowledge, expertise, education, experience, training, interests, personality attitudes, physical conditions and physiological needs, social needs and egoistic needs.[4] Factors that influence performance are internal factors, namely individual characteristics such as years of service and attitudes towards tasks and external factors.[5]

Materials and Method

This research used observational analytic study, with the time approach of data collection using a cross-sectional design. This study uses secondary data analysis from monthly and annual reports on maternal and child health for neonatal health services and nominative list data of civil servant for the Balangan District Health Office especially for midwives, midwife training data and compensation data. The population in this study were all midwives in the village and public health center who had civil servants (PNS) status and at least one year of service in their working area, totaling 92 people out of 116 midwives. The sample of this study was 70 people in which was obtained purposively based on the proportion of the total population who met the criteria for inclusion and then for each public health center. Analysis of the data used is descriptive and statistical analysis of the test chi-square and test logistic regression doubled the significance level of 95%.

Findings and Discussion

Table 1. Frequency Distribution of Education, Compensation, Training, and Working Period of Midwives in The Neonatal Health Service on Balangan District

Variable	Frequency	Percentage (%)
Education		
Diploma IV/ Bachelor of Midwifery	5	7.1
Diploma III Midwifery	65	92.9
Compensation

The influence of education on the performance of midwives in neonatal health services

Based on the results of the fisher's exact test obtained p-value of 0.230 (p>0.05) which means midwife education has no influence on the performance of midwives in neonatal health services. The level of education of midwives have an important role on the performance of midwives in neonatal health services. It should have the competence to midwife consisting of a set of knowledge, skills and attitudes acquired through higher education and continuing education. The higher level of midwife education can be interpreted to have more knowledge, skills, and high ability in neonatal health services. At least midwives who have diploma/bachelor education so that midwives who have good knowledge, skills and abilities about neonatal health services according to the standard are also very little that have an impact on the low performance of midwives in neonatal health services. The level of employee performance will greatly depend on the ability of the employee itself such as the level of education, knowledge, experience where the higher the level of ability is likely to have higher performance as well.[6] The results of this study are in line with research Purwaningsih et al. (2015) which states that there is no significant relationship between education and the implementation of neonatal visits by midwives.[7]

The influence of compensation on the performance of midwives in neonatal health services

Based on the results of the fisher's exact test obtained p-value of 0.193 (p>0.05), which means midwife compensation has no influence on the performance of

midwives in neonatal health services. The compensation distribution to midwives in the form of additional allowances for a certain amount of money each month does not affect the performance of midwives in neonatal health services because the compensation provided is not proportional. Compensation provided is not based on the performance of midwives in providing neonatal health services but based on consideration of the workplace and rank of midwife. If compensation were given to midwives in accordance with the performance made by midwives to neonatal health services will improve the performance of midwives.[8] This study is in line with Rachmawati (2014) which states that the performance of village midwives in performing a neonatal visit is increasingly poor due to the poor perception of village midwives towards a compensation system and in line with Merita (2016) that midwives receive financial compensation that is not appropriate, will encourage dissatisfaction in him, so that in doing work will be less good.[9,10]

The influence of training on the performance of midwives in neonatal health services

Based on the results of the fisher's exact test obtained p-value of 0.000 ($p<0.05$), which means that the complete training that midwives have participated in affects the performance of midwives in neonatal health services neonates with PR of 17.778, which means midwives who have completed training have a 18 times greater chance to perform well. Training is a systematic and planned effort so that employees get additional capabilities so that the quality of work gets better.[11] Training is a process that teaches certain knowledge and expertise, and attitudes so that employees become more skilled and able carry out their responsibilities better, in accordance with the standards.[12]

To improve the performance of midwives in neonatal health services, midwives should take a comprehensive series of technical training related to neonatal health services such as midwifery competency training, APN, asphyxia management and LBW management and MTBS. The full technical training followed by a midwife obstetrics can improve the competence to midwife. Factors that influence employee performance is influenced by training.[4] This study is in line with research Suryaningtyas et al (2014) which states there was an influence between training and midwife performance in neonatal visits and supported by Purwaningsih et al (2015) research that training related to handling infants to midwives through asphyxia management training, LBW management, MTBS/MTBM can affect neonatal services in accordance with the service standards that should be provided to neonates.[7,8] There were differences in performance between midwives who have been trained and midwives who have not been trained on MTBM in terms of quality aspects of midwife performance in the management of neonatal visits.[13]

The influence of working period on the performance of midwives in neonatal health services

The chi square statistical test results with a 95% confidence level in the cross table 3 x 2, showed that all expected counts were 2 cells (33.3%) less than 5. So the p-value could not be analyzed so the working period can not be concluded whether or not influence to the performance of midwives in neonatal health services.

Multivariate Analysis

Table 3. Final Models of Multivariate Logistic Regression

Independent Variable	p-value	PR
Training	0.000	23.33
Compensation	0.999	0.000

The results of multivariate analysis showed that the independent variables included in the model were training and compensation and the variable with the strongest influence was the training variable. Variable training is the most dominant variables that affect the performance of midwives in neonatal health services with exponential beta (Exp. B) 23.33. This revealed that training was the most influential variable after gaining control of the education, compensation and training variables. Training is a process that teaches certain knowledge and expertise, and attitudes so that employees are more skilled and able to carry out their responsibilities better, in accordance with standards.[12]

To improve the quality of midwives in accordance with service, non-formal education is developed through training programs, internships, seminars or workshops held in collaboration with professional organizations, the ministry of health, health service facilities, international institutions and others.[14]

The main objectives of the training are to improve performance and upgrade expertise so that it is in line with technological progress. Training is specific, practical and immediate. Specific means that training is related to the field of work being carried out. Practical and immediate means those that have been trained can be put into practice.[15] Training that has been followed by someone who is related to their field of work will be able to affect skills and mentality and will increase their confidence in their abilities, this will positively affect the performance of midwives.[13]

Conclusion

Education has no influence on the performance of midwives in neonatal health services. Compensation has no influence on the performance of midwives in neonatal health services. Training has an influence on the performance of midwives in neonatal health services. The tenure cannot be concluded whether there is no influence or not. The most influential factor on the performance of midwives in neonatal health services in Balangan District is the training.

Ethical Clearance

Before conducting the data retrieval, the researchers conducted a decent test of ethics conducted at the Faculty of Medicine, Lambung Mangkurat University to determine that this study has met the feasibility. Information on an ethical test that the study is eligible to continue. The feasibility of the research was conducted to protect the human rights and security of research subjects.

Source Funding: This study was done by self-funding from the authors.

Conflict of Interest: The authors declare that they have no conflict interests.

Identification of Risk Factors in Cervical Cancer

Dewi Rosita Hendriana[1], Dwi Susanti[2], Budi Prasentyo[3], Punky Mulawardhana[3]

[1] Student at Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [2] Lecturer at Department of public health and preventive medicine, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [3] Lecturer at Department of obstetrics and gynaecology, General Hospital of dr. Soetomo, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background: The prevalence of cervical cancer was about 528.000 cases with mortality rate of 266.000 around the world and was ranked first as the most female genital cancers in developing countries. One of the factors suspected to be the cause of cervical cancer is the long-term use of hormonal contraception. This research aimed to identify risk factors of cervical cancer in General Hospital of Dr. Soetomo Surabaya.

Method: Analytical retrospective study with case control method was used in this study. Information about contraception use and other risk factors was obtained from personal interview. Sampling was done by *accidental sampling technique*. The sample meeting the inclusion and exclusion criteria was divided into two groups, namely 124 case groups and 124 control groups. The data was analysed using *chi-square test* and logistic regression.

Result: Patient using oral contraception for more than 5 years showed the results of OR 5.410; 95% CI = 2.403-12.176 and patient using *Intrauterine Device* (IUD) for more than 5 years had OR 3.016; 95% CI = 1.122-8.113. While prim-gravida age under 20 years was OR 2.621; 95% CI = 1.465-4.688. This data was contrast if compared with female having prim-gravida age above 20 years.

Discussion: Theoretically, the use of the hormonal contraception causes cancer. It is correlated with existence of oestrogen and progestin hormone's role to increase the protein expression of E6 and E7 from HPV. Moreover, young age is indicated to have the condition of intimal genital cells which are immature, so that if pregnancy occurs, it can induce a cell damage and facilitates genital infection.

Conclusion: The use of oral combination contraception and non-hormonal contraception more than 5 years and prim-gravida age is under 20 years are dominant factors influencing cervical cancers in woman

Keywords: *Cervical Cancer, Risk Factors, Oral Contraception, Prim-gravida*

Introduction

Cervical cancer is a global problem experienced by almost all countries in the world, particularly in developing countries. Nowadays, there are more than one million women in this world predicted to suffer cervical cancer.[1] The prevalence of it in 2012 was 528.000 cases and around 266.000 cases ended in death (7.5%) for woman. The mortality caused by cancer almost reached nine-tenth (87%) and occurred in less-developed region.[2]

The main cause of cervical cancer is often associated with infection with human papilloma virus (HPV). Human papillomavirus is a double-stranded group of viral DNA, known to be the most potential HPV types 16 and 18 to cause 70% of cervical cancer cases.[1] Various factors have been reported to be risk factors, including

Corresponding Author:

Email: dewirosita1305@gmail.com

early sexual intercourse[3], sex multi-partner, smoking[4], and long-term use of hormonal contraception contributes as risk factors of cervical cancer's cause.[5]

The use of hormonal contraception is thought to cause changes in gene expression and increase the incidence of cervical cancer. A study has shown that women using oral hormonal contraception for five years or more have a greater risk of cervical cancer. [6] A systematic review notes that as many as 28 studies, including 12.531 women with cervical cancer showed that the risk of cervical cancer decreased after stopping use of oral hormonal contraception.[7] In 2005, the International Agency for Research on Cancer decided oral hormonal contraception was included in the carcinogenic classification for human uterine cervix based on clinical results, in vitro studies and experimental animals.[2]

Method

This study aimed to identify the risk factors in cervical cancer as an option to prevent this disease. An analytical retrospective study using case control design was used. Period of research was from January to October 2017.

Sample

The accidental sampling technique was used to take the sample. The total sample of the study was 252 respondents divided into two groups consisting of case and control group samples, which each amounted to 126 respondents per group. Case sample was a cervical cancer patient in the One-Stop Oncology Clinic (POSA) Dr. Soetomo. Meanwhile, the control sample was a no-cancer patient in the Gynaecology Clinic Dr. Soetomo with a number of 1:1 from the total of cases' sample.

Research Instrument and Data Analysis

Research instruments included: Data on medical records of female patients with cervical cancer in General Hospital Dr. Soetomo, informed consent and questionnaire. Data analysis used bivariate technical of chi-square test and multivariate technical of logistic regression multivariate. Statistical analysis was found to be significant if the number of p-values reached about <0.05. The data collected was processed by using SPSS program version 17. (SPSS.Inc. Chicago, IL)

Result

Distribution of Respondents Demographic

The average age in the control and case group was 47 and 52 years, with the main occupation as a housewife. Respondents, as farmers, were found more in the case group of 20 respondents (16.3%), whereas the control group were 5 respondents (4.1%). The most common type of contraception used in the case group was the combined oral pill (OCC) as many as 49 (39.5%) respondents and in the control group as many as 40 (33.1%) respondents chosen not to use contraception. (Table 1)

Results of Bivariate Analysis of Factors Affecting the Incident of Cervical Cancer

The most chosen type of contraception in the case group is OCC contraception. All contraception groups were analysed using a bivariate test and showed a p-value of 0.004 (p-value <0.05) which means that there is an influence of the use of contraception on cervical cancer events. (Table 2)

The first age to have sex in the most cases group at age <20 years was 70 respondents (56.5%) while in the control group the most had sex at the age >20 years were 79 respondents (65.3%). Bivariate test results on this variable showed a p-value of 0.001 (p-value <0.05) which meant that there was a correlation between the age of first sex with cervical cancer with an OR value of 2.438 (95% CI = 1.456-4.084).

The number of sex partners showed a difference between the case group and the control group. A total of 30 respondents (24.2%) in the case group had sex partners >1 person, whereas in the control group only 21 respondents (17.4%). Bivariate test in this variable showed a p-value of 0.189 (p-value>0.05) which meant that there was no influence between the number of partners in sex with the incidence of cervical cancer.

Bivariate testing on age of prim-gravida variable shows a p-value of 0.002 (p-value <0.05) which meant that there was an influence between the age of first pregnancy and the incidence of cervical cancer in women. Parity data of respondents in the study showed as many as 107 (86.3%) respondents in the case group had a history of parity > 2 times during life while, in the control group showed as many as 82 respondents (67.7%).

Multivariate Analysis' Result of Factors Affecting the Occurrence of Cervical Cancer

Non-hormonal contraception users >5 years have an odds ratio (OR) of 3.016 (95% CI=1.122-8.113), meaning that women who use non-hormonal contraception >5 years tend to have a risk of contracting cervical cancer 3.016 times greater than women who do not use contraception. (Table 3)

The prim-gravida age has a significant value with OR 2.621 (95% CI=1.465-4.688), meaning that women who are first pregnant less than 20 years tend to have a risk of cervical cancer 2.621 times greater than women who are pregnant when they are above 20 years old.

Based on the final results of the analysis, it can be seen that the value of Negelkerke R square is 0.165, which means that the variability of the dependent variable that can be explained by the independent variable is 16.5%, while the remaining 83.5% is explained by other variables outside the model research.

Table 1. Distribution of Respondents Demographic

Variable	**Case (n=124)**	**Control (n=121)**
	n (%)	n (%)
Age		
20-29 Years	0 (0%)	11 (9%)
30-39 Years	8 (6.4%)	22 (18%)

Discussion

A study conducted in 2014 showed 75% of cervical cancer sufferers were contraceptive users with the most choices, namely hormonal contraception as much as 69.2%.[8] The choice of contraception found 80 case group respondents chose to use hormonal contraception compared to 40 control group respondents who mostly chose not to use contraception. Cervical cancer patients who use oral contraception as much as 26.67%, injection contraception as much as 25.71%, IUD contraception as much as 20.95% and implant contraception as much as 3.81%.[9]

The use of contraception is often associated with the incidence of cervical cancer, specifically the use of hormonal contraception.[10] The mechanism that occurs theoretically is the role of the hormones oestrogen and / progestin to increase the expression of E6 and E7 proteins from HPV. The functions of E6 and E7 proteins themselves as degradation of tumour suppressor genes p53 and pRb.[11] The duration of contraception is often a factor in increasing the risk of cervical cancer. Risk factors will continue to increase with the length of time of exposure to hormonal contraception.[7] The effect is very weak, however, it can become stronger as the duration of use increases.[4]

There was a correlation between the age of first sexual intercourse and the incidence of cervical cancer with the results of bivariate analysis p-value = 0.001 (p<0.05). Women with the age of first sexual intercourse <20 years had an increased risk of cervical cancer by 1.75 when compared with women who have first sexual intercourse at age >20 years (95% CI=1.01-3.03). [12]

The number of sex partners is also a risk factor for cervical cancer. Cervical cancer is closely related to HPV infection. HPV is a virus that can be transmitted

through sexual intercourse whether vaginal, anal, or oral sex. The bivariate test showed the number of sex partners did not show a significant correlation to the incidence of cervical cancer with p-value = 0.189 (p>0.05).

Prim-gravida occurring in too young age is also a risk for cervical cancer. This is proved by the results of bivariate analysis that have been carried out showing a correlation between the age of first pregnancy <20 years and the incidence of cervical cancer with p-value = 0.002 (p <0.05). Most cervical cancer sufferers experience prim-gravida at the age of ≤ 18 years as many as 51 people (57.3%), whereas cervical cancer patients for those > 18 years were 38 people (42.7%).[13] Other studies conducted at Sanglah Hospital Denpasar, Bali, showed the highest incidence of cervical cancer in the 2-4 parity group of 33 people (68.8%).[14]

The variables having a significant effect on response variables were the use of OCC>5 years which meant that women who use OCC>5 years tended to have a risk of contracting cervical cancer 5.410 times greater compared to women who do not use OCC. Women using oral contraceptives for >5 years were more at risk of suffering from cervical cancer 4.17 times compared to those using oral contraceptives for less than five years or having never used oral contraceptives.[15, 16]

The use of non-hormonal contraception, the IUD, indicates meaningfulness in this study. The use of non-hormonal contraception (IUD)>5 years had an OR value of 3.016 (95% CI = 1,122-8,113) which means that women using an IUD>5 years have a risk of 3.016 times greater occurrence of cervical cancer than women who do not use contraception. Women using an IUD have a 12.7 times greater risk of cervical cancer than women who have never used an IUD before.[17]

The analysis result of the variable age for the first time pregnant showed that prim-gravida women aged under 20 years were likely to have a risk of cervical cancer 2.621 times greater than women aged over 20 years. This can be caused because pregnancy at a young age has the condition of cells in the internal genitalia of women are still too young, so that if pregnancy occurs can cause a cell damage and facilitate the occurrence of genital infections.[18] Women having prim-gravida age <20 years have a risk of 2.1 times affected by cervical cancer compared to women who are pregnant at the age of> 20-25 years (95% CI = 1.20-3.67).[12, 19]

Conclusion

The use of OCC and non-hormonal contraception for more than 5 years and the age of prim-gravida less than 20 years are two dominant factors that influenced the risk factor of cervical cancer in women.

Risk Factors of Hypoxemia in Children With Pneumonia

Eko Wahyudi[1], Tutwuri Handayani[1], Retno Asih Setyoningrum[2]

[1]Resident, [2]Lecturer, Department of Child Health, Faculty of Medicine, Universitas Airlangga

Abstract

Objective To evaluate the risk factors of hypoxemia in children with pneumonia.

Methods A retrospective study was conducted for children aged 2 months until 5 years old with pneumonia who were hospitalized from 2015 to 2016 at Dr. Soetomo Hospital. We evaluated comorbidities as risk factors of hypoxemia in children with pneumonia. Hypoxemia was defined as the arterial partial pressure of oxygen below 80 mmHg recorded from arterial blood gas analysis. We used the chi-square test and logistic regression presented as adjusted odds ratio (OR) and 95% confidence interval (95% CI), two tail test with $p<0.05$.

Result One hundred and ninety-six children with pneumonia enrolled in this study, with 62.2 % were male and 75.5% aged 2-12 months old. Hypoxemia was mostly found in children between 2 until 12 months old (OR 2.012, 95% CI 1.000 to 4.046, $p=0.048$). Univariate analysis revealed sex and almost all comorbidities (malnutrition, down syndrome, neurological disorder, encephalitis, HIV infection, and congenital heart disease) were not risking factors of hypoxemia in children with pneumonia. Logistic regression revealed anemia and severity of pneumonia based on WHO criteria as a risk factor of hypoxemia. Anemia occurred in 89.3% with hypoxemia (adjusted OR 4.984, 95% CI 2.239 to 11.097, $p<0.001$). Hypoxemia occurred in 93.9% of children with severe pneumonia (the OR 6.313, 95% CI 1.418 to 28.106, $p=0.016$).

Conclusion Anemia and severity of pneumonia were risk factors of hypoxemia in children with pneumonia, aged 2 months until 5 years old.

Keywords**:** *children with pneumonia, hypoxemia, risk factor, arterial blood gas analysis, severe pneumonia*

Introduction

Pneumonia is a leading killer of children. More than 2 million children under 5 years old die from pneumonia each year, almost 20% of under 5 deaths worldwide.[1] In 2010, there were almost 4 million new cases of pneumonia in children 0-4 years old in Indonesia. 11.5% of cases were severe and 4.2% severe cases led to death.[2] The etiology of pneumonia can be viral or bacterial. A cohort study in two hospitals in Semarang, Indonesia was found the most common causative agents were Influenza virus (18%), *Klebsiella pneumoniae* (14%), and *Streptococcus pneumoniae* (13%).[3] A study found that age under 4 months or hypoxia (oxygen saturation < 85 percent) were risk factors for mortality in children with pneumonia. The children who had either of the risk factors were 5.6 times more likely to die than children without the factors.[4] To reduce mortality, predictive factors need to be addressed with more attention. Since the decrease in oxygen saturation is an important factor, this research is aimed to find risk factors of hypoxemia in children with pneumonia.

Materials and Method

A retrospective study was performed at the pediatric ward at Dr. Soetomo Hospital. The subjects were children aged 2 months until 5 years old hospitalized

with pneumonia from January 2015 until December 2016. Pneumonia was defined by WHO criteria fast breathing of at least 50 breaths per minute in a child aged 2-11 months and at least 40 breaths per minute in a child aged 1-5 years and also chest indrawing.

Age, gender, and clinical presentations were recorded. The severity of pneumonia was based on WHO criteria which are a cough or difficulty breathing with at least oxygen saturation below 90% or severe respiratory distress or one of the danger sign (inability to drink, reduced level of consciousness, convulsions). Comorbidities as risk factors of hypoxemia were evaluated from clinical, laboratory and radiology data. Complete blood count and blood-gas analysis were performed on admission. Hypoxemia was defined as the arterial partial pressure of oxygen below 80 mmHg recorded from arterial blood gas analysis.

Chi-square test and logistic regression were performed using SPSS. Adjusted odds ratio (OR) were presented using 95% confidence interval and two-tail test. *P*-value of <0.05 was considered significant. This study was approved by The Ethical Committee of Faculty of Medicine Universitas Airlangga – Dr. Soetomo Hospital.

Results

196 patients were enrolled in this study. Patients' age ranged from 2-56 months, with 75.5% being 2-12 months old. 62.2 % of patients were male (Table 1). Apparently, hypoxemia was very common from our patients. From all the pneumonia patients, 144 children (73.5%) had hypoxemia from the blood gas analysis. We found that mostly hypoxemic patients were in the age group 2-12 months old.

We analyzed several comorbidities in the subjects (Table 2). Comorbidities were common among the patients. Most patients with comorbidities were more likely to have hypoxemia, except malnutrition and congenital heart disease. From univariate analysis using chi-square, anemia (OR 5.193; 95% CI 2.358-11.43) and severe pneumonia (OR 6.858; 95% CI 1.580-29.77) were significant risk factors for hypoxemia.

The risk factors significant during univariate analysis were entered into a multivariate model using logistic regression. We found that anemia (adjusted OR 4.984; 95% CI 2.239-11.097) and severe pneumonia (adjusted OR 6.313; 95% CI 1.418-28.106) continued to be associated with hypoxemia (Table 3).

Anemia occurred in 84 patients (42,9%). 89.3% children with anemia had hypoxemia. Most children (41.8%) had moderate anemia (Hb=7-10). 20.4% patients had mild anemia, while only 1.5% patients had severe anemia (Hb<7). Severe pneumonia occurred in 33 patients (16.8%), yet 93.9% of them had hypoxemia.

Discussion

Most of the patients were in the age range of 2-12 months old. This result was similar to a 2009 study in Taiwan where children aged younger than 1-year-old had the highest incidence of pneumonia.[5] The hypothesis was that in this age group, viral etiology is greater. However, pneumococcal/lobar pneumonia was greater in children aged 2-5 years old, due to higher pneumococcus colonization rate in kindergarteners. Another study also found that community-acquired pneumonia was higher in children aged under 2 years than in those aged 2-6 years.[6] Almost two-thirds of our patients were male. Some studies also had more male child with pneumonia than female, usually around 60% male and the rest female.[7,8]

Malnourished children in our study were less likely to have hypoxemia than children without malnutrition. This finding was different from what a study in Bangladesh which found more children with hypoxemia had malnutrition, although it was not significantly related.[9] The case fatality rate, however, was still higher in malnourished children due to late recognition of pneumonia, immunodeficiency, comorbidities such as diarrhea, and delayed health-seeking behavior.

From our finding, children with Down syndrome, neurological disorder, and encephalitis was more vulnerable to hypoxemia, even though they were not significantly related. Children with neurologic disorder such as cerebral palsy, developmental delay, Down syndrome, epilepsy, and other diseases were more commonly hypoxic than children with other non-neurological underlying conditions or without underlying conditions. Children with neurological disorders also were more likely to be admitted to ICU.[10]

Hypoxemia occurred in all of the patients with HIV infection, but HIV status was not significantly related to hypoxemia. HIV exposed children had higher rates of treatment failure and in-hospital mortality than HIV-unexposed children. But, the same study found no

significant differences in hypoxia and WHO disease severity by HIV exposure status.[11]

34.2% of the children in this study had congenital heart disease (CHD). However, the proportions of hypoxemia were higher in children without CHD. The prevalence of CHD was higher than a study in Nigeria with the prevalence of 11.6%.[12]

We found that anemia was a significant risk factor for hypoxemia. A study found that anemic children were four times more susceptible to develop pneumonia compared with non-anemic children.[13] Anemia caused erythrocytes' inability to provide adequate oxygen to the body's tissues.[14]

Furthermore, iron deficiency made it easier to contract acute lower respiratory tract infection. Alveolar macrophages may be difficult to obtain iron from red blood cell metabolism in iron deficiency states.[15]

One study found that cyanosis was higher in children with iron deficiency anemia.[16] Anemia also was associated with severe acute lower respiratory infection in another study.[17] It is reasonable that early and accurate diagnosis of iron deficiency anemia in children and supplementation iron can reduce the incidence and severity of pneumonia in children.

Severe pneumonia also was significantly related to hypoxemia. This consolidated that blood oxygenation remained an essential factor for evaluating pneumonia severity and need for hospitalization. Risk of death in children with hypoxemia was 1.4 to 4.6 times higher than in those without hypoxemia.[18] Oxygen administration is essential in treating severe pneumonia, with the recommendation of giving by nasal cannulae.

Conclusion

From the multivariate analysis, we found anemia (adjusted OR 4.984; 95% CI 2.239-11.097) and severity of pneumonia (adjusted OR 6.313; 95% CI 1.418-28.106) were risk factors of hypoxemia in children with pneumonia, aged 2 months until 5 years old. Early diagnosis and management of risk factors associated with hypoxemia can help reduce mortality in cases of pneumonia in children.

Table 1. Characteristic of Pneumonia Patients at Pediatric Ward of Dr. Soetomo Hospital from January 2015-December 2016

Comorbidities	Patients n (%)	Hypoxemia proportions in children with comorbidity	Hypoxemia proportions in children without comorbidity	OR (95% CI)	p
Malnutrition	83 (42.3)	71.1	75.2	0.810 (0.428-1.533)	0.517
Down syndrome	13 (6.63)	84.6	72.7	2.068 (0.443-9.658)	0.346
Neurological disorder	26 (13.3)	76.9	72.9	1.237 (0.467-3.272)	0.668
Encephalitis	7 (3.6)	85.7	73	2.217 (0.261-18.87)	0.455
HIV infection	5 (2.6)	100	72.8	1.374 (1.260-1.499)	0.173
Congenital heart disease	67 (34.2)	70.2	75.2	0.775 (0.401-1.498)	0.448
Anemia	84 (42.9)	89.3	61.6	5.193 (2.358-11.43)	0.000
Severe pneumonia	33 (16.9)	93.9	69.3	6.858 (1.580-29.77)	0.003

Table 2. Univariate Analysis of Comorbidities in Pneumonia Patients at Pediatric Ward of Dr. Soetomo Hospital from January 2015-December 2016

Table 3. Multivariate Analysis of Risk Factors for Hypoxemia

Risk factors	Adjusted OR (95% CI)	p
Anemia	4.984 (2.239-11.097)	<0.001
Severe pneumonia	6.313 (1.418-28.106)	0.016

Frequently Seen Advertising to Negative Body Images Arising in Adolescents in East Java

Faizatur Rohmi[1], Hardiyanto[1], Sekarini[1], Ronal Surya Aditya[1]

[1]Lecturer, Sekolah Tinggi Ilmu Kesehatan Kepanjen

Abstract

Background: Mass media has a very important role in the life of millennial society today, this is because the mass media is one of the communication media as well as educational media which are the main choice for information sources for the community. Poor perceptions of body image have proven that it can have consequences that can damage health. Even body image is an important aspect of mental health, self-esteem and well-being.

Methode : This study was used a cross-sectional method. The sampling technique in this study was used Random Sampling with a total of 90 students. This research was conducted in Malang. Data collection procedures in this study used the Multidimensional Body-Self Relations Questionnaire-Appearance Scale (MBRSQ-AS) body image questionnaire and the modification of the Stress Level Questionnaire.

Result : This study shows that 70 respondents (77,8%) of the total 90 respondents still had a Advertising beauty products. Spearman correlation value of - 0.430 shows a correlation with moderate strength and a negative correlation direction which means there is an inverse relationship between body image with Ads that are often seen

Conclussion : Advertising of beauty products affects the body image of teenagers. This is likely caused by the mass media ads which is often seen by adolescents. So teenagers are want to look like in the ads that are displayed

Keywords: *Advertising, Body Images, Adolescents*

Background

Mass media has a very important role in the life of millennial society today, this is because the mass media is one of the communication media as well as educational media which are the main choice for getting information sources for the community[1]. Advertising is one type of mass media that is much favored by the public[2]. On a daily basis, the average public is exposed to various types of advertisements and even these advertisements are able to become one of the lifestyle inspirations for the community at large. On the other hand this ad is considered something important to display because it is related to economic and social growth issues. So it is not uncommon for advertisers to make some manipulations to convince the public to imitate, idolize or even use as advertised[3].

Adolescence is a transition from children to adulthood. At this time they tend to be emotionally unstable and often feel insecure, making it easier to convince what has been advertised. Moreover, during adolescence, physical appearance is often a symbol of beauty and feminism as well as the confidence to be able to appeal to the opposite sex. Adolescents who are generally young women are often targeted targets for advertising. The existence of characteristics like the one above that has been inherent in most young women in particular, serve as a reason for advertisers to always display proportional beauty and body features as one of the attractions in these advertisements[3].

Corresponding author:
Ronal Surya aditya
Kepanjen STIKes
Email: Suryaronal@gmail.com

Based on the results of research that has been done mentioned that more than 50% of young women assume that their peers have problems that are not good with their body image[4]. Nearly one-third and half of young women are afraid and worried about their appearance and weight gain or getting fat so often they go on an excessive diet5.

Poor perceptions of body image have proven that it can have consequences that can damage health. Even body image is an important aspect of mental health, self-esteem and well-being. In several studies that have been carried out mention that the media always depicts an ideal body image and this is often a factor that causes someone to be like what is advertised so that not infrequently many young women who do ways that tend to be extreme even some teenage girls especially until they arise against eating disorders5.

Methode

This study was used a cross-sectional method. The sampling technique in this study was used a Random Sampling System with a total sample of 90 students. This research was conducted in Malang.

Ads that are often seen Advertising beauty products Idol figure advertisement Total	 70 20 90	 77,8 % 22,2 % 100 %

Data collection in this study used the Multidimensional Body-Self Relations Questionnaire-Appearance Scale (MBRSQ-AS) body image questionnaire and the modification of the Stress Level Questionnaire which refers to the theory of Distress and Eustress Hans Selye which refers to body image. The questionnaire was then given and filled out by students who were willing to become respondents and had fulfilled the inclusion and exclusion criteria. After all data has been collected and checked for completeness then a data analysis is performed.

Result

Table 1 Characteristics of respondents by age, advertisements viewed, and indicators on body image in Malang Regency.

Characteristics of Respondents	**Freq**	**(%)**
Age 15 years 16 years 17 years 18 years Total	 11 33 23 23 90	 12,1 % 36,7 % 25,6 % 25,6 % 100 %
Body image Indicator Appearance Evaluation Appearance Orientation Satisfaction with Body Parts Anxiety becomes Fat Categorization of body size Total question	 Number of question 7 12 9 4 2 34	 % 20,4 % 38,2 % 25,7 % 10,2 % 5,5 % 100 %

Table 2 Distribution of body image type in Malang Regency.

No	**Body image**	**Frek**	**(%)**
1	Positive body image	47	52,2%
2	Negative body image	43	47,8%
	Total	90	100%

Table 2 shows that 47 respondents (52.2%) of the total 90 respondents still had a negative body image.

Table 3 Distribution of add frequently seen.

Ads that are often seen		
Advertising beauty products	70	77,8 %
Idol figure advertisement	20	22,2 %
Total	**90**	**100 %**

Table 3 shows that 70 respondents (77,8%) of the total 90 respondents still had a Advertising beauty products.

Table 4 Spearman's Rho Test Results Relationship of Body Image with Ads that are often seen

		Ads that are often seen
Body image	R	- 0,430
	P	0,000
	N	90

Table 4 shows that the Spearman's Rho test obtained a p-value of 0,000 <a (0.05) and a Spearman correlation value of - 0.430 shows a correlation with sufficient strength and a negative correlation direction which means there is an inverse relationship between body image with Ads that are often seen.

Discussion

The results of this study highlight the effects of advertising on the body image of teenage girls, aged between 17 and 19 years at vocational high school studying in Sumberpucung District, Malang Regency. This study focuses on body image owned by teenage girls due to the influence of beauty advertisements. The source of these advertisements comes from the mass media that are seen everyday by them. These sources include Instagram, television, youtube which are very popular among teenagers at the vocational high school. The specific hypothesis of this study is that there will be a negative correlation between exposure to beauty advertisements and body image in adolescent girls, which means that more media exposure is used as an ideal beauty concept, so their body image is more likely to be negative[5].

This research is supported by other studies which which states that the negative feelings they have about their bodies are due to the large contribution of beauty advertisements that they often see[6]. The exposure of advertisements that are often see by them is able to become socio-cultural values or to be a certain understanding of the ideal body concept[5]. Similar research states that the body image they possess is one of the reflection aspects of a person's mental health, self-esteem, and well-being[7].

Research on 135 children found that the desire to have a thin body shape is often found around the age of 13 years old. This relates to the mindset or perception of their parents, especially their mothers, because at the age of adolescence they tend to fulfill their own need, especially in terms of appearance [8]. Another study also revealed that 59% of young women want a thinner body than young men. As many as 42% of girls have wanted their bodies to be thinner. Data colected on 785 women from various ethnic backgrounds was found that only one of these tests showed that black and Hispanic women did not have ideal skinny internalization compared to white women. Indeed, they concluded that socio-cultural factors might now have the same effect in all ethnic groups [9]the number of maternal mortality in Balangan in 2014 there were 294.3/100,000 live births. One of the efforts to decrease MMR through antenatal class pregnancy, right election for the delivery assistance and optimize the program through the role of midwife. This study used qualitative method. Population is the midwife in the working area of Health Office Balangan District and informant is 13 midwife coordinator. The research instrument is indepth interviews guide. Data were analyzed qualitative (interview transcript. The similarity of ethnic groups was also found when they concluded that while white women were slightly more dissatisfied with body image than other ethnic groups, the difference was very small and might indicate that body image problems were not the only the problem[10].

Based on previous research, it was stated that ethnic or racial differences also triggered the emergence of perceptions about the ideal body concept of a relatively thin body. In a study using in-depth interviews with 49 white women and 11 black women it was found that women from the black race tended to have a different perspective on the effects of beauty advertisements compared to women who had white skin[11]. White respondents indicated that the desire to appear as shown in advertisements to have a thin body was relatively high, and black respondents were more likely to criticize the appearance of a model with a thin body shape and they said that black men wanted women who had bodies that were not too thin [12].

Actually it has also been recognized that the concept of body image always changes from generation to generation. Around the 1950s the ideal body indicator is if you have a curved body with a small waist. But in this era changed that the ideal body is considered a thin body condition. One study found that 94% of women's magazine covers were depicted with images of ideal thin bodies. Adolescent perceptions, especially young women about advertising, locus of control and self-efficacy are related to eating habits and body image [13]. Based on the results of research that has been done it is mentioned that young women who have a realistic perception of body image and eating habits tend to have a higher internal locus of control and a higher level of self-efficacy [14]such as the provision and delivery of Methadone (as legal drugs. Vice versa, women who are satisfied with their weight tend to have a positive appearance evaluation as part of their body image[15]

Another Research states that young girls with white skin who are often exposed to beauty advertisements

such as fashion magazines report having a higher level of body dissatisfaction[16]. And they also found that young girls with blacks showed that they did not compare themselves to the images in advertisements or even just wanted to look like them because they assumed that beauty was not a white and thin problem[17].

Conclusion

Advertising of beauty products affects the body image of teenagers. this is supported by the mass media which is often seen by adolescents. so teenagers are affected to be like the ads that are displayed

Conflict of Interest Statement : None

Teachers Perspectives and Practices of Assessment in Health Education in Primary School

Faiznur Maisya Annur Sani[1], Azali Rahmat[2], Gunathevan a/l Elumalai3 & Ali Md Nadzalan4

[1]PhD Candidate, [2]Associate Professor, [3]Associate Professor, [4] Senior Lecturer, Faculty of Sports Science and Coaching, Universiti Pendidikan Sultan Idris, Malaysia

Abstract

Health Education is one of the core subjects studied in primary and secondary schools in Malaysia. However, assessment through Health Education is not widely used among teachers as there is no standardized assessment to test the level of students understanding. This study was conducted to determine the perspectives and practices of assessment among Health Education teachers. 40 Health Education teachers from 5 schools in Bukit Mertajam, Pulau Pinang were involved in this study. A set of questionnaires were used as a research instrument containing 37 items using Likert scale. The reliability value of the instrument is $\alpha = 0.80$. Data were analysed using Statistical Package for the Social Science (SPSS) software version 23.0. Results showed all the teachers are only at 'Agree' and 'Undecided levels for all the perspectives items about assessment that have been given. The component item for types and forms of assessment component showed the highest percentage of 37.5% and 20% teachers are at 'agree' level with mean value of 3.30. Meanwhile, as for the frequency of assessment practices results showed all the items were rated only at 'Sometimes' and 'Frequently'. No significant difference was found in the mean item level between male and female teacher for both agreement and frequency item. The overall mean of assessment items is at a 'agree' and 'sometimes' level of 3.45 and 3.74 respectively. Results demonstrate the effectiveness of assessment activities involvement teachers in developing their knowledge in classroom assessment.

Keywords: *perspectives, practices, assessment, health, education.*

Introduction

Assessment is defined as 'the process of gathering, recording, interpreting, using and reporting information about students' progress and achievements in developing knowledge, skills and attitudes[1]. Assessment has become the medium to acknowledge children's achievement and understanding in schools[2]. There two types of assessment which involves a variety of practices including Assessment for Learning and Assessment of Learning which is formative and summative techniques[3,4]. Formative assessment is frequent interactive assessment of student progress to identify learning needs and feedback teaching skills appropriately. While summative assessment is an appraisal learning at the end of every sub unit to compares student knowledge or skills against standards[5].

Assessment is well known as main part of the teaching and learning cycle in and health education context[6]. Traditionally, health education assessment has focused on testing student knowledge through examination task to help assess what a student gain form their learning process of understanding of health related concepts, their ability to demonstrate health skills, and ability to apply conceptual learning and skills in ways to improve their personal health.

Health education context can, however, provide assessment challenge for educators in order to set academic standard or learning targets, indicating what students understand an applied as a result of instruction. These includes the difficulties of assessing learning in the affective and psychomotor component which their very nature and fleeting[7,8]. According to schools

Azali Rahmat
Associate Professor, Faculty of Sports Science and Coaching, Universiti Pendidikan Sultan Idris, Malaysia, Email: azali@fsskj.upsi.edu.my

today relay 100 percent on the cognitive component in making assessment through the mid-year and final year examination[9]. However, the teachers should not sort their students in rank but to access student work over time and provide descriptive feedback for them to improve and succeed.

Therefore, an effective classroom assessment should occur including variety of methods, providing student achievement records and descriptive feedback to the student. It is necessary that the student noted the objectivity of learning and the assessment criteria to work toward proficiency with their teachers. Both teachers and students will take their responsibility for learning and teaching skills to improve their instruction.

This study aimed to examine the perspective and practices implemented by the Health Education teachers in primary schools. The classroom assessment practices questionnaire will detect all the agreement perspectives and practices the teachers applied during their teaching process. The results of this study are great importance to all the educators in improving their knowledge in applying their teaching skills for accessing student.

Methodology

Participants

In this study, researchers have selected Health Education teachers who have option in Physical Education and Health Education for their qualification. There were 40 Health Education teachers selected as samples in this study. They have been teaching for three (3) years and above in primary school.

Instrument

Classroom assessment questionnaires[10] was used to access perspective and practices of the implementation in assessment. The item of the questionnaire consists of; Item 1 – Alignment, Item 2 – Belief in Assessment, Item 3 - Types and Forms of Assessment, Item 4 - Assessment Management and Item 5 - Creativity and Innovation.

The criteria used in the Classroom Assessment Practices for assessing teacher's perspectives and practices in assessment are the percentage agreement and frequency level. The perspectives level of agreement and frequency used in the Classroom Assessment Practices Questionnaires are; 1 – Strongly disagree, 2 – Disagree, 3 – Undecided, 4 – Agree and 5 – Strongly disagree. The level of frequency is determined by the following; 1 – Never, 2 – Seldom, 3 – Sometimes, 4 – Frequently and 5 – Always.

Data collection

A total of five (5) teachers from among the teachers of the school selected have been appointed to assess and implement the instruments. All the sample were assessed in their perception and practices during the teaching process.

Statistical Analysis

Descriptive statistics were used to obtain participants background and mean score. Independent t-test was used to compare the mean score between male and female among the teachers selected. All statistical analysis was done by using Statistical Package for the Social Science (SPSS) software, version 23 (IBM, USA).

Result and Discussion

This study was conducted on the Health Education teachers in primary schools which represents the whole district of Bukit Mertajam, Pulau Pinang. Here's a detail of the demographic background for this study. Table 1 showed the percentage distribution of students by gender. A total of 20 (50%) male teachers and 20 (50%) female teachers were involved in this study.

Table 1. Percentage distribution of teachers by gender and program followed

Gender	N	(%)
Male	20	50
Female	20	50

For the level of agreement classroom assessment practices among the teachers during the assessment, it was found that the teacher perspective the most are only at a "undecided" and "agree" level. For types and forms of assessment component at least 20% of the teachers are at "agree" level and 37.5% of the teachers are at "undecided" level with a mean value of 3.30 in item 22. While the alignment component in item 1 showed the highest percentage of "agree" level that are 52.5% of all the teachers while 12.5% teachers are at "undecided level with mean value of 4.23. The overall mean of classroom assessment agreement is at "agree" level of 3.45.

For the level of frequency classroom assessment practices among the teachers during the assessment, it was found that the teacher frequency in practicing assessment the most are only at a "sometimes" and "frequently" level. For types and forms of assessment component at least 40% of the teachers are at "sometimes" level and 5% of the teachers are at "frequently" level with a mean value of 3.30 in item 22. While the alignment component in item 1 showed the highest percentage of "frequently" level that are 52.5% of all the teachers while 25% teachers are at "sometimes" level with mean value of 4.23. The overall mean of classroom assessment agreement is at "sometimes" level of 3.74.

Table 1 showed the difference in the level of agreement of classroom assessment practices component between male and female teachers. Analysis showed that the value of t (38) = 0.209, p= .087 is insignificant. There was no significant differences in mean agreement level between male and female teachers (M = 101.45, SD = 15.26), with male students (M = 102.60, SD =19.30).

Table 1. Mean Differences in Teachers Agreement Level using Classroom Assessment Practices between Sex.

Gender	**N**	**Mean**	**SD**	**F**	**Sig**	**t**	**df**
Male	20	102.60	19.30	3.08	.087	0.209	38
Female	20	101.45	15.26			0.209	36.07

Table 2 showed the difference in the level of frequency of classroom assessment practices component between male and female teachers. Analysis showed that the value of t (38) = 0.555, p= .159 is insignificant. There was no significant differences in mean frequency level between male and female teachers (M = 113.00, SD = 26.53), with male students (M = 118.15, SD =31.89).

Table 2. Mean Differences in Teachers Frequency Level using Classroom Assessment Practices between Sex.

Gender	N	Mean	SD	F	Sig	t	df
Male	20	118.15	31.89	2.06	.159	0.555	38
Female	20	113.00	26.53			0.555	36.78

Conclusion

The classroom assessment practice component relates to the quality of teaching and learning process in physical and health education and impacted positively on teachers' and learners' perceptions of this subject[1]. Findings of this study demonstrated the benefits for teachers to improve the implementation of assessment in classroom such as Health Education Teachers in enhancing their knowledge in classroom assessment and teaching skills in line with the aspiration of the National Education Philosophy.

Correlations among Age, Parity, and Contraception Using with Pap smear Results in Medan Sumtera Sumatera

Fatwa Imelda[1], Diah Lestari Nasution[1]

[1]Universitas Sumatera Utara, Faculty of Nursing, Medan, Sumatera Utara, Indonesia

Abstract

Objects: to determine correlations among age, parity, and contraception using pap smear results.

Methods: the study was a correlative descriptive. The independent variables are age, parity, and contraception using, while the dependent variable the result of pap smear examination. The samples were 60 respondents. Data were collected using a questionnaire and analysis using the Chi-Square test at an error rate of 0.05.

Results: there was no significant correlation between age and the result of a pap smear examination ($p>0.734$). There was no significant correlation between parity and the result of a pap smear examination ($p>0.204$). There was a correlation between contraception using and the results of pap smear examination $p<0.004$.

Conclusion: it is expected that health workers can improve education and health promotion about cervical cancer prevention by holding seminars or examinations of cervical cancer detection by doing pap smears, and women who have done pap smears with normal results can have repeat pap smears a year later, and abnormal pap smears can repeat. Pap smear again performed 6 months after the previous pap smear.

Keywords: *Age; Parity; Using contraception; Pap smear; Cervical cancer*

Introduction

Cervical cancer becomes a problem for women in Indonesia. Cervical cancer causes the second death in developing countries with reproductive age. In Indonesia, there are 15,000 new cases with 8,000 deaths annually. This cancer is the most common in Indonesian women. It is estimated that one woman dies every hour [(1)].

To reduce the morbidity and mortality of cervical cancer prevention efforts need to be made, which consists of several stages, namely: 1. Primary prevention carried out at this stage is the promotion, education, and vaccination of HPV (Human Papilloma Virus). 2. Secondary prevention is early detection. 3. Tertiary Prevention is a treatment for cases that are found in early detection and prevent complications and early death [(2)].

Early detection in Indonesia is done by pap smear examination, colposcopy, kinescope, cervicography, spectroscopy, automated screening cytology, liquid-based cytology/thin prep, HPV tests, and visual acetate acid inspection (IVA) inspection methods. Pap smear test coverage is estimated to be less than 5%. To fulfill this, an alternative Pap smear test with IVA is sought, which is expected to get wider coverage [(3)].

Pap smear is a simple and quick examination to determine the presence of abnormal cells in the cervix by taking a smear of cells in the cervix and then examined under a microscope to see whether or not the cells are abnormal. This examination can be done at any time, except during menstruation. All women who have had sexual intercourse are encouraged to have regular Pap smears, once a year/at least 3 years. For women who have gone through menopause, a Pap smear can be done until the age of 65 years [(4)].

The risk factors of cervical cancer are women who have been active in sex from a very early age, contraception using, and having children more than five.

Method

This study used a cross-sectional study design with a study design by measuring or observing research subjects at the same time or once, measurement of independent variables (age, parity, and contraception using) and the dependent variable (results of pap smear) without a repeat visit. This type of research was descriptive correlative, which was research that aims to explain the relationship, estimate, test based on existing theories. In this study, researchers used a consecutive sampling technique with a total of 60 respondents. The research site in Medan, North Sumatra. By using a simple logistic regression test that was by connecting between several independent and dependent variables.

Results

Table 1.frequency distribution base on variables

Variables	**Frequency normal pap smear**	**%**	**Frequency abnormal pap smear**	**%**	**Frequency sample**	**%**
Age						
≤ 35 years	9	15	9	15	18	30
36-45 years	15	25	16	26.7	31	51.6
>45 years	4	6.7	7	11.7	11	18.4
Total	28	46.7	32	63.3	60	100
Parity						
≤ 2	13	21.7	21	35	34	56.7
>2	9	15	11	28.3	26	43.3
Total	22	36.7	38	63.3	60	100
Contraceptive using						
Hormonal	0	0	8	13.4	8	13.4
IUD	1	1.7	5	8.3	6	10
Non-contraceptive	26	43.3	20	33.3	46	76.6

Table 1 shows that the majority of samples aged 36-45 years were 31 people (51.7%) with normal pap smears as many as 15 people (25%) and abnormal pap smear of 16 people (26.7%). In parity ≤ 2 in the majority of samples were 34 people (56.7%) with normal pap smear results of 13 people (21.7%) and abnormal pap smear results of 21 people (35%). The majority of samples with contraception using were no using 46 samples (76.6%) with normal pap smear results of 26 people (43.3%) and abnormal pap smear results of 20 people (33.3%).

Table 2.correlations among age, parity, and contraception using with pap smear results.

Parity	-.149	.116	-.301	-1.288	.204
Contraception using	-.278	.091	-.395	-3.041	.004

Table 2.shows that the correlation between age and pap smear results with a t value of .341 and Beta 0.51 and a significant level of 0.734 means greater than 0.05 ($p>0.05$) meaning that there was no significant correlation between age and pap smear results. The correlation between parity and pap smear results with a value of t=1.288 Beta -.301 and a significant level of 0.204 means greater than 0.05 ($p>0.05$) means that there was no significant correlation between parity and pap smear results. The correlation between contraceptive using and pap smear results with a value of t=-3.041 Beta value -.395 and a significant level of 0.004 means greater than 0.05 ($p>0.05$) meaning that there was a meaningful correlation between contraception using with pap smear results.

Discussions

The results of this study it was found that the majority of samples aged 36-45 years were 51.6% and more than the results of abnormal pap smears were 26.7 than the results of normal pap smears. The older a person is, the greater the risk of uterine cancer. The increased risk of cervical cancer in the elderly is a combination of the increasing length of time of exposure to carcinogens and the weakening of the immune system due to age. In adult women over 35 years old, the condition of the reproductive organs begins to undergo an aging process, and in theory it is explained that risk factors that can increase the incidence of women suffering from cervical cancer one of which is the age of pre-menarche and post-menopause Generally new mucosal cells mature after women aged 20 years and over. The peak development of cervical cancer is at the age of 47 years. About 47% of women with invasive cervical cancer are under 35 years of age when diagnosed. About 10%, cervical cancer occurs in older women (> 65 years) and tends to die of disease due to their advanced stage when diagnosed. So if a woman is having sex at teenage age, it is most vulnerable if it is done under the age of 16 years [(5)].

This study there was no significant correlation between age and the results of pap smear examination with a significance p=0.734; meaning that the study showed no significant correlation between age and pap smear examination results. The results of the study that showed no correlation between age and pap smear results were possible because the number of respondents who had normal pap smear results was greater at 36-45 years old, this result was also possible because cervical cancer is not only influenced by a single factor but multiple factors not examined in this study. Other risk factors were not examined because this study used a documentation study, where there was some information from the medical record data that was not filled out by health workers. Women who are prone to cervical cancer are those who are at risk (35-50 years). Although the facts show that there is a reduction in the risk of HPV infection with age, on the contrary, the risk of persistent/ persistent infection increases. This is thought to be because as we age, changes in anatomy and histology.

The results of this study found that the majority of parity history ≤2 is (56.7%) with abnormal normal pap smear results more than 35% than normal pap smear results. The higher the risk of suffering from cancer of the cervix in women with many children, especially with labor distances that are too short. A

woman who often gives birth (many children) belongs to a high-risk group for cervical cancer, the higher the parity of the mother, the less good the endometrium. This is caused by reduced vascularization or atrophic changes in the decidua due to past labor, which can lead to complications in the reproductive organs. With the frequent birth of a mother, it will have an impact on the frequent occurrence of injury to her reproductive organs which ultimately the impact of the injury will facilitate the emergence of Human Papilloma Virus (HPV) as a cause of cervical cancer. In line with the results of Hidayat said that parity of more than> 3 is 16.03 times at risk of developing cervical cancer than people who have some parities <3 [6]. Women with high parity are associated with cervical columnar epithelial eversion during pregnancy which causes new dynamics of immature metaplastic epithelium that can increase the risk of cell transformation and trauma to the cervix making it easier for HPV infection [7].

Hormonal changes during pregnancy may make women more vulnerable to HPV infection or cancerous growth. The risk of cervical cancer will increase in young marriages or first-time coitus, ie at the age of 15-20 years or in a dozen years and the latent period between the first time of coitus until cervical cancer is detected for 30 years. This is related to the maturity of mucosal cells in the cervix. At a young age, mucosal cells in the cervix are immature. That is, still vulnerable to stimuli so they are not ready to accept stimuli from outside. Including chemicals carried by sperm. Because it is still susceptible, mucosal cells can change properties to become cancerous. The nature of cancer cells is always changing at any time ie die and grow again.

The study showed no significant correlation between parity and pap smear examination results with significance p=0.204. The study measured the number of majority parity> 2. So that there are probably still many who fall into the category of having children 2 or more than 2, because the dangerous parity is to have children more than 3 or the distance of pregnancy is too close, because it can cause the emergence of changes in abnormal cells in the cervix which can develop into malignancy [8].

According to the American Cancer Society (ACS) that women who have experienced 3 or more pregnancies in the full term have an increased risk for cervical cancer. Research has shown that hormonal changes during pregnancy may make women more vulnerable to HPV infection or cancerous growth [9].

The results of this study the majority of respondents did not use contraception by 76.7% and the majority with normal pap smear results of 43.3% and the remaining 33.3% with abnormal pap smear results. The use of hormonal contraception for more than 4 or 5 years can increase the risk of cervical cancer 1.5-2.5 times [10]. Taking a family planning pill for more than 5 years containing progesterone and estrogen harms the uterus, which is an infection in the uterus and allows a woman to suffer from uterine cancer [11]. It can be concluded that the use of contraception affects the incidence of cervical cancer. Oral contraceptives with high estrogen levels cause adhesions of Candida albicans which is a bacterium that causes flour albous. Candida albicans can cause adhesions in the vaginal epithelium and is a medium for fungal growth. Candida albicans develop well in a pH 5-6.5 environment, this change can be asymptomatic or cause infection.

The results of this study found there is a correlation between the use of contraceptives with the results of pap smear examination with a significance p=0.004. According to ACS states that the risk of cervical cancer is doubled in women who take birth control pills for more than 5 years, but the risk returns to normal 10 years after they stop. Combined oral contraceptives are a mixture of synthetic estrogens such as ethinylestradiol and one of several C19 steroids with progesterone activity such as norethindrone. This contraception contains a fixed dose of estrogen and progesterone. The use of estrogen can be risky because it stimulates the thickening of the endometrial walls and stimulates endometrial cells so that it changes properties [9].

Conclusion

The result showed that there was a significant correlation between contraception using and the results of pap smear examination with a significance p<0.004.

Suggestions

Health care provider, providing information to women of reproductive age, is recommended to use contraception so that the number of children can be limited and the birth spacing can be regulated properly. Health care provider gives information about contraceptive using so that women who use hormonal contraception can use non-hormonal contraception.

Abstract

To analyze the function of the family towards the quality of life in elderly in Palu City, which is expected to be a basis for the target of a health promotion program on the quality of life in elderly. The research method used an analytic survey of the elderly in the city of Palu. The sample size was 390 respondents. The sample was the 189 elderly victims of natural disaster who lived in the Temporary Shelter (Huntara) and the 201 elderly people who did not live in the Non-Temporary Shelter (Non-Huntara) which conducted in May - June 2019. The research variable was measured by using questionnaires. The characteristics of elderly namely: Age, gender, education, working status, ethnicity, marital status, history of illness, and history of falls. Family function (A = Adaption, P = Partnership, G = Growth, A = Affection, R = Resolve). The quality of life in eldery was measured by using the questionnaires of WHOQOL-BREF. The data analysis used univariate and bivariate analysis with the SPSS application. The results of the study showed that respondents were 53.33% women and 46.67% men, with 47.95% were junior high school graduated and 73.85% were not working. 67.18% elderly were married. Elderly who has a history of illness of 57.69% and history of fall of 36.92%. Mean score of adaption = 1.49, partnership = 1.44, growth = 1.47, affection = 1.29, and resolve = 1.37. Total mean score of APGAR was 7.07. The mean score of physical dimension = 21.7, psychological dimension= 19.9, social relationship dimension = 9, dan environmental dimension = 23.4. The total mean score of quality of life was 74.0. It can be concluded that the family had a good function (score 7.07) for the elderly and the quality of life in elderly was good (score 74.0).

***Keyword**: family function, quality of life, elderly.*

Introduction

One of the impacts of the science and technology advancement, especially in the health sector, is the decrease in infant and child mortality and the increase in life expectancy so that it has an impact on increasing the number of elderly people [1]. In general, in Indonesia, the quality of life in elderly is greatly influenced by family functions for a variety of reasons. The family as the smallest unit of society is greatly influenced by the social environment such as the family's interaction with neighbors, the activeness of the family to participate in community activities [2].

In determining a person's level of welfare that reflects the quality of life, many factors are the focus of attention, because in determining the quality of life, it cannot be based on a single causative factor. Factors that need to be considered are age, gender, education level, marital status, employment status, income, and the presence of chronic illness in the elderly. This factor is a risk factor in determining the future quality of life in elderly, because changes or disruption in any of these points can reduce the quality of life in elderly. So that in assessing the quality of life a person needs an instrument that includes how a person's basic needs can be met. The instrument is a tool that can measure based on observations from outside a person such as living standards, income, education, individual age, health and most importantly, how to direct or control the way of life and the future life [3].

Elderly population is increasing in number in many countries including in Indonesia. The number of elderly population above 60 years is predicted to increase to 20% in 2015-2050. Indonesia is in the fourth position after China, India, and Japan. The 2014 National Socio-Economic Survey results informed that the number of elderly people in Indonesia was 20.24 million or 8.03%. When compared to the results of the 2010 National Socio-Economic Survey, there was an increase in the number of elderly people, namely 18.1 million people or 7.6% [4]. In Palu City, in 2000 the number of elderly population was 8,968 people or 3.39% of the total population. This number increased to 16,958 people (5.02%) in 2010, then increased again to 18,469 people (5.02%) in 2015 and is projected to reach 21,225 people (6.01%) in 2020 [5].

The optimal quality of life in elderly can be interpreted as the functional condition of the elderly at the maximum or optimum conditions, so that they can enjoy their old age with meaningful, happy, useful and good life. If the family function decreases it can cause the quality of life in elderly to decrease and eventually it will cause the morbidity rate in the elderly to increase and the mortality rate also increases. So this study aimed to determine the family function to the quality of life in elderly in Palu City which is expected to be a foundation as a target of a health promotion program about the quality of life in elderly.

Method

The research method used was an analytical survey of the elderly in the city of Palu. The sample size was 390 elderly. The research variables were the characteristics of the elderly, APGAR, and the quality of life in elderly. Measurement of the characteristics of the elderly used a questionnaire namely gender, education, working status, ethnicity, marital status, history of illness, history of falls. Measurement of family function of the elderly used the APGAR questionnaire or Adaption, Partnership, Growth, Affection, and Resolve questionnaire. APGAR value categories are divided into 3 namely: 0-3 (very high family dysfunction); 4-6 (moderate family dysfunction), 7-10 (low family dysfunction). The quality of life in elderly was measured by using the WHOQOL-BREF (The World Health Organization Quality of Life) questionnaire which consists of 26 questions and is divided into 4 dimensions, namely the dimensions of physical health, psychosocial, social relations, and the environment. Data analysis used descriptive analysis for all variables with the SPSS program.

Results

Table 1 Characteristics of Elderly

Characteristics		**n**	**%**
Gender	Male	182	46.67
	Female	208	53.33
Education	Elementary School	7	1.79
	Junior High School	187	47.95
	Senior High School	80	20.51
	Higher Education	116	29.74
Working Status	Working	102	26.15
	Not Working	288	73.85
Ethnicity	Kaili	302	77.44
	Bugis-Makassar	46	11.79

Cont... **Table 1 Characteristics of Elderly**

	Javanese	29	7.44
	Others	13	3.33
Marital Status	Married	262	67.18
	Widowed	112	28.72
	Divorced	16	4.10
History of Illness	Yes	225	57.69
	No	165	42.31
History of Falls	Yes	144	36.92
	No	246	63.08
Total		390	100.00

Table 1 shows that the majority of elderly respondents were women (53.33%) with education level of junior high school (47.95%) and higher education/diploma (29.74%). Most respondents did not work (73.85%) and came from the Kaili ethnic (77.44%). Then in marital status, most respondents were married (67.18%). There are 42.31% of respondents who have a history of illness while 36.92% of respondents who have a history of falls.

Table 2 APGAR value distribution of Elderly

Value	**FAMILY FUNCTION**					**Total Score**
	A (Adaption)	**P (Partnership)**	**G (Growth)**	**A (Affection)**	**R (Resolve)**	
Mean	1.49	1.44	1.47	1.29	1.37	7.07
SD	0.63	0.65	0.66	0.71	0.66	2.76
Minimum	0.00	0.00	0.00	0.00	0.00	0.00
Maximum	3.00	2.00	4.00	3.00	2.00	13.00

Table 2 shows that the family function of the elderly was good with a mean score of 7.07 which is an accumulation of the functions of adaption, partnership, growth, affection, and resolve. APGAR is the physiological functions of the family.

Table 3 Quality of life in elderly people

Value	Dimension				QOL
	Physical	Psychological	Social Relationship	Environment	
Mean	21.7	19.9	9.0	23.4	74.0
SD	2.6	2.6	1.7	3.7	8.2
Minimum	14.5	24.0	8.0	27.0	99.0
Maximum	27.5	25.0	13.5	32.5	94.5

Table 3 shows the mean score of quality of life in elderly people was good (74.0) with a score on the physical dimension of 21.7, psychological dimension of 19.9, relationship dimension of 9.0, and environment dimension of 23.4.

Discussion

The results showed that the APGAR of elderly family was good. Family function is an important factor in supporting the improvement of the quality of life of patients with chronic diseases. Good quality of life will reduce the risk of complications that can worsen the situation [6]. Family support is one of the factors that influence the quality of life in elderly. Family support is a form of family behavior in the form of information, assessment/appreciation, instrumental and emotional in providing services to the elderly [7]. Family is the main support system for the elderly in maintaining their health [8]. Family support is included in supporting factors that can influence a person's behavior and lifestyle so that it has an influence on their health status and quality of life [9].

The results showed that the quality of life in elderly was good. Life expectancy, life satisfaction, psychological health, cognitive function, health and physical function, income, living conditions, social support and social networks are complex components of quality of life. The family has an important role in the concept of health and illness in elderly family members and provides direct care for sick family members so that the physical, psychological, social, and environmental impact will affect the quality of life in elderly [10,11].

Other studies showed that medically healthy elderly people have good family support, because healthy elderly people carry out their daily activities assisted by families and also independently [12]. Basic care for the elderly is related to basic daily activities for the elderly which include daily personal care from personal hygiene, nutrition, to other activities such as physical training in order to maintain the quality of life [13]. Family function had a positive correlation with the quality of life in elderly [14]. If the family function is "healthy" (a state of well-being physically, mentally, and socially) then it is possible for a whole family to live normally socially and economically, so it can reduce morbidity and mortality which in turn will improve the quality of life in elderly.

Conclusion

The family function in caring for the elderly can be the main key in dealing with elderly problems such as physical, psychological, and social decline so that the quality of life of the elderly does not decline. For the elderly, the family is a source of satisfaction and assistance that can provide an energy to fight the pressure and stress. The existence of adequate family support can reduce mortality, easily recover from illness and can improve cognitive, physical and emotional function.

Self Regulation Effect on Glycemic Control of Type 2 Diabetes Melitus Patients

Hariyono Hariyono[1], Leo Yosdimyati Romli[1]

[1]Lecture Medical Surgical Nursing Department School of Health Science Insan Cendekia Medika Jombang

Abstract

Background: Self regulation is an effective way for people with Diabetes Mellitus in order to get good glycemic control for the diabetes mellitus patient recovery. The purpose of this study was to analyze the effect of self regulation on the patient glycemic control. **Method:** This research used pre experimental pre post test design. The population of this research is all DM patients in Bulurejo Village, Diwek District, Jombang Regency with a sample of 30 respondents. In this research we used purposive type sample. The variable of this research are: self regulation and glycemic control. The way of collecting data is by laboratory test. **Result and analysis**: The results showed that self regulation affect on glycemic control in DM patient according to the wilcoxon test, the glycemic control score p=0.046 (p<0,05). The glycemic control before the intervention almost all respondents had uncontrolled HbA1C levels of 28 respondents or 93.3% and after intervention almost all respondents had uncontrolled HbA1C levels of 24 respondents or 80%. **Discuss and conclusion**: Self regulation can improve glycemic control quite well, but still needs integration with other components related to treatment and care in diabetes mellitus patient, with self regulation it is expected that they will be able to increase their motivation to support increased self care abilities, change behavior and carry out activities to maintain glycemic control.

Keyword*: Self Regulation, Glycemic Control, Diabetes Mellitus*

Introduction

Diabetes mellitus in some developing countries has increased significantly due to the increasing population of aging, changes in diet, severe physical activity, and unhealthy behavior patterns. The level of blood glucose in diabetes mellitus is also influenced by low self regulation in which sufferers cannot control themselves against factors that can trigger disorders of blood glucose level regulation in patients with type 2 diabetes mellitus [3]. Diabetes mellitus has a severe impact on the psychological, social, physical, economic and cultural aspects of individuals, a person with diabetes mellitus tends to try to adapt as best they can, but not infrequently they do not have the knowledge and skills to make decisions and act accordingly so that a sustainable process is appropriate with the patient's condition, hospital care is more meaningful if it is continued with home care, but until now the planning for patients treated has not been optimal [6].

International Diabetes Federation (IDF) calculates the incidence of Diabetes Mellitus in the world in 2012 was 371 million, in 2013 it increased to 382 million and it is estimated that in 2035 people with Diabetes Mellitus will increase to 592 million [2]. Based on the 2013 Annual Report of Hospitals in East Java, Diabetes Mellitus sufferers (102,399 Cases) [8]. Based on data from the Jombang district health office, the number of people with Diabetes Mellitus in 2014 was 21,992 [3].

Various problems that arise due to diabetes mellitus can not be separated from the occurrence of various kinds of complications, especially long-term complications, so that maximum effort is needed to prevent the occurrence of complications, the main key to delaying even preventing complications of diabetes mellitus is by controlling blood sugar [12]. Besides that we also need to improve the quality of life of patients. So the goal of managing patients includes two important things, namely metabolic control and quality of life of patients[9]. Recurrence of diabetes mellitus can be done in many ways to reduce recurrence. One of them is self regulation, where the method of self regulation is

a person's self control process in controlling behavior and monitoring behavior to achieve certain goals by using strategies and involving physical, cognitive, motivational, and social elements. Components which also constitute self regulation include: self monitoring/ self observation and self evaluation/judgmental process [8].

Self monitoring/self observation is a process where individuals observe and feel sensitivity to everything about themselves and their environment [4]. Self evaluation / judgmental process is how a person evaluates himself against his behavior in the surrounding environment. Self response is someone who can evaluate themselves positively or negatively, cognitive function makes a balance that can evaluate positive or negative becomes less meaningful individually [9].

Materials and Method

This study uses a pre-experimental pre-post test design. The study population was all DM patients in Bulurejo Village, Diwek District, Jombang Regency with a sample of 30 respondents. The sampling technique is purposive sampling. The variables of this study include: self regulation and glycemic control. Glycemic control data collection using laboratory tests HbA1c levels.

The process of data collection begins first by selecting prospective respondents and given the opportunity to understand about research. Filling out the questionnaire sheet for the pre test is done after the prospective respondent gives approval, then the HbA1c value is measured by the family.

Respondents were then given self regulation interventions, after the intervention period was completed, the researcher conducted a post test on the respondents of the study by measuring HbA1c levels. The collected data is then processed by the researcher and analyzed for the results and conclusions of the study using the Wilcoxon test.

Research Result

The results of the study of the effects of self regulation on glycemic control of patients with type 2 diabetes mellitus in the village of Bulurejo, District of Diwek, Jombang Regency, collected data including general data such as age, gender, education and employment.

Table 1 Characteristics of Age

No.	Age	f	%
1.	<20 year	0	0
2.	20-35 year	6	20,0
3.	>35 year	24	80,0
Total		30	100

Table 2. Characteristics of Education

No.	Education	f	%
1.	Elementary School	8	26,7
2.	Junior High School	8	26,7
3.	Senior High School	9	30,0
4.	Diploma/Bachelor	5	16,7
Total		30	100

Characteristics of respondents based on education according to the results of research as shown in table 3, it is known that almost half of them have high school education, namely as many as 9 respondents or 30%.

Table 3. Characteristics of Job

No.	Job	f	%
1.	Does not work	6	20,0
2.	Farmer	6	20,0
3.	Entrepreneur	14	46,7
4.	Civil Cervant	4	13,3
Total		30	100%

Characteristics of respondents based on work according to the results of the study as shown in table 4, it is known that half of them have self-employment, namely as many as 14 respondents or 46.7%.

Table 4. Characteristics of HbA1C

No.	HbA1C	Pre	
		f	%
1.	Controlled	2	6,7
2.	Not controlled	28	93,3
Total		30	100

Characteristics of respondents based on HbA1C levels according to the results of the study as shown in table 4, it is known that before the intervention almost all respondents had uncontrolled HbA1C levels of 28 respondents or 93.3%.

No.	**HbA1C**	**Post**	
		f	**%**
1.	Controlled	6	20,0
2.	Not controlled	24	80,0
Total		30	100

Characteristics of respondents based on HbA1C levels according to the results of the study as shown in table 5, it is known that after intervention almost all respondents had uncontrolled HbA1C levels of 24 respondents or 80%.

Table 6. Crosstab of HbA1C

No.	Pre	Post				Total	
		Controlled		Not Controlled			
		f	%	f	%	N	%
1.	Controlled	2	6,7	0	0	2	6,7
2.	Not controlled	4	13,3	24	80,0	28	93,3
Total		6	20,0	23	80,0	30	100
		p=0,046 (p<0,05)					

Characteristics of respondents based on HbA1C levels in accordance with table 7 shows that almost all respondents before the intervention and after intervening remained had uncontrolled HbA1C levels of 24 respondents or 80% and a small proportion of respondents before intervention and after intervention had controlled HbA1C levels namely as many as 4 respondents or by 13.3%.

Discussion

Glycemic control of diabetes mellitus patients before self regulation

Glycemic control in people with diabetes mellitus based on the results of research before giving self regulation shows that almost all of the study respondents had uncontrolled glycemic control and only a small proportion of the study respondents had controlled glycemic control.

Self-care for people with diabetes mellitus is a process of developing knowledge or awareness to learn to survive the complex nature of diabetes mellitus and self-care in people with diabetes mellitus should be directed related to healthy food behavior, physically active, monitoring blood glucose levels, appropriate treatment, problem solving with healthy coping, as well as behaviors that reduce risk (Shrivastava, 2013).

Poor control of glucose metabolism is characterized by increasing blood sugar levels or hyperglycemia [6].

The results of the study also showed that almost all respondents were over 35 years old and a small percentage were under 35 years old.

States that there are several factors that can affect the glycemic control of people with diabetes mellitus such as type of diabetes, type of treatment, degree of control to be achieved, age of the patient, available facilities, knowledge and motivation of the patient [3].

The age factor according to the researcher influences the condition of the respondents' glycemic control. Although no age-related analysis was carried out, the age of respondents according to the researchers significantly contributed to uncontrolled glycemic control conditions because knowledge and attitudes with increasing age play a role in shaping a person's health behavior, although there are also other factors that influence health behaviors such as personality systems, experiences, customs held by individuals and the existence of supporting factors or conditions that allow such adequate facilities[7].

Glycemic control of diabetes mellitus patients after self regulation

Glycemic control in people with diabetes mellitus based on the results of the study after being given self regulation showed that almost all of the study respondents had uncontrolled glycemic control and only a small proportion of the study respondents had controlled glycemic control.

States that one of the factors that influence self regulation is an environment that depends on the form of support from the environment, the existence of family support coupled with health workers causes the client's controlled self regulation to be high because of two sources of support that trigger pressure greater for self-regulation, support from health workers in the form of monitoring the course of therapy triggers patients to try to meet external demands, namely managing diabetes mellitus well. People with diabetes mellitus should get education about self-care because it is important to support self care, their glycemic control and education is an important element because it helps optimize blood glucose control to prevent complications [2]. This is also supported by the opinion of Shrivastava, who states that self-care of people with diabetes mellitus is a process of developing knowledge or awareness to learn to survive the complex nature of diabetes mellitus and self care in people with diabetes mellitus. physical, monitoring blood glucose levels, appropriate treatment, solving problems with healthy coping, and reducing risk behavior [12].

The results of the study also showed that almost half of the study respondents had education at the high school, junior high and elementary levels and only a small proportion possessed education at the level of D3 or Bachelor. Knowledge or cognitive is a very important domain for the formation of a person's actions or behavior. The patient's knowledge of diabetes mellitus is a tool that can help patients to manage diabetes during their lives so that more and more people understand the disease better understand how to change their behavior [14]. Education and training for people with diabetes mellitus is an education about knowledge and skills for people with Diabetes Mellitus to support behavior change, improve understanding of the disease so that optimal health is achieved, adjusting psychological conditions and improving quality of life [13].

Age factors according to researchers although in this study no statistical analysis was conducted, educational factors also contributed to changes in glycemic control conditions in people with diabetes mellitus. Patients who have higher education will be able to receive the knowledge provided through education, so that it will change the mindset of patients and can increase knowledge about diabetes mellitus and management. In addition, with a good education base, people with diabetes mellitus will be easier and able to respond well to any intervention given so that changes in the condition of the glycemic control are able to change to be controlled. However, the absence of significant changes related to the condition of glycemic control in respondents indicates that management in Diabetes Mellitus patients does not only focus on one model or intervention method, but also requires treatment, care or education and requires a comprehensive approach in an effort to meet complex needs. for Diabetes Mellitus patients both physiological related needs, education and psychological support [14].

Effect of Self Regulation on Glycemic Control in People with Diabetes Mellitus

Glycemic control based on the results of the study showed that almost all respondents after self regulation still had uncontrolled glycemic control as many as 24 respondents but the results of the analysis statistically

showed that there was an effect of self regulation on glycemic control in people with diabetes mellitus.

Management of Diabetes Mellitus to prevent complications includes 5 pillars, namely eating planning, physical exercise, medication, counseling, and monitoring glucose levels themselves, management of this Diabetes Mellitus must be done for life so often patients are not obedient and tend to become discouraged [10]. The characteristics of people who are able to perform self-regulation properly depend on one of them is the regulation of emotions, a process that always checks or intentionally changes feelings that might lead to counterproductive behavior [11].

Sudden changes in life related to the management of disease treatment and care for people with diabetes mellitus who have to undergo routine life make people with diabetes mellitus lead to the emergence of several negative psychological responses such as anger, feeling useless, increasing anxiety, and stress. Such conditions according to researchers indeed play an important role in the ability of patients to carry out self-care management and if they are able to do so the results they get can be seen one of which is a controlled blood glucose condition[7].

Glycemic control based on the results of the study showed that a small proportion of respondents who had glycemic control from uncontrolled became controlled after being given self regulation and respondents who before being given self regulation had controlled glycemic control and after that remained constant controlled [11].

Controlled self regulation is caused by interpersonal or intrapsychic pressure [5]. One form of self regulation is external, one example of this external form of self-regulation is that people are involved in an activity or pursue goals to meet external demands, avoid punishment, or get prizes [4].

Controlled self regulation according to researchers is influenced by external factors that cause a person to experience pressure so that they conduct self regulation. This is what distinguishes patients who get support only from families. Patients who get support from the family feel that they do not get support from health workers in undergoing therapy so that the external demands they feel are fewer, this causes respondents to have low self-regulation so that the ability to change glycemic control conditions is affected[3].

Conclusions

Glycemic control of diabetes mellitus sufferers is almost entirely before uncontrolled self regulation. Glycemic control of people with diabetes mellitus are almost entirely partially before uncontrolled self regulation is given but there are changes. Self regulation affects the glycemic control in people with diabetes mellitus

Abstract

Dengue hemorrhagic fever (DHF) has become an endemic in major cities in Indonesia. Climate change, and poor level of awareness and knowledge of the community in Indonesia causes the case of DHF to continue to exist and it tends to increase. In the extraordinary events in 2015 the morbidity rate reached 50.75. The Intergovernmental Panel on Climate Change (IPCC) prediction in 1996 stated that the incidence of dengue hemorrhagic fever in Indonesia will increase threefold from 2070, if the environment and community conditions do not change. This study aims to produce a system dynamics model with ecological analysis to determine the dynamics of the DHF incidence with climate variability patterns in Depok and Bogor. The design of this study is ecologic study with hypothesis test, modeling, simulation, and intervention. Interviews with respondents include the level of knowledge, attitudes, and behavior (PSP) of the community. Measurement of climate factor includes rainfall, temperature, humidity, and CO2 level in the ambient environment. The results of DHF system dynamics model simulation show the program intervention scenario that has the most significant effect on the decline of Breeding Places and the decrease of DHF cases by increasing the participation of the community to actively control water places that are potential for mosquito breeding places.

Key words: *system dynamics model, intervention, simulation, dengue hemorrhagic fever, climate change*

Introduction

The increasing population has caused cases of communal disease to increase. DHF cases in Indonesia have relationship between environmental changes and an increase in cases of disease. The number of environmental factors that are identified as having an effect on the incidence of DHF which tend to recurred encourage researchers to figure out what environmental factors can be used as indicators in predicting the occurrence of DHF cases and DHF transmission system in Depok and Bogor, as well as predicting the incidence of DHF through intervention models on system dynamics.

This study produces a dynamics model of DHF transmission in relation to climate variability patterns that will contribute to improvements in development on a local and even national scale. The dynamics model of DHF transmission is expected to be an innovation to reduce the incidence of DHF, especially in Depok and Bogor.

Method

This study includes ecological studies by using hypothesis test. Modeling and simulation is carried out to identify factors that are relevant to future DHF cases. The eminence of this study links environmental factors in ecology such as rainfall, temperature and humidity as well as basic indicators of air quality, namely CO_2, with

larva free index.

Study related to the determination of dynamics model to recognize early warning of the emergence of DHF cases has been started since 2006. It is expected that the patterns that have been found are continued in the concept of this study for a broader area, namely in Jakarta, Bogor, Depok, Tangerang and Bekasi (Jabodetabek).

The samples in this study are air quality sample, larva free index, case sample, house sample, and respondent sample. Air quality sample is taken from the research location. Larva free index obtained from the Depok and Bogor Health Services. Case samples are DHF experienced by respondents in the last two years. House sample is determined based on WHO standards for larvae and mosquito surveys according to the area and population: "Cluster Design Sampling".[1]

The minimum number of samples calculated based on the prevalence of DHF in the preliminary study was 14%, while the expected prevalence of control variables that had been found was 4%. In the hypothesis test using a 5% confidence level and 90% test strength. The distribution of household sample was carried out by dividing the sample proportionally according to the number of cities in the Special Capital Region of Depok (Depok Village and Pancoran Mas Village, Pancoran Mas District and Beji Village and Tanah Baru Village, Beji District) and Bogor (Kedung Badak Village, Kayu Manis Village, Kencana Village, and Mekar Wangi Village, Tanah sereal District). In each region, a total of 220 houses were taken with individual analysis units.

The study is conducted within three years starting in 2018. Data is collected from the Special Capital Region of Jakarta, include: Environmental data (rainfall, temperature, humidity, and CO_2 level in the ambient air through direct measurements at the sampling point) and Community data to find out the knowledge, attitudes and behavior of the community about DHF.

Rainfall measurements are carried out every rainy day using rain gauge. Temperature and humidity are measured using thermo hygrometer, and CO_2 level is measured using RAC sampling. Community data collection is carried out through interviews using a questionnaire to determine social, economic and education status of the community, as well as knowledge, attitudes and behavior of the community about DHF, prevention and eradication of *Aedes* vectors.

To obtain the concept of DHF control in the future, a system dynamics model is used. The stages of the study to obtain the research outcome are: (1) validation of environmental components (2) demonstration of the model in the relevant environment, (3) report on comprehensive activities. In this study, the case of DHF is considered as one of the components of the causal system in a scenario simulated through intervention.

Simulation is carried out through modeling, model production, simulation and validation of the simulation results stages to determine the compatibility between the simulation results and the imitated mechanism. Simulation results are used to understand process behavior and predict future trends.[2]

Results and Discussion

Dengue Hemorraghic Fever Case Prediction based on Model Simulation Based on Figure 1, it is known that climate variability patterns affect the incidence of DHF because the life of the disease vectors and dengue virus as an agent is very dependent on environmental conditions. Temperature, humidity, air chemical composition, water chemical composition as the breeding place for mosquitoes, rainfall, wind speed and other environmental factors are the limiting factors of its life. Therefore, the environmental system associated with the incidence of DHF has 4 subsystems, namely: climate subsystem, *Aedes* mosquito, human and DHF. These four subsystems are interconnected and they influence each other.

Climate subsystem is a series of climate factors related to global climate change that triggers an increase in global earth temperature. As a result, this global warming phenomenon can affect living things. The most dominant insect causing DHF is *Aedes aegypti*. CH_4, N_2O, CO_2 and CFC-11 are gases that cause the global climate change or the so-called greenhouse effect if it is at a concentration exceeding normal concentration. The increase in global temperatures will increase sea surface temperatures so that the next impact is to encourage the El Nino phenomenon. According to the World Meteorological Organization (WMO), there is a relationship between the occurrence of El Nino and the incidence of DHF in Indonesia.[3] This cycle forms the climate subsystem in the model.

The second subsystem is the *Aedes* mosquitoes, from eggs to adult mosquitoes, which is indicated by a positive arrow. The connecting factor of the climate

subsystem and mosquito subsystem is the breeding places for mosquitoes. Breeding places are highly affected by rainfall. When rainfall is high, containers are easily filled with water and this relationship is indicated by a positive arrow. Another connecting factor of the climate subsystem is the ambient temperature which then affects the Extrinsic Incubation Period (EIP). Extrinsic Incubation Period is influenced by environmental temperature, humidity, level of viremia in humans, and viral strains.[4] Temperature increase will shorten EIP and increase transmission. Temperatures that increase to 34ºC will affect the temperature of the water in breeding places which also accelerates the hatching of eggs into larvae.

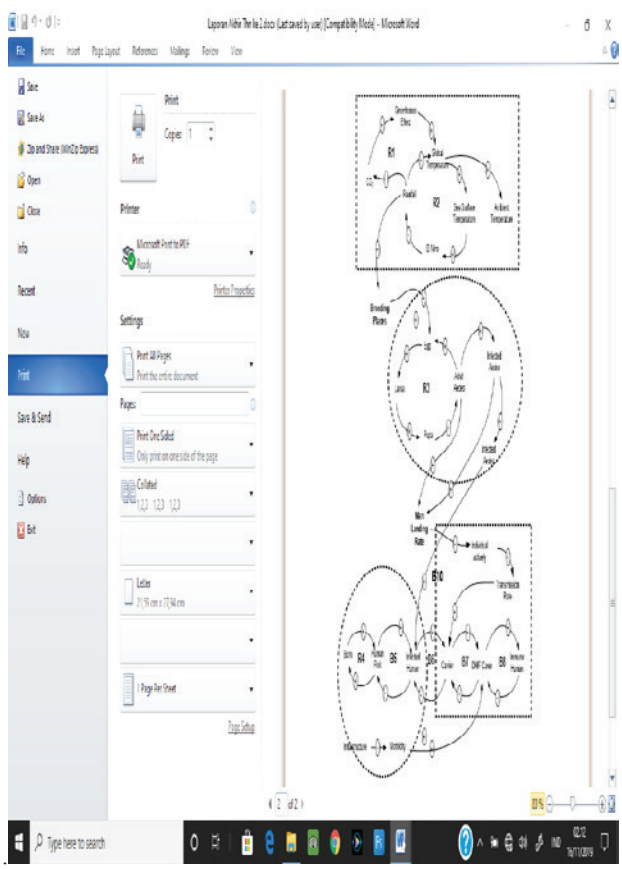

Figure 1. Dynamics System Model of DHF Cases with Community Role Improvement (PSP) intervention

Vector subsystem and disease subsystem are connected by Landing Rate and the role of dengue virus factors. The presence of DHF is determined by the contact between mosquitoes and humans. It is assumed that the larger the mosquito population the higher the Landing Rate, so the connecting arrow becomes positive. The larger the *Aedes* mosquito population the larger the infective *Aedes* population that carries the Dengue virus. This relationship is indicated by a positive arrow

After the *Aedes* mosquito bites a human, the virus replicates in the human body. The more viruses incubated into humans the more humans become infectious so that the number of DHF cases in the community increases. This link is indicated by a positive arrow.

Human activity is indicated by the intensity of petroleum fuels usage. The impact of fuel utilization is the increase of CO_2 emissions; the relationship is indicated by a positive arrow. The Landing Rate factor is also related to the human subsystem through the individual activeness factor. The more inactive a person is, the easier for mosquitoes to approach, especially during peak hours.

In this case, intervention in increasing the knowledge, attitudes and behavior (PSP) of the community is required. From the analysis, it is known that the factors that are significantly related to the occurrence of DHF in the community are knowledge, attitudes and behavior factors. This program provides community awareness education. This relationship is indicated by a positive arrow for PSP. Figure 3 shows the diagram stock flow scheme which is the model production stage, where all variables are included as factors that influence the incidence of DHF.

Conclusions

System dynamics model simulation of DHF shows the program intervention scenario that has the most significant effect on the decline of Breeding Places and the decrease in DHF cases is by increasing the participation of the community to actively control water places that are potential to be mosquito breeding places. Environmental factors influence DHF cases and the vectors *Aedes aegypti* and dengue viruses related to climate change. The Indonesia geography, knowledge, attitude and practice have caused DHF cases were increase.

Simulation in this study has produced a model that can be used for other infectious diseases. Through system dynamics modeling, the transmission model of the disease can be known in details, so that the most effective interventions can be determined in handling infectious disease cases.

Abstract

In low-income countries, 90% waste accumulates in landfills without sorting processes and some are even eliminated by burning it. In 2019, the amount of waste in Depok reaches 1,300 tons every day, there is an increase from the previous year. Data shows that public sectors, such as schools, contributes 5% of the total waste. Based on this condition, the researchers held community service activities in schools to give motivation in managing the waste to reduce the volume of waste in landfills. The methods used were quantitative and qualitative. The activities held were in the form of training, improvement of soft skills in processing waste and preserving the environment, as well as monitoring and evaluation activities. From the results of the post-test scores after the training, it was found that the teachers' insight increased by 28.3%, while in the students by 25%. Adiwiyata school criteria achievement score also increased by more than 60% in each school. However, we need to know that changes in behavior cannot occur in a short time. Continuous change requires time and a strong commitment to ensure that the program continues to run routinely in the coming years.

***Keywords**: Adiwiyata, Biopore, Vertical Garden, Waste Management, Elementary School*

Introduction

The amount of waste in the world always increases annually. The World Bank reports that every person produces 0.74 kg of waste every day. In low-income countries, 90% waste accumulates in landfills or eliminated by burning it [(1)]. Solid waste that is not managed properly can cause flood, air pollution, and health problems such as diarrhea and dengue fever [(2)].

Indonesia is a developing country that has problems in managing waste. The Ministry of Environment and Forestry reports that around 72% of the population does not care about waste and 69% of waste ends up in landfills without sorting processes [(3)]. The types of waste produced by the population include organic waste (60%), plastic waste (14%), paper waste (9%), metals and other materials (17%) [(4)].

Depok is one of the cities in West Java Province with a high population growth. High populations result in increased waste production [(1)]. In 2019, the amount of waste in Depok reaches 1,300 tons every day, an increase of 61.5% from the previous year [(5)]. The types of waste are dominated by organic waste. Sources of waste can come from household activities (63%), traditional markets (9%), shopping centers (7%), public sectors such as schools, hospitals, and others (5%) [(6)].

Inadequate waste management systems and bad behavior of people who do not care about waste management at the household level are the causes of the increase in waste volume [(3)]. The government continues

Corresponding Author:

phone: +62 813 805 47 570

to improve the waste management system by developing TPS3R (Waste Disposal Sites of Reuse, Reduce, Recycle) to reduce the volume of waste in landfills. The purpose of the TPS3R development is to reduce the quantity and sorting of waste based on its type before being transported to landfills [7].

Another reason for the increase in waste volume is bad behavior of the people. Behavior is related to awareness level [8]. Behavior that is based on awareness will have a lasting impact compared to behavior without good awareness [9]. From this theory, we can determine that increasing people awareness is one way to change behavior because we can always rely on government programs in managing the waste we produce.

Awareness on waste management must be delivered earlier. We must educate children about waste at home and school. School is a place for students to learn new things and a place for the formation of behavior and character. Therefore, curriculum based on environmental conservation needs to be established in schools. Curriculum based on environmental preservation is held with the aim of increasing student knowledge[8]. The aim is to make students closer to the environment so that they can develop awareness to exploit wisely [10].

The Indonesian government has grown the participation of every school in managing the environment through the Adiwiyata Program. It is a program for schools in environmental culture. Every level of education can participate in this program and this program is voluntary, currently. The principles of this program are based on education, participation, and sustainability[11]. Until 2018, not many schools participated in this program. It was only about 30 schools out of 877 schools in Depok receiving Adiwiyata award. This means, there are several schools implementing environment-based curriculum and many schools have few activities concerning on the environment. One of the programs assessed by the Adiwiyata Program is waste management at the school level.

Based on this reason, we organized a counseling program for teachers and students to increase awareness on waste management programs at the school level. In addition, we also attempted to increase the participation of this program to all school communities. We also conducted monitoring and evaluation to see the development of program implementation at the school level.

Materials and Method

Research Design

This Community Service Activities was located in Elementary Schools in Depok City on July-November 2019. We collaborated with two schools, namely Sukatani 6 Primary School and Cilangkap 6 Primary School. We selected these two schools based on inclusion criteria in which both schools have sufficient land to make biopore hole, have never participated or participated in the Adiwiyata Program, and have a commitment to join and run the program.

Biopore is one of replication methods of natural processes for water absorption. The technique of making biopore hole can be seen in Figure 1. The advantage of biopore hole is to increase surface water absorption, reduce standing water, and increase water supply in the soil. However, currently, the biopore hole can be used as a decay hole for organic waste which can later be utilized as compost [11]. We used the Communication, Information and Education methods, and Participation to run this program.

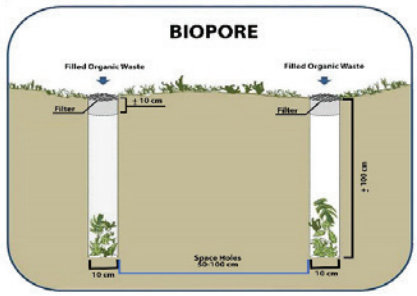

Figure 1. Technique of making biopore

Source: www.pu.go.id

Procedure

The team coordinated with the Principal and Teachers regarding the program focusing on waste management at the school level in the preliminary survey. We provided information about the implementation time, objectives, and series of activities to be performed. After obtaining permission from the Principal, the team continued with the training program.

A total of 6 teachers and 10 students from each school were involved in the training. We provided information on the types of waste, how to sort the waste, how to make biopore hole for the use of organic waste, how to

make a vertical garden using old bottles, how to reduce plastic waste, and others. To evaluate the absorption of information from training activities, the team conducted pre-test before training and post-test after training.

The team realized that training for Teachers and Students was not possible using the same method. Therefore, the team divided two methods, namely question and answer lectures for the teacher and learning while playing using the Snakes and Ladders tool that the team had prepared for the students. The team also provided facilities and supporting infrastructure to the schools in the form of posters, augers to make biopore hole, and plant seeds to make vertical gardens.

After three months, the team visited the schools for monitoring and evaluation activities regarding the implementation of the program in each school. We used evaluation instruments to measure the progress of program implementation. The evaluation instrument contained the types of waste produced by schools, the conditions of waste processing (separated or still mixed between organic and inorganic waste), and obstacles found during the program implementation. We also discussed with the Principal and Teachers as well as Students who have been trained on the obstacles found and the progress of the program implementation to provide appropriate solutions to solve existing problems.

Figure 2. Making biopore

Findings

From the comparison results of pre-test and post-test scores, it is known that there is an increase in the level of awareness before and after training. The increase in grades in the Teachers group is by 28.3%, while the increase in grades in the Students group is by 25%. Data on the number of respondents, gender, and pre-test and post-test mean values can be seen in Table 1.

Table 1. Respondents and Score of pre-test and post-test from training

Variable	N	%	Mean	Max-Min	Information
Teacher					
Male	6	50			
Female	6	50			
Student					
Male	10	50			
Female	10	50			
Score of pre-test*					
Teacher			51.7	26.7 – 93.4	
Student			54	30 – 90	
Score of post-test*					
Teacher			80	60 – 93.4	
Student			79	50 – 100	

* Note: Post-test and pre-test scores increased by 28.3% for teachers, while for students increased by 25%

From the evaluation results of the monitoring activities, it is known that the types of waste produced by schools are in the form of food scraps, dried leaves and twigs, paper, plastic cups, straws, plastic bottles, cardboard, rice paper, and styrofoam. In addition, the researchers conducted a scoring to assess school achievements in the Adiwiyata program assessment. After receiving intervention, each school had a score increase of around 60%. However, it is still below 56 (70%), which means these schools require improvement efforts in every aspect of assessment. Schools with grades less than 56 (70%) have not been able to participate in the Adiwiyata School Competition.

Discussion

Awareness is one of the factors that can affect behavior change in a person [12]. Behavior that is based on sufficient awareness will last longer, compared to behavior that is not based on sufficient awareness [9]. Referring to the theory, in order to realize zero waste at the school level, the researchers focus on increasing awareness before continuing on to the participation program.

Efforts to increase knowledge were performed by providing training to school community, including teachers and students appointed. The trainees are expected to become agents of change in their respective schools and be able to motivate their colleagues and friends to participate in the waste segregation and environmental preservation program as an effort to realize the Adiwiyata school.

From the results of the pre-test and post-test assessment of the trainees, both teachers and students, it showed an increase in knowledge before and after the training activities (Table 1). After the participants were determined to have increased knowledge, the intervention activities continued with growing participant participation by providing soft skills to the participants. The type of soft skills provided is how to make biopore hole as an effort to reduce the volume of organic waste such as leaf litter and food scraps (Figure 3) and create a vertical garden by utilizing used items found at school.

The series of activities consisting of training and soft skills improvement increases the score on the fulfillment of Adiwiyata aspects in schools in the third aspect, that is participatory-based environmental activities. Participatory-based environmental activities increasing scores include training attended by school community in environmental conservation, increasing awareness of waste in schools by collaborating with the Waste Management Unit by sending excess leaf litter to compost and scavengers for removing plastic bottles, plastic cups, and used cardboard, as well as showing environmental preservation efforts undertaken by all school community, that is making biopore holes by utilizing organic waste as compost and making vertical gardens by utilizing used bottles.

The training activities provided also have an impact on increasing the awareness and motivation of school community in maintaining and providing supporting appropriate facilities and infrastructure for their purpose. The form of this activity is the procurement of bins by its type to sort organic and inorganic waste (Figure 3) by the schools, sorting plastic bottles and cups, making biopore holes, making vertical gardens from used bottles (Figure 4), and campaigning carrying packaged meal from house to reduce plastic and styrofoam waste from canteens or food vendors. The form of providing supporting facilities and infrastructures adds a score to the fourth aspect, that is the management of environmentally friendly supporting facilities.

Figure 3. Trash bin before (left) and after training (right)

(1) (2) (3)

Figure 4. Composting organic waste (1,2) and vertical garden (3)

In addition to training aimed at increasing the awareness and concern of the school community in implementing environmental conservation activities and creating zero waste schools, there are other factors in supporting the success of the program. This factor is commitment from the top management [13], in this case is the Principal. The principal as a leader in the school is an important factor in keeping the program running and able to run sustainably [14,15].

Commitments from the School Principal can be realized by making a policy or regulation and socializing the policy or regulation to all school community [12,14].

The Principal has shown his commitment to the waste management program by conveying it regularly during Monday's ceremony to teachers and students in their respective schools.

Changes as a whole and continuously require sufficient time because they cannot change in a short time [16]. Third party can help motivate the change process because the third party can become role models and trigger perceptions [17] of school community in implementing waste management behavior at the school level.

In implementing waste management interventions in the schools, the researchers had several difficulties in keeping the program running continuously. We can only describe the conditions of waste management before and after the intervention without knowing for sure how much the volume of waste is reduced after the intervention. In open discussions with the teachers and students, the researchers also had several matters that hindered the program's sustainability, including the busy schedule of schools to fulfill educational activities such as exam preparation so that there was a lot of time allocated in learning activities. Regarding the results of discussions with the Principal and Teachers, this issue can be overcome by adding waste management activities and environmental preservation efforts into the education curriculum activities so that the activities can be controlled and run without disrupting other activities. Adding a series of waste management and environmental preservation activities to the structure of the formal education curriculum in schools can also improve scores on aspects of implementing an environment-based curriculum in Adiwiyata assessment.

Conclusion

Various efforts can be made in realizing zero waste schools such as training to increase awareness and motivation for behavior change and to increase soft skills to trigger citizen participation in efforts to change behavior and provide supporting facilities and infrastructure in optimizing waste management programs in schools. From the programs provided such as training to make biopore holes as a means to reduce organic waste and training to make vertical gardens using used goods, it is expected to help the schools increase participation in achieving Adiwiyata scores better. However, this is not enough without the support of the superior (Principal) in the form of a superior commitment.

Financial Support

This activity is funded from the Community Service Grant, Universitas Indonesia.

Conflic of Interest: No conflict of interest in this activity.

Ethical Clearence: The Ethical Review was issued by the Ethics Commission of the Faculty of Public Health, Universitas Indonesia.

Acknowledgement: The researchers would like to express their gratitude and highest appreciation to the Directorate of Research and Community Service at the Universitas Indonesia as a funder in supporting the implementation of this program. In addition, the researchers also expressed their gratitude to all community, both the School Principal, Teachers, and Students from Sukatani 6 Primary School Depok and Cilangkap 6 Primary School Depok for allowing and participating in this community service program.

Effects of Health Perception, Generativity, and Wisdom on Job Competency of Korean Care Workers

Hee Kyung Kim[1], Cheol Hee Park[2], Nan Young Lee[3]

[1]Professor, Department of Nursing, Kongju National University, Gongju, South Korea, [2]Master degree student, Department of Nursing, Kongju National University, Gongju, South Korea, [3]Lecturer, Department of Nursing, Kongju National University, Gongju, South Korea

Abstract

Purpose: The purpose of this study is to produce fundamental materials for nursing intervention development for care workers' job competency enhancement by analyzing impact of care workers' health perception, generativity and wisdom on job competency.

Methods: Data was collected by means of self-report questionnaire with ethical considerations from 116 care workers at two nursing homes and one care worker center in D Borough in D City, two nursing homes in J Borough, and one nursing home in S Borough. The collected data was then analyzed by frequency scale, mean, standard deviation, t-test, ANOVA, Pearson correlational coefficients, and stepwise multiple regression.

Results: The care workers' health perception scored 3.86 points out of 5 points, generativity scored 2.75 points out of 4 points, and wisdom scored 3.49 points out of 5 points, and job competency scored 3.79 points out of 5 points. The job competency of care workers was a moderate positive correlation with health perception ($r=.49$, $p<.001$), generativity ($r=.34$, $p<.001$), wisdom ($r=.47$, $p<.001$). The health perception ($\beta=.346$, $p<.001$) of care workers had a significant influence on job competency. Health perception, wisdom and work experience of care workers explained 39.6% of job competency.

Conclusion: Care workers should be provided with environmental and institutional strategies for constant service provision without career disruption. Job competency affected by care workers' health, wisdom and work experience, therefore, regular check-up and spur for maintenance of good health are required, in addition to constant refresher and capability enhancement education for extended wisdom on caring and life in daily lives. On top of that, a capability management program should be developed in consideration of the said factors. Job competency increased in proportion to work years in elder caring, therefore, institutional management of manpower is needed in policy-level.

Keywords: *Health perception, Generativity, Wisdom, Job competency, Care workers*

Introduction

The country's current population is 51,635,000 as of 2018 and expected to increase until otherwise in 2031, while the current population over age 65, which is 7,381,000, is expected to increase until 2050 (18,813,000). Given the rapid population ageing, the elderly over age 65 is forecasted to reach 41.0% in 2060[1] from 14.3% in 2018. Accordingly, there has been a need of health and welfare policies for the elderly called out to date, especially of high-quality services of health and medical employees for elderly's better health and life quality.

In this regard, the country implemented the National Long-Term Care Insurance in 2008 whereby complimentary caring is provided to the elderly of great age or with a senile disease struggling in daily lives to assist in housework and physical activities in order to help improve their health and life in later years, and also ease burden on their families to ultimately enhance the national quality of life, and has been reinforcing medical

and nursing service, day and night caring service, senior welfare centers and elderly care facilities for those over age 65 annually.[1] Professional nursing centers, elder care hospitals and educational institutions have devoted to cultivating care workers as the professionals to provide quality in-home services

Care workers' job competency can be seen as a worker's capability to provide efficient in-home care services using its acquired skills and knowledge as internalized with its own values and job attitude. Internalization processes differently by individual, and thus the quality of service appears differently depending on how the worker internalizes its acquired skills and knowledge upon its own values and attitudes when rendering care services[2]. Simply put, care workers' job competency is an integral of worker's set of values, attitude, knowledge and skills.

Impact factors on enhancement of care workers' job competency will vary, although the primary should be worker's subjective perception of its own health. The subjective health perception is an overall wellness of physical, psychological and social functional ability[3], being neutral between human and environment, with an ability to adapt to environment, perform social tasks and roles[4]. Hence, positive self-perception of health is seen to reduce work stress and enhance job competency.

According to Erikson's human development and life cycle theory, generativity is an adult's ability to self-survive and create fruits and thoughts that will outlast for next generations as it looks after families, society and system, maintains and succeeds cultural tradition, and also an affection to nurture and lead next generations.[5] Generativity ideally arouses one's passion and resolution to provide a guidance outside the range of caring, nurturing and family, and takes a form of advice, teaching, guidance and volunteer activity in work place and local community. Accordingly, an individual with high generativity is influential on others with desirable results.[6] Most care workers are falling in the middle-aged bracket, whose development task is achievement of generativity. Generativity is also considered an essential element and value for care workers' job competency enhancement given its attributes.

A research on job competency of 120 care workers at elders nursing home[7] revealed wisdom as the most influential factor on job competency. A wise man has problem-solving capability and insights to embrace life and build a stronger relationship with others. As wisdom refers to, in cognitive terms, keen eyes, insights and exceptional judgement, while in private terms, balanced integration and consonance of ego[8], a wise care worker assumes positive attitude and performs impartial, empathic communication in elder caring.

Therefore, this study attempts to identify impact factors on enhancement of care workers' job competency after defining the degree of health perception, generativity and wisdom in respect of the level of job competency.

Method

Subjects: The subjects of this study are 116 care workers with more than 6 months of work experience selected from two nursing homes and one care worker education center in D Borough in D City, two nursing homes in J Borough and one nursing home in S Borough. All participation was made voluntarily by grownup male and female workers upon their understanding of purpose of this study as submitted with written consent. As the least number of samples for 5 predictors, effect size 0.15, significance level 0.05 and power 0.90 was calculated to be 116 by G-power 3.1.9.4 program, but given elimination rate 10%, a total of 128 workers were surveyed initially, with those with less than 6 months of work experience excluded later on, leaving the final number to be 116. Ahead of the survey, the participants were informed of this study's purpose and survey method, that the survey results would be anonymized as confidential and be only used for study purpose. They submitted a study participation acceptance form, knowing participation could be revoked anytime if desired.

Instruments

Health perception: The Korean version of THI (Todai Health Index) [9], developed by Health Department of Tokyo University Medical School, was used as amended and supplemented for this study. The tool consisted of 30 questions across 4 sections-physical, psychological, spiritual and social. Using a 5 point Likert scale, a higher score indicated a better condition of health perceived. For this study's reliability, Cronbach's α was shown .94.

Generativity: LGS (Loyola Generativity Scale), developed by McAdams and Aubin[10], used by Hong[11], was employed as amended for this study. It consisted of 19 questions on such concepts as teaching, knowledge

transfer, positive contribution to society, caring and responsibility for others, creativity and productivity, sustainable legacy. Using a 4 point Likert scale, a higher score indicated a higher level of generativity. For research reliability, Cronbach's α of this study was shown .79.

Wisdom: Korean Men's Wisdom Scale (KMWS), developed by Kim[12] was used. It consisted of 43 questions across 4 sectors of cognitive ability, refinement and balance, positive attitude toward life, empathic interpersonal relationship. Using a 5 point Likert scale, a higher score indicated a higher level of wisdom. For research reliability, Cronbach's α of this study was shown .97.

Job competency: National Capability Standard (NCS), restructured for care workers by Lee[13] was used. It consists of 24 questions on communication capability, problem-solving capability, self-development capability, interpersonal relationship capability, technique capability and professional ethic capability. Using a 5 point Likert scale, a higher score indicated a higher degree of job competency. For research reliability, Cronbach's α of this study was shown .94.

Data collection: The researchers of this study visited 5 nursing homes and 1 care worker education center in D City to provide explanation on the purpose of this study to care workers directly after getting approval of the center head and manager upon explanation of the purpose and method of this study. Written consent was submitted by participants ahead of survey for data collection.

Ethical consideration: Approval was acquired by the ethics committee of K University on the objective, methodology and protection of rights of study participants (KNU_IRB_2019-90). During the study period the guidelines on ethical studies were observed.

Data analysis: Using the SPSS/WIN 23.0 program, the general characteristics and variables were analyzed for frequency, percentage, mean and standard deviation. The difference in job competency across different general characteristics was analyzed using a t-test, ANOVA and Scheffe test. The correlation between care workers' variables was analyzed using Pearson's correlation coefficients. Multiple regression analysis was conducted to analyze the factors affecting the subjects' job competency.

Results

General Characteristics of Korean Care Workers

The average age of 116 care workers was 57.43±0.51, with the majority in the age bracket of 50-59 (44.0%). Female care workers accounted for most (112 people, 96.6%). For educational background, 93 had a minimum high school education (80.2%). The average years of work experience was 42.5±33.20 months, with 47 workers less than 24 months (40.5%). The majority of respondents had received 1 or more refresher education or professional education for the past one year (85 people, 73.3%). More than a half earned less than KRW1 million (73 people, 62.9%). For the form of job, in-home care service job took up the majority (112 people, 96.6%). Those who care one person a day were 62 (53.4%).

Degree of Health Perception, Generativity, Wisdom and Job Competency in Korean Care Workers:

Korean care workers' health perception scored 3.86 points out of 5 points, generativity scored 2.75 points out of 4 points, and wisdom scored 3.49 points out of 5 points, and job competency scored 3.79 points out of 5 points (Table 1).

Table 1. Degree of Health Perception, Generativity, Wisdom and Job Competency in Korean Care Workers

Variables	M±SD	Range
Health perception	3.86±0.51	1~5
Generativity	2.75±0.32	1~4
Wisdom	3.49±0.50	1~5
Job competency	3.79±0.48	1~5

Difference in Job Competency across General Characteristics

Comparative analysis of job competency According to general characteristics found that work years (F=5.19, p=.007) and form of job (t=4.38, p=.016) make differences in job competency: A group of people with more than 5 years of work experience showed a higher level of job competency than a group with years between 2 and 5; a group of people who provide in-home care

service showed a higher level of job competency than a group on shifts at institutions.

Correlation between Perceived Health Perception, Generativity, Wisdom and Job Competency in Care Workers

The job competency of Korean care workers was a moderate positive correlation with health perception (r=.49, p<.001), generativity (r=.34, p<.001), wisdom (r=.47, p<.001) (Table 2).

Table 2. **Correlation between Health Perception, Generativity, and Wisdom on Job Competency in Korean Care Workers**

Variables	**Health perception r(p)**	**Generativity r(p)**	**Wisdom r(p)**	**Job competency r(p)**
Health perception	1			
Generativity	.43(<.001)	1		
Wisdom	..43(<.001)	.45(<.001)	1	
Job competency	.49(<.001)	.34(<.001)	.47(<.001)	1

Factors affecting Job Competency in Korean Care Workers

To find out the factors affecting the job competency of Korean care workers was conducted multiple regression analysis by the stepwise method with health perception, generativity, and wisdom as independent variables, and work experience and type of working agency among general characteristics. The problem of multicollinearity expected in the multiple regression analysis was 0.1 or higher with the tolerance limit of 0.533~0.785, and the variance inflation factors (VIF) was 1.274~1.877 that did not exceed the standard of 10 or higher, so there was no problem of multicollinearity. Also, the Durbin-Watson value was 1.795, with no problem of autocorrelation. The analysis showed that health perception (β=.346, p<.001) had a high influence on the job competency of Korean care workers and As it shows explanation power of 39.6%, showed that the higher the degree of health perception and wisdom, and the longer of work experience, the higher the job competency is. Health perception, wisdom and work experience were the variables affecting the job competency of Korean care workers (Table 3).

Table 3. Factors affecting Job Competency in Korean Care Workers

Variables	B	SE	β	t	p
Constant	1.552	.341		4.554	<.001
Health perception	.330	.080	.346	4.138	<.001

Work experience (25~60 months)	-.368	.099	-.375	-3.735	<.001
Work experience (over 61 months)	-.261	.100	-.264	-2.615	.010
R^2=.396 Adj. R^2=.375 F=18.218 *p*<.001					

Reference: work experience (less than 24 months)

Discussion

This study's job competency was shown 3.79 out of 5 possible, similarly to that of Kim's[2] research (3.68±0.51) on 217 in-home service care workers. These levels are merely modest, requiring improvement. Generativity was shown 2.75 out of 4 possible, also moderate and similar to that of Hong[11]'s research (2.70±0.42) on adults in senescence. The average age of this study's subjects was 57.4, with the majority over age 50, whose development task should be considered generativity achievement. According to McAdams & Aubin[10], an adult fosters, educates, leads and promotes a progressive spirit of next generation and attains generation of products and fruition of life beneficial to social systems, i.e., generativity. Generativity is a drive for one's better perception of itself and its own life to help assess oneself more positively and meaningfully. People with more generativity associated resources and abilities tend to be more supportive for others and feel more responsibility for society.[11] Generativity is deemed the main concept to motivate in care workers' job performance who are mostly middle-aged, therefore, they should be aided with a chance of improvement.

This study found that job competency had pure correlations with health perception, generativity, and wisdom, while impact factors on job competency as health perception, wisdom and work experience. Subjective perception of good health is a comprehensive self-evaluation in physical, physiological, psychological and social terms where health is the key element of every life. Generativity is also a main element of caring for others.[11] Wisdom is another essential element of care workers' performance as a wise man displays comprehension, communication skill, competence, interpersonal relationship and social humbleness.[14] Therefore, it is always needed to consider and devise measures to improve the said concepts for enhancement of care workers' job competency. On top of that, care workers should make daily efforts to stay fit through regular check-up and to make early detection of possible disease for timely treatment, and further to nurture wisdom while constantly pursuing relevant job experiences for extended knowledge and skills. There should also be institutional aids; local governments, educational institutions and practical affair institutions should exert best possible endeavors to achieve job competency improvement and quality environment formation.

Conclusions

For enhancement of care workers' job competency, daily care for health management is needed, for early detection of possible disease for timely treatment as well. They should endeavor to increase generativity, the development task of the middle-aged, and to live a wise life individually. As this study finds health perception, wisdom and work experience as the main impact factors of job competency, care workers should be provided with a chance to improve their knowledge and skill for continued caring service without career disruption, assisted by job capability enhancement programs and quality environment devised by their employer institutions in consideration of the said elements, health, wisdom and generativity.

Effects of Self-efficacy and Wisdom on Job Competence of Care Workers in Korea

C, Nan Young Lee[2], Cheol Hee Park[3]

[1]Professor, Department of Nursing, Kongju National University, Gongju, South Korea, [2]Lecturer, Kongju National University, Gongju, South Korea, [3]Master degree student, Kongju National University, Gongju, South Korea

Abstract

Purpose: The purpose of this study was to analyze the effect that self-efficacy and wisdom on job competence in care worker in Korea.

Method: The subjects of this study were 123 care workers. The data were analyzed using descriptive statistics, t-test, ANOVA, Pearson's correlation coefficient and stepwise multiple regression using the SPSS Window 23.0 program.

Results: The care workers' self-efficacy scored 3.80 points out of 5 points, and wisdom scored 3.63 points out of 5 points, and job competence scored 3.66 points out of 5 points. The job competence of care workers was a high positive correlation with self-efficacy ($r=.53$, $p<.001$), wisdom ($r=.72$, $p<.001$). The wisdom ($\beta=.715$, $p<.001$) of care workers had a significant influence on job competence, showing a 51.1 percent explanation power.

Conclusion: The self-efficacy and wisdom of care workers showed a positive correlation with job competence, the higher the degree of self-efficacy and wisdom was found to be, the higher the job competence. Wisdom is the most influential variable on the job competence of care workers. Therefore, in order to improve the health and quality of life of the elderly who living at home by increasing the job competence of the care workers, it is necessary to provide the intervention program so that self-efficacy and wisdom can be developed. Especially, wisdom has the attribute that can be acquired through experience while living, so it is also necessary to train them to make a successful resolution in response to various problems. This study is aimed at the care workers who provide home care, so it is suggested that the study is repeated targeting the care workers who work in the hospital by expanding the institution.

Keywords: *Care workers, Self-efficacy, Wisdom, Job competence*

Introduction

The medical expenses of the elderly aged 65 or older are 34.5% of the total medical expenses according to the statistics of 2013, and the medical expenses of the elderly will account for 45.6% of the total medical expenses in 2020, which is caregiving and health management for the elderly is emerged as an important national issue. [1]According to the statistical data of the elderly in 2018, The elderly aged 65 tend to increase their medical and caregiving services to 38.6% among the social concerns for their aging, and In 2017, the number of welfare facilities for the elderly is 76,371, which is increasing every year, and the number of elderly care facilities and day and night protection services is continuously increasing. [2]Among the health workforce who care for the elderly, the care workers are the primary workforce who care for the health of the elderly such as nursing and bathing in the geriatric hospitals, the care facilities, and the home, their professional ability play significant role in managing the health of the elderly. Also, only those who have completed a specific education at an

Corresponding Author:
Nan Young Lee
Lecturer, Dept. of Nursing, Kongju National University, Gongju, South Korea
E-mail: 317nan@naver.com

educational institution recognized by the Ministry of Health and Welfare and obtained a certificate through a qualification test may work as a care worker.

On the other hand, competence is an internal characteristic of an individual who causes effective and excellent performance by the criteria in a specific situation or job, it is defined as the total aggregate of the features, actions, and [3]characteristics necessary to achieve successful job performance. [4]Competence means the individual's performance as a result of applying what the learner has learned to work, and measuring competency means measuring an individual's performance. Jang[5] stated that the competence of the care worker who directly provides the service is a critical factor that governs the quality of service and that the environment should be developed so that he or she can acquire nursing skills with a sense of occupation. Shin[6] defined Job competence as a whole of a given role within the organization, such as the mission and strategy that an individual seeks to perform a successful job in the enterprise or organization, and such as skills, attitudes, and knowledge necessary to perform. Therefore, this job competence of care workers plays an essential role in the service targeting the elderly, and it is considered to be an essential factor in improving the quality of life and health preservation of the elderly. In particular, since the care workers who belong to the visiting care center visits the elderly's home and takes care of the elderly almost alone, it is thought that the level of individual competence plays a significant role in the health and quality of life of the elderly.

Once we analyze the factors that are relevant to Job competence so far, we can take into account the variable of self-efficacy and wisdom. When care workers perform caring, they need assurance and judgment of their actions in dealing with complex situations. Self-efficacy is the primary source of action and is caused by subjective judgments in repeated tasks that are truly self-assured of their ability, and this can be enhanced by the development of active ability to react and expertise, and if this process is repeated, subjective judgment is likely to lead to objective judgments7, so the self-efficiency is judged to have a positive effect on the job competence of care workers who take care of the elderly in vulnerable situations and also contributes to the improvement of job competence volume.

Also, Wisdom is the core of human development8 because it is the work of the mind to discern the reason or good or evil of things, and positive qualities such as self-integration and maturity, judgment and interpersonal skills, and understanding of life. Wisdom can be said as a mature mental activity that solves various problems in life through a balanced integration of cognitive, emotional, mental, moral, and relational factors. In the case of a wise care workers, it is thought that they will be able to perform the job well if they take care of the elderly with such as a positive attitude, a sympathetic interpersonal and a perspective.

Therefore, in this study, we intend to use that targeted on care workers to identify the extent of their job competence and analyze the extent to which their effectiveness and wisdom affect the job competence of the care workers as a baseline data for developing an arbitration program to increase the amount of job competence of care workers.

Methord

Subjects: The subjects of this study were 123 care workers in charge of visiting care centers located in Dong-gu, Jung-gu, and Seo-gu, D city. They are adult men and women who understood the purpose of the study and voluntarily expressed their willingness to participate and provided written consent. The study subjects were those with at least six months of experience as care workers. The number of samples was calculated using the G-power 3.1.9.4 program. The number of samples required to maintain the effect size .15, significance level .05, power .90, and four predictors was 108 people, and the subjects were 130, considering a 20% dropout rate.

Instruments

Self-efficacy: The tool that the general Self-efficacy scale developed by Chen, Gully, & Eden[9] then adapted by Noh[10] was used. It is a 5-point Likert scale with 8 questions in total and is from 'Strongly disagree' of 1point to 'Strongly agree' of 5points, which means that the higher the score is, the higher the degree of self-efficacy. The reliability in the study of Noh[10] was Cronbach's α=.83 and this study was .85

Wisdom: KMWS developed by Kim11 was used. In total, 43 questions consist of 4 sub-regions as 16 questions for cognitive competence, 11 questions for purify and balance, 10 questions for positive attitudes of life, and 6 questions for empathetic interpersonal relations. By the scale of from 'Strongly disagree' of 1point to 'Strongly agree' of 5points, we could see that

the higher the score, the higher the degree of wisdom is. The reliability at the time of development was Chronbach's α=.93 and this study was .95.

Job competence: We use the tools from National Occupational Capacity Standards with (NCS) adapted by Lee to suit for care workers. In total, 24 questions consisted of sub-regions as 4 questions for communication competence, 3 questions for problem-solving competence, 4 questions for self-development competence, 4 questions for interpersonal competence, three questions for technical competence, and 6 questions for vocational ethics competence. By the scale of from 'Strongly disagree' of 1point to 'Strongly agree' of 5points, we could see that the higher the score, the higher the degree of job competence is. The reliability at the time of development was Chronbach's α=.85, and this study was .93.

Data collection: Researchers were visited four visiting care centers located in Dong-gu, Jung-gu, and Seo-gu in D city in person to explain the purpose and method of research to the Director of the Center and got permission, then explain the purpose of the study to the care workers, and complete the questionnaire after obtaining written consent. Use time to complete the questionnaire was about 15 to 20 minutes.

Ethical consideration: Approval was acquired by the ethics committee of K University on the objective, methodology and protection of rights of study participants (KNU_IRB_2019_66). During the study period the guidelines on ethical studies were observed.

Data analysis: Using the SPSS/WIN 23.0 program, the general characteristics and variables were analyzed for frequency, percentage, mean and standard deviation. The difference in job competence across different general characteristics was analyzed using a t-test, ANOVA and Scheffe test. The correlation between the subjects' variables was analyzed using Pearson's correlation coefficients. Multiple regression analysis was conducted to analyze the factors affecting the subjects' job competence.

Results

General Characteristics of Care Workers: The average age of 123 nursing care providers was 56.13, and 39.8 % (49 people) of them was over 60 years old as the most significant number, and most of them 83.7% (103 people) was female, and for the graduation level was mostly high school graduates as 64.2 %(79 people) . The average working experience of care workers was 41 months, with 70.6% (72 people) groups of less than three years as the most significant number. The group that said they had no experience in receiving remuneration or professional education within the past year as the most significant number 44.7 percent (55 people), and in total income accounted, 510,000 won ~ 1 million won was more than the majority as 61.8 % (76 persons). Service institutions were mostly cases of visiting care performing as 87.8 % (108 people).

Degree of Self-efficacy, Wisdom and Job Competence in Care Workers: The care workers' self-efficacy scored 3.80 points out of 5 points, and wisdom scored 3.63 points out of 5 points, and job competence scored 3.66 points out of 5 points (Table 1)

Table 1. Degree of Self-efficacy, Wisdom and Job Competence in Care Workers

Item	M±SD	Range
Self-efficacy	3.80±0.52	1~5
Wisdom	3.63±0.44	1~5
Job competence	3.66±0.47	1~5

Difference in Job Competence across General Characteristics: Looking at the difference in job competence according to general characteristics of care workers was, it has shown that there was no difference in the degree of the job competence in all characteristics of age, gender, education, work experience, In-service education or professional education, total income, and the type of service institution.

Correlation between Self-efficacy, Wisdom and Job Competence in Care Workers: The self-efficacy and wisdom (r=.70, p<.001) of the care workers showed a high positive correlation, and the self-efficacy and job competence (r=.53, p<.001) and the wisdom and job competence (r=.72, p<.001) also showed a high positive correlation. In other words, the higher the degree of self-efficacy of care workers, the higher the degree of wisdom and the higher the degree of self-efficacy or the higher the degree of wisdom was found to be, the higher the degree of job competence (Table 2).

Table 2. Correlation between Self-efficacy, Wisdom and Job Competence in Care Workers

Variables	Self-efficacy r(p)	Wisdom r(p)	Job competence r(p)
Self-efficacy	1		
Wisdom	.70(<.001)	1	
Job competence	.53(<.001)	.72(<.001)	1

Factors affecting Job Competence in Care Workers: To find out the factors affecting the job competence of care workers was conducted multiple regression analysis by the stepwise method with self-efficacy and wisdom as independent variables. The problem of multicollinearity expected in the multiple regression analysis was 0.1 or higher with the tolerance limit of 1.000, and the variance inflation factors (VIF) was 1.000 that did not exceed the standard of 10 or higher, so there was no problem of multicollinearity. Also, the Durbin-Watson value was 1.341, with no problem of autocorrelation. The analysis showed that wisdom(β=.715, p<.001) had a high influence on the job competence of the care workers and As it shows explanation power of 51.1%, showed that the higher the degree of wisdom, the higher the job competence is, and wisdom was the only variable affecting the job competence of the care workers.

Table 3. Factors affecting Job Competence in Care Workers

Variables	B	SE	β	t	p
Constant	.878	.249		3.526	.001
Wisdom	.765	.068	.715	11.243	<.001
R^2=.511 Adj. R^2=.507 F=126.408 p<.001					

Discussion

This study analyzes the relationship between self-efficacy and wisdom and to identify the influential factors of job competency in order to provide high-quality care services on visiting the elderly's home by using their job competency targeted to care workers belonging to the visiting care center.

According to the study, Most of the care workers were middle-aged women. That is similar to Lee13's study result. Middle-Aged women cover most of the care worker jobs. As their level of job competency is moderate, they need continued and planned training for enhanced job competency. The care workers who are visiting the home must use their competence to provide care services without the supervision of the medical practitioner, so they should seek to improve job competence through training. Since the job training with inappropriate timing and duration act as an obstructive factor to care workers, it should be considered and provided the job training.

As self-efficacy can increase performance by making efforts, challenges, and actions as the primary source of behavior, so it is necessary to consider for job competence. Also, care workers should be able to demonstrate their job competence through efforts to increase wisdom, as wisdom, which is the result of the study targeting the counselors, was an important factor affecting the counseling process and performance. Wisdom people are enhanced in their ability to accept life and build relationships with others from a high problem-solving ability and insight, so it becomes a positively necessary factor for care workers.

Therefore, it is necessary to provide job education programs considering the variables of self-efficacy and

wisdom of care workers.

Conclusions

Self-efficacy and wisdom of care workers had a positive correlation with job competence, the factor affecting the job competence of care workers was wisdom, which had a significant effect. Therefore, should be developed and applied to the caring arbitration programs that encourage caregivers to increase their self-efficacy, which is the confidence that they can do, and to exercise their wisdom to pay more attention to their duties and solve various problems.

Thereby it can bring about the effect of the quality of life and health recovery of the elderly who are provided with care at home by improving the competencies of care workers. In the future, it proposes that the study is repeated targeting the care workers working in hospitals.

Risk Factors of Chronic Energy Deficiency in Pregnant Women in The Working Area of Sungai Jingah Public Health Center Banjarmasin 2019

Helwatin Najwa[1], Triawanti[2], Lenie Marlinae [3], Roselina Panghiyangani [2], Meitria Syahadatina Noor[2]

[1] Master of Public Health Science Study Program, [2] Medical Education Study Program, [3]Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Banjarmasin, Indonesia

Abstract

Chronic Energy Deficiency (CED) is a problem of malnutrition, especially in pregnant women. The prevalence of CED in South Kalimantan Province is 18% and Banjarmasin City has 1296 cases. The highest CED was in the Sungai Jingah Public Health Center of 141 cases. This study was to analyze the relationship of age, knowledge, occupation, income, parity, distance of pregnancy, and the number of family members with CED in pregnant women in the working area of Sungai Jingah Public Health Center, Banjarmasin. The research using a cross sectional with a questionnaire. Statistical analysis using chi square test and multiple logistic regression. The study population were pregnant women at Sungai Jingah Public Health Center month period from January to March the year 2019 a number of 289 mothers and sampling of 103 people. The result showed p-value age (p=1.000), knowledge (p=0.001), occupation (p=0.996), income (p=0.006), parity (p=1.000), space of pregnancy (p=0.371), the number of family members (p = 0.017) to CED in pregnant women. Multivariate analysis showed knowledge (Exp.B=5.050), income (Exp.B=2.402), number of family members (Exp.B=3.644) to chronic energy deficiency (CED) in pregnant women. Knowledge, income, and number of family members have a relationship with CED in pregnant women. Age, occupation, parity, and space of pregnancy were not related to CED in pregnant women. The most dominant factor related to CED was knowledge.

Keywords*: knowledge, income, number of family members, chronic energy deficiency, pregnant women*

Introduction

The proportion of pregnant women with CED in Indonesia was 17.3% and the province of South Kalimantan was currently still above the national scale of 18%.[1] Whereas based on data from the Nutrition Status Monitoring (PSG) of South Kalimantan Province in 2017, the percentage of pregnant women with CED in Banjarmasin was 21.5%.[2] The number of pregnant women who did upper arm circumference (LILA) measurements was 14,087 (97.21%) and the number of pregnant women with CED was 1296 (8.94%). Public health center with the highest CED among pregnant women were in the Sungai Jingah Public Health Center area with a percentage of 141 (12.35%).[3]

Chronic Energy Deficiency (CED) in pregnancy the most common cause of bleeding and infection is a major factor maternal mortality. Bleeding ranks the highest cause of maternal death in Indonesia, amounting to 30.3%. In addition, pregnant women who experience chronic energy deficiency also affect the condition of the fetus they contain. CED is caused by several factors including age, education, knowledge, low economic status, workload, health services, health status/history of illness, parity and space of pregnancy, the amount of food consumed in the household, absorption of food, and consumption of iron tablets.

Materials and Method

This research is a quantitative study with an analytic observational research design through a cross sectional approach. The research analyze the relationship between independent variables (age, knowledge, occupation, income, parity, pregnancy spacing, and number of family members) with dependent variable (CED in pregnant women).

The research location is the working area of Sungai Jingah Public Health Center, Banjarmasin. Study period start from August to October 2019. The population in this study was the pregnant women in Sungai Jingah Public Health Center month period from January to March 2019 of 289 people. The minimum sample needed in this study was 93 people. To avoid the possibility of samples coming out or missing during the study, it is necessary to increase the number of samples by 10% from what was determined. bringing the total sample to 103 pregnant women. Samples were taken by purposive sampling technique. The instrument in this study will use a questionnaire that has been tested for validity first.

Findings and Discussion

Table 1. Bivariate Analysis Results

Variable	CED				Total		Chi-Square
	Yes		No

Low	11	13.9	68	86.1	79	100	

Relationship of Age with Chronic Energy Deficiency in Pregnant Women

The Fisher's exact test results with p-value 1.000 (p> 0.05) which means there was no relationship between age and chronic energy deficiency (CED) in pregnant women at Sungai Jingah Public Health Center Banjarmasin in 2019. It can be due to the data based on the age of the respondents at most at the age of 20-35 years (94.2%) which is the best age for pregnant women. Reproductive organ systems and cells in the body are in the healthiest and safest conditions, and minimal risks can occur to the mother and fetus, so it is expected that women can undergo a healthy pregnancy. The results of the study are in line with research Risqah (2017) and Musni (2017), where the p-value is 0.15 which means that age is not associated with CED in pregnant women.[4,5]

Relationship of Knowledge with Chronic Energy Deficiency in Pregnant Women

The Chi-square test results with p-value 0.001 (p <0.05), which means that there is a relationship between knowledge and CED in pregnant women at the Sungai Jingah Public Health Center in Banjarmasin in 2019. Mothers who have good knowledge are able to understand balanced nutritional intake, differentiate the types of nutrients in food that must be consumed every day during pregnancy, know the risks that can occur if mothers experience malnutrition, and understand how to improve nutrition and maintain maternal health and fetus during pregnancy, and be able to apply good attitudes and behavior in the selection of food to meet the intake of nutritious food during pregnancy.

PR results of 5.118 (PR>1) which means that mothers with lack of knowledge 5.1 times will experience CED compared to mothers who have good knowledge. Good knowledge about nutritional health will have an impact on maternal behavior in meeting nutritional needs during pregnancy. This condition will have a direct impact on the health of the mother and fetus. The results of this study are strengthened by Triwahyuningsih (2018) where mothers who have less knowledge are 9.7 times more likely to have CED compared to mothers with good knowledge.[6]

Relationship of Occupation with Chronic Energy Deficiency in Pregnant Women

The Chi-square test results with p-value 0.996 (p> 0.05), which means there was no relationship between occupation and CED in pregnant women at the Sungai Jingah Public Health Center Banjarmasin in 2019. Mother's occupation is not associated with CED because work factors are influenced by other factors, namely lack of mother's knowledge, low family income, and high number of family members. The results of this study are in line with the research of Syarifuddin (2013) which states that there is no meaningful relationship between maternal occupation with CED. It can be caused by the activity factors of the respondents are required to do activities outside the home due to workload so as to make them feel more stressed, lifestyle and irregular eating patterns so that it is not impossible if the respondent can risk chronic energy shortages.[7] Mother's busyness is not one obstacle to meet the adequacy of nutrition during pregnancy.[8]

Relationship of Income with Chronic Energy Deficiency in Pregnant Women

The Chi-square test results with p-value 0.006 (p<0.05), which means there was a relationship between income and CED in pregnant women at the Sungai Jingah Public Health Center Banjarmasin in 2019. Low family income will have an impact on the ability of families to meet nutritional needs in the household, families with low incomes tend to limit food consumption to save family expenses. Result of PR 4.112 (PR> 1) means that income is one of the risk factors for CED in pregnant women. Mothers with low family income 4.1 times more likely to experience CED compared to mothers who have family income high. Families with low economic status have a 5.7 times greater risk of pregnant women experiencing CED. It is because economic status or income has always been one of the determining factors in a healthy pregnancy process.[9] Families with a sufficient economy can check their pregnancies regularly, plan for delivery in health workers, and make other preparations properly. The level of income can determine consumption patterns. Limited family income limits the ability of families to buy nutritious food ingredients, thus the level of income plays an important role in determining the nutritional status of pregnant women.[10]

Relationship of Parity with Chronic Energy Deficiency in Pregnant Women

The Fisher-exact test result with p-value 1.000 (p>0.05), which means there was no relationship between parity and CED in pregnant women at the Sungai Jingah Public Health Center Banjarmasin in 2019. It could be due to the fact that based on existing data there was no risk of multipara of 103 pregnant women. The results of this study are in line with Yulianti (2018) that there was no relationship between parity and CED. Even though the risk of the CED occurrence is pregnant women with risk parity, if basically the mother has good knowledge about the nutritional status of pregnant women which is part of an effort to optimize the ability of mothers. It is expected that pregnant women have good nutritional status as well. Widita (2011) also stated that there was no significant relationship between parity and malnutrition in mothers in the third trimester with p-value 0.361.[11]

Relationship of Pregnancy Spacing with Chronic Energy Deficiency in Pregnant Women

The Fisher-exact test result with p-value 0.371 (p>0.05), which means there was no relationship between the space of pregnancy and CED in pregnant women at the Sungai Jingah Public Health Center Banjarmasin in 2019. It was allegedly because the results of the description of the pregnancy spacing was not at risk ≥ 2 years. The results of this study are in line with Wijanti (2016) which states almost all respondents have no risk from pregnancy spacing because other factors such as age and mother's education. Other factors are associated with CED, namely physical work and family income.[12]

Relationship of Family Members with Chronic Energy Deficiency in Pregnant Women

The Fisher-exact test result with p-value 0.017 (p<0.05), which means there was a relationship between the number of family members and CED in pregnant women at the Sungai Jingah Public Health Center Banjarmasin in 2019. The large number of family members is certainly different from the number of small family members in the distribution and distribution of food, the large number of family members will cause the food consumed is insufficient in terms of quantity.

The PR results are 3.709 (95% CI, 1,307-10,529), means that the number of family members is a risk factor for CED in pregnant women. Mothers who have a high number of family members (>4 people) 3.7 times have risk of CED. There was a relationship between the number of family members in the CED incidence of pregnant women. Mothers with a large number of family members have an 8 times greater chance of experiencing CED. It is due to the number of family members or family size will affect consumption patterns. Nutritional status is influenced by the number of family members. The greater the number of family members, the greater the proportion of family expenses for food, and vice versa. The large number of family members without offset high income results in uneven distribution of food in the family.[13]

The most influential factor with the prevalence of CED

Table 2. Final Models of Multivariate Logistic Regression

Independent Variable	p-value	PR
Knowledge	0.003	5.050
Number of family members	0.023	3.644

The results showed that the factor most associated with Chronic Energy Deficiency (CED) in pregnant women was the knowledge variable (PR=5.050). Knowledge plays an important role in one's life, especially in daily behavior, although mothers have a good family income and a low number of family members, but mothers who lack knowledge will affect the behavior of mothers in choosing nutritious food consumption every day. Mother's knowledge about nutrition and health greatly influences the attitude and behavior of mothers to meet nutritional intake during pregnancy. Mothers who have knowledge can better prepare foods with balanced nutrition for mother and fetus and can understand good nutrition of pregnancy according to the nutritional adequacy rate, whereas mothers who had lack of knowledge can cause a person to perform the selection of food the less careful.

Based on research results mothers with good knowledge are able to understand balanced nutritional intake, as well as differentiating the types of nutrients in food that must be consumed every day during pregnancy. In addition, mothers also know the risks that can occur if mothers experience malnutrition, and understand how to improve nutrition and maintain

health during pregnancy. This study is in line with Febriyeni (2017) which shows that knowledge is the most related factor to CED in pregnant women. It can be seen from the Odds Ratio (OR) that mothers with less risk knowledge 12 times more likely to experience CED. The results of this study are also in line with the research of Taslim (2011) which states that mothers with less knowledge about nutrition are at risk 0.25 times more likely to experience CED than mothers with good knowledge. It is due to mothers who have insufficient knowledge to determine the behavior of mothers in choose foods that are consumed every day.

Conclusion

There was a relationship between knowledge and CED in pregnant women. There was a relationship between income and CED in pregnant women. There was a relationship between the number of family members and CED in pregnant women. There was no relationship between age and CED in pregnant women. There was no relationship between occupation and CED in pregnant women. There was no relationship between parity and CED in pregnant women. There was no relationship between the pregnancy spacing and CED in pregnant women. Knowledge variable is the most related factors to CED in pregnant women at the Sungai Jingah Public Health Center in Banjarmasin.

Ethical Clearance: Before conducting the data retrieval, the researchers conducted a decent test of ethics conducted at the Faculty of Medicine, Lambung Mangkurat University to determine that this study has met the feasibility. Information on an ethical test that the study is eligible to continue. The feasibility of the research was conducted to protect the human rights and security of research subjects.

Abstract

Objectives: The purpose ofthis study is to verify the effects of MTBI applied peer-to-peer relationship improvement training programs on the self-esteem, depression, and anger of female students at Nursing Vocational High Schools.

Method: This study is a Nonequivalent control group pretest-posttest design. The participants included 21 female students attending a Nursing Vocational High School at "D" city, and a total of 8 programs were conducted from October 20th, 2014 to December 3rd, 2014, twice a week, 50 minutes per session. The data analyzed are based on the SPSS/WIN 20.0 Program. The Chi-square (Fisher exact probability) and t-tests were used.

Results: After participation of the MBTI applied peer-to-peer relationship improvement training programs, the self-esteem (t=-2.80, p=.011) of the participants, depression (t=3.61, p=.002), and anger (t=2.22, p=.039), all expressed a statistically significant difference.

Conclusion: It was shown that the MBTI applied peer-to-peer relationship improvement training program that was used in this research had an effect on improving self-esteem, and reducing depression and anger. Based on this research, it will be necessary for the Ministry of Education and local community to cooperate with each other, so that friendly relationship improvement programs with MBTI applications can be applied to regular classes.

***Keywords**: MBTI, Self-esteem, Depression, Anger*

Introduction

Adolescence creates a desire to gain independence from parents, and autonomy, which increases conflicts with parents, and creates a closer relationship with peers[1]. Unlike regular high schools, peer relationships of students at vocational high schools are less intimate, and the levels of conflict and confrontation are high[2,3]. This is due to the fact that students at vocational high schools prefer broad relationships over deep relationships to avoid frequent conflicts between peers, not because they have higher interpersonal or communication skills.

Female students have a stronger desire for new peer relationships than male students, desire deeper relationships between peers[3], and female students complain of difficulties in peer relationships of maintaining technical skills such as talking to, dating, voicing their opinions, and working in teams, unlike

Seung-Woo Han
Assistant Professor, Department of Emergency Medical Technology, KyungilUniversity. Gamasilgil Hayangeup, Gyeongbuk 38428 Korea,
email:swhan@kiu.ac.kr

male students who complain of difficulties in dealing with issues of the opposite sex[4].

Students at vocational high schools often lack self-esteem from lower grades or economic problems, opposed to their will, from the beginning of their admission[5]. The self-esteem of adolescents is influenced by social behaviors acquired through interaction with peers, where they consider themselves important and by social development that keeps them in contact and around their peers[6].

According to the Korea Youth Health Behavior Survey, 42.5% of high school students thought they were depressed, higher than 32.8% of middle school students, 44.3% of female students, higher than 19.4% of male students, and 39.2% of students were from vocational high schools[7]. This is due to students at vocational high schools having an inherent depression in their present or future pessimism due to lower learning skills and dissatisfaction with their school lives, and a sense of defeat[8]. Female students' attachment to their peers are more correlated with depression than male students due to their expressive roles and relationship-oriented tendencies acquired when socializing[1].

Anger that appears in adolescence is difficult to control, and is often expressed in aggressive and violent actions[9].Students at vocational high schools have already experienced frustration compared to regular high school students and have a higher level of anger amid conflicts, due to relatively lower self-esteem, socioeconomic background, and low expectations from their parents [10].

Therefore, negative peer relationships such as bullying, neglect, and rejection between female students at vocational high schools can further reduce not only one's education or career path[4], but also lower self-esteem[6], depression[1], and anger and negative sentiments as well[11].

Background

The group counseling program that applies the MBTI (Myers Briggs Type Indicator) focuses on positive dynamic formation by providing information on the characteristics, attitudes, and function of a person's personality type, and by allowing them to experience other people's experiences through interaction with group members[12]. In order for adolescents to achieve independence and autonomy as a person, peers of different personality types need to understand the behavioral characteristics and attitudes they see in their interaction with peers, and acquire appropriate countermeasures.

Research Hypothesis

The level of self-esteem of the experiment group participating in the MBTI applied peer-to-peer relationship improvement training program will be higher than those of the control group that did not participate.

The level of depression of the experiment group participating in the MBTI applied peer-to-peer relationship improvement training program will be lower than those of the control group that did not participate.

The level of anger of the experiment group participating in the MBTI applied peer-to-peer relationship improvement training program will be lower than those of the control group that did not participate.

Method

Design and Sample

This research is a similar experimental study with an experimental group participating in the program and a control group not participating in the program, which is a Nonequivalent control group pretest-posttest design.

This research is consisted of 1st and 2nd grade female students at "G" Nursing Vocational High School at "D" city in Korea, and was conducted by researchers who completed MBTI courses. Based on the Cohen's formula[13], the program was initiated for 22 experimental and control groups who agreed to participate in this study, considering a 20% elimination rate, based on a minimum of 17 people in each group with a significance level (α) of .05, effect size (d) of .50, test power (1- β) of .80. Overall, 21 experimental groups and 18 control groups participated in the study, with an exception of 1, who gave up the study in the middle due of experiments due to personal reasons.

Instruments

This study of self-esteem employed a self-esteem scale for high school students, which was developed by Rosenberg[14] and was adopted by Lee and Won[15]. This scale comprises of 10 items that are answered on a 4-point Likert Scale (1 = strongly disagree, 4 = strongly agree) and higher scores indicate higher levels of self-

esteem. This tool contains 2 subscales: positive and negative self-evaluations. Cronbach's alpha at the time of development Rosenberg,[14] was .84, Cronbach's alpha for our sample was .85.

Depression was measured by the Korean version of the Center for Epidemiological Studies Depression Scale (CES-D), which was developed by Chon and Lee[16] to readily measure depression symptoms in healthy individual. This scale comprises of 20 items that are answered on a 4-point Likert Scale (1 = strongly unlike me, 4 = strongly like me) and higher scores indicate higher levels of depression. The main factors of the tool are composed of melancholy moods, guilt, helplessness, anorexia, disturbed sleep and mental exercise retardation, etc. Cronbach's alpha at the time of development (Chon and Lee[16]) was .89, and Cronbach's alpha for our sample was .89.

Anger was measured by a development by Moon and Kim[17]. This scale comprises of 26 items that are answered on a 5-point Likert Scale (1 = strongly disagree, 5 = strongly agree) and higher scores indicate higher levels of anger. This tool contains 3 subscales: cognitive (8 items), emotional (8 items) and behavioral (8 items). Cronbach's alpha at the time of development (Moon and Kim[17]) was .90, and Cronbach's alpha for our sample was .73.

Data collection and Procedures

Approval was obtained from the research ethics committee of xxxHospital in South Korea. Prior to the start of the experiment, the students to be studied received explanations from the researchers about the purpose and the method of the study, anonymity, and confidentiality, etc., and informing them that they would not be required to participate if they did not wish, and received written consent from students whom voluntarily agreed to participate.

The subjects of this study were assigned to the first, third, fifth, seventh, and ninth selected classes to the experimental group separated into 10 classes using a table of random sampling numbers, and the rest were assigned to the control group. The pre-survey was conducted for those who agreed to participate in the study after fully explaining the purpose of the study before the program began. In order to unify the information given to the subjects, one research assistant facilitator was trained for 1 hour a week before the experiment by developing a protocol on data collection methods, procedures, and tools. The experimental group conducted a preliminary survey in the 1st session of the program and a follow-up survey after the mediation was completed. From October 20th, 2014 to December 3rd, 2014, 8 programs were provided twice a week with 50-minute sessions, using the discretionary activity time, and conducted by the collective counseling program room at the school. The control group was conducted a pre-post survey on the same day as the experimental group, and the pre-trained research assistant conducted the survey to prevent measurement errors due to the halo effect of this study.

50 minutes of sessions were conducted from the first to the last session using the consultation room during after-school hours during the week. The program was composed of one session of "orientation", "2-3 sessions of "This is me!", 4-6 sessions of "Opening the window between you and me," and 7-8 sessions" of "Looking outside the window together." The training program for friendship improvement using specific MBTI is as shown in Table 1.

Data Analysis

Date were analyzed using SPSS. Chi-square(Fisher exact probability) and t-tests were used to compare demographics and self-esteem, depression and anger scores between the experimental and the control groups.

Results

Socio-Demographic Characteristics of Respondents

Grades included 64.1% 1st graders, 35.9% 2nd graders, 56.4% did not have a religion, those with 3-5 close friends was 53.8%. In terms of satisfaction with school life, 46.2% said average, 43.6% said they had bad grades, 22.3% said average, and 23.1% said their grades were good. The family atmosphere for 43.6% were average. Birth ranking for 61.5% were second or younger, the largest of 33.3% had fathers working blue collar jobs, and the largest of 76.9% were middle class in their socioeconomic status. Insert Table 2.

Table 1. Peer-relation improvement program utilizing the MBTI.

Session	Title	Peer-Relation Improvement Program utilizing the MBTI	Time
1	Orientation	-Pre-survey -Introduction of the program and the coordinator -Setting rules before the program: "We promise to ~" -Greeting each other through putting stickers -Realizing differences between individuals through watching a video -MBTI test	50
2	This is me!	-Understanding my personality type and the difference between the 16 personality types through looking at various situations	50
3		-Understanding my personality type and the difference between 16 personality types through looking at various situations	50
4	Opening the window between you and me	-Understanding the difference in communication ways between opposite personality types through role playing	50
5		-Learning effective communications skills for improving relationships with friends through a game of Bingo	50
6		-Finding the way of growing up in my personality type and showing it through role playing	50
7	Looking outside the window together	-Showing others my best -Finding win-win strategies with friends and showing it through role-playing	50
8		-Confirming my strengths and my friends' strengths with the "apple basket of compliments" -Sharing impressions -Post survey	50

Differences in Variables for Experimental Group

The self-esteem and depression of the subjects were improved efficiently after participating in a MBTI applied peer-to-peer relationship improvement training program(Table 3).

Table 3. Differences in Variables for Experimental Group

Variables	**Pre test**		**Post test**		**t**	**p**
	M	**SD**	**M**	**SD**		
Self-esteem	32.0	4.69	34.1	5.04	-2.80	.011

Anger	76.7	7.05	72.5	10.42	2.22	.039

Discussion

As a result of this research, the self-esteem of the subjects was improved efficiently after participating in a MBTI applied peer-to-peer relationship improvement training program. This is research was similar to researches conducted to regular high school students that resulted in an improvement in self-esteem through a MBTI applied friend relationship improvement program[18] and a research that resulted in improvements to self-esteem for workers through a MBTI applied adult relationship improvement program[12]. These results display that not only does the MBTI applied collective counseling program discover the advantages of each category, but it also objectively presents an individual's innate preference and develops the undifferentiated attitudes and functions that had been latent in the individual[12], so that self-esteem is improved. The subjects participated actively in this program because they were curious about their personality types, careers, and academic work that fit their personality types. As a result, the subjects of the research are considered to have a positive impact on their self-esteem[18], by correctly understanding personality patterns of their peers and by reducing distorted self-defense mechanisms in the process of accepting each other's strengths and weaknesses.

After participating in the MBTI applied peer-to-peer relationship improvement training program, the subjects' depression was significantly reduced. This was in line with a research conducted[18], which displayed that MBTI applied friendship relationship improvement training programs for regular high school students have reduced depression. However, the results of the research[19] displayed that there were no significant differences in depression after applying a MBTI applied peer-to-peer help training program to female students of vocational high schools. A research by Han and Kim[18] on regular high school students resulted in an average depression score of 36 points before participated in the program, but a research conducted by Jung et al[19] resulted in a score of 19 points before participation in the program. Through MBTI, the program reduced misunderstandings and conflicts with each other by letting them know the personality types of themselves and others, and by acknowledging differences due to their own uniqueness[12]. Also, self-esteem has improved and negative self-assessment has been reduced by discovering and encouraging other people's unknown strengths through a compliment basket[18]. In addition, satisfactory and effective peer-to-peer experiences during the 8 sessions is believed to have a positive effect on the development and formation of a healthy personality and identity in individuals, thereby reducing depression.

After participating in the MBTI applied peer-to-peer relationship improvement program, the anger of the subjects was significantly reduced. This is different from the results of a research[18] conducted on regular high school students which displayed that the MBTI applied friend improvement relationship program decreased the anger from 76.7 points before the test to 73.5 points after the test, but did not show a significant difference statistically. While the search by Han and Kim[18] did not provide an opportunity to practice actual relaxation techniques and behavioral adjustments to control anger, the study was subdivided so that people could learn to listen to their peers well through a game of bingo and experience anger control through role playing. Youth anger is influenced by important people's reactions to anger expression[20]. Understanding the strengths and weaknesses of their peers through the 8-session peer-to-peer relationship training program, and understanding of their behavior characteristics and attitudes is thought to have had a positive effect on reducing anger.

Conclusions and Suggestion

After participating in the MBTI applied friend relationship improvement training program in this research, self-esteem increased, depression and anger decreased, and statistically significant differences were noted.

Based on this research, it is believed that MBTI applied friend relationship improvement training programs can be useful for providing nursing interventions in promoting effective peer relations at community health promotion centers or counseling centers in schools.

However, since this research was conducted mainly on students who wanted to participate in the program, it suggests that students who were selected for emotional screening should be conducted at a later date.

Conflict of Interest: The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Source of Funding and Ethical Clearance

The researchers received no financial support for this

paper. This study was a literature study using secondary data, and did not harm the subject ethically.

Factors that Contributed Against the Incident of Unintended Pregnancy (UP) in Women Aged 15-49 Years (IDHS 2017 Data Analysis)

Ika Permatasari [1], Ella Nurlaella Hadi [2]

[1] Student of Reproductive Health, Faculty of Public Health, Universitas Indonesia, [2] Department of Health Education and Behavioral Sciences (PKIP), Faculty of Public Health, Universitas Indonesia

Abstract

Unintended pregnancy (UP) could affect the health of the mother and the baby which could cause perinatal maternal morbidity and mortality. This study aimed to determine the contribution of maternal age, number of children alive, family planning history and knowledge of contraception methods to the incidence of unintended pregnancy in women aged 15-49 years in Indonesia. This study was a further analysis of the IDHS 2017 data and analyzed multivariately with multiple logistic regression using SPSS version 24. A total sample of 1930 respondents who met the inclusion requirements of women aged 15-49 years old who were still alive, had been pregnant, and had living children aged >12 months by the time the survey was conducted. Based on the results of the analysis we obtained factors that contributed to the occurrence of UP were maternal age (OR: 2.079; 95%CI: 1.443-2.996; *P* value <0.005), number of children alive (OR: 2.118; 95%CI: 1.109-4.045; *P* value = 0.023) and family planning history (OR: 0.473; 95%CI: 0.332-0.696; *P* value <0.005). The number of children alive was the most dominant factor contributing to UP. Mothers who owned living children >3 had a chance of 2 times experiencing UP compared to those who had <3 after being controlled for maternal age and family planning history.

Keywords*: unintended pregnancy; maternal age; number of children alive; knowledge of contraception methods; Indonesia*

Introduction

Unintended pregnancy (UP) is defined as a pregnancy that occurs when we do not want a child at all or a pregnancy that is desired but not at the right time (mistimed pregnancy), whereas pregnancy is described as a desired pregnancy if the it occurs at the right time or after having a desire to get pregnant[(1)]. In line with this, according to dictionary of term in family planning program, an unintended pregnancy is referred as a pregnancy experienced by a woman who actually does not desire yet or does not want anymore to become pregnant [(2)].

Unintended pregnancy is something real and experienced by many women for various reasons[(3)]. Unintended pregnancy can be the root of problem in carrying out abortions which have the risk of causing maternal and child mortality. WHO estimates that among the 200 million pregnancies per year, around 75 million (38%) are unintended pregnancies[(4)]. In Indonesia according to the data of Indonesian Demographic and Health Survey (IDHS) in 2017, about 8 out of 10 births (84%) of pregnancies were intended at the time, 8% of births were desired later, and 7% were unintended. The proportion of unintended births or pregnancies had remained constant since the 2002-03 IDHS, which was (7%)[(5)]. There are various reasons why a woman does not want to get pregnant at a certain time in her life, including marital status, suffering from a chronic illness, psychological reasons, education or occupation [(6)].

This study aimed to determine the contribution of maternal age, number of children alive, family planning history and knowledge of contraception methods to the incidence of unintended pregnancy in women aged 15-49 years as an effort to reduce the risk of unintended pregnancy.

Method

This study was a further analysis of the IDHS data

in 2017 on individual data sets (IDIR71FL.sav). The population were all women aged 15-49 years old in Indonesia. The sample of this study were all women aged 15-49 years old who had been pregnant and gave birth to the last child during the survey. Inclusion criteria for the sample were women aged 15-49 years who were still alive, had been pregnant, and had living children aged >12 months by the time the survey was conducted. While the exclusion criteria were mothers who had children <12 months old, mothers and children whose data were incomplete.

The dependent variable was the occurrence of pregnancy which actually was not expected, including the pregnancy being not on the right time and having no desire of pregnancy at all. The independent variables included maternal age, number of children alive, family planning history and knowledge of contraception methods. Data analysis was performed bivariately using the chi-square test and multivariate analysis was carried out with multiple logistic regression of several independent variables to predict the most dominant factor contributing to the occurrence of UP.

Based on Lemeshow, Hosmer, Klar, and Lwanga [7], to meet the required sample size, sample size formula for the estimation of two proportions was used. From the calculation of sample size, a minimum sample of 608 respondents was obtained, with the proportion of unintended pregnancies in mothers having number of children >3 (P1 = 0.649) and the proportion of unintended pregnancies in mothers having number of children <3 (P2 = 0.482). Values of P1 and P2 were obtained from previous studies [8], but this study used secondary data with a larger number of samples than the minimum sample size, so that the number of samples to be analyzed were all samples in the survey that matched the assessment criteria of 1,695 respondents.

Table 1. Correlation Between Maternal Age, Number of Children Alive, Knowledge of Contraception Method and Family Planning History With Unintended Pregnancy, IDHS 2017

Variables	**Pregnancy Status**				***P* value**	**OR**	95% CI
	Intended		Unintended				
	n	%	n	%			
Maternal Age							
No risk (20-35 years)	1343	69.6	87	4.5	<0.005	0.137	0.465-0.786
Risky (<20 years and >35 years)	352	18.2	148	7.6			
Number of Children Alive							
No risk (≤ 3 children)	1652	85.6	19	1.0	<0.005	3.447	2.074 – 3.926
Risky (> 3 children)	43	2.2	215	11.2			
Knowledge of Contraception Method							
Good	847	43.9	135	7.0	0.073	0.964	0.676 – 1.039
Poor	849	44.0	100	5.2			
Family Planning History							
Ever Never	1087 608	56.3 31.5	187 47	9.7 2.5	<0.005	0.456	1.243 – 2.035

The results indicated that respondents knowledge of contraception methods did not contribute to the incidence of UP (P = 0.073). While the other three variables namely maternal age (P <0.005), number children alive (P <0.005), and family planning history (P <0.005) contributed to the occurrence of UP. Based on the table above, the four independent variables produced P values <0.25 so that all of these variables met the requirements to be included in multivariate modeling.

Table 2. Initial Multivariate Modeling

Variables	P value	OR	95% CI
Maternal age	<0.005	2.108	1.460 – 3.045
Number of Children Alive	0.022	2.139	1.114 – 4.108
Knowledge of Contraception Methods	0.127	0.763	0.539– 1.080
Family Planning History	<0.005	0.494	0.335– 0.727

The results of the initial multivariate modeling found that the variable of knowledge about contraception method had P value of 0.127 (>0.05), so it was excluded from the multivariate modeling.

Table 3. Final Multivariate Modeling

Variables	P value	OR	95% CI
Maternal age	<0.005	2.079	1.443– 2.996
Number of Children Alive	0.023	2.118	1.109 – 4.045
Family Planning History	<0.005	0.473	0.332– 0.696

The results of the analysis it was noted that the variables which simultaneously contributed to the occurrence of UP were maternal age, number of children alive and family planning history. The most dominant factor contributed to the incidence of UP was the number of children alive (OR 2.18; 95%CI = 1.109 – 4.045). This indicated that mothers who owned more than 3 living children had a chance of 2 times experiencing UP compared to those who had living children <3 after being controlled for maternal age and family planning history.

Discussion

Contribution of the Number of Children Alive to Unintended Pregnancy Events

The analysis showed that the number of children alive contributed to the occurrence of UP. Other research stated that the incidence of UP was highest in the group of women who had three or more children and the number of children contributed to the UP event which were affected by socioeconomic interaction [9]. Another studies suggested that women who had more than three children would intensify the risk of UP events [10]. Mothers with fewer number of children were able to fulfill the needs of the children better, while mothers with larger numbers of children were economically more burdened. As a result, the mothers were prone to consider that the pregnancies were unintended. In this group, there were parents' fear about the costs to be spent for food, health, clothing, house, education and others.

In Indonesia, boys and girls have different values in families according to the ancestors and customs that are believed by each ethnic group. For example, the principle of Toba Batak descendant is patrilineal, meaning that the ethnic lineage is from the son[11]. Sons play important role in the continuation of generations, implying that someone who does not have a son can be considered *napupu* for being unable to continue the father's genealogy and will never again be remembered

or taken into account in the genealogy.

It is different in the Minangkabau people of Indonesia who follow the matrilineal system. One of the characteristics of the Minangkabau matrilineal is (1) Lineages are drawn based on maternal lines which more broadly then form groups of clans and tribes; (2) the control of inheritance is in the hands of mothers led by a senior woman called *bundo kanduang*[12]. These characteristics confirm that the position and role of women are very important in the life of the Minangkabau community.

Basically a woman's desire to have children once again or not, is motivated by the number of children they have. The desire to have children of a certain gender according to customs believed by someone is likely causing someone to still insist to have children even though they have already had children before. This was supported by a study in Iranian culture which showed that the desire to have children and certain gender contributed to the events of UP [13]. The number of children born to a woman during her life greatly affected her health. This caused the number of children to be related to the occurrence of UP.

Contribution of Maternal Age to Unintended Pregnancy Events

The analysis pointed that there was a significant contribution between maternal age and the incidence of UP. This was in accordance with a descriptive study on the 2010 Riskesdas data which stated that UP in Indonesia mostly occured in women over 35 years old and in young marriages (16-20 years) [14]. A study of UP in Egypt on 1999 found that women in the group of age over 35 years old reported more of their pregnancies as unintended pregnancies [10].

The safest age for a mother to get pregnant is 20-35 years because in women starting from the age of 20, the uterus and other body parts are fully ready to accept pregnancy, nevertheless, at that age women are usually ready to become a mother[15]. This was because women's readiness to be able to accept their pregnancy included physical, emotional, socioeconomic, and psychological aspects. The more mature the mother's age and not included in the high risk group in medical terms, the more acceptable the pregnancy.

Contribution of Family Planning History to Unintended Pregnancy Events

The results of the analysis indicated that the family planning history contributed to the occurrence of UP. These results were in line with a study using the 2013 Riskesdas data, stating that the use of contraception contributed to the occurrence of UP. Couples who were currently using contraception were more likely to experience UP events compared to couples who never used contraception[16]. These were in accordance with study from India which found that in couples using contraception the possibility of UP was higher than couples who did not use contraception[17].

Couples who were currently using contraception but have UP might be due to the failure of contraception used. Failure of contraception is a case of pregnancy in the active acceptor who is currently using contraception. This contraception failure can be caused by the failure of the contraception method itself or due to the non-compliance of the acceptors in using contraception.

Based on IDHS 2017, 34% women stopped using these FP methods/devices within 12 months after use. There were various reasons to stop using contraception including the failure of the method, desire to get pregnant, side effects/health problems, intention for a more effective method, limited access, too expensive and being not comfortable to use[5]. In couples who had used contraception and experienced the events of UP, it might be caused by the unsustainable use (drop out) of the contraception they were using. In the type of non-long-term contraception method (LTCM) including pills, injections, and condoms, the level of compliance was lower than the type of LTCM. The IDHS 2017 data showed that the highest drop-out rates for FP use in Indonesia were pills (46%). Its might also be caused by the side effects of contraceptions experienced. 33% of married women stopped using FP methods/devices due to the side effects/health problems[5].

Contraception was a method used as an effort to control pregnancy. The history of FP methods/devices use became important as an effort to prevent the occurrence of UP.

Contribution of Knowledge About Contraception Methods to Unintended Pregnancy Events

According to Martin, et al. the measurement for knowledge of contraception methods was categorized as good if the respondents were able to answer more than 50% of the questions (score >10)[18]. The knowledge was grouped based on the knowledge value gained

from answering the question "Have the mothers ever heard of FP methods/devices which could delay or prevent pregnancy, namely: female sterilization, male sterilization, IUD, pills, injections, implants, condoms, diaphragms, MAL, periodic abstinence, interrupted coitus and condoms?".

In the results of the study, most of the good knowledge respondents have UP occurrence and there was no significant correlation between the knowledge of FP and UP incidence. it's accordance with Afifah study that there was no significant correlation between knowledge and the events of UP[19].

It's different from a study in Nepal which stated that women who were exposed to information of contraception over the radio had lower rates of UP compared to those who were not exposed[8]. While in Nigeria, as many as 22% of women who experienced UP not used contraception, because of poor knowledge about side effects and benefits[20].

Conclusion

The strongest factors that contributing to UP incidence were the number of living children owned. Mothers who had living children >3 were twice likely to experience UP compared to mothers who had children <3 after controlling for their age and family planning history. Based on these results, it is necessary to increase the provision of information about the importance of family planning program and its method as an effort to reduce the risk of UP. In addition, to prevent dropout and contraception failure, it is needed to conduct initial counseling regarding contraception side effects which can be experienced by acceptors.

Health Risk of Particulate Matter on Primary School Students in West Jakarta

Lailatul Qomariyah[1], Bambang Wispriyono[2], Haryoto Kusnoputranto[3], Abdur Rahman[4], Meliana Sari[4]

Faculty of Public Health, Department of Environmental Health, Universitas Indonesia, Depok, Indonesia

Abstract

Background: Particulate matter (PM) is the most common air pollutant found in West Jakarta, with the main source being the increase of the motor vehicle used.

Methods: This study investigated the PM concentrations and the related health risk from PM exposure on primary school students in West Jakarta. The $PM_{2.5}$ concentration was measured using instrument HAZDUST, Model: SKC EPAM-5000, PA 15330.

Results: The highest mean concentration of $PM_{2.5}$ measured from three primary schools in West Jakarta was 129 $\mu g/m^3$.

Discussion: The health risk analysis of the students showed that the $PM_{2.5}$ intake was lower than the reference dose or safety limit.

Conclusions: The findings of this study showed that primary school students were not under the risk of exposure to $PM_{2.5}$ in the school environment.

Competing Interests: The authors declare no competing financial interests

Keywords: *Particulate matter, student, primary school, risk assessment.*

Introduction

The air quality in West Jakarta was considered as unhealthy and polluted according to the national air quality criteria (KEPMEN LH NOMOR: KEP-45/ MENLH/10/1997[(1)]. The data of air quality in West Jakarta is collected from the monitoring stations throughout Jakarta. According to the Jakarta province regulation number 2 year 2005, the government has done efforts on tackling air pollution and air quality recovery. Regardless, those efforts did not seem to succeed in lowering the level of air pollution[(2)].

One of the main sources of air pollution was the high number of motor vehicles in busy traffic. The motor vehicles released several gasses and particulate matter (PM). There are several categories of PM, i.e., PM_{10}, $PM_{2.5}$, and ultrafine PM with a diameter of 0.1 μm[(3)]. Smaller-sized PM caused a higher risk than the bigger-sized PM[(4)]. The most common pollutant from the incomplete fossil fuel combustion was $PM_{2.5}$, which has similar characteristics with gas molecules that can reach the gas exchange areas in the lungs, translocate the lungs, and reached the blood circulation system[(5)]. $PM_{2.5}$ can be easily inhaled into the respiratory system and kept in the lung's alveoli where toxic particles can cause lung damage and disrupt the lung functions[(4,6,7)] . The $PM_{2.5}$ also contributes to the steady increase of asthma prevalence in humans, especially in children[(8)].

Children spend most of their time in school. Therefore, the air quality in school was considered as an important factor which affects the health of children[(9)]. Children are more vulnerable to a higher amount of air pollution since their respiratory volume is higher compared to adults[(10)t]. In general, the children's organ is more vulnerable to toxic compounds since it is not fully developed[(11)]. Therefore, a proper approach to

calculating and predicting the health risk which called the risk analysis on environmental health is needed, which taken into account several steps, i.e., identification of uncertain factors, investigation on certain exposure, consideration on characteristics of concerning pollutant agent and the specific target. This study aims to estimate the risk of $PM_{2.5}$ on primary school students in West Jakarta.

Abbreviations	
RQ	Risk quotient
RFC	Reference concentration

Methods

The samples in this study were taken from three primary schools in West Jakarta which located near the highway. The samples were coded as follows: CT 05, CB 03, PS 06.

Sampling

The measurement of $PM_{2.5}$ concentration was taken from 3 points in the school area during the school hours. The sampling point was based on the most visited areas of students during school hours. The $PM_{2.5}$ concentration was measured with instrument HAZDUST (Model: SKC EPAM-5000, PA 15330) and was being done at the same time with the health survey.

Study Participants

Several inclusion criteria for sampled students used were students from fourth and fifth grade in a healthy condition and were willing to be respondents by signing the form of consent. Besides that, the bias in this study was minimized by ensuring that there were no friendship or sibling relations between the students as the study subject with the researcher.

Particulate Analysis

The results of $PM_{2.5}$ concentration measured was compared to the threshold value of the national threshold value (i.e., PermenLH, Permenkes), WHO, and EPA (see Table 1 for more details).

Health Risk Assessment

Parameters used to predict the health risk through various inhalation ways are described in Table 2. We calculated intake as the amount of risk agent concentration (mg) which enters the human body with a certain weight (kg) daily (Equation 1).

(Equation 1)

With:

I = daily intake (mg/kg/day)

C = risk agent concentration (mg/m^3)

R = inhalation rate (m^3/hour)

L = exposure time (hour/day)

Ef = frequency of exposure (day/year)

Ed = duration of exposure (year)

Bwt = weight (kg)

At = average daily period

We then compared the intake value with the reference dose (RfC), which resulted in the Risk Quotient (RQ) value (mg/m^3/day).

(Equation 2)

The reference dose (RfC) used was based on the value of the National Ambient Air Quality Standards (NAAQS) for the $PM_{2.5}$ (35 μg/ m^3). We did not use the national air quality value since the default value of the exposure factor was not known. The value of RfC used on determining the risk of $PM_{2.5}$ exposure was 0.005 mg/kg/day (16).

Results

Respondent characteristics

The total number of the respondent in this study is 103 primary school students from three public primary school in West Jakarta. The statistical descriptive of the respondents studied is shown in Table 3. In all three primary schools, respondents from the eleven-year age group have the highest percentage on every school compared with the other age groups.

Physical description of the study sites

The measurement of the physical environment of each school was done on different days. Besides the measurement of $PM_{2.5}$ concentration, we also measured the classrooms' temperature and relative humidity. The $PM_{2.5}$ concentration on each study site was measured from 9 points of sampling which were spread on each

school for 6 hours. The lowest and highest value of $PM_{2.5}$ concentration found were both at primary school CB with the lowest being 30 μg/m^3 (fifth-grade classroom) and the highest being 197 μg/m^3 (fourth-grade classroom).

Analysis of environmental health risk

Anthropometry characteristics and respondents' activity pattern

We used the default value of exposure time and inhalation rate as described in the guidelines on the analysis of environmental health risk[12]. Other related variables, i.e., respondents' weight, exposure frequency, and exposure time were variables that depend on each respondent. The exposure frequency was calculated from the number of appointed school days or effective school days (209 days) subtracted by the number of students' absence days. We assumed that the exposure time is four years for the fourth-grade students and 5 years for the fifth-grade students. The students' weight was measured directly during the study.

The results showed that the respondents' weight was normally distributed (Table 5), except in the primary school CB. From the total of 103 respondents, the lowest weight recorded was 22.6 kg and the highest was 69.6 kg. Based on the calculation of estimated risk, the RQ value was ≤ 1, which indicated that the health exposure risk of $PM_{2.5}$ on the primary school students was considered safe during the moment of study. The risk management will only be done if the value of RQ exceeds 1.

Discussion

The results of indoor $PM_{2.5}$ concentration measurement in three primary schools in West Jakarta showed a higher value compared with the national threshold of the ambient air quality[13]. However, this result cannot conclude that the air quality in the studied areas being harmful to human health since the national air quality threshold[13, 14] require 24 hours of ambient air $PM_{2.5}$ measurements. Besides the ambient air, the indoor $PM_{2.5}$ concentration from three schools was higher than the national threshold (i.e., 35 μg/m^3) for offices for 8 hours. However, this value also cannot conclude that the indoor air quality from the studied schools being harmful to human health, since the threshold value is based on the office environment. A specific value designated for schools was not available yet. Meanwhile, our study only measured the $PM_{2.5}$ concentration during teaching activities. A relatively long period of measurement may reflect better the health risk caused by the $PM_{2.}5$ exposure since the effects of air pollutants were not only depending on the pollutants' concentration, but also the exposure time. The longer a person is being exposed to pollutants, the higher the chance of related health risks might appear.

Our study showed similar results with another study[15], where the ambient air $PM_{2.5}$ concentration was higher than the air quality standards. The safe intake (RfC) of $PM_{2.5}$ concentration for students was 0,031 mg/kg/day. Our $PM_{2.5}$ concentration value was higher compared with the ones recorded at a secondary school in Bandung (SMPN 16 Bandung), West Java, Indonesia[16]. The study on this secondary school showed a lower $PM_{2.5}$ concentration compared to the national air quality standards, but higher compared with the EPA standards. Another study in the industrial area (20) showed an overall higher value than the national air quality threshold and several points of sampling also showed a higher value compared to the EPA standards. The Indonesian national air quality standard is indeed being less restricted compared to other countries' air quality standards. Several related studies highlighted the need of special attention on the air quality; therefore, it is important for various groups working on the health and environment quality sectors (i.e., researcher, government, students, and related stakeholders) to know methods to measure the health risk, e.g., the analysis of environmental health risk.

Based on the calculation of the intake values, the lowest and the highest values were shown by the primary school PS. The possible explanation was due to the students' body weight; the lower body weight will result in a high intake value and the higher eight will result in a lower intake value. Another similar result was shown by other studies that explain that bodyweight is one of the determining factors of the intake value[16,17].

The health risk of $PM_{2.5}$ was only considered the value of RQ, this was due to the toxicity of $PM_{2.5}$[18,19] which was not allowing to further assess the carcinogenic health risk. The RQ value ≤ 1 found means that the students of primary school in West Jakarta was not under the risk at the moment of the study was conducted. This value can be

interpreted as the inhalation exposure of $PM_{2.5}$ with the exposure time of 692-1,045 days and a duration of 4-6 years was considered safe to non-carcinogenic risk. This result was similar to another study[16], which also shown the $PM_{2.5}$ was not causing a health risk.

Conclusions

The lowest and the highest $PM_{2.5}$ concentration was found in fifth grade (35 ug/m^3) and fourth grade (129 ug/m^3) of primary school CB. The lowest and the highest intake was found in the primary school PS. The non-carcinogenic health risk from $PM_{2.5}$ exposure of the three primary schools has a value of RQ ≤ 1 which was considered safe in the time being.

Abstract

Background: Frailty is a syndrome characterized by diminished strength, endurance, and reduced physiologic function caused by multiple etiologies, leading to a higher rate of vulnerability for functional loss and death. Low muscle mass is reported to be an important link between sarcopenia and frailty. A progressive decrease in muscle mass occurs at annual rate of 1% to 2% after the age of 30 years and accelerates to 1,5% to 3% year after the age of 60 years then even faster after the age of 75 years. The strong association between muscle mass and frailty leads us to find out the association between muscle mass and frailty status in elderly.

Method: The study was a cross-sectional with 77 subjects of aged ≥60 years. Frailty defined as meeting ≥ 3 of 5 criteria: unintentional weight loss, reduced gait speed, reduced grip strength (weakness), self-reported exhaustion, and low physical activity level. Muscle mass was determined by bioelectrical impedance analysis (BIA) TANITA BC-601. Asian Working Group on Sarcopenia (AWGS) recommends cut off values were <7 kg/m2 in men and <5,7 kg/m^2 in women, defined by appendicular skeletal muscle mass/$height^2$ (ASM/$height^2$)

Results: The study shows the prevalence of low muscle mass was 11,7%. The prevalence of prefrail and frail was 44,2% and 24,7%. Frail was significantly higher in subjects with low muscle mass, whereas robust and prefrail were higher in subjects with normal muscle mass (p<0,05). Among frailty components, reduced gait speed was the most prevalent (51,9%).

Conclusions: Muscle mass was signifinantly associated with frailty status in elderly people.

Keywords: *muscle mass, frailty, elderly*.

Background

Aging process in an irreversible and inenoraxable process.[1] Increasing longevity, coupled with rising frailty and sarcopenia of aging, significantly affects function and quality of life of older adults.[2]

Frailty is a syndrome characterized by diminished strength, endurance, and reduced physiologic function caused by multiple etiologies, leading to a higher rate of vulnerability for functional loss and death.[3] Becoming frail is a dynamic process. Frailty is considered as a continuum from robustness to prefrail to fully expressed syndrome of frailty. However, prefrail individuals may either enter the frailty state or reverse/recover to the non-frail one. With this dynamic concept of frailty, there is an "intervention window" to prevent frailty or reverse it particularly in the group of prefrail individuals.[4]

Low muscle mass is reported to be an important link between sarcopenia and frailty.[5] A progressive decrease in muscle mass occurs at annual rate of 1% to 2% after the age of 30 years and accelerates to 1,5% to 3% year after the age of 60 years then even faster after the age of 75 years.[6] Diabetes increases the risk of physical dysfunction and disability. Diabetes-related complications and coexisting morbidities partially explain the deterioration in physical function. The decline in muscle mass, strength and function associated with diabetes leads to sarcopenia, frailty and eventually disability. Frailty acts

as a mediator in the pathogenesis of disability in older people with diabetes and its measurement in routine daily practice is recommended. Frailty is a dynamic process which progresses from a robust condition to a pre-frail stage then frailty and eventually disability. Therefore, a multimodal intervention which includes adequate nutrition, exercise training, good glycaemic control and the use of appropriate hypoglycemic medications may help delay or prevent the progression to disability.

A decrease in muscle mass and muscle function (strength and physical performance) may result in reduced physical capability, poorer quality of life, impaired cardiopulmonary performance, unfavourable metabolic effects, falls, diasability and mortality in older people.[7]

The strong association between muscle mass and frailty leads us to find out the association between muscle mass and frailty status in elderly.

Method

A cross sectional analytic study included 77 patients who fulfilled the inclusion criteria (aged 60 years or above). The subjects were consecutively recruited from geriatric outpatient clinic of Wahidin Sudirohusodo Hospital, Makassar and agreed to be assessed for baseline data. Exclusion criteria included cognitive impairment (i.e., a score of Abbreviated Mental Test ≤7), acute diseases (e.g., severe infection, acute cerebrovascular events), malignancy and refusal to participate in the study. The sample size for the study was determined based on the equation for the sample size of the estimated proportion with minimum number of subjects to be recruited was 60 subjects. This study mostly used primary data obtained using questionnaires, only data about comorbidities were collected from medical records. Data collection included demographic data, anthropometric, frailty status, muscle mass and comorbid. The data collection started from July through October 2019.

The Cardiovascular Health Study frailty phenotype consists of 5 objective components; unintentional weight loss more than 5% of body weight in the previous year, self-reported exhaustion, self-reported low physical activity, reduced grip strength, and reduced gait speed. Older adults were considered as frailty when they met 3 or more of the 5 criteria, prefrail when they met 1 or 2 criteria, and robust when they met no criteria.[8] Exhaustion was determined by self-reported of feeling that "in the last week, everything was an effort or I could not get going" for three or more days. Physical activity level was considered low if the participant's PASE score was in the lowest quintile, based on gender. Maximum grip strength was measured using a Jamar dynamometer and standardised protocol.[9] Gait speed, indicated by the average time in seconds (s) in which each elderly toured three times a distance of 4.6 m.[10] Muscle mass was determined by BIA TANITA BC-601. Asian Working Group on Sarcopenia recommends cutoff values were < 7 kg/m2 in men and < 5,7 kg/m^2 in women, defined by appendicular skeletal muscle mass/$height^2$ (ASM/$height^2$).[7] Comorbidities based on Cumulative Illness Rating Scale-Geriatric Version (CIRS-G). All subjects gave written, informed consent before data collection.

Data were processed and analyzed using the computer program SPSS (Statistical Package for the Social Science Program) version 25. Chi-square statistical analysis was used for the data and considered significant if $p < 0.05$.

Results

The present study included 77 elderly subjects (table 1). The age ranged from 60 to 92 years with a mean age of 68,16 ± 6,45 years. Most subject were female (62,3%) and 36,4% were obese (obese I 28,6%; obese II 7,8%). Muscle mass was low in 9 subjects (11,7%). Based on frailty status, prefrail was 44,2% and frail was 24,7% respectively. Among comorbid disease, hypertension was the most prevalent (77,9%), followed by metabolic-endocrine disease (63,6%).

The association between muscle mass with frailty status is shown in table 2. Frail prevalence was significantly higher in subjects with low muscle mass (66,7%), whereas prefrail and robust were higher in subjects with normal muscle mass (35,3% and 45,6% respectively). This shows a significant association between decreased muscle mass with frailty status ($p<0.05$).

Table 1. Baseline characteristic

Subjects Characteristics

Seventy seven elderly subjects were recruited during regular health examination in geriatric outpatient clinic of Wahidin Sudirohusodo Hospital which characteristic shown in table 1. Obese subjects were 36,4% based on body mass index (BMI). Gabat et al in Philippines found lower prevalence (14,02%).[12] The cause of the differences in the prevalence of obesity lies in the category used. In this study, subject was categorized as obese if the BMI ≥25 kg /m^2, whereas research in the Philippines used the BMI category ≥30 kg /m^2.

Table 2. Association between muscle mass with frailty status

Muscle mass			Frailty state			Total	p

Discussion

Skeletal muscle undergoes quality and quantity modifications with aging, which lead to a progressive decline in muscle mass and strength. The age-related loss of muscle mass may not be an isolated phenomenon, but rather it is strongly connected with a parallel increase in fat mass. The fat mass increase and the muscle mass decrease may act synergistically and lead to sarcopenic obesity, an important risk factor for physical disability.[11]

Low muscle mass prevalence in this study was 11,7%. A similar finding was found by Vitriana et al. in community-dwelling population (9,1%).[13] A higher prevalence was found by Tamura et al. in Japan (45,2%).[14]

An excessive loss of muscle mass that is associated with aging was originally defining sarcopenia. It is influenced by multifactorial pathology. Disuse coupled with aging is the major underlying cause: poor blood flow to muscle, especially the muscle capillaries due to a decline in nitric oxide production, is another important age-related cause of sarcopenia. Aging is associated with an increase in mitochondrial abnormalities leading to damage to the mitochondrial membrane permeability pore and apoptosis. Another factors include loss of motor end plate, decrease anabolic hormones, obesity and higher level of proinflammatory cytokines.[15]

In the present study, prefrail (44,2%) was more prevalent than frail (31,2%) and robust (24,7%).In the other study, Setiati et. al found robust 13,2%, pre-frail 61,6% dan frail 25,2% with associated risk factors were

age, nutritional status and functional status.[16]

In this study, most comorbid disease were hypertension (77,9%) and metabolic-endocrine diseases (63,6%). In line, Tamura et al. found hypertension (78,0%), dislipidemia (62,5%) dan diabetes melitus (57,3%) as the frequent comorbid.[14] Castrejón-Pérez et al. also revealed the association of frailty with hypertension and diabetes mellitus. In highly prevalent populations, it would be expected that frailty would appear in an accelerated manner.[17]

It is known that oxidative stress increases with age and its progressive development can be considered as one of the aging markers. It is generally accepted that an increase in OS during aging is a consequence of a decrease in the effectiveness of antioxidant protection. The quantitative determination of 8-OH-dG is suggested as one of the markers of free-radical processes occurring in the body under normal circumstances and with the development of various pathological processes. It is believed that an increased level of 8-hydroxy-2-deoxyguanosine (8-OH-dG) is associated with the aging process, as well as with many pathological conditions, including diabetes mellitus and hypertension.[18]

Association Between Muscle Mass And Frailty Status

In this study, normal muscle mass was found higher in prefrail state (45,6%). In contrast to the study by Falsarella et al, a greater muscle mass was found in robust compared to prefrail and frail state.[10]

For lower muscle mass, it was more prevalent in frail state (66,7%). This is indicated a significant association of muscle mass with frailty state of the subjects ($p<0,05$). Cesari et al, assessed the association of muscle density with frailty state and revealed that subjects with a higher muscle density were robust, whereas the subjects with lower muscle density were prefrail and frail.[11]

Among frailty component, reduced gait speed was the most prevalent (51,9%). Savva et al, found reduced gait speed and weakness become more common in their study.[19] Muscle mass in this study was also significantly associated with reduced grip strength, reduced gait speed and self-reported exhaustion ($p<0,05$). In another study, Falsarella et al, found the association of muscle mass with grip strength and weight loss, whereas gait speed, exhaustion and physical activity were not.[10]

Walking requires the coordination of various organ systems and consumes energy, thus decreased organ function and increased energy consumption for walking may be reflected through slowing gait speed. Slowing gait speed can be caused by the presence of comorbidities (e.g., cardiovascular disease and musculoskeletal problems) and frailty. Gait speed can be used to assess multiple organ systems simply and comprehensively. Numerous prior studies have reported the association between gait speed and frailty.[16]

Conclusion

Muscle mass was signifinantly associated with frailty status in elderly. The higher muscle mass was found among robust subjects compared to prefrail and frail subject.

Conflict of Interest

No potential conflict of interest relevant to be declared.

Source of Funding: This study was conducted with self funding and did not receive any specific grant from funding agencies in the public, commercial, or not for profit sectors.

Ethical Clearance: The study protocol was approved by the Ethics Committee in Research of our instituion (Hasanuddin University), following the ethical reccomendations from the Helsinki Declaration of 1975.

Translucency of Cad/CamVeneers Using Different Internal Relief Spaces and Luting Cement Shades

Khaled Ibrahim Khaled Zaghloul[1], Cherif Adel Mohsen[2]

[1]Assistant Lecturer (Delta University), Faculty of Dentistry Minia University, [2]Prof. of Fixed Prosthodontics, Department Chairman of Fixed Prosthodontics Department Faculty of Dentistry Minia University

Abstract

Statement of Problem: Many studies have investigated translucency of ceramic veneers in association with different trial insertion paste materials.[1,2,3]. Little information is available on the ef- fect of cement space thickness on the final shade color of glass ceramic, feldspathic and zirconia reinforced glass ceramic veneers.

Purpose: The aim of the study is to evaluate translucency of three different CAD/CAM ve- neer materials with different internal relief spaces and different cement shades.

Material and Method: Sixty samples were constructed and classified according to the type of materials into three main groups (I) IPS e.max CAD MT , (II) VITA Vitablocs Mark II and group (III) Vita Suprinity (20 samples each). Each group were subdivided into two subgroups (10 samples each) according to the internal relief space (100 µm and 30 µm).The internal relief space was determined based on data from a previous 123 study and available resources. Each subgroup were further subdivided into six classes according to the 4 type of trial cements used : the control class (glycerine) and five trial paste class- es according to their shade (Translucent Shade, White Opaque Shade, A1/Light Yellow Shade, A3 Opaque/Yellow Opaque Shade and B0.5/ White Shade (10 sam- ples each) according to shade of the trial cement used.

The color test was done using reflectance spectrophotometer device (Vita Easy shade V). Color coordinates were measured in the body region of all laminate ve- neers with different combinations of laminate veneer material, internal relief space, and trial insertion paste color on composite resin abutment A3 .

Results: The consistency of the translucency among the tested specimens was confirmed using a 2-way ANOVA and the Tukey HSD post hoc test ($P<.05$). The luminous transmittance exhibited a statistically significant dependence on different ceramic restorations with a cad cam veneers in various internal relief space and different cement shades combinations. ($P<.05$).

Conclusions: The underlying color of the tested trial insertion pastes caused color change ($\Delta E >3.7$) for all ceramic material used in this study.

Keywords : *CAD/CAM , Translucency , Laminate veneers*

Introduction

The CAD/CAM ceramic blocks have become a popular restorative material due to their high esthetic quality, wear resistance, durability, color stability, and biocompatibility[5,6]. Also, the CAD/CAM ceramic blocks are fabricated under opti- mum conditions, creating a restoration with higher intrinsic strength without the variation in materials found in laboratory fabricated restorations[7]

Translucency has been emphasized as one of the primary factors in control- ling the esthetic outcome[11] because it makes ceramic restorations appear more natu- ral[8.9] As translucency permits the passage of light and also disperses light, it could be described as a state

between complete opacity and transparency,[10] the light being diffused rather than reflected or absorbed.[11,12] Errors in brightness among teeth are considered the most noticeable esthetic error[13,14] because the human eye is more sensitive to the differences in value (brightness) than hue or chroma.[15,16] In addi- tion, the translucency of ceramics is closely related to the light transmission and polymerization efficiency of underlying resin based luting agents.[17,18]

However, little information is available about the translucent characteris- tics of contemporary CAD/ CAM materials.

Until today, many studies have investigated translucency of ceramic veneers in association with different trial insertion paste materials. Other studies concluded that luting film thickness had a significant effect on bond strength.[19] and ceramic strength.[20,21] Nonetheless, no study has yet evaluated the effect of cement space thickness on the final shade color of Zirconia reinforced glass ceramic veneers.

Materials and Method

Materials

1) Three different types of ceramic CAD/CAM blocks were used in this study as seen in table 1.

Table 1: Different ceramic materials used.

Ceramic Blocks	Brand name and company
Glass ceramic	IPS e.max CAD MT , Ivoclarvivadent .
Feldspathic	VITABLOCS MARK II .
Zirconia reinforced glass ceramic	VITA Suprenity PC

Also trial cement paste with five different shades were used as seen in table 2.

Table 2: Trial cement paste shades used.

Trial Cement paste colour	Brand name and company
Translucent Shade	Rely x try in paste 3M ESPE
White Opaque Shade	Rely x try in paste 3M ESPE
A1/Light Yellow Shade	Rely x try in paste 3M ESPE
A3 Opaque/Yellow Opaque Shade	Rely x try in paste 3M ESPE
B0.5/ White Shade	Rely x try in paste 3M ESPE

The definitive dies used were machined from composite resin blank

(Tempo CAD,98.5mm x 20mm; On Dent dental systems) with A3 shade colour as a control.

So, six different colors of trial cement pastes were used for cementation of all ceramic veneers with two different internal relief spaces over the composite resin abutments .

Methods

Acrylic tooth preparation

An acrylic maxillary left lateral incisor on acrylic model cast(Model #R861; Columbia Dentoform Corp, Long Island City, NY, USA) was used for the veneer preparation .

Preparation was done using microvision kit (komet, REF TD2194). Facial re- duction was done in two planes (cervical and incised two thirds) using depth cuts of 0.5 mm to control the depth of cutting and complete the facial reduction using tapered stone with round end making a uniform chamfer finish line of 0.5mm. One mm incisal edge reduction was done with a butt joint design using 0.5mm depth cut to control the incisal depth and tapered stone with round to complete the incisal reduction.

Abutment fabrication

An impression of the prepared tooth with adjacent teeth was made with polyvinylsiloxane impression material (Aquasil Ultra digit XLV Regu- lar Set; Aquasil Monophase; Densply Intl, York, Pa). Type IV die stone (Jade Stone; Whip Mix Corp, Louisville, Ky) was used to pour the impression to fabricate the de- finitive cast.

The definitive cast was scanned using Dentsply Sirona in Eos X5 extra oral scanner and the restoration site designed with CAD technology (Sirona inlab SW

15.1 softwere). The abutment design was exported to CAM software (sirona inlab 16 cam software) and the milling was done according to the manufacturer's instruc- tions using the sirona MCX5 milling machine .

The composite resin abutment was machined from composite resin blank with A3 shade color.

Veneers fabrication

Three different types of ceramic CAD/CAM blocks were machined using a CAD/ CAM technology (SIRONA INLAB 3D CAD/CAM; Sirona Dental Systems LLC, Charlotte, NC) according to their manufacturer instructions as seen in figure 1.

Figure 1: SIRONA INLAB CAD/CAM system.

Application of trial insertion paste

Each laminate veneer was loaded with six types of trial cement paste separately,

Glycerin was used as control class and five different trial pastes Rely x try in paste 3M ESPE (Translucent,White Opaque, A1/Light Yellow, A3 Opaque/Yellow Opaque and B0.5/White Shade) according to their shade before the colour testing.

Statistical Analysis

Color Measuring Test Procedures (colorimetric evaluation)

The color test was done using reflectance spectrophotometer device (VITA EASY SHADE V). This device is wireless comprising a dental shade matching de- vice which consists of a base unite and hand piece .

Color coordinates were measured in the body regions of all laminate veneers with different combinations of laminate veneer material, internal relief space, and trial insertion paste color on composite resin abutment A3 and readings were re- peated 3 times for each combination.

The color changes (ΔE) were calculated between the control laminate ve- neers (with 30 microns internal relief spaces and glycerin on the composite resin abutment A3) and the experimental laminate veneers (with a combination of 2 in- ternal relief spaces and 5 trial insertion paste colors on the same composite resin abutment) in the 3 tooth regions with the following equations.[22] :

$\Delta E = [(E \text{ control} - E \text{ experiment})^{2}]^{1/2}$ and $\Delta E = 3.7$ was considered as the percep- tibility threshold.[23]

The mean and standard deviation (±SD) of ΔE for each veneer material was calcu- lated and averaged for the combinations of the internal relief space and trial inser- tion paste color in each veneer region. 2 way ANOVA was used to compare be- tween different groups and different shades for each thickness at different sites.

When the ANOVA was significant, the Tukey Honestly Significant Difference (HSD) test was used to determine which comparisons were significantly different.

A.30 µm internal relief space:

- Comparison of ΔE between different groups of ceramic veneer materials and dif- ferent shades of trial cement paste for 30 µm internal relief space is presented in Figure 2.

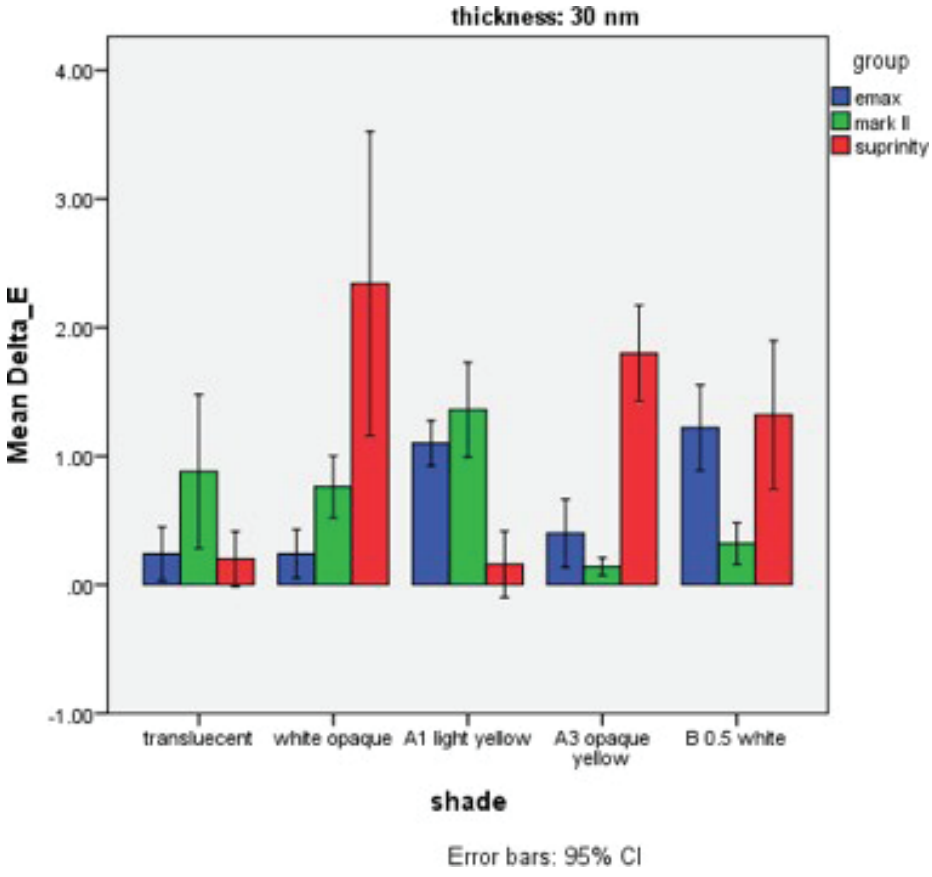

Figure 2: Comparison of ΔE between groups of ceramic veneer materials with 30 nm internal relief space.

B.100 µm internal relief space:

- Comparison of ΔE between different groups and different shades of trial cement paste for 100 µm internal relief space is presented in Figure 3.

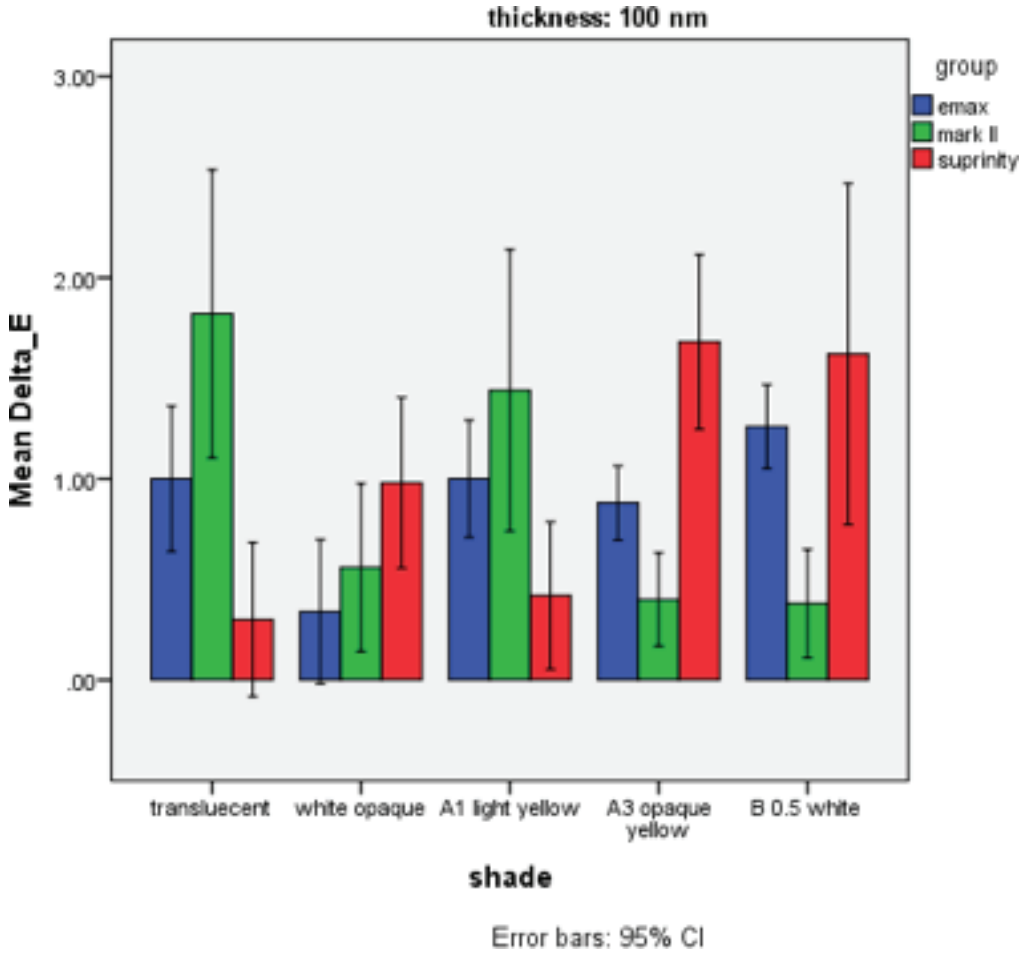

Figure 3: Comparison of ΔE between groups of ceramic veneer materials with 100 µm internal relief space.

Discussion

The hypothesis that there is an effect of trial cement paste shades on the final color of the laminate veneers was confirmed. There was a significant effect from the trial cement paste shades on the final color of all laminate veneers placed with 30 µm and 100 µm internal relies spaces at the body region for glass ceramic, feldspathic and zerconia reinforced glass ceramic laminate veneers . This was in 24 agreement with other researchers such as Xing W et al who stated that the effect of resin cements on the final color of veneers depended on cement shades and thickness of the restorations. Also, some shades of resin cements created percepti- ble color change in the final color of veneer specimens with thickness of 0.5 or 0.8 mm.

The effect of every trial cement shade on the final color of different materials of laminate veneers with 30 µm internal relief space was recorded.For translucent and A1 trial cement shade groups , It was found that the color difference was supe- rior to Vitabloc Mark II followed by IPS e.max CAD then Vita Suprinity.

This phenomenon can be explained by the greater translucent effect of felds- pathic (Vitabloc Mark II) than glass ceramics (IPS e.max CAD) and zirconia rein- forced glass ceramic (Vita Suprinity). These results were in agreement with Karine 25 et al who reported that their is statistically significant differences in the translu- cency parameter found among porcelain systems indicated for veneers according to the following rank: Vita VM9 >Vita PM9, Empress Esthetic > Empress CAD > Mark II, Everst, e.max CAD > e.max Press >

Lava zirconia. Also, significant dif- ference were noted when different shades and thickness were compared.

As regard white opaque trial cement shade groups, it was found that the color difference was significant for Vita Suprinity followed by Vitablocs Mark II then IPS e.max CAD. Also, For A3 opaque yellow and B 0.5 white trial cement shade groups, it was found that the color difference was superior for Vita Suprinity followed by IPS e.max CAD then Vitablocs Mark II.

The significant color difference result of Vita Suprinity could be explained by increasing the effect of the darker shades trial cements and relatively dark abut- ment shade A3 on the final color of zirconia reinforced glass ceramic material that have smaller translucent properties than Vitablocs Mark II and IPS e.max CAD. Their were other studies have shown that a large color difference was obtained for 26 different types of zirconia, such as 1.99 to 2.89 for DC-Zirkon. 1.8 to 3.6 for Digident Digizon, 27 2.1 to 3.6 for Vita 2000 YZ cubes, 28 and 0.9 to 2.1 for Katana. 28

The limitations of correlations between in vitro simulations of intraoral func- tion are recognized. In this study, the simulations did not include light aging. How- ever, the data on zirconia laminate veneers provide an initial step to better under- stand the optical properties of zirconia as a laminate veneer restoration. Further in vivo studies should be conducted to determine how long the suprinity laminate ve- neers and their color stability in the oral environment.

Conclusions

Within the limitations of this study design, the following conclusions were drawn:

1- The underlying color of the tested trial insertion pastes caused color change (ΔE

>3.7) for all ceramic material used in this study.

2- For translucent and A1 trial cement shade groups , It was found that Vitablocs Mark II laminate veneers were more affected by trial insertion paste color than IPS e.max CAD then followed by Vita Suprinity laminate veneers.

3- Vita Suprinity laminate veneers with relative opaqueness were more affected by opaque trial insertion pastes (White Opaque Shade, A3 Opaque/Yellow Opaque Shade and B0.5/ White Shade) than Vitablocs Mark II and IPS e.max CAD lami- nate veneers.

4- No significant effect of the two internal relief spaces (30 &100 μm) with differ- ent shades of trial cement paste on translucency of each ceramic material used.

Detection of Bla_{IMP} and $Bla_{OXA-23-LIKE}$ Genes in *Acinetobacter Baumannii* Isolates at Dr. Wahidin Sudirohusodo Hospital

Kartika Paramita[1], Tenri Esa, Benny Rusli[1]

[1]Department of Clinical Pathology, Faculty of Medicine, Hasanuddin University/Dr. Wahidin Sudirohusodo Hospital, Makassar, South Sulawesi, Indonesia

Abstract

Background/Objective: Carbapenem resistant *Acinetobacter baumannii* (CRAB) is an *A. baumannii* resistant to one or more carbapenem antimicrobials. Some of resistance mechanisms that can be found in CRAB are carbapenemase production, outer membran protein (OMP) or penicillin binding proteins (PBP) structure modification, or efflux pump increase. Carbapenemase production can be affected by carbapenemase-encoding genes such as bla_{IMP} and $bla_{OXA23\text{-}like}$ gene. This study aimed to detect the bla_{IMP} and $bla_{OXA23\text{-}like}$ gene in *A. baumannii* isolates.

Material and Method : It was observational descriptive study with cross sectional approach. Subject of this study were all *A. baumannii* isolates collected during the period of October 2018 until January 2019 at Dr. Wahidin Sudirohusodo Hospital, Makassar, South Sulawesi, Indonesia (consisted of 30 CRAB and 20 sensitive carbapenem *A. baumannii* (CSAB) isolates). Isolates were examined by polymerase chain reaction (PCR) and agar electrophoresis techniques.

Results : There were 5 CRAB isolates with bla_{IMP} gene and 23 isolates with $bla_{OXA23\text{-}like}$ gene. There were no CSAB isolates with bla_{IMP} gene and 2 isolates with $bla_{OXA23\text{-}like}$ gene.

Conclusion : Carbapenemase-encoding genes could be found in CRABs and CSABs. In this study, $bla_{OXA23\text{-}like}$ gene was found in both CSAB and CRAB isolates but bla_{IMP} gene was only found in CRAB isolates.

Keywords: *Acinetobacter baumannii*, *carbapenem resistant*, *carbapenem sensitive*, *bla_{IMP}*, *$bla_{OXA\text{-}23\text{-}like}$*

Introduction

Antimicrobial resistance (AMR) is the ability of microorganisms to survive from one or more antimicrobials which are initially effective for treating infections caused by these microorganism. The development of AMR is a natural phenomenon caused by bacterial genes mutation, or the acquisition of extrinsic resistance genes that can be transmitted horizontally between bacteria. Bacteria can have different resistance mechanism simultaneously so that they become resistant to several classes of antibiotics.[1,2]

Acinetobacter baumannii is one of extended-spectrum β-lactamases (ESBLs) bacteria group. Carbapenem resistant *A. baumannii* is *A. baumannii* that is resistant to one or more carbapenems (imipenem, meropenem, atau doripenem). Carbapenems, among all the **β-lactam antibiotics**, are able to withstand many types of β-lactamases produced by the ESBLs bacteria so they become drug of choice for ESBLs. Excessive use of carbapenems in last few years has caused the emergence of CRAB.[3–5]

The main mechanism of carbapenem resistance is carbapenem inactivation by carbapenemases, especially oxacillinases (OXAs) and metallo-β-lactamases (MBLs) type. Carbapenemases such as OXA-58, OXA-24/40, OXA-23, and OXA-51 (OXAs) or imipenem hydrolyzing β-lactamase (IMP) and verona integron-encoded metallo-β-lactamase (VIM) (MBLs) often found in *A.baumannii*. These enzymes are produced by carbapenemase-encoding genes such as $bla_{OXA\text{-}58}$, $bla_{OXA\text{-}24/40}$, $bla_{OXA23\text{-}like}$, $bla_{OXA\text{-}51}$, bla_{IMP}, or bla_{VIM} respectively. The other mechanism is related to the smaller number and size of OMP compared to other gram-negative bacteria thus reducing the permeability

of bacteria to antibiotics. Other mechanisms that can be found in CRAB are active expulsion of antibiotics as soon as they enter bacterial membrane wall through the efflux pump system and modification of PBP thus decreasing the affinity of bacteria for antibiotics.[3,4,6–9]

This study aimed to detect the bla_{IMP} and $bla_{OXA23\text{-}like}$ gene in *A. baumannii* isolates in Dr. Wahidin Sudirohusodo Hospital, Makassar.

Materials and Method

Design and Subject

The study was observational descriptive with cross sectional approach. Subject of this study were all *A. baumannii* isolates during the period of October 2018 until January 2019 at the Central Laboratory of Dr. Wahidin Sudirohusodo Hospital, Makassar, South Sulawesi, Indonesia that met the inclusion criteria.

The inclusion criteria was *A. baumannii* isolat identified by Vitek® 2 Compact and had antibiotics sensitivity test result based on Clinical and Laboratory Standards Institute (CLSI) guidelines. The *A. baumannii* isolate was excluded if isolat was contaminated by other bacteria. Isolates were examined by PCR and agar electrophoresis techniques to detect the bla_{IMP} and $bla_{OXA23\text{-}like}$ genes.

Acinetobacter baumannii is coccobacillus bacteria isolat identified by Vitek® 2 Compact. The CSAB is *A. baumannii* which is sensitive to all carbapenems (imipenem meropenem, ertapenem, dan doripenem) identified by antibiotics sensitivity test with MIC ≤ 2. The CRAB is *A. baumannii* which is resistant to one or more carbapenems (imipenem meropenem, ertapenem, dan doripenem) identified by antibiotics sensitivity test with MIC ≥ 8. The bla_{IMP} gene is MBLs type carbapenemase-encoding gene identified if a band is found at position 183 bp by PCR and electrophoresis agar techniques. The $bla_{OXA\text{-}23\text{-}like}$ is OXAs type carbapenemase-encoding gene identified if a band is found at position 736 bp by PCR and electrophoresis agar techniques.

Ethic

Ethical clearence had been accepted before study from Medical Research Ethics Committee of Faculty of Medicine, Hasanuddin University, Makassar, South Sulawesi, Indonesia.

Statistic Analysis

The data was analyzed using descriptive statistic method.

Result and Discussion

55 *A. baumannii* isolates consisted of 30 CRAB and 20 CSAB isolates were collected during this research. *Acinetobacter baumannii* isolates were more commonly found in male patients (52.7%). This fact is in line with research by Gustawan et al. (2014), An et al. (2017), and Irfan et al. (2011) who also found that *A. baumannii* isolates were more common in males patients.[10-14]

Acinetobacter baumannii isolates were more commonly found in group of age 40-60 years (38.2%). Research by An et al. (2017) reported that the average age of patients with CSABs was 64 ± 15 and 63 ± 15 for patients with CRABs. Research by Zheng et al. (2013) also reported that the mean age of patients with CSABs was 60.9 ± 9.8 and 62.2 ± 9.7 for patients with CRABs. This shows that *A. baumannii* infection is often affecting people with old age. This is probably because older patients usually have other comorbid factors and also experience a decline in the immune system so they are susceptible to *A. baumannii* infection.[10,14-15]

The majority of *A. baumannii* isolates in this research came from sputum (54.6%). This fact is in line with the research of Cucunawangsih et al (2016), Sarmad and Eftekhar (2015), and Chang et al. (2015) who reported that most of *A. baumannii* isolate was obtained from sputum. *Acinetobacter spp.* generally considered part of the normal flora of the pharyngeal mucous membranes and secretions of human respiration so that these bacteria are often found from respiratory secretions such as sputum.[7,12,16-18]

Acinetobacter baumannii isolates were found most frequently in patients with infectious diseases (56.4%) especially pneumonia and sepsis. This is in line with the research of Kulah et al. (2010) and An et al. (2017). Tal-Jasper et al. research on bloodstream infections by *A. baumannii* in 2016 found that these infections were mostly derived from previous pneumonia. *Acinetobacter baumannii* is often involved in various diseases such as pneumonia, osteomyelitis, peritonitis, endocarditis, septicemia and meningitis. Several studies had shown that patients with burns were also susceptible to *A. baumannii* infections during hospitalization.[10,19-21]

The majority of patient outcomes, as many as 61.8%, were discharged from the hospital in improved condition while the rest died in the hospital. Most of the patients who died in the hospital (13 person) were CRABs positive. Only 8 patients with CSABs positive. Tal-Jasper et al. research (2016) found out that the percentage of patients with CRABs died in the hospital was greater than CSABs (70.5% compared to 40.5%). Gustawan et al. (2014) found that most of patient outcomes in *A. baumannii* infections were died in the hospital.[11,21]

The average length of stay (LOS) patients with CRABs was 40 days. This was longer than average LOS patients with CSABs (13.9 days). This is in line with the research of Tal-Jasper et al. (2016) who found LOS patients with CRABs was longer than CSABs. The characteristics of this research samples can be seen in Table 1.[11,21]

Table 1. Characteristics of Research Samples

Research Samples Characteristics		n (%)	CSAB	CRAB
Sex	Male	29 (52,7)	11	18
	Female	26 (47,3)	14	12
Age	< 20 years	13 (23,6)	3	10
	20-40 years	15 (27,3)	6	9
	40-60 years	21 (38,2)	11	10
	> 60 years	6 (10,9)	5	1
Specimens	Pus	13 (23,6)	1	12
	Sputum	30 (54,6)	15	15
	Blood	5 (9,1)	5	0

Median Hospital Length of Stay			40,0 (6-233)	13,9 (0-37)
CSAB - carbapenem sensitive A. baumannii, CRAB - carbapenem sensitive A. baumannii				

Sources : Primary Data

Most of the CRABs were found in intensive care rooms such as Neonatus Intensive Care Unit (NICU), Pediatric Intensive Care Unit (PICU), dan Intensive Care Unit (ICU). The CRABs were most commonly found in the ICU. The CRABs were also found in regular hospital rooms with the most isolates found in Lontara 2 rooms. Only 1 CSAB was found in the ICU and 2 in the PICU. Most of CSABs were found in the Lontara 1 rooms. *Acinetobacter baumannii* emerges as an important pathogen in critical care settings in the recent years. Outbreaks caused by A. baumannii were often found in ICUs and burns injury care units. The distribution of CSAB and CRAB based on the treatment room can be seen in Figure 1.[16,19-20]

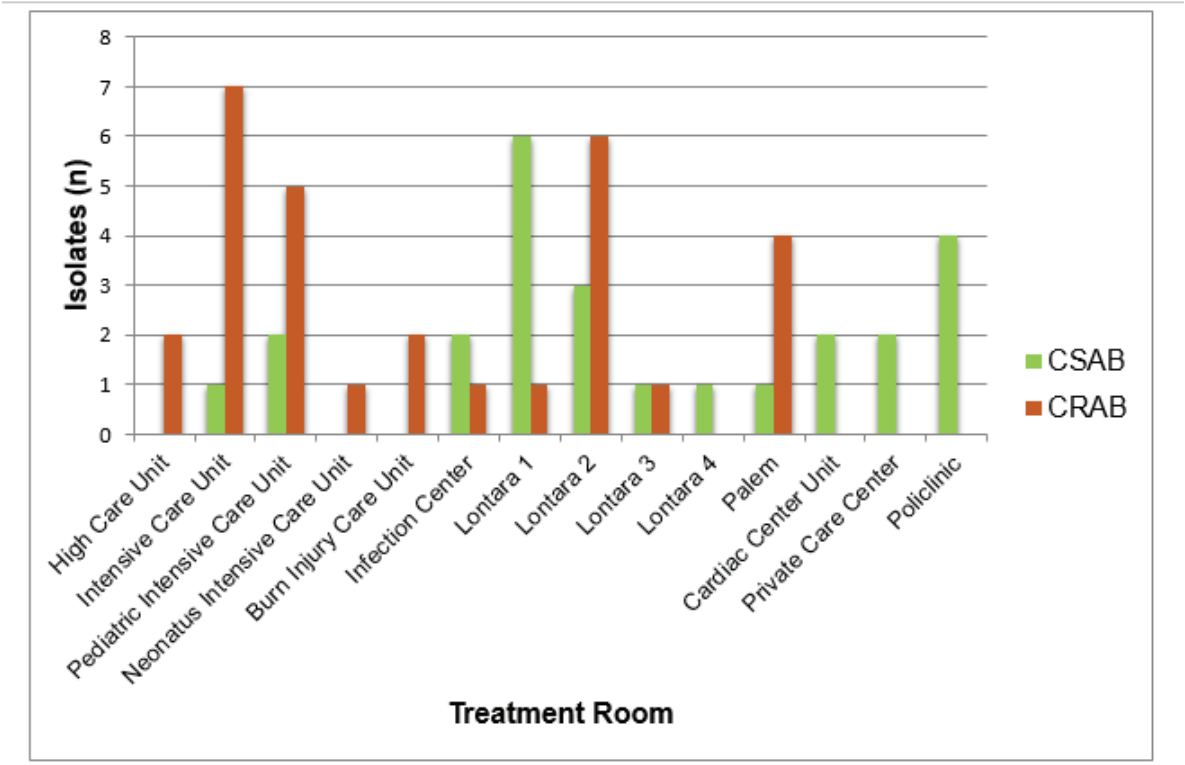

Figure 1. *Carbapenem Sensitive A. baumannii* **(CSAB) and** *Carbapenem Resistant A. baumannii* **(CRAB) Distribution Based on Treatment Room**

There were 5 CRABs with bla_{IMP} gene and 23 with $bla_{OXA23\text{-}like}$ gene. There were no CSAB with bla_{IMP} gene and 2 with $bla_{OXA23\text{-}like}$ gene. The distribution bla_{IMP} and $bla_{OXA\text{-}23\text{-}like}$ genes can be seen in Table 2.

Table 2. Bla_{IMP} and $Bla_{OXA\text{-}23\text{-}like}$ Genes Distribution

Gen	CRAB		CSAB	
	Positif	Negatif	Positif	Negatif
IMP	5	25	0	25
blaOXA-23-like	23	7	2	23

The results of this study indicates bla_{IMP} and $bla_{OXA\text{-}23\text{-}like}$ genes as carrier genes for the carbapenem resistance characteristics of *A. baumannii*. These results are in line with Santimaleeworagun et al. (2014) research who found 42 out of 43 CRABs had $bla_{OXA\text{-}23}$ gene. Amiri et al. research (2017) found 85.2% from 27 CRABs had the $bla_{OXA\text{-}23\text{-}like}$ genes ($bla_{OXA\text{-}23}$, $bla_{OXA\text{-}27}$, $bla_{OXA\text{-}49}$).[22-24]

This study reported that carbapenemase-encoding gene also found in the CSABs, especially $bla_{OXA-23-like}$ gene. This is likely to occur because these genes can be transmitted to other bacteria through acquired resistance mechanisms such as the acquisition of mobile genetic elements that are able to spread the determinants of resistance. There are 3 classic methods of natural deoxyribonucleic acid (DNA) transfer, namely bacterial conjugation, natural transformation, and transduction. Conjugation is often regarded as the main transfer mechanism. Exogenous DNA can be transferred from one bacterium to another through horizontal gene transfer. The discovery of $bla_{OXA-23-like}$ gene in CSABs shows some CSABs already have a tendency to have carbapenem resistant genotype even though they have not been maximally expressed so that the results of antibiotic sensitivity test are still sensitive.[25-26]

Negative results on CRABs in this research may be caused by the presence of other carbapenemase-encoding genes outside the genes examined in this research such as the intrinsic gene bla_{AmpC} and bla_{OXA-51} or the extrinsic gene $bla_{OXA-24/40}$, bla_{OXA-58}, bla_{VIM}, or bla_{SIM}. Another possibility that can occur is the existence of other carbapenem resistance mechanisms such as the active expulsion mechanism mediated by the tripartite efflux pump system and PBP or OMP structure modification.[6,9,27-28]

The limitation of this study is that there was no examination of the carbapenemase phenotype in *A. baumannii* isolates using a modified double-disk synergy test (DDST) to confirm that these isolates were true carbapenemase-producing type. This research also was not researching other carbapenem resistance mechanisms.

Conclusion

Carbapenemase-encoding genes could be found in CRABs and CSABs. In this study, $bla_{OXA23-like}$ gene was found in both CSAB and CRAB isolates but bla_{IMP} gene was only found in CRAB isolates.

The Appearance of Hbeag Status in Patients with Chronic Hepatitis B Virus

Kartika Wensdi Renantriandani[1], Ummi Maimunah[2], Priyo Budi Purwono[3], Retno Handajani[4]

[1]Clinical Student at Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [2]Lecturer at Department of Internal Medicine, Faculty of Medicine – General Hospital of Dr. Soetomo, Universitas Airlangga, Surabaya, Indonesia, [3]Lecturer at Department of Clinical Microbiology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [4]Lecturer at Department of Medical Biochemistry, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background: Chronic hepatitis B is a global burden disease with the mortality rate of over one million around the world because of the complication. In Indonesia the number of hepatitis B sufferers in a healthy population is estimated to reach 4-20.3%, where the figure is higher outside of Java. This study aims to analyze the description of HBeAg serological status in patients with chronic hepatitis B. **Method:** a descriptive study using medical records and sera of patients with chronic hepatitis B was used as primary data. The population of this study were patients with chronic hepatitis B in Gastroenterology and Hepatology Center of Dr. Soetomo General Hospital Surabaya in purposive sampling. The number of samples that fulfilled the inclusion and exclusion criteria was 82 people. **Result:** Most patients are between the ages of 50-59 (29,3%), males (67,1%), HbeAg loss (52,8%) receiving telbivudine (31,5%) and lamivudine (31,5%) as monotherapy for more than two years (42,1%) and have normal ALT (46,3%). **Discussion:** People with inactive (carriers) chronic HBsAg that are characterized by HBsAg last more than six months, also HBeAg negative, have serum ALT levels within normal limits. A temporary increase in ALT before remission can occur in some patients with chronic HBV infection after one year of treatment interruption. **Conclusion:** Telbivudine and lamivudine, separately as monotherapy, demonstrated greater HBeAg loss which reached within more than two years therapy.

Keywords: *chronic hepatitis B, HBeAg loss, ALT normalization, therapy*

Introduction

In the world, it is estimated that more than one million people die each year due to complications of chronic hepatitis B virus (HBV). In Indonesia, the number of hepatitis B sufferers in a healthy population is estimated to reach 4-20.3%.[1, 2]

HBV infection is characterized by the presence of Hepatitis B Surface Antigen (HBsAg) in the serum, which will stay for a long time as long as the virus is still in the body. HBV infection is classified as chronic if HBsAg is positive ≥6 months. Chronic HBV infection is a liver disease due to hepatitis B virus infection where inflammation and necrosis of the liver occur for at least 6 months, during which serum levels of Alanine aminotransferase (ALT) fluctuate fluctuate.[3]

The natural course of HBV infection is influenced by interactions from hosts, viruses, and the environment. HBV infection is transmitted through perinatal, sexual, percutaneous and close relationships between individuals through open wounds. Perinatal transmission is the transmission pathway that causes the most new infections in the world, contributing to 50% of people with positive HBsAg careers.[4] Hepatitis B seropositive Envelope Antigen (HBeAg) indicates active viral replication, and is a significant risk factor for hepatic cirrhosis and hepatocellular carcinoma.[5] HBeAg seroconversion is still considered an important endpoint

in the management of chronic HBeAg-positive HBV infection patients.[6]

Method

This study aims to analyze the description of HBeAg serological status in patients with chronic HBV infection. A cross-sectional study using isolates stored in the form of blood serum and the Health Medical Document (HMD) of chronic HBV infection patients was used.

Sample, Research Instrument and Data Analysis

The population were all patients with chronic HBV infection at the Center for Gastroenterology and Hepatology of Internal Medicine General Hospital of Dr. Soetomo Surabaya in 2017. Samples were obtained using a purposive sampling method that patients who met the criteria were 82 subjecs.

The data that has been collected was checked for completeness and carried out coding data (coding) using the McNemar test. The data was analysed using statistical software program Statistical Package for the Social Science (SPSS) version 17.0. (SPSS.Inc., Chicago, IL).

Result

Distribution of Subjects

The most age group of Chronic HBV infection patients who were the subject of the study were aged 50 to 59 years, with the youngest age of 16 years, and the oldest age of 80 years. The mean age of the subjects of this study was 47.5 ± 13.4 years. Based on the data obtained, chronic HBV infection affects more men. The ratio between male and female patients is 2: 1. (Table 1)

Status of Serology Subjects: Status of HBeAg

Past HBeAg status obtained from HMD of study subjects, compared with current HBeAg status obtained from serum ELISA examination of study subjects. After being treated, about 17 (20.7%) HBeAg patients were positive and 65 (79.3%) HBeAg patients were negative. About 36 patients with initial HBeAg status positive, found 19 patients (52.8%) who later became negative. (Table 2)

Current HBeAg Status and Pain Diagnosis, HBeAg Status loss and Duration of Therapy, and HBeAg Status and Types of Therapy

The negative HBeAg status was more prevalent in the study subjects. Positive HBeAg status is most common in asymptomatic chronic hepatitis B cases. BeAg loss was found most in study subjects who had received therapy for more than two years. HBeAg loss was highest in the group receiving telbivudine and lamivudine therapy. HBeAg status that remained positive was found most in the group who had never received therapy. (Table 3)

Biochemical Response of Research Subjects

The mean ALT levels of the subjects of this study were 87.7IU/L with a median of 39.5IU/L. ALT obtained with the normal category at most in patients who have received therapy for one to two years. High ALT levels were highest in patients who have never received therapy. ALT with the normal category was highest in patients on telbivudine therapy. High ALT levels were also highest in patients on telbivudine therapy. (Table 4)

Discussion

The most age group in this study is between 50 to 59 years, amounting to 29.3%. The results of this study were not much different from other studies which stated the most age group of chronic HBV infection patients is between 46 to 55 years or in a similar study found an average age of 56.8 ± 15.8 years with the youngest age 21 years and the oldest age 84 years.[7, 8] The age factor contributes to the incidence of chronic HBV infection, this can be attributed to an increase in the prevalence of HBsAg which is quite large.[9]

Patients with chronic HBV infection are predominantly male, with a ratio of male and female patients of 2: 1.[8, 10, 11] 12 14 This is related to sex hormones which play a role in increasing risk factors for hepatocellular carcinoma. The risk of hepatocellular carcinoma increases due to the active pathway that androgen receptors have in men. In women the process of hepatocarcinogenesis in necrotic hepatocytes is inhibited by Kupffer cells with the role of the hormone estrogen.[12]

All chronic HBV infections have positive HBsAg status. Hepatitis B surface antigen (HBsAg) is the earliest serological sign of HBV infection.[8] A positive HBsAg test result indicates someone has been infected by the hepatitis B virus.[13]

After comparing past and present HBeAg status, it was found that 52.8% of patients experienced HBeAg loss, ie HBeAg was not detected in patients who were initially HBeAg positive. The occurrence of HBeAg loss, with or without anti-HBe seroconversion, in patients with chronic HBV infection is positive HBeAg is an important end result, as it often illustrates immune control in chronic HBV infection.[14]

In the past HBeAg status, the percentage of HBeAg patients was negative at 56.1% and 79.3% in the current HBeAg status. There were more HBeAg negative groups than HBeAg positive.[7] The HBeAg negative group was always more abundant, both in cases of asymptomatic chronic hepatitis B, hepatic cirrhosis, and hepatocellular carcinoma.[15]

Acute exacerbations occur together with high viral replication, ALT increases to five times more than the upper limit of normal and twice more than the baseline, and histological development is a common feature of negative HBeAg groups developing into hepatic cirrhosis faster than in the group HBeAg positive.[16, 17] Persistent cirrhosis and persistently high levels of viremia are the two main risk factors for hepatocellular carcinoma in chronic HBV infection.[18]

HBeAg loss occurred most in the group with a duration of therapy of more than two years and the least occurred with a duration of therapy of less than one year, namely in the order of 42.1% and 26.3%. In the group that had received therapy for one to two years, HBeAg loss was 31.6%.[19]

In this study, the highest HBeAg loss occurred in the group receiving telbivudine and lamivudine therapy, each at 31.5%. HBeAg status that remained positive was found most in the group who had never received therapy. From other studies it can be concluded that telbivudine gives better results compared to entecavir and lamivudine to achieve HBeAg loss during one year of therapy.[19, 20] The occurrence of high HBeAg seroconversion in telbivudine shows that telbivudine not only inhibits viral replication, but also stimulates the patient's immune response. This can be attributed to HBV DNA that depends on the immune system of patients compared to pharmacological suppression.[21]

Patients with chronic HBV infection had an average ALT level of 87.7 IU/L and a median of 39.5 IU/L with the lowest levels of 6 IU/L and the highest 882 IU/L. The most common group was patients with normal ALT levels, which was 46.3 %.[8, 22] People with chronic HBsAg carriers that are characterized by persistent HBsAg for more than six months, as well as negative HBeAg, have serum ALT levels within normal limits.[1, 14]

Normal ALT levels are most common in patients who have been receiving therapy for one to two years. High ALT levels are highest in patients who have never received therapy.[19, 23, 24] Post-therapy monitoring continues, at least for one year every three months to confirm ongoing biochemical responses that are sometimes difficult to evaluate. A temporary increase in ALT before remission can occur in some patients with chronic HBV infection after one year of treatment interruption.[1, 14]

In this study, normal ALT levels were highest in patients on telbivudine therapy. High ALT levels are also highest in patients on telbivudine therapy. In randomized controlled trials (RCTs), it was concluded that telbivudine was better than lamivudine in normalizing ALT.[20]

Conclusion

Telbivudine and lamivudine, separately as monotherapy, demonstrated greater HBeAg loss. Greater HBeAg loss reached within more than two years therapy.

Social and Psychological Impact of Allergic Rhinitis among University Students in Malaysia

Kavitha Ashok Kumar[1], Darshini Devi Sarun[2], Ashok Kumar Jeppu[3]

[1]Discipline lead, Otorhinolaryngology, International Medical School, Management and Science University Shah-Alam Malaysia, [2]BMS, International Medical School, Management and Science University Shah- Alam Malaysia, [3]Discipline lead, Biochemistry, International Medical School, Management and Science University Shah- Alam Malaysia

Abstract

Background: Allergic rhinitis is a global health problem. It is a symptomatic disorder of the nose after allergen exposure due to IgE mediated inflammation of membrane lining the nose with clinical manifestation of rhinorrhea, sneezing, itching and nasal congestion. It is the sixth most prevalent chronic disease in the world with approximately 1 million people affected each year including up to 40% of the student population. This study aims to explore the social and psychological impact of allergic rhinitis among university students. **Methodology**: This descriptive cross sectional study was conducted on 1000 students of a private university in Malaysia who were willing to participate. Convenient sampling technique was used. The study tool used was a well structural questionnaire. Inferential statistical analysis was done. **Results**: In our study group,800 students were found to have allergic rhinitis (AR). They were in the age group of 18-26 years. Among them, 55% were females and 45% were males. Most of them, 495 (61.87%) were symptomatic for <3 years. Rhinorrhea was the most annoying symptom of AR stated by 37.5% of the study population. Sinusitis was the commonest cited comorbidity (29%). Communication and socialization problems were reported by 79% of our study group, while 50% were affected psychologically. Sleep, mood and concentration were the most affected. **Conclusion**: Allergic rhinitis can adversely affect the social and psychological life of students. These effects though not life threatening need to be borne in mind while dealing with students with allergic rhinitis.

***Keywords**: Allergic rhinitis, social and psychological impact, university students.*

Introduction

Allergic rhinitis(AR) is a symptomatic disorder of the nose secondary to allergen exposure due to an IgE mediated inflammation of the mucous membrane lining the nose[1]. It is clinically defined as a condition with four major symptoms namely rhinorrhoea, sneezing, nasal itching and nasal congestion[2]. It is believed to affect 10-30% of adults and 40% of children worldwide[3]. It is the sixth most prevalent chronic disease in the world with approximately 1 million people affected each year including up to 40% of the student population[4]. The common triggers of allergic rhinitis are domestic allergens such as mites, domestic animals, insects while outdoor allergens include pollens and moulds, tobacco smoke and automobile exhaust[4]. There may be associated allergic conjunctivitis, postnasal drip, Eustachian tube dysfunction, otitis media and sinusitis which may deteriorate the quality of life of AR patients[1,5]. It can also be associated with co-morbid conditions like asthma, atopic dermatitis and nasal polyps. Pharmacologic treatments of this condition can have adverse effects such as sedation[6]. The indirect costs resulting from allergic rhinitis associated absenteeism result in losses to employers that exceed those for other common conditions such as a migraine, diabetes and also asthma [10]. Hence this health problem can cause considerable

economic and societal burden[2]. Students who lead an active life may be exposed to these common allergens and many may suffer from this condition. Though the symptoms are not life threatening, it may compromise the social and academic life of students. This study was therefore conducted to evaluate the impact of allergic rhinitis on life of university students.

Methodology

This study adopted a cross sectional study design. The study population was students of different faculties in a private university in Shah Alam, Malaysia. Convenient sampling technique was used. The study tool used was a well -structured questionnaire prepared after extensive literature review. It was pilot tested on ten random students, checked for ambiguity and later used. The questionnaire had three components a) Demographic profile of the study population b) Allergic rhinitis symptoms and duration c) Impact of allergic rhinitis on the social, financial and psychological aspects of student life. The study was conducted after obtaining approval from the ethical committee of the university. A written informed consent was sought from all the participants. Data was analyzed using SPSS version 13 using descriptive statistics.

Results

A total of 1000 students from various faculties of a private university in Shah Alam, Malaysia willingly participated in this study. Our study population consisted of young adults of the 18 to 26 year age group. We observed that 800 (79.5%) of our study population had symptoms of allergic rhinitis of varied duration. The demographic profile was as depicted in figure 1a, 1b and 1c.

Figure 1a,1b and1c: Demographic profile of the study population

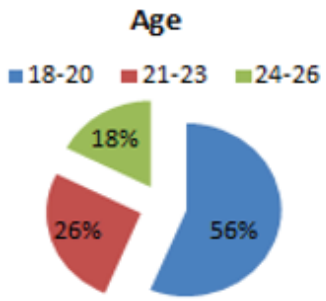

Fig 1a

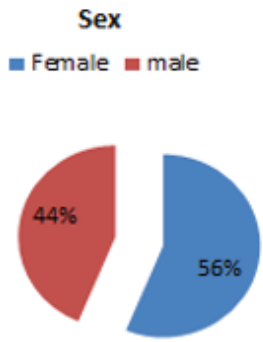

Fig 1b

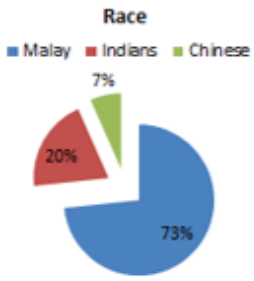

Fig 1c

In our study, out of the 1000 students who participated, 800 had symptoms of allergic rhinitis. Of them, 495 (61.87%) had symptoms of allergic rhinitis for 1-3 years duration while 103 (12.8%) had for more than 3 years, 100 (12.5%) had since childhood and 100 (12.5%) were not sure of the duration of their symptoms.

Watery nasal discharge was the commonest symptom seen in 300 (37.5 %) of our study population, followed by frequent sneezing in 200 (25%) nasal obstruction in 200 (25%) and itching in the nose and palate in 100 (12.5%) as seen in Fig 2.

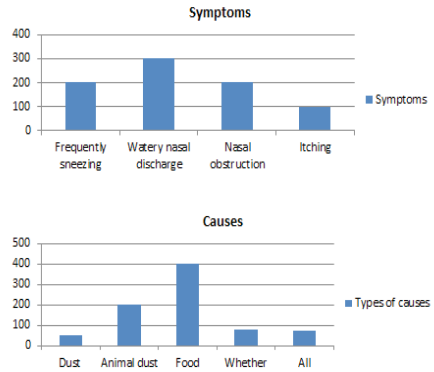

Figure 2. Symptoms of allergic rhinitis

In our study, 50% our participants considered food as the commonest allergen for their rhinitis followed by animal dander (25%), weather changes (9.38%), dust(6.25%**)** and all of them by (9.38%) as shown in Fig 3.

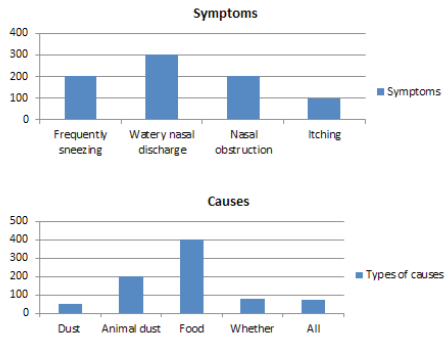

Figure 3 : Causes of allergic rhinitis

In our study group, 635 (79%) reported feeling of being ashamed to communicate with others and socialize due to their annoying symptoms. They felt that their allergic symptoms was responsible for their inability to integrate with peers and lead to family dysfunction. They therefore spent a significant amount of their free time on social network with 49.5% spending more than 3hrs/day while 29.8% and 18.25% spending >2 hrs an 1-2 hrs on social network respectively. They also complained of fatigue, decreased enthusiasm and poor general health perception.

The psychological impact of allergic rhinitis was also observed in 400 (50%) of our study population. 246 students (30.7%) had multiple symptoms. The common complaints expressed were sleep deprivation 340(42,5%),headache 232 (29%), feeling at edge 30(3.8%), mood fluctuations 6 (0.75%) feeling tearful 16 (2%)and lack of concentration(25%). Sleeping and playing games on internet were the commonest strategies adopted by 50% of the students to alleviate their stress that was attributed to allergic rhinitis. Eating, chatting on social media and others like doing yoga were also mentioned by a minority of the study population.

Discussion

Demographic profile:

Among the study group of 1000 students ,800 (79%) were found to have symptomatic allergic rhinitis. This high prevalence of allergic rhinitis among our study population can be attributed to living in the city areas with contaminated air. R. Mosges and L. Klimek in their study in Germany made a similar observation. They have implicated western lifestyle and air pollution for the high prevalence of allergic rhinitis among adults[11].

The mean age of the study group was 21+/- 3 years. In a similar study by Kalmaizi et .al in western Iran the mean age reported was 29+/- 10 years[12]. Among the symptomatic group, 18% were of 24-26 years,26% of 21-23 years and 56% of 18-20 years suffered from allergic rhinitis. Though our study population focused on a limited age group, a difference in incidence was noticed even among them. This age-related diminishing feature seen in the allergic rhinitis might be because of the allergen-explicit IgE level abatement that happens with maturing in atopic people [13].

In our study population, 56% were female and 44% were males. The higher incidence of allergic rhinitis among females was also reported in a similar study on allergic rhinitis patients in western Iran, where 61% of their participants were female and 39% were male [12]. Similar observations were also made by Shariat et al. in which 62% were female and 38% were male[14].This observation has been documented in a systematic review and meta- analysis by Pinart et .al [15] where they stated

that female preponderance for asthma and allergy in adulthood was seen worldwide except in Asia.However, our findings and those of the above studies show that similar prevalence is seen in Asia also. Nasal obstruction has been specifically accounted for in pregnancy, menses, menarche, and while on oral contraceptives showing that the increased prevalence among female students might be identified with hormonal levels. However, in contrast to our observation Hubert ,Chen et al in their study on allergic rhinitis reported 37% female and 63% male participants [16].

With respect to ethnicity, our study population included 73% Malays,20% Indians and 7% Chinese. This can be attributed to the larger population of Malay individuals in the campus in contrast with the other ethnic groups. Similar observations were made in an earlier study on food allergy in the same university[17].

Symptoms of allergic rhinitis:

In our study, watery rhinorrhoea was the most troublesome symptom of allergic rhinitis complained by 37% of the study population. Similar observations were made in a study on allergic rhinitis conducted in Tehran[14]. Nasal congestion however, has been documented to be the most bothering symptom in some other studies on allergic rhinitis [2,6,7,8] Most of the students in our study population correlated their symptoms with food and considered it to the commonest cause for their allergic rhinitis. A similar observation was made by Redhwan AA[17].

In our study group, 29% complained of co morbidities like sinusitis and 12% had asthma. Sinusitis, asthma, a poor sense of smell and taste were reported as comorbidities in a similar study in western Iran [12]. A similar observation was also made by Shariat et.al in 2012. Irritation of the nasal mucosa by allergens causes oedema and clogging of the sinus ostia prompting sinusitis[14].

Social and psychological impact on student life:

Most of the students in our study reported that their social life had been influenced by the hypersensitive rhinitis. Other than the nasal blockage and runny nose; different issues like exhaustion, feeling of inconvenience and decreased efficiency were the common complaints. When those side effects showed up, individuals expressed felling ashamed to speak with other individuals, which in-turn affected their public activity. Meltzer too drew attention to these social effects of allergic rhinitis in their study on quality of life of allergic rhinitis in adults and children[5].

In our study group, 79.5% acknowledged that they felt ashamed to communicate with others due to their annoying symptoms which in turn lead to difficulty in mingling with peers leading to social disjunction. Cingi et.al in their study in Turkey also drew attention to the negative effects of allergic rhinitis on the quality of life and social communication[2]. The students of our study group therefore spent a large amount of their time on social network with 49.5% spending more than 3hrs/ day, while 29.8% and 18.25% spending >2 hrs an 1-2 hrs on social network respectively. R. Mosges and L. Klimek argue that increase in time spent indoors expose individuals to a variety of novel allergens and the psychological stress due to this lifestyle change leads to an increase in sensitization to a wider variety of allergens which worsens their situation [11].

We found that allergic rhinitis symptoms were related with poor mental status among the university students. The symptoms which the students correlated with worse outcomes were sleep deprivation, headache and lack of concentration. The other common complaints expressed were mood fluctuations, feeling at edge and feeling tearful. It was worse among perennial allergic rhinitis sufferers when compared to those with seasonal allergic rhinitis. Similar observations were made by other researchers. [9.10,13,14].This can be explained by nasal congestion in allergic rhinitis patients due to the release of inflammatory intermediates which leads to disrupted sleep and subsequent daytime sleepiness [6]. Sleeping and playing games on internet were the commonest stress coping strategies adopted by 50% of the students. Eating, chatting on social media and doing yoga were also mentioned by a minority of the study population.

Conclusion

This cross-sectional study on 1000 undergraduate students of a private university in Shah Alam, Malaysia shows that allergic rhinitis is common among the university student community. It adversely influences their social and mental life. These effects though not life threatening need to be borne in mind while dealing with students with allergic rhinitis. Steps need to be taken to reduce the environmental allergens which may prevent allergic rhinitis and concomitant diseases like sinusitis and asthma among the student community.

Limitations of the study: This study involved young adults of 18-26 years age group and many of them belonging to one ethnic group. Hence the outcomes of this study would probably be pertinent and relevant to this population. Furthermore, the examined information could be influenced by the perspectives of students regarding their illness. Besides, the anxiety and mental status of the symptomatic students maybe influenced by other factors like family income, informal community utilization and parental expectation of their achievements.

Conflict of Interest: Nil.

Abstract

Home delivery is common in sub Saharan states including Ethiopia leading to cause morbidity and mortality of maternal and child health. This study aims to determine factors affecting utilization of institutional delivery among mothers of under two-year-old children in Gambella regional state, Ethiopia**.** Methods: A cross sectional study which approach 404 mothers of under two years old children by using multistage and purposive sampling technique. Data was collected by self-administer questionaire to examine the prevalence of institutional delivery and factors affecting. Descriptive statistic and Pearson's Chi-square were performed to describe and determine the associations. Results: The study shows that 69.3% of respondent's delivery in the health facility, whereas, 26.7% delivery at home and those deliveries on the road and ambulance was 4%. This study disclosed that most of respondents had low level of knowledge on pregnancy complications (65.6%). Education of the mother, ethnicity, attitude, transport accessibility, availability of maternal source of health information, availability of female skilled birth personnel, Antenatal Care visit, and accessibility to 24 hours' service were significantly associated to institutional delivery. Conclusion: Institutional delivery is affected by many factors. The government and health professionals should promote education regarding the danger signs of pregnancy, pregnancy complications, and benefits of institutional delivery.

Keywords: *Institutional delivery, Prevalence, Gambella Region, Ethiopia*

Introduction

Maternal mortality remains a universal significant health problem. Low- or middle-income countries encountered the complication with pregnancy or related consequences for the maternal death during the reproductive-aged women [1,2]. Institutional delivery service utilization is one of the key interventions to reduce maternal mortality ration in the world. It ensures safe birth, reduces both actual and possibly potential pregnancy complications, and increases the survival of most mothers and newborns [3,4]. The World Health Organization (WHO) approximate that nearly 580,000 mothers had lost their life due to complications related to pregnancy. Still, maternal mortality ratio (686 per 100,000 live childbirths) is the highest in Ethopia throughout the world [5].

In developed countries, almost 97 % of mothers attained antenatal care services whereas only 52 % of mothers attained routine antenatal check-up in developing countries and 68% of deliveries were attended by skilled health personel through 53 % of skilled birth personel in Sub- Saharan Africa[5-7]. The maternal death percentage in 2000 was 816 per 100,000 livebirths, and the newborn death percentage was 113 per 1,000 [3,5]. Single clarification for poor health results amongst mother and youngsters is connected to the non-use of present health care facilities by a large percentage of Ethiopian mother. Earlier educations have obviously established that mother usage to health facilities low in the state. Some trainings in 1990s have shown that about 25% of Ethiopian mothers expected ANC, and less than 10% received professionally-assisted delivery care [4,5,6,8]. Home delivery is common in sub Saharan states including Ethiopia, 42% of mothers in Malawi,

69% in Nepal,70% in Zaria (Nigeria),74% in Pakistan [8-10] and 87.65% in eastern Burma give birth at home, 81.8% of women in Dodota district, 95% in Tigray, and 87.7% of mothers in Arsi reported those who get delivery at home[11]. There were 45% of institutional delivery in Gambella region which lower than Addis Ababa (96.5%), Tigray (56.9%), Diredawa (56.2%) and Harari (50.2%) [12]. However, despite the removal of financial barriers, home delivery was still found to be very high. Thus, we need to understand the factors that influence women's decision on institutional delivery service utilization.

Methods

This study is a cross-sectional study which conducted in Gambella Region, Western Ethiopia. The total sample size needed was 404 respondents including 5% refusal rate calculated using Cochran formula: $n = Z^2 P (1-P)/ (d)^2$. This study used a multi-stage sampling technique. First, 5 out of 14 districts in Gambella Region was selected by purposive sampling technique with the lowest rate of institutional delivery; the eligible districts selected were Abobo, Gog, Itang, Gambella Zuria, and Jekaw. The 2nd stage, among 5 districts, 2 villages were selected by simple random sampling from each district. Finally, the participants were selected by convenience sampling technique with proportionate to size. The study population was mothers age between 15- 49 years with under two years old children.

The questionnaire consists of 6 parts: 1) Socio-demographic characteristics 2) Knowledge on pregnancy complications, Antenatal Care (ANC), Postnatal Care (PNC) and good place of service care for delivery 3) Attitude towards institutional delivery and maternal health delivery 4) Enabling factors 5) Need factors and 6) Utilization of institutional delivery. The content validity was checked by three experts by using the Item Objective Congruence Index. A pilot study was also conducted, the Cronbach's alpha results were 0.82.

Data collection procedure

Researchers had been explained the study and its associated procedures, risks, and benefits to each participant. All women had been asked for their signed consent before continuing with data collection. The ethical approval for conducting the study was received from Research Ethics Review Committee, Chulalongkorn University and the permission to conduct the study was obtained from Ethiopia Federal Ministry of Health (EFMOH) and Gambella Regional Health Bureau.

Data Entry and Analysis

Data analysis were processed by using SPSS software version 22. The results had been presented using descriptive statistics including frequency, percentages, mean, and standard deviation. The chi-square test was run to find the association between the instutional delivery and the independent variables.

Results

In this study among 404 participants; over little half (50.7%) age 15-24 years. Most of respondents were married (94.3%). Thirty-three percent of respondents had finished secondary education, the rest had completed primary school, high school, higher education, and no education, respectively. About 77% of participants were housewives and/or no occupation, while 23% had an occupation. Ethnicity of the respondent were Nuer (61%), whereas, Anywaa were 39%. For Autonomy in the decision making found that those who responded to both mother and husband were 45.3%, only husband was 29.2%, and mother in law/relatives were 17.1%.

Level of Knowledge and attitude

Table 1 shows that the level of knowledge of respondents of pregnancy complications, ANC, and PNC, and good place of service care for deliver. The study found that most of respondents had low knowledge level (65.6%), follow by moderate knowledge level (26.0%), and the high knowledge level (8.4%). For the attitude of the participant toward institutional delivery found that most of participants had neutral attitude (62.9%), the rest had negative attitude (20.5%), and positive attitude (16.6%), respectively.

Table 1 Level of Knowledge and attitude toward institutional delivery and maternal health *(n=404)*

Variables	Frequency	Percentage (%)
Level of knowledge		
Low knowledge (<60%) (0-17)	265	65.6
Moderate knowledge (60-80%) (18-23)	105	26.0
High knowledge (>80%) (24-28)	34	8.4
Level of attitude		
Negative attitude	83	20.5
Neutral atititude	254	62.9
Positive attitude	67	16.6

Enabling and need factors

Table 2 shows enabling and need factors. The respondents who had access to information on maternal health care were 94%. According to source of information, the respondents who got the information from the health provider were 57. 9%, family and friends were 13.1%, and those with no information about health were 4.2%. The study also found that respondents who had a poor access to transportation 21.8%. Regarding the ANC attendance found that those who attended the ANC were 95.3%.

Discussion

The current study shows that the institutional delivery was 69.3%, home delivery was 26.7%, on the way to health facility, on the road delivery was 3% which is institutional delivery seems to be higher than home delivery which could be due to better accessibility to health service. The study also shows high percentage of ANC service utilization (95.3%) which contradict with other studies reported that participants who had attended ANC vist were very low [11-14]. The previous findings showed that institutional delivery service utilization was 12.1% in the district and the majority of mothers (87.9%) gave birth at home and also revealed that overall delivery assisted by skilled birth attendants was 12.7%.[11]. Our study finding was higher than National and Amhara region EDHS result of 2005 which was 6% and 3.5% respectively, this might be due to the time gap, i.e., since 2005 there could be improvement in accessing and utilizing the service. This study showed that institutional delivery service utilization in the study area was high 69.3%, however when compared to other findings this finding is not constant with the other finding in Ethiopia; EDHS 2011[12] in the urban Arsi Zone and in Metkel and in Metekel [15-16].

Additionally , current study shows the women who attended institutional delivery, who had attainded 24 hours' service care were 72% and those that attened the post natal care was 28% which consistent with studies done in northwest Ethiopia, delivering at health facility led women to seek for PNC services [13]. The previous study showed that individual attitude towards health care providers and perceptions on the quality services provided in health facilities were mentioned as influencing factors for maternal health service seeking behaviors of women consistent with previous studies [13]. This was also consistent with study done in Dembecha district, Northwest Ethiopia. This could be explained in three reasons; (i) low institutional delivery in the study setting, (ii) low antenatal health coverage, and (iii) lack of knowledge on the importance of the service [13,17,18].

This study found that the womens educational status to their antenatal health care service seeking behavior in maternal health care service. Women who were able to read and write were more likely to seek antenatal health care, and institutional delivery. It is understood that education is likely to enhance women autonomy and it make them near to information and obtain good knowledge [13,19,20]. Women autonomy of this study the respondents who responded to decision made by both respondent and her husband were 45.3% and the respondents who responded to the decision only made by the husband for seeking health seeking were 29.2%, whereas, espondents to the decision made by mother in law were 17.1% repondents who responded to the autonomous 8. 4% which means that it is less likely for the respondent to seek for health service behavior. This finding is inconsistent with systematic review conducted in sub Saharan Africa (SSA), which stated that women with highest levels of autonomy most likely seek facility-based delivery. This might be due to the fact that the

SSA review assesses power of the women in relation to other activities such as household purchase and freedom of movement in addition to decision on place of delivery [15].

The magnitude of risk of home delivery, pregnancy complications, and benefit of institutional delivery, free service care for delivery and child are should be displayed to the public as it is necessary to help people in the society consider about these issues. The campaigns for women empowerment regarding knowledge and awareness of institutional delivery, settlement, and trainings for mother of under two years' children should be created. Furthermore, the health sectors should have a plan to give training about the risk of home delivery, and pregnancy complications to guarantee the safety for mothers of under two-year-old children. Legal regulation and punishment should be strictly enforced to the family who doesn't allow mothers to seek for a health care in order to reduce maternal mortality, child death occurrence and protect to women's right.

Effects of Self-efficacy, Health Perception, Social Support and Perceived Disability on Health Promoting Behavior of Nursing Students

Mi Sun Lee, Hee Kyung Kim

[1]Doctoral student, [2]Professor, Department of Nursing, Kongju National University, Gongju, South Korea

Abstract

Purpose: This study is a descriptive survey to investigate the relationship between health promoting behaviors and self-efficacy, health perception, social support and perceived disability and to identify factors affecting health promoting behaviors among nursing students.

Methods: With the permission of the Education Committee of the Department of a University, 249 nursing college students explained the purpose and method of research and collected data with written consent. The data were analyzed by the t-test, ANOVA and Pearson's correlation and Stepwise Multiple Regression using the SPSS 24.0 program.

Results: The health promoting behaviors of the subjects were a positive correlation at the statically significant level at the self-efficacy (r=.73, p<.001), health perception (r=.50, p<.001), Social support (r=.62, p<.001) and a negative correlation at the perceived disability (r=-.29 p<.001). Regression analysis showed that health condition (β =-.144, p <.001), health concern (β=-.147 p<.001), self-efficacy (β=.523, p<.001) and social support (β=.199, p<.001) explained 62.0% of health promoting behaviors, and health conditions, health concern, self-efficacy, and social support were the main factors influencing health promoting behaviors of nursing student.

Conclusion: Through the result of this study, it is necessary to develop programs that allow nursing students to observe their health conditions and raise their interest in health, and promote self-efficacy and social support.

***Keywords**: Nursing students, Health promoting behaviors, Self-efficacy, Social support, Perceived disability*

Introduction

With the growing interest in health, health care methods are emerging to improve health levels through changes in personal lifestyles and living environments, rather than health care which is practiced after getting a disease. The WHO[1], which calls the health care method as a health promoting behaviors, defines it as a health promoting behaviors which improves the health level of individuals and society that needs to be improved and maintained, and maximizes health potential. Health promoting behaviors are affected by various sub-components, such as personal physiological, psychological, sociocultural factors, cognitive factors, previous related behaviors, and behavior intentions. Specific health promoting behaviors include anti-smoking, anti-alcoholism, exercise, diet, and stress management, and such actions require a community-oriented and systematic approach, along with the legal and institutional support of the state, rather than a personal approach to effectively operate health promotion.

The results of the study using the health promoting behavior model of Pender[2] shows that the variables of self-efficacy, health perception, perceived disability, and

Corresponding Author:
Hee Kyung Kim
Professor, Department of Nursing,
Kongju National University, Gongju, South Korea
E-mail: hkkim@kongju.ac.kr

social support were highly relevant with health promoting behaviors and influencing factors. Self-efficacy has been shown to be a main predictor and the most important factor for motivating health promotion. Health perception is said to have a significant impact on physical activity as it forms the basis for health promoting behaviors.[3] The study also found that perceived disability is a variable that affects health promoting behaviors[4]and the lower perceived disability of behavior, the higher level of health promoting behaviors.[5] The higher level of social support and relationship satisfaction was reported to have a positive effect on the practice of health promoting behaviors. [6]

Since nursing college students are prospective nurses, it is important to establish proper health promoting behaviors for nursing students because they will be responsible for education and role models for improving health promotion activities. However, health promoting behaviors are fundamentally not bounded and multidimensional, so it is necessary to study whether the health of college students has a significant effect on college life or how it is effective to help them improve their health. Although there are many papers that investigate health-related variables for nursing college students, comprehensive studies on factors such as self-efficacy, health perception, perceived disability, and social support, which have been shown to significantly affect health promoting behavior, are not sufficient, therefore these important factors are used to help nursing college students establish health promoting behaviors and to provide basic data for developing health promotion programs.

Method

Subjects: The subjects of this study were 250 nursing college students in 2nd, 3rd and 4th grades who majored in nursing at H University located in H province, Cheongnam in Korea. The number of participants was calculated by setting the level of 0.05 for significance, power of 0.95, effect size of 0.15 and 14 predictors using the G*Power 3.1.9.2 program, and the number of samples calculated was 194 among 250 subjects which were randomly selected considering the dropout rate of 20%. A total of 249 parts (99%) of 250 questionnaires were used as final analysis data, except for one of the unfaithful responses. A total of 249 copies were used as the final analysis data.

Instruments

Health promoting behavior: Measured by the health-promoting lifestyle measuring tool of Korean (adults) developed by Park[7]. It is a 5point Likert scale with total of 60 questions and indicates that the higher the score, the higher the level of health promoting behavior. The reliability at the time of development was Cronbach's α=92 and the reliability of this study is .94.

Self-efficacy: Measured by a tool which was developed by Sherer and Maddux[8] and supplemented by Lee[9]. It is a 5point Likert scale with total of 17 questions and indicates that the higher the score, the higher the level of self-efficacy. The reliability at the time of development was Cronbach's α=85 and the reliability of this study is .95.

Health perception: Measured by a tool which was developed by Ware, and supplemented by Lee[10.] It is 4point Likert scale with total of 20 questions and indicates that the higher the score, the higher the level of health perception. The reliability at the time of development was Cronbach's α=72 and the reliability of this study is .74.

Perceived disability: Measured by a tool which was developed by Moon[11] as a health belief measurement tool and modified by Seo.[12] It is a 4point Likert scale with total of 10 questions, and indicates that the higher the score, the higher the level of perceive disability. The reliability at the time of development was Cronbach's α=73 and the reliability of this study is .86.

Social support: Measured by a tool which was developed by Park[13] It is a 5point Likert scale with total of 18 questions, and 1 point of 'never', 5 point of 'always' indicates that the higher the score, the higher the level of social support. The reliability at the time of development was Cronbach's α=95 and the reliability of this study is .96.

Data collection: This study was approved by the Board of Education of H College, and published the research contents on the bulletin board of the nursing department between September and November 2019 and distributed questionnaires in groups at certain times and places. The research was collected after a fully trained assistant obtained written consent from the candidate and completed the questionnaire in a written manner.

Ethical consideration: Approved by the K University Institutional Bioethics Committee (KNU_IRB _2019-58) for this study. The survey was prepared with voluntary participation, there were no disadvantages of discontinuing the questionnaire and that the data would be processed anonymously. The information collected was used for three years for the study and promised to be stored in lockers.

Date analysis: Using the SPSS/WIN 24.0 program, the general characteristics of the subjects were analyzed as frequency and percentages, the difference in health promoting behavior according to the general characteristics was t-test, ANOVA and Scheffe test, variables was mean and standard deviation, and the correlation between variables was analyzed as Pearson's correlation coefficient, and the influence factor analysis was stepwise multiple regression.

Results

General Characteristics of Subjects

The sex of the subjects was 214 (85.9%) of females, most of them were 222 (89.2%) under 29 years of age, and 138 (55.4%) of third graders were more than half. 171 people (68.7%) did not have a religion, 166 people (66.7%) were drinking alcohol, and 230 people (92.4%) did not smoke, and the academic grades of 161 people (64.7%) was in middle. The health condition answered their condition was moderate was 153 (61.4%), 142 (57.0%) ware interested in their health, and 184 (73.9%) responded that the economic status was moderate.

Difference in Health Promoting Behavior across General Characteristics

Gender (t=-1.97, p=.049), age (t=-2.58, p=.010), grade (t= 3.16, p=.044), and religious status (t=2.45, p=.015), drinking (t=.75 p=.454), smoking (t=-. 921, p =.358), grades (t=5.05, p=.007), Health condition (t=25.35, p<.001), health concern (t=18.80, p<.001) and economic level (t=9.04, p<.001) showed differences in health promoting behavior. Male students, those in their 30s and over, and those in a religious group, those who reported middle grades had higher levels of health promoting behavior. It is showed that the higher or moderate health condition, health concern, and economic status tend to do health promoting behaviors (Table 1).

Table 1: Difference in Health Promoting Behavior across General Characteristics

Characteristics	Categories	Number	Frequency (%)	Mean±SD	Health promoting behavior t or F(p) Scheffe test
Sex	Female	214	85.9	3.19±.52	-1.97(.049)

Health Promoting Behavior, Social Support, Self-efficacy, Health Perception and Perceived Disability

The average score of health promoting behavior was 3.22 ±.52 out of 5 points, self-efficacy was 3.55 ± 0.73 out of 5 points, health perception was 2.73 ± 0.33 out of 4 points, and social support 3.82 ± 0.66 out of 5 points. The perceived disability score was 2.08 ± 0.55 out of 4 points.

Correlation between Social Support, Self-efficacy, Health Perception, Perceived Disability and Health Promoting Behavior

Health promoting behaviors were positive correlation in statistically significant with self-efficacy (r=.73, p<.001), health perception (r=.50, p<.001), social support (r=.62, p<.001). There was negative correlation with perceived disability (r=-.29, p<.001) (Table 2).

Table 2: Correlation between Related variables and Health Promoting Behavior

Variables	**Self-efficacy r (p)**	**Health perception r (p)**	**Social support r (p)**	**Perceived disability r (p)**
Health promoting behavior	.73(< .001)	.50(<.001)	.62(< .001)	-.29(< .001)

Factors affecting Health Promoting Behavior

In order to identify factors affecting the health promoting behavior of the subject, significant variables among the general characteristics were piled up as covariates, and multiple regression analyses were performed in a step-by-step manner, including independent variables. In the regression analysis, there was no autocorrelation (Dubin-Watson=1.94), and the problem of multicollinearity was the tolerance limit -.915 was more than 0.1, and the VIF was not more 1.09 to 1.78 under 10, so there was no problem.

The regression model for health promoting behavior was significant and explanator power was 62.0%. the health status (β=-.144 p.001), health concern (β=-.147, p<.001), self-efficacy (β=.523, p<.001) and social support (β=.199, p<.001) was a significant factor in health promoting behavior (Table 3).

Table 3: Factors affecting Health Promoting Behavior of Subjects

Variables	B	SE	β	t	p
a constant	1.75	.202	8.690	.000	
Health condition	-.121	.036	-.144	-3.346	.001
Health concern	-.131	.037	-.147	-3.562	<.001
Self-efficacy	.372	.037	.523	10.120	<.001
Social support	.158	.042	.199	3.789	<.001
R=.788 R^2=.620 Adj. R^2=.614 F=99.63 p<.001					

Discussion

The health promoting behavior of the subjects was 3.22 out of 5 points, which was higher than 2.71 of Park & Kim[14] and lower than 3.28 of Kim & Yoon[15]. The health promoting behaviors of nursing college students need to be guided to live up to the point with health promoting behaviors continue to be moderate.

Health promoting behavior according to general characteristics showed significant differences in gender, age, grade, religion, academic grade, health status, health interest, and economic status. Since men have higher health promoting behavior than women, it is necessary to encourage them to increase their interest in women. Age is under 29 years old and higher grades have lower health promoting behavior, so it is necessary to give more attention to them. The health condition and health-related group showed better health promoting behavior than the lower group A study in Baek et al.[16] found that groups with higher health conditions and higher health concerns performed better than those with lower health conditions, consistent with the results of a study in Kim, Kim and & Park[17] that showed that the better health conditions, the more health importance is perceived, it tends to do actions such as health promoting behaviors. Therefore, it would be desirable to increase interest in health for nursing college students to maintain good health.

There was a significant correlation between the health promoting behavior, self-efficacy, health perception, social support, and perceived disability of nursing college students, and the most descriptive factors affecting health promoting behavior were self-efficacy, accounting for 52% of the total. These results are higher than 23.5% for them[17], and 23.9% for Park & Kim.[15] Since self-efficacy is believed to be able to successfully perform the necessary actions to achieve the desired results, it is necessary to develop programs that enhance the ability to communicate with health-related beliefs to improve the self-efficacy of nursing college students. Health perception was recognized at a normal level and was a correlated with influenced by health promoting behavior. These results were similar to those of Hong[3] with an average of 3.42±.66 points. Nursing college students who are interested in health and maintain a steady state of health need to be encouraged to take good care of their health so that they can recognize their health as well as their patients in the future. Social support was also a main factor in health promoting behavior. The study by them[17] also showed high correlation with health promoting behavior, which is consistent with the results of this study. It is also advisable to establish a support group of family, peers and experts in relation to health in order to enhance the practice of health promoting behavior for nursing college students.

On the other hand, perceived disability has a negative relationship with health promoting behavior, so we should try to eliminate the uncomfortable environment that makes us avoid health promoting behaviors and create conditions for active health promotion.

Conclusions

The purpose of this study was to identify factors affecting health promoting behavior for nursing college students. Since the health promoting behavior of the subjects shows moderate values, the self-efficacy, health perception and social support should be considered and ongoing efforts and should be made to reduce health-related obstacles to better conduct health promoting behaviors. The higher the self-efficacy, health perception, and social support of nursing students, the lower the perception of disability show the higher health promoting behavior so it is necessary to be included in the study. Factors affecting the health promoting behavior of nursing students are health conditions, health concerns, self-efficacy, and social support, so that the health conditions are recognized well during everyday life, and programs should be prepared to increase self-efficiency for students. It is also necessary to develop a well-developed support system to recognize that it has social support.

Since the subjects who were participated in this study are the future nurses, it is desirable to prepare policies and systems so that students can increase their health-promoting behaviors and implement them in the middle of their daily lives. In addition, research is also needed on the remaining factors that affect the health promoting behavior of nursing students.

Factors Related to The Obstetric Complications in The Working Area of Halong Public Health Center Balangan District 2017

Mina Elfa[1], Triawanti[2], Syamsul Arifin[2], Roselina Panghiyangani[2], Lenie Marlinae[3]

[1]Master of Public Health Science Study Program, [2]Medical Education Study Program, [3]Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Banjarmasin, Indonesia

Abstract

Around 80% of maternal mortality are due to increased complications of obstetrics. High obstetric complications in Balangan District 18.1% where in Halong Public Health Center is 41.89%. The research aim to analyze the factors related to obstetric complications in the working area of the Halong Public Health Center 2017. Research method using analytic observational with case control study design. The population of this study was 327 postpartum mothers in the Halong Public Health Center Working Area. Proportional random sampling that has been determined based on inclusion criteria with a total sample of cases 74 and 74 controls. Calorie energy deficiency (CED) (p=0.80), anemia (p=0.038), weight gain (p=0.032), age (p=0.517), parity (p=1,000), pregnancy spacing (p=0.069), antenatal care (ANC) (p=0.014), height (p=0.743) for obstetric complications. Multivariate analysis using multiple logistic regression showed anemia variables (p=0.031; Exp.B=2.704), weight gain (p=0.033; Exp.B=2.112), and ANC (p=0.028; Exp. B=3.132) to obstetric complications. There was no relationship of CED, age, parity, space of pregnancy, and height with obstetric complications and there was an relationship of anemia, weight gain, and ANC with obstetric complications in the working area of Halong Public Health Center in Balangan 2017.

***Keywords**: anemia, weight gain, ANC, obstetric complications*

Introduction

The direct cause of MMR is related to complications during childbirth such as bleeding, hypertension, eclampsia, infection and prolonged parturition. Around 80% of maternal deaths are due to increased complications during pregnancy, childbirth and after childbirth.[1] The obstetric complications is present in about 20% of all pregnant women, but the cases of obstetric complications handled are still less than 10% of all pregnant women. As for the types of complications as a direct cause of maternal death are bleeding 42%, eclampsia 25%, infections 3%, old parturition 3% and other pregnancy complications 27%. Based on data from the South Kalimantan Health Office profile in 2017, it was found that MMR in South Kalimantan was 103 per 100,000 live births (75 people). The second highest MMR in Balangan District was 175.97 per 100,000 live births (5 people). The number of obstetric complications in South Kalimantan Province in 2017 was 20.45%. One of the high obstetric complications is Balangan District in 2017 as many as 537 people (18.1%).[2] Based on the monitoring report of the local area (PWS) maternal and child health program in Balangan District in 2017, the highest obstetric complications at the Halong Public Health Center were 137 people (41.89%). Most of these obstetric complications occur during pregnancy (40.41%) and childbirth (55.48). While obstetric complications that occur in childbirth as much as 4.1%.[3] One strategy to reduce maternal mortality is to prevent/reduce the possibility of pregnant women experiencing complications in pregnancy, childbirth and the puerperium. The complications of pregnancy and childbirth are direct factors causing maternal death. The

email: bintangara@ulm.ac.id

indirect factors that cause maternal death and also affect the incidence of complications of pregnancy and childbirth are health status, namely nutritional status, infectious diseases, chronic diseases, heart disease, kidney disease, history of complications. Reproduction status, namely gestational age, number of births, marital status. Access to services is affordability of location, type and quality of service, affordability of information. Healthy behaviors are contraception, pregnancy check-up, childbirth assistance, uterine abortion behavior.

Materials and Method

This research is a quantitative study, with an analytical observational research design through a case control study. The case control study was carried out by identifying the case group (obstetric complications) and the control group (postpartum mothers with no complications), then retrospectively (backward tracking) investigated risk factors that might explain whether the case and control were exposed or not. Population was postpartum mother in Halong Public Health Center amounting to 327. The sampling technique is proportional al random sampling, the minimum number of samples was 74 cases and 74 controls.

Findings and Discussion

Table 1. Frequency Distribution and Risk Factors of Obstetric Complications at the Working Area of Halong Public Health Center 2017

Relationship of CED and Obstetric Complications

The results of the Chi-Square test, obtained p=0.80 (p≥0.05), which means there was no relationship between CED and obstetric complications. It could be due to the fact that based on the data available the most respondents were not CED (87.8 %) which was not a risk factor for pregnant women. In addition, the Halong Public Health Center has carried out nutrition interventions on CED pregnant women by providing supplementary food to pregnant women. Actions given to pregnant women with CED in general are adding more food portions than before pregnancy, resting more, as well as more adequate antenatal checks to monitor adequate weight gain. The results of this study are in line with Aeni (2013) that there was no relationship of CED (LILA <23cm) with obstetric complications.[4]

Relationship between Anemia and Obstetric Complications

The results of the Chi-Square test, obtained p=0.038 (p<0.05), which means there was a relationship between anemia with obstetric complications. Results OR=2.6; 95% CI=1.126-6.356 which means that mothers who have anemia have a risk of developing obstetric complications 2.6 times greater than mothers who do not have anemia.

A standardized and regular pregnancy check-up will be able to monitor maternal weight gain during pregnancy and anemic mothers will receive treatment and counseling regarding anemia management. The results of this study are strengthened by Edyanti and Indawati (2014) which shows that there was an anemic relationship (p=0.0001) to obstetric complications.[5]

Relationship between Weight Gain and Obstetric Complications

The results of the Chi-Square test, obtained p=0.032 (p<0.05), which means that there was a relationship between risky weight gain and obstetric complications. Results OR=2.1; 95% CI= 1.11-4.16 which means that women who experience risky weight gain have a risk of experiencing obstetric complications 2.1 times greater than those of mothers who gain weight.

During pregnancy, mothers will gain weight around 10-12 kg, where in the first trimester it is less than 1 kg, trimester II around 3 kg, and trimester III around 6 kg. A habit that is commonly practiced in Indonesia but is not beneficial one of which is limiting eating and drinking to prevent large babies. The habit that occurs is also the head of the family who is prioritized first to fulfill the new nutrition of his wife and children. The results of this study are in line with research conducted by Khoiriah et al (2015) which states there is a significant relationship between maternal weight gain with obstetric complications and Shiddiq's research (2014).

Relationship between Age and Obstetric Complications

The results of the Chi-Square test, obtained p=0.517 (p≥ 0.05), which means that there was no relationship between the age of mothers with obstetric complications. Age <20 years or >35 years is actually a risk factor for obstetric complications. However, many respondents (age <20 years or> 35 years) in this study were located near the sub-district (Halong village, Tabuan village) making it easier for health workers to detect pregnant women at risk and monitor their pregnancies. Access to health services is largely determined by the distance of the house from the health facility. The availability of health workers, especially midwives in the villages, is also available in every village who is ready at any time to help pregnant, childbirth and postpartum mothers. The results of this study are in line with the results of the study of Diana, et al (2012) which showed no relationship between the age of pregnant women with the obstetric complications (p =0.290). In accordance with the results of the study Simarmata et al (2015) age was not associated with obstetric complications.[6]

Relationship between Parity and Obstetric Complications

The results of the Chi-Square test, obtained p=1.0 (p≥0.05), which means that there was no relationship between parity and obstetric complications. The proportion of the risky parity in the case and control groups was equal to 31.1%. It is in line with the study of Simarmata et al (2015), there was no relationship between maternal parity and obstetric complications (p=1.0). Likewise with the study of Astuti,et al (2017), there was no relationship between maternal parity and obstetric complications (p=0.427).[7]

Relationship between Antenatal Care and Obstetric Complications

The results of the Chi-Square test, obtained p=0.014 (p<0.05), which means that there was a relationship between incomplete antenatal care with obstetric complications. Results OR=3.6; 95% CI=1.355-9.797 which means that a mother who is pregnant with an incomplete antenatal care has a risk of obstetric complications 3.6 times greater than a mother who has a complete pregnancy check-up.

Antenatal care should start as early as possible, namely immediately after no longer menstruating. The goal is to keep pregnant women through pregnancy, childbirth and childbirth well and safely. The standard time for antenatal care is recommended to guarantee protection to pregnant women, in the form of early detection of risk factors, prevention and management of complications. The existence of antenatal checkups that is in accordance with the standards and is continually accompanied by good records can reduce the risk factors causing obstetric complications.

Research Sulistiyowati et al (2017) found that the causes of obstetric complications in the mother, in the form of poor antenatal care pose a risk of obstetric complications. Research Nurrizka et al (2018) found that the main problem of obstetric complications was the problem of poor maternal health access in most districts/cities in Eastern Indonesia. One of them is antenatal coverage, especially the fourth pregnancy visit (K4) which is low, the OR value of the variable coverage

of the fourth pregnancy visit (K4) is 1.682.[8,9]

Relationship between Height and Obstetric Complications

The results of the Chi-Square test, obtained p=0.743 (p≥0.05), which means that there was no relationship between the height and obstetric complications. This study is in accordance with the research of Huda (2006) which showed no relationship between maternal height <145 cm with obstetric complications.[10]

Multivariate Analysis

Table 3. Final Models of Multivariate Logistic Regression

Risk Factors	B	Exp (B)	95% CI	Sig.
Antenatal Care	1.142	3.312	1.128-8.692	0.028
Anemia	0.995	2.704	1.094-6.685	0.031
Weight gain	0.748	2.112	1.062-4.200	0.033

The results showed that the risk factors for antenatal care were the most related variables for obstetric complications (p=0.028) compared to anemia and weight gain. Respondents with incomplete antenatal care, 3,312 times will have a risk of obstetric complications compared with respondents who have complete antenatal examinations. This is because the antenatal care greatly affect the maternal pregnancy, fetal development and emergencies that may occur. Pregnant women who have their pregnancies checked according to standards to ensure that they can get through the period of pregnancy, childbirth and childbirth properly so that the mother and baby are safe. Routine antenatal check-up according to the schedule that has been determined at least 4 times during pregnancy in accordance with the standards set by the Republic of Indonesia Ministry of Health, mothers can know the progress of their pregnancy conditions and can detect early complications that can occur during pregnancy.[11] Mothers who check their pregnancy routinely will have the opportunity to carry out examinations including laboratory services (Hb examination). Anemia of pregnant women can also be known and treated if it occurs. Every time a pregnant woman checks her pregnancy, weight will be weighed. Weight gain will be monitored so that the mother will know the increase in body weight during pregnancy and know the benefits of weight gain during pregnancy and the risks that occur if an unsafe weight gain occurs.

Conclusion

There was no relationship of CED, age, parity, space of pregnancy, and height with obstetric complications. There was an relationship of anemia, weight gain, and ANC with obstetric complications. The antenatal care is the most related factor in the obstetric complications in the working area of Halong Public Health Center in Balangan 2017.

Ethical Clearance: Before conducting the data retrieval, the researchers conducted a decent test of ethics conducted at the Faculty of Medicine, Lambung Mangkurat University to determine that this study has met the feasibility. Information on an ethical test that the study is eligible to continue. The feasibility of the research was conducted to protect the human rights and security of research subjects.

Source Funding: This study was done by self-funding from the authors.

Conflict of Interest: The authors declare that they have no conflict interests.

Abstract

Bacground and purpose : Non-verbal intelligence is one of the cognitive skills that plays a key role in academic performance in children and adolescents. Hence, this study intends to evaluate non-verbal intelligence in a sample of Moroccan adolescents to situate them in relation to their counterparts in other countries.

Materials and Method : To assess non verbal intelligence, we used Raven's Progressive Matrix Test, which consists of 60 items, categorized into five series of 12 items.

Results : There were 286 adolescents, 46.8 % of whom were women, with an average age of 15.2±1.7 years. Cronbach's alpha value is 0.94, the correlations between the different series of the test are highly significant, reflecting the high internal reliability of the test. The scores of the adolescents are low compared to the international standard and more than 4% of the participants are in an intellectually impaired state.

Conclusion : We consider it important to have a national standardization of the test and to establish a precise diagnosis in order to identify adolescents with an intellectual disability.

Key words : *Cognitive assessment, non-verbal intelligence, Raven's Standard Progressive, Matrices, adolescents, Morocco.*

Introduction

The diversity of models and theoretical approaches developed illustrates the difficulty encountered in defining the notion of intelligence. However, the Cattell-Horn-Carroll model remains the most validated psychometric model of cognitive skills [1]. This model includes several cognitive capacities at its base, at its summit we find the general intelligence factor or g factor[2]. Factor (g) refers to general intellectual ability, based on Spearman's theory [3]. Raven's Progressive Matrices (SPM) are generally considered to be good non-verbal indicators of general intelligence or factor (g) [4]. This makes it one of the best psychometric tests measuring the (g) factor [5].The paradigm of the (SPM) test is intended to measure the ability to extract and process information from a new situation [6]. The (SPM) test is the most widely used test for screening in many countries around the world [7]. It has been widely used in clinical, professional, educational, and research settings [8]. Court and Raven (2004) note that learners' ability to solve Raven's matrices may act as a predictor of academic success[9]. This test has become widely used and is used in many countries on five continents. Furthermore, to our knowledge in Morocco, studies that have been conducted on (SPM) are rare and have been limited to middle school learners [3,10, 8]. The objective of our study is to evaluate non-verbal intelligence in a sample of Moroccan adolescents to situate them in relation to their counterparts in other countries.

Materials and Method

Participants

There are 286 adolescent learners, 53.2% of whom are boys (n=152) and 46.8% girls (n=134). The average

age is 15.2±1.7 years, with a maximum of 18 and a minimum of 13 years. Learners are distributed over two cycles of education, with 51.20% in middle school and 48.8% in high school. People with obvious disabilities or a diagnosis established by doctors or who are undergoing treatment with psychostimulant drugs were all excluded from this study.

Measuring instrument

Raven's progressive matrices appear to be one of the best measures of the g-factor. The g-factor refers to general intellectual ability, according to Spearman's theory [3]. It is highly recommended because it minimizes cultural and linguistic barriers in the evaluation of intellectual functioning. This test measures non-verbal reasoning ability, by analogy. The version used consists of 60 items, divided into five series or sub-tests of 12 items. In order to succeed, the subject must find the rule of progression. Each item constitutes a pattern with a missing part, 6 to 8 images are proposed below which the subject must choose the missing part adequately (figure 1).

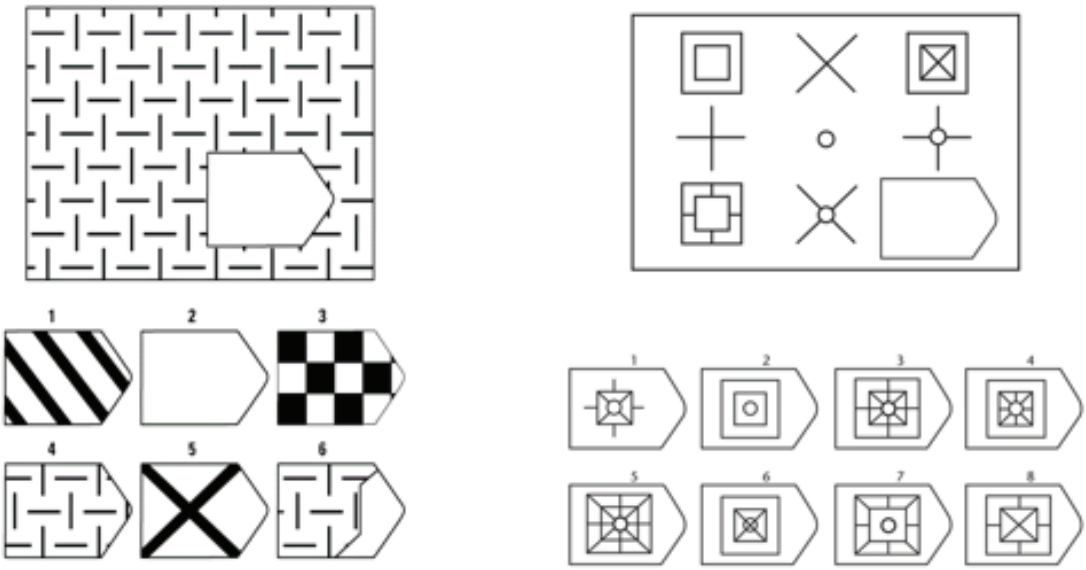

Figure 1 : Examples of items used in Raven's progressive matrices (PM 38)

Procedure

We proceeded to fill out an information sheet for each learner. The test was done in groups after having carried out two pre-tests, it was done in two phases :

- The first phase concerned series A, B, C.

- The second phase concerned series D, E.

Statistical methodology

The collected data are first entered on an Excel sheet, after filtering the matrix is transferred to an SPSS statistical processing software. The statistical analyses used are descriptive and analytical, a significance level of 5% was used for this study. To determine the internal reliability of the measuring instrument we have calculated the Cronbach index, this value is considered "acceptable" from 0.7[11].

Results

A. Psychometric properties

• The determination of the internal reliability of the test (SPM) and the five test series is performed by calculating the Cronbach alpha value (Table 1)

Table 1 : Cronbach's Alpha Coefficient for Subtests and for the Total Score

Sub-test	Number of items	Cronbach's Alpha
Serie A	12	0.75
Serie B	12	0.80
Serie C	12	0.82
Serie D	12	0.85
Serie E	12	0.83
Total Score	60	0.943

The determination of the value of the Cronbach's alpha coefficient shows that the different subtests or series have values respectively of 0.75 for series A, 0.80 for series B, 0.82 for series C, 0.85 for series D, 0.83 for series E and a value of 0.94 for the total test score.

- The Pearson test is used to examine the correlation between the scores of the five series A, B, C, D and E of (SPM) (Table 2).

Table 2 : Pearson correlation between the scores of the five series A, B, C, D and E of (SPM) (N= 286)

		Serie A Score	Serie B Score	Serie C Score	Serie D Score	Serie E Score	Total Score
Serie A Score	Correlation r	1					
	P-value						
Serie B Score	Correlation r	.58**	1				
	P-value	.000					
Serie C Score	Correlation r	.58**	.72**	1			
	P-value	.000	.000				
Serie D Score	Correlation r	.59**	.70**	.80**	1		
	P-value	.000	.000	.000			
Serie E Score	Correlation r	.45**	.52**	.68**	.67**	1	
	P-value	.000	.000	.000	.000		
Total Score	Correlation r	.71**	.82**	.90**	.90**	.80**	1
	P-value	.000	.000	.000	.000	.000	

****. The correlation is highly significant at the 0.01 level.**

According to Perason's correlation, a highly significant positive correlation between the scores of the different subtests and with the total score is noted, with respectively: [(r=.58; p<0,000 between the scores of series A and B), (r=.58. ; p<0,000 between the scores of series A and C), (r=.59. ; p<0,000 between the scores of series A and D), (r=.71 ; p<0,000 between the scores of series A and E) , (r=.71 ; p<0,000 between the scores of series A and the total score)]. [(r=.72; p<0,000 between Series B and Series C scores), (r=.70; p<0,000 between Series B and Series D scores), (r=.52; p<0,000 between Series B and Series E scores), (r=.82; p<0,000 between Series B scores and total SPM score)]. [(r=.80; p<0,000 between Series C and Series D scores), (r=.68; p<0,000 between Series C and Series E scores), (r=.90; p<0,000 between Series C scores and total score)]. [(r=.67; p<0,000 between Series D and Series E scores), (r=.90; p<0,000 between Series D scores and total score)]. [(r=.80; p<0,000 between Series E scores and total score)].

B. Learner Performance in the SPM Test

Learners' performance in SPM is assessed by determining the average scores totalled by the learners and the average of the errors made in the test series (table 3).

Table 3 : Average scores totalled by learners and average errors in the test series with correlations between scores and errors (n=286)

		Minimum	Maximum	Mean	Standard Deviation	Pearson Correlation	P-value
Serie A	Score	2.0	12.0	10.45	1.85	-0.99**	,000
	Erreurs	.0	10.0	1.55	1.85		
Serie B	Score	.0	12.0	9.55	2.83	-0.98**	,000
	Errors	.0	12.0	2.41	2.79		
Serie C	Score	.0	12.0	7.96	2.88	-1**	,000
	Errors	.0	12.0	4.03	2.87		
Serie D	Score	.0	12.0	7.77	2.98	-1**	,000
	Errors	.0	12.0	4.22	2.98		
Serie E	Score	.0	12.0	4.20	3.15	-0.96**	,000
	Errors	.0	12.0	7.74	3.17		
Total	Score	7.0	59.0	39.82	11.59	-0.98**	,000
	Errors	1	53	19.97	11.52		

****. The correlation is highly significant at the 0.01 level.**

The analysis of the results of the mean scores and the means of the errors committed in the test series shows that for series A, the learners totalled a mean of 10.45 items and a mean of the errors of 1.55. For Series B, adolescents in our population recorded an average score of 9.55 and an average of 2.41 for errors made. In series C, the average score is 7.96 and an average error of 4.03. For Series D, learners had a mean score of 7.77 and a mean error score of 4.22. In Series E, the mean score for correct items was 4.20 and the mean error score was 7.74. For the average total score, learners recorded an average score of 39.82 and an average error of 19.97. According to the bi-variate analyses, we found a highly significant negative correlation between scores and

errors committed by adolescents in SPM.

C. The profile of non-verbal intelligence of adolescents in the population

- Distribution of learners' scores in SPM by age in percentiles (Table 4).

Table 4 : Percentile distribution of test scores (PMS) by age.

	Age (years)					
Percentiles	13	14	15	16	17	18
5	12,200	11,300	10,650	15,600	19,500	32,750
10	19,600	13,000	13,300	26,200	34,200	36,500
25	34,000	27,000	27,250	32,500	42,000	45,000
50	40,000	36,000	36,500	46,000	49,000	48,000
75	44,000	43,000	42,500	50,000	52,000	51,750
90	49,000	49,800	50,400	53,000	54,800	55,000
95	51,000	55,100	51,700	54,000	55,900	57,750
Mean	37.701	34.778	34.615	41.514	45.976	47,250
Standard Deviation	10.0830	12.3966	12.1964	11.0821	8.9763	7,8685

Calibration of Raven's progressive matrices by age showed that the 50th percentile had a score of 40 points at age 13 ; 36 points at age 14 ; 36.5 points at age 15 ; 46 points at age 16 ; 49 points at age 17 and 48 points at age 18.

- The authors propose a categorization of subjects into five classes, from group I "higher intellectual abilities" to group V "intellectual disability". The status of the results obtained allowed us to classify the subjects into 5 intellectual classes (Figure 2).

According to the categorization of adolescents in our population according to intellectual abilities, we find that : 4% of adolescents in our population correspond to an intellectually defective state.

Discussion

The present study, which aimed to assess non-verbal intelligence among adolescents in the Moroccan Middle Atlas, was able to highlight the following points:

The calculation of Cronbach's alpha coefficient for the total test score is 0.94. The correlations between the scores of the different series of the test l are positive and highly significant. Therefore (SPM) has a very high degree of reliability, which supports the results obtained at the national and international level [8].

Analysis of the results shows that the participants recorded an average score of 39.82±11.59 and an average error of 19±11.52, and a negative correlation is noted between the scores of the totaled items and the errors made. The same result is observed among Argentine an adolescents[12].

The average score of our population is higher than the score totalled by learners from Moroccan populations in other studies [3- 8-10].

Calibration of Raven's progressive matrices in our age-dependent study showed that adolescent performance increases with age from 14 to 17 years of age with the exception of 13 and 18 years of age. These results are consistent with several studies conducted in

Morocco [3-10- 8] and international studies from Icelandic, Slovenian [8] and Kuwaiti [13]. The increase in non-verbal intelligence with age is explained by the fact that intellectual maturation continues in parallel with physical maturation [8]. In other studies, a steady increase in the overall volume of white matter until the age of 21 has been observed [14]. The functional consequences of this increase are rapid and effective communication within the fronto-cortical circuit and other cortical and sub-cortical regions [15]. Other studies have shown continued growth of the corpus callosum during childhood and adolescence [14-15-16].

In order to situate the results of adolescents in our population at the international level, we're going to rank them against international standards. Compared to several international studies, the scores obtained by respondents are considerably lower than those of the British [13], American [10], Chilean [10], Indian - Pune and Mumbai population[8], Icelandic [8], Slovenian [10] and Kuwaiti [13] international standardization standards. As we can add that 4% of the adolescents of our population corresponds to an intellectually defective state. These revealed differences in mean test scores may be related to several factors, including the Flynn effect[17]. The low performance recorded in the test could also be explained by the high level of illiteracy among parents [18] and also by malnutrition [19]. Other work links cognitive functions to non-verbal intelligence to explain intra-individual variability, such as updating skills [20], processing speed [21] and working memory [1]. Recent studies have demonstrated links between cognitive strategies and performance on fluid intelligence tasks [22].

Conclusion

The study realized has reconfirmed the very high degree of test reliability (SPM). The scores totaled by the adolescents in (SPM) show that they present a superior non-verbal intelligence compared by studies carried in Morocco, however in comparison with the international standardization norms these scores are considerably lower, all the more so as 4% of the adolescents of our population corresponds to an intellectually defective state. These low performances in non-verbal intelligence could be explained by several factors including the Flynn effect, the socio-economic environment of learners, the development of cognitive functions and the reasoning strategies used by adolescents. In addition, we must underline the importance of having national standardization of (SPM) and the importance of to realize an accurate diagnosis to identify adolescents who may show signs of intellectual deficits.

Significance Statement:

This study assessed nonverbal intelligence in a population of adolescent adolescents, as well as, this study will help researchers discover areas of neuroscience that many researchers have not been able to explore.

Conflict of Interest: The Authors declare that there are no conflicts of interest.

Ethical approval: The procedures were carried out in accordance with the recommendations of the internal ethics committee of the Ibn Tofail University of Kenitra. This procedure has been reviewed and approved by the Committee.

Source of Funding: This work is not financial

The Influence of Parents and Other Factors on Adolescents' Fish Consumption in Selected Senior High School Students, Jakarta

Nabilah Shofa Fauziyah[1], Triyanti[1]

[1]Department of Nutrition, Faculty of Public Health, Universitas Indonesia

Abstract

Fish is an important source of animal food for adolescents because it contains various nutrients. Indonesia has high fish availability, but the level of domestic fish consumption in adolescents is still low. Lower fish consumption during adolescence will affect health status in the future. It is thus important to understand the various factors that influence fish consumption in adolescents. This study aimed to obtain information on fish consumption frequency; to investigate the associations between individual, socio-physical and environmental factors of adolescents and their fish consumption; and to examine the influence of parental eating behavior and support on adolescents' fish consumption. Samples were chosen from adolescents aged 15-17 years. This study used a cross-sectional design. Data collection was obtained through filling out questionnaires, anthropometric data, and completing a semi-quantitative food frequency questionnaire (SFFQ). Bivariate analysis was conducted using the chi-square test and multivariate analysis was conducted using multiple logistic regression. The average fish consumption was found to be 34.1 grams/day. Fish consumption was significantly associated with attitude, preference, parental influence, and availability of fish at home ($p<0.05$). Further analysis showed that parental influence was the dominant factor related to fish consumption in students. This means that various parties, especially parents, can take a role in increasing fish consumption in students.

Keywords: *fish consumption; senior high school student; parent influence.*

Introduction

Fish is one of the most important animal food sources in a healthy diet because it is rich in protein, unsaturated fatty acids, various vitamins, selenium, and iodine[(1)]. Fish is also a major food source of long-chain omega-3 polyunsaturated fatty acids, including docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), which are well-known for their anti-inflammatory effects and protective role against non-communicable diseases, such as heart disease coronary, hypertension, stroke and Alzheimer's disease[(1,2)]. Bonaccio et al. showed that fish consumption 4 times per week was associated with a 40% reduction in the risk of coronary heart disease and stroke[(3)]. Fish consumption also has a good impact on cognitive development in adolescents. Handeland et al. in Norway stated that consumption of fish, especially fatty fish, can improve cognitive performance in adolescents, increasing their vocabulary skills and concentration on learning[(4)]. Morris et al. also showed that fish consumption ≥4 times per week was associated with lower memory loss rates[(5)].

Although the benefits of fish consumption are numerous, there are still many adolescents who do not consume enough fish. The results of the National Diet and Nutrition Survey Rolling Program (NDNS) in Europe in 2008-2012 showed that only 5.3% of adolescents aged 12-18 years consumed fish in accordance with the recommendations[(6)]. St-Jules, Watters, and Novotny also showed that the average fish consumption in adolescent girls in Asia was only 24 g/day[(7)]. Fish consumption in Indonesia, especially in adolescents, is also still far below the national consumption target. The results of the Indonesian Individual Food Consumption Survey in 2014

Corresponding author:
Nabilah Shofa Fauziyah
nabilahsf2894@gmail.com, *triyantigizi@gmail.com*

showed that adolescents (13-18 years) who consumed fish in Indonesia had an average consumption of 58.3 g/day[8]. Adolescents (13-18 years) who consumed fish in Jakarta had an average consumption of 26.9 g/day[9].

Low fish consumption in adolescents can be caused by several factors, such as individual factors (nutritional status, knowledge, attitude, and preference), social environmental factors (parents' education, parents' influence, peer influence, and mass media influence), and physical environmental factors (availability of fish at home)[1,10,11] . Individuals also may be averse to consuming fish because of a perceived difficulty in buying, preparing and cooking fish, the belief that it is expensive, or the unpleasant physical properties of some varieties of fish, such as bones, taste, smell, and texture[10,12].

This research was conducted with adolescents, especially high school students, because in this period the consumption of nutrients is one of the critical things that must be achieved well to be able to improve the quality of individual health in the future. The researcher chose East Jakarta as the research location because the prevalence of non-communicable diseases in Jakarta is still high, while the average fish consumption in adolescents in Jakarta is still very low and the research on fish consumption on adolescents in East Jakarta remains limited.

Method

Design

This research was conducted using a cross-sectional design. Independent variables in this study were individual factors (gender, nutritional status, pocket money, knowledge, attitude, and preference), social environmental factors (parents' education, parental influence, peer influence, and mass media influence), and a physical environmental factor (availability of fish at home), while the dependent variable used was fish consumption.

Sample

The study was conducted in April 2019 at SMAN 39 Jakarta. The sample used in this study comprised students of classes X and XI. Inclusion criteria in this study were all students from five classes with active status in 2019. Exclusion criteria from this study were unwell students or those who had certain physical disabilities. Then, 150 students from five classes were selected by the school and all of them were taken as research samples.

Data Collection

Primary data collection was carried out through asking students to fill out questionnaires, SFFQ and measuring nutritional status based on anthropometric data. The time needed to complete the questionnaire and anthropometric data was 30 minutes. Data collection was carried out by the researchers and four enumerators who were students at the Nutrition Department in the Faculty of Public Health, Universitas Indonesia. Parental influence, peer influence and availability of fish at home were assessed using a four-point Likert scale, with responses ranging from 'strongly disagree' (1) to 'strongly agree' (4). Knowledge was obtained from the answers students scored by adding up all the questions that were answered correctly. Preferences were categorized as positive and negative. Anthropometric data was measured using weight scales and a microtoise and was calculated with BMI according to age based on classification by the Indonesian Ministry of Health (2010) to determine the classification of nutritional status.

A semi-quantitative FFQ was developed to assess dietary intake among senior high school students in Jakarta. The SFFQ included three sections: the food list, the portion size and the frequency response. The final SFFQ list included a total of 21 types of fish. The reference portion for each fish item was represented by how many pieces of fish and what parts were eaten (tail/body/head), or how many pieces of whole fish were eaten, and fish size (large/medium/small). The results were converted into grams. In order to assist in quantifying the reference portion size, the standard two-dimensional fish portion visual chart by the Indonesian Ministry of Health was also used. The frequency of adolescents' fish intake was indicated by how many times per day/week/month the adolescents consumed fish. For all fish items in the SFFQ, the frequency per day was multiplied by the portion size of the fish item in order to calculate the total amount of fish consumed in grams per day.

Data Analysis

Univariate analysis was conducted to provide an overview of the data. Bivariate analysis used chi-square to determine whether there is a relationship between the dependent variable and the independent variable. Results are reported in terms of odds ratios (ORs), 95%

confidence intervals (CIs) with the respective p-values with a significance level set to $p < 0.05$. Multivariate analysis used multiple logistic regression to determine the independent variables that have a dominant relationship to the dependent variable.

Findings

The average fish consumption among students is 34.1 grams/day. The results show that 57.3% of students are still low in fish consumption. All main results are displayed in Table 1.

The results of this study show that fish consumption is significantly related to attitude, preference, parent influence, and availability of fish at home. Thorsdottir et al.[13] and Tomić et al.[1] state that attitude has a significant relationship with fish consumption. Can et al.[10], Thong & Olsen[14] and Jimoh et al.[15] also state that preference has a significant relationship with fish consumption. Lai et al.[16] demonstrate that fish consumption in adolescents has a significant relationship with parental influence at home. Tamale et al. also show that the availability of fish at home is significantly associated with fish consumption in children[17].

It was also found that most students did not like consuming fish because of bones (50%), unpleasant taste (18%) and unpleasant smell (18%). It was also found that catfish, carp, tuna fish and salmon are the most liked fish among students. The most preferred processing of fish by most students (57,3%) is frying, followed by roasting (30%).

Next, a multivariate analysis was carried out to obtain the dominant factor in adolescents' fish consumption. Following the final model of the multivariate stage, the independent variables that are most strongly related to the dependent variable are seen from the magnitude of the OR value. The greater the OR, the greater the effect.

Table 2. The Dominant Factors in Adolescents' Fish Consumption

Variable	p-value	OR (95% CI)
Nutritional status	0,280	0,647
Attitude	0,339	1,505
Preference	0,198	2,107
Parent Influence	0,001	3,407
Availability of Fish at Home	0,045	2,130

Table 2 is the result of the analysis of the final multivariate model, which shows that the most dominant variable is parental influence, with an OR value of 3.407. This means that students who have less parental influence will have 3.407 times the risk of having less fish consumption compared to students who have good parental influence.

Discussion

The results of this study showed that parents have the most important role in adolescents' fish consumption. Parents have an important role as role models in helping adolescents to adopt and learn to maintain a healthy lifestyle. This means that parental influence is an important factor in regulating nutrient intake in adolescents. Selection of the consumption of unhealthy foods in adolescents has been shown to be related to lack of supervision from parents[18].

Parents tend to pay attention to their children's health and nutritional status, which influences a stronger desire for parents to provide fish at home as family food[19]. Parents who want to maintain the health and nutritional status of their children also tend to follow the recommended food consumption patterns, including those recommended for weekly fish consumption[20]. The influence of parental consumption on children's consumption can occur directly through the transmission of attitudes towards food. Parents' attitudes towards food consumption can influence certain behaviors, such as cooking seafood as a family dinner if parents have a good attitude towards fish consumption. This will certainly affect fish consumption in adolescents[1,14] .

Other factors that are also related to fish consumption in adolescents are attitudes, preferences, and the availability of fish at home. Adolescents who have a positive attitude towards healthy eating tend to consume fish more than other meat because it is high in protein and unsaturated fatty acids, as they believe that it brings many health benefits[21,22]. Preference is also an important factor related to fish consumption. Can et al.[10] and Thong and Olsen[14] stated that preferences are influenced by sensory factors (bones, taste, color, smell and texture) and non-sensory factors (habits, beliefs, individual characteristics and perceptions of risk). The availability of fresh fish that has been cooked for the family table is also important because family members will usually tend to eat food according to what is available at the dining table[1]. Tamale et al. also showed that children usually tend to consume food that is available at home[17].

Conclusion

This study shows that the average fish consumption among students is 34.1 grams/day with the majority of students still categorized as low in fish consumption. Attitude, preference, parental influence and availability of fish at home are significantly related to fish consumption. These factors can be influenced through cooperation between the ministries of maritime and fisheries, government health agencies and schools through the Gerakan Memasyarakatkan Makan Ikan (GEMARIKAN) program. Parents are also important, as they can serve as role models and support their children regarding fish consumption. Parents are also expected to be able to provide fish as an animal dish at home at least twice per week with enough portions to be consumed by all family members.

Under Five Child Mortality & Its Risk Factors in Bangladesh and other South Asian Countries: A Literature Review

Nahian Rahman[1], Md. Ruhul Kabir[1], Oumma Halima[1], Mohammad Rahanur Alam[1], Md. Abdullah Al Mamun[1], Homayra Islam[2]

[1]Department of Food Technology & Nutrition Science, Noakhali Science & Technology University, Bangladesh, [2]Deputy Commissioner Office, Noakhali, People's Republic of Bangladesh

Abstract

Under five child mortality is one of the serious public health issues in all over the world especially in South Asian region. Significant achievements have been made in last ten decades to reduce child mortality globally, but South Asian region still has one of the highest child mortalities in the world (51 deaths per 1000 live births). Out of ten child deaths, three occur in South Asian region. Various risk factors influence this high mortality rate, however, some of the risk factors show similarities and other varies time to time across countries in the South Asian region. Parents literacy, occupation, household wealth, health care accessibility and utilization, poverty and inadequate food intake, poor access to information, mother's age and several socio-cultural factors contributes mostly to the high number of mortalities in young children. However, it is imperative to study the country specific reasons and useful comparison of contexts might be useful to address the immediate, underlying and basic causes of child malnutrition. There, this paper aimed to study the difference in under five child mortality in different South Asian countries and determine whether the associated risk factors are similar or different across those eight countries. For increasing the under-five child survival and achieving the Sustainable Development Goals, South Asian regional countries needs to give serious efforts on maternal and child health sector as it affects national development. Country specific strategies and interventions should be based on most prevalent risk factors.

Key words: *Under-5 mortality, Infant mortality, Determinants of mortality, South Asian countries, Risk factors.*

Introduction

Under five child mortality is a very important public health indicator for estimating a country's progress and overall wellbeing of a nation [(1)]. United Nations International Children's Emergency Fund (UNICEF) describes under-5 mortality as "the probability of dying between birth and exactly five years of age". Early childhood is an important period for determining their future health status. Infant mortality is one of the contributing indicators that can be used to assess the physical quality of life index (PQLI) and wellbeing of a nation [(2)]. According to World Health Organization (WHO), notable global improvement has been done in decreasing child deaths, from 12.7 million in 1990 to 5.9 million in 2015.Since 1990, worldwide under five mortality rates decreased 53%, from 91 deaths per 1000 live births in 1990 to 43 in 2015. Globally, approximate 4.6 million deaths appear annually and 99% of which is occur in developing countries at infancy [(3)].

South Asia contributes a major portion in neonatal mortality in the world. Time period between 1990-2009, countries having more than 50% of neonatal deaths were: India 27.8% (19.6% of global live births), Pakistan 6.9% (4.0%), Nigeria 7.2% (4.5%), China 6.4% (13.4%), and Democratic Republic of the Congo 4.6% (2.1%) [(4)].

The main aim of this paper is to assess the trends, socioeconomic and demographic risk factors associated with under-5 mortality in South Asian region (Bangladesh, India, Maldives, Nepal and Pakistan).

Child Mortality, Infant Mortality, Neonatal Mortality and risk group

Child mortality or under-5 mortality refers to "death of children under the age of 5 years" (UNICEF). During the last two decades, remarkable improvement has been

done in declining under five child mortality. Globally, under five child mortality rate "dropped 53% (from 91 deaths per 1000 live births in 1990 to 43 deaths in 2015)" [5]. In South Asia 1 child from 19 children dies before their reaching 5th birthday. In 2015, 6 million child deaths occurred from which 30% take place in South Asian nations. Three deaths occur out of every 10 children globally happen in South Asia. According to Centre for disease and control (CDC), infant mortality is defined as "child dies before reaching his/her first birthday". The Infant Mortality Rate (IMR) is referred to the rate of children death before one year of age per 1000 live births. In 2015, infant mortality accounted about 4.5 million. therefore, the infant mortality rate reduced globally from "63 deaths per 1000 live births in 1990 to 32 deaths per 1000 live births in 2015" [6].

Methodology

The study accesses the determinants and consequences of under-five mortality after a live birth, using the definition of child mortality: death occurring death of children before five year of age. For the purpose of the study, 1990-2016 was chosen as comparative time periods.

Data Source

For reviewing, searches are done for getting journal articles into Pub Med/Medline, Google scholar, Data base of open Access journal, Research gate and Science direct. The name of eight South Asian countries was added to these terms for getting information of respective countries. Estimates for under five child mortality rates were collected from the UNICEF Report of levels and trends in child mortality 2015. For certain countries within South Asian region, BHDS data for Bangladesh, NDHS for Nepal and PDHS for Pakistan.

Search strategy and identification of studies

The search for under five child mortality in South Asian region and combining used key words were: under five child mortality, child morbidity, neonatal mortality, infant mortality, risk factors of child mortality and cause specific child mortality. For countries with very few studies reporting under five mortality rate such as Maldives, Bhutan consider little source. In this paper, try to estimate the difference in under five child mortality in Bangladesh & South Asian countries and determine whether the associated risk factors are similar or different across the South Asian countries.

Child mortality trends in Bangladesh

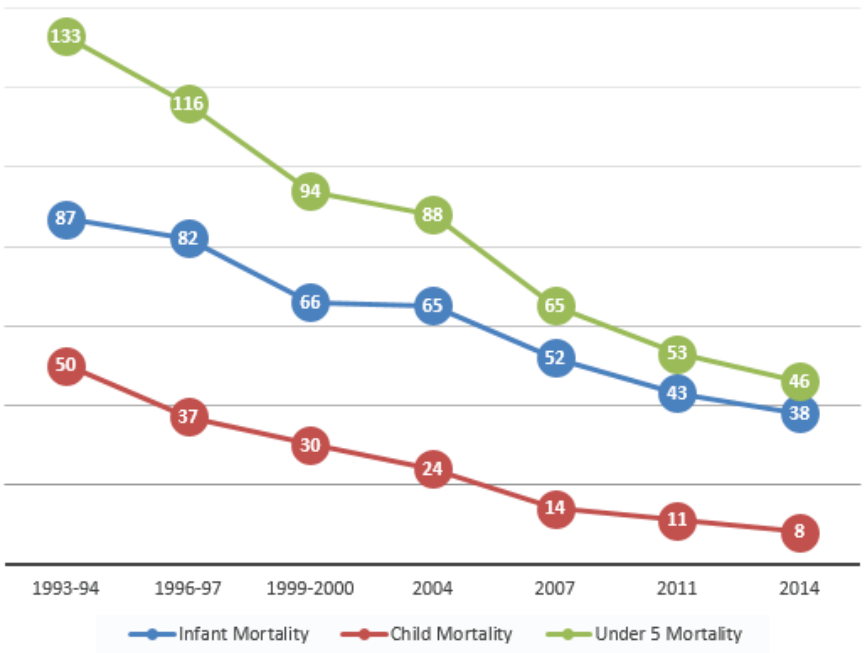

Figure 1: child mortality trends in Bangladesh

Time period of 1993-2014 where the infant mortality rate was 87 deaths per 1000 live births in 1993-94 and reducing by 66 in 1999-2000, 52 in 2007, 43 in 2011 and 38 in 2014. Child mortality rates also reducing trends from 1993-2014; 50 deaths were in 1993-94, 30 in 1999-2000, 14 in 2007, 11 in 2011 and 8 in 2014 per 1000 live births. In contrast to, Under-5 mortality rates, were 133deaths per 1000 live births in 1993-94 and reached at 94 in 1999-2000, 65 in 2007, 53 in 2011 and even 46 in 2014 [6].

Risk factors of under-five mortality in Bangladesh

Maternal age, Poor gestational weight gain, Maternal malnutrition, Marriage age, Poor education level, Wealth index, Insufficient food intake, lack of health facility are key contributors for child mortality in Bangladesh [6, 7].

Age of mother

Mother age is one of the vital factors for gestational risk and child mortality. Adolescent and older age (>45) pregnancy are dangerous for both the child and mother. Giving of births in adolescent period have reduced globally since 1990 but remain young age (11-19) fertility contributes 11% of the births and 95% of these births occur in low and middle-income countries [8].

Women's employment

Most important issue for mother is providing the quality of care by mother to her child. For employed mother has tough responsibility especially for take care of the health outcomes of under-five age children. In India, mortality rate for children under age of five is higher for the working mother. Mothers working for long hours influence the children's nutritional status and management of adequate care [9].

Parental Education

Parental education plays vital role to develop the health status of children. Maternal education contributes to fertility and economic wellbeing. Beside the formal education level, improving reading skills are also very much useful for mother and child survival [10].

Sex of child

Child mortality differing by sex is a vital concerning issue to consider. Under five mortality differing with sex vary from country to country. In developing countries, such as India and China, boys have lower under five mortality rates in comparison to girls [11].

Unintended Pregnancy

Unintended pregnancy influences the mother health status. Mother with unintended pregnancies has less intake of folic acid from the dose of recommended, prenatal/post-partum smoking and depression. Children born by unintended pregnancies are at greater risk of receiving poor antenatal care in developing nations [12].

Contraceptive use

Unintended pregnancy is prevented by using contraceptives which contribute to reduce maternal and child mortality. According to demographic and Health Survey in Bangladesh, use of contraceptives contribute to reduce infant mortality of birth order 2 and higher by 7.9%. In Bangladesh, complete use of contraceptive methods contributes to decrease the child mortality with a birth order of two or higher. Similarly, in Afghanistan higher contraceptive methods are used which is one of the key factors for reduction in child mortality [13].

Smoking

Smoking tobacco cigarette is very familiar sight though non-smoking tobacco products are highly used in developing countries. Passive smoking also caused affects to non-smokers indirectly and about 28% of child death occur globally [14].

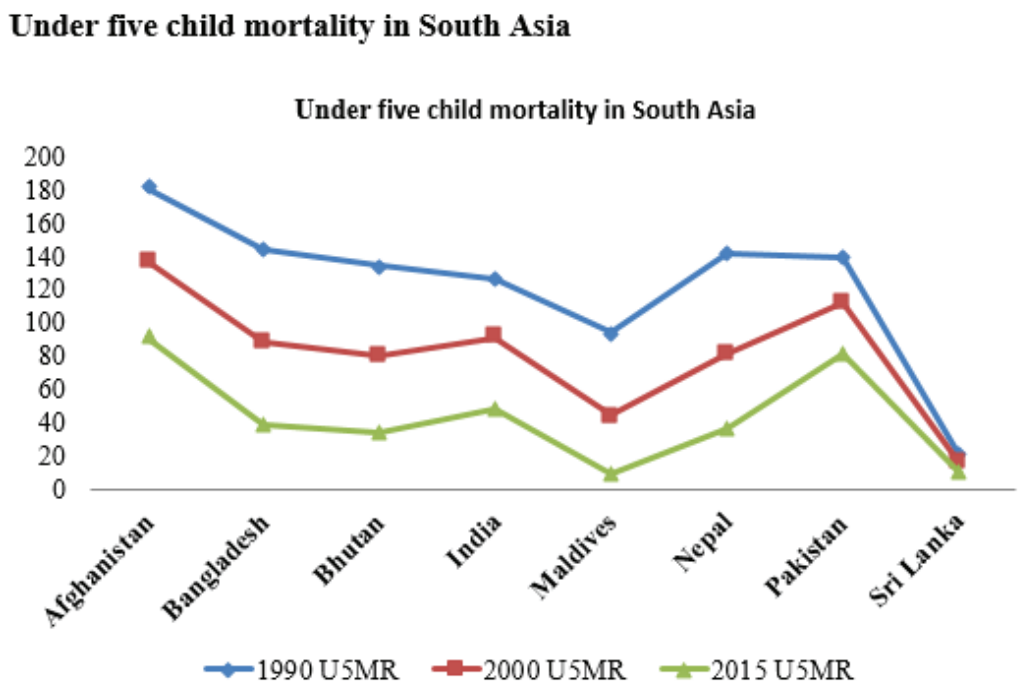

Figure 2: Levels and trends in under five child mortality among South Asian countries, 1990-2015. (Data source: The United Nations Children's Fund, September 2015).

Plotting under five mortality rates against time period of 1990, 2000, 2015 for South Asian countries. Figure 2 presents the under-five mortality distribution per 1000 live births from 1990-2015 where the observation pointed that highest mortality rate was 180 deaths per 1000 live births in Afghanistan at 1990 and decreased to 86 deaths in 2015. Similarly, lowest deaths of 21 per 1000 live births in Sri Lanka at 1990 and reduced to 16 deaths per 1000 at 2015.

Cause specific under-5 mortality

Mortality rate with a considerable cause for a population is referred as cause-specific mortality and Globally out of every 10 deaths, non-communicable conditions contribute for six, three for communicable, nutritional or reproductive and one for injuries. Potential causes are leading to under five mortality were preterm birth issues, maternal complications and pneumonia. The vital causes of child death in South Asian regions with highest under-5 mortality were preterm birth issues. Six conditions are caused for more than 70% of the under-5 child mortality globally, pneumonia (19%), diarrhea (18%), malaria (8%), measles, (4%), HIV/ AIDS (3%), and neonatal issues like as birth pre-term birth, and infections (37%). Malnutrition also consider as key contributor for the neonatal deaths [7].

Discussion

The focus of this study was to access the comparison and determinants associated with under-5 mortality in five South Asian countries (Bangladesh, India, Maldives, Nepal and Pakistan).According to the *State of the world's children*, Under-five mortality rate in Afghanistan is 257 deaths per 1000 live births which are the third highest in the world [15].India is the most populated country in the South Asian region which have the highest number of under-five children deaths in the region (2.1 million deaths in 2006) and one-fifth of under-five deaths globally. Nepal, which has developed in public health and declining under five mortality from 158 (per 1000 live births) in 1990 to 54.4 in 2011 [16].

In Sri Lanka, under five mortality rates was determined at 11 deaths per 1,000 live births before reaching age of five, which estimating a reduction of about 30 per cent during the last 15 years. About 70% of deaths are caused by diarrheal, preterm delivery pneumonia, neonatal infection, and lack of oxygen at birth. Poor sanitation, inadequate of safe water and malnutrition are contributing risk factors to half of under-five child deaths. Maternal malnutrition and

poor gestational weight gain are vital causes of low birth weight and high rates of newborn mortality in Bangladesh. Other factors such as immunization status of children and delivery practice may also accelerate under five child mortality rates. Low economic status of household, lower female literacy, inadequate mother nutritional status, early marriage age of mother, larger family and insufficient access to health care facility lead to high risk for under five mortality in India [17].

Comparison of Country specific risk factors

Risk factors causing under-5 mortality in different South Asian countries vary from each other. Old age of mothers (45-49) had constantly highest risk of under-five mortality in Bangladesh compared with Nepal, India, Maldives and Pakistan. Bangladesh has significant association of mother's age with under five mortality [18]. In India, highest risk of under-5 mortality in children is caused by poor wealth quintile and there are strong relationship between household wealth and under-5 mortality [19].

The association between education level of mother and under-5 mortality also vary between South Asian nations. Lowest level of education or no education of mother had significantly highest risk for under-5 mortality in Nepal comparison with other South Asian countries. In Nepal, there is a significant relationship between mother's level of education and breastfeeding practices [20]. The intention of using contraceptive methods or not also has major role to the risk of under-5 mortality in all countries of South Asia especially India having the highest risk of under five deaths for mother who does not use contraceptive.

Conclusion and Recommendation

This study focused on comparing the prevalence and risk factors of under-five mortality in South Asian countries. Findings from different studies in these countries reveals that the levels of under-5 mortality still unacceptably high among all South Asian countries with marginal differences. Risk factors like old age of mother, poor education, lack of using contraceptive, poor wealth quintile, and maternal smoking are key contributors of under-5 mortalities in each country and overall region.

Women's education is a key factor for improving the child survival among all other socioeconomic factors. The practice of early marriages should be controlled for decaling adolescent pregnancy which could increase child survival. Any specific strategy for reducing under five mortality in any South Asian country should be based on risk factors that are specific to that country. For achieving the Sustainable Development target of reducing child mortality by 2030, countries in South Asian region crying need to take serious attempts on child and mother health.

The Influence of Oral Cryotherapy on Prevention from Mucositis in Cancer Patients under Chemotherapy in RSUP H. Adam Malik, Medan

Nataria Yanti Silaban[1], Siti Saidah Nasution[2], Cholina Trisa Siregar[3]

[1]Master Program, Faculty of Nursing, Universitas Sumatera Utara, Medan, Indonesia, [2]Lecturer, Faculty of Nursing, Universitas Sumatera Utara, Medan, Indonesia

Abstract

Objects: to identify effectiveness of oral cryotherapy on prevention from mucositis in cancer patients under chemotherapy.

Methods: the study used quasi experimental method with pre-post test with control group. The samples were 32 patients for intervention group and control group, taken by using consecutive sampling technique. Mucositis was measured by using questionnaires on Oral Assessment Guide (OAG) while the data analyzed by Wilcoxon test and Mann Whitney test.

Results: The result showed, in the post intervention in the intervention group, 24 respondents were not affected by mucositis at p-value=0.008 ($p<0.05$); in the post-intervention in both groups, there were difference in the value of mucositis measured by OAG at p-value=0.003 ($p<0.05$).

Conclusion: Oral Cryotherapy could prevent mucositis in cancer patients who were under chemotherapy.

Keywords: *Oral cryotherapy; Mucocities; Cancer; Chemotherapy*

Introduction

Cancer is the second leading cause of death after cardiovascular disease worldwide. According to a report by the International Agency for Research on Cancer (IARC) in 2012, the estimated incidence of cancer worldwide is 14.1 million in new cases and 8.2 million in cases of death. Lung cancer still leads the list of the highest incidence rates, 1.82 million followed by breast cancer (1.67 million) and colorectal (1.36 million). The highest ranking causes of death are lung cancer (1.6 million) and followed by liver cancer (745,000), and stoma cancer (723,000)[(1)]. Data from RISKESDAS in 2013, stated that cancer prevalence in Indonesia is 14% or estimated to be around 347,792 people. Province D.I. Yogyakarta has the highest prevalence for cancer, which is 41% [(2)].

Based on the KPKN, there are various types of cancer treatment therapies including surgery, radiation therapy, chemotherapy, hormonal therapy, and immune therapy. The treatment can be given in one type or in combination depending on the stage of the cancer, tumor characteristics, age, health, and preferences of the patient [(3)]. More than half of cancer patients treated with chemotherapy, where chemotherapy is a type of therapy done to kill cancer cells and the most effective therapy for cancer patients. Treatment given to cancer patients aims to cure the disease and prolong life, and improve the quality of life[(3)(4)].

Chemotherapy can cause side effects such as fatigue, nausea, vomiting, anorexia, myelosuppression (suppress blood production), hair loss, mucositis, and even death in severe cases [(4),] but the side effects that often occur in patients undergoing chemotherapy are mucositis [(5)].

Early intervention for oral mucositis is very important. In this case the role of nurses is needed because more nurses time in providing services in hospitals, nurses can provide immediate care according to the patient's condition. In addition, nurses are responsible for managing chemotherapy schedules. If mucositis prevention interventions are given according to the chemotherapy schedule, nurses are the most appropriate personnel to carry out these treatments. Oral mucositis occurs about 7 to 14 days after chemotherapy[6]. The majority of patients require chemotherapy treatment every two weeks. Patients who have undergone mucositis during the previous chemotherapy cycle that are not treated immediately will experience an increase in the degree of mucositis in the next chemotherapy cycle.

Martin and Perez said that oral mucositis treatment is also carried out with oral hygiene protocol, chlorhexidene digluconate, cytoprotective agents (amifostin, Sucralfate, Glutamine, Allopurinol, Cryotherapy, Growth factors, and Low Level Laser Therapy / LLLT) [7].

Method

This research was a quasi-experimental research with pre-post test control group design. This research was carried out in the RSUPH. Adam Malik Medan from January 2018 till April 2019. Sixty four respondent were involved in this study using consecutive sampling. Inclusion criteria: 1) patients aged 18-65 years old, 2) patients who first took chemotherapy treatment, 3) mucositis has not occurred, 4) no sensitivity to ice, 5) respondents want to participate in research, 6) respondents are fully aware and able to answer questions, 7) has good communication

The measuring instrument used in this study was the Oral Assessment Guide (OAG) to assess mucositis and observation sheets of documentation on the implementation of oral cryotherapy. Oral Assessment Guide (OAG) is a tool used to measure the assessment of mucositis due to chemotherapy. Oral examination using OAG is carried out through clinical assessments including sound, swallowing, lip, tongue, saliva, mucous membranes, gums, and teeth. Each aspect is assessed with a score of 1 to 3, a score of 1 if normal, a score of 2 if there is a change in function but not all, or minor damage, and a score of 3 if there is damage and loss of function of that aspect. The score is then added to produce a mucositis score between 8-24. The Royal Children's Hospital Australia categorizes OAG ratings into three categories, namely category 1 with an OAG score of 8 being categorized as normal, mild-moderate mucositis when the OAG score of 9-16 falls into category 2, and category 3 (severe mucositis) with an OAG score in the range 17-24. The number is categorized into two categories, namely no mucositis at an OAG score <10, and mucositis at an OAG score of ≥10[8]. The reason for using the Oral Assessment Guide (OAG) in this study is because this instrument is a measurement scale of the degree of mucositis commonly used to measure the degree of mucositis and is easy to do or assess.

Observation sheet implementation of oral cryotherapy measures is a tool used to observe the implementation of oral cryotherapy in accordance with the protocol that has been made. If you take action according to the protocol, check the checklist (√) on the observation sheet, but if you do not perform according to the protocol, put a dash (-) on the observation sheet.

The bivariate analysis used in this study was the Wilcoxon signed ranks test. This test was to see differences in mucositis score before and after oral cryotherapy in each intervention group, while the Mann-Withney U test is used to see differences in mucositis score between intervention and control group.

Table 1 shows that the average age of respondents in this study was 44.00 ± 5,067 in the intervention group and 44.13 ± 4,784 in the control group. Based on age grouping, respondents were in the age range of 35-54 years namely 71.9% in the intervention group and 96.9% control group. Based on gender, the respondents of this study were dominated by men, as many as 68.8% in the intervention group and 68.2% in the control group. Based on educational background, respondents graduated from high school were 71.9% in the intervention group and 7%% in the control group. There were 81.3% of respondents working as entrepreneurs in the intervention group and 81.5% in the control group. Based on marital status, as many as 90.6% were married in the intervention group and 87.5% in the control group. Most ethnics in this study came from the Batak, namely 75.0% in the intervention group and 71.9% in the control group. For the chemotherapy cycle the majority of the first cycle was 71.9% in the intervention group and 58.3% in the control group.

Table 2. Mucositis Value Before and After the Intervention and Control Groups in Cancer Patients with Chemotherapy

Variabels	Pre				Post			
	No mucositis		Mucositis		No mucisitis		Mucositis	
	f	%	f	%	f	%	f	%
Intervention group	32	100	0	0	29	88.6	3	9.3
Control group	32	100	0	0	12	37.3	18	63,9

Table 2. shows that the mucositis value in the intervention group before treatment has an OAG value <10 32 respondents and after the intervention 29 respondents with an OAG value <10 and 3 respondents with an OAG value ≥10. OAG values of all respondents in the control group before treatment <10 and after treatment 12 respondents with OAG values <12 and 18 respondents with OAG values ≥10.

Table 3. Difference in Mukositis Value after Action in the Intervention and Control Groups

Variabel	Intervention group (N=32)			Control group (N=32)		
(OAG) value	Mean Rank	Z	p-value	Mean Rank	Z	p-value
	4.50	-2.640	0.008	12.06	-4.238	0.000

Table 3. shows that there were differences in the value of mucositis between before and after the oral Cryotherapy measures measured by OAG after being statistically tested using the Wilcoxon Signed Rank Test with a mean rank of 4.50 and p=0.008 (p<0.05) and in the control group the mean rank 12.06 with p=0.003 (p<0.05).

Table 4. Difference in Mukositis Value after Action in Intervention and Control Groups Based on the Mann-Whitney U Test

Variabel OAG value	Median (Minimal-Maximal)	Nilai Z	p value
	9.00 (8-14)	-3,007	0.003

Table 4. shows that there were differences in the values of mucositis between the intervention group and the control group with p=0.003 (p <0.05).

Discussions

The measurement results show that the number of respondents who did not experience mucositis was more in the intervention group than in the control group. This is because respondents in the intervention group carried out the oral cryotortion treatment that researchers had designed in their lives during chemotherapy. From the results of the study it can be seen that the action of oral cryotherapy in the intervention group is more effective in preventing mucositis. It can be concluded that the oral cryotherapy action can prevent mucositis in cancer patients with chemotherapy.

These results are consistent with Katrancı, Ovayolu, Ovayolu and Sevinc research that oral cryotherapy affects the protection of oral health by reducing mucositis scores according to the WHO mucositis scale, especially on days 7 and 14. Oral mucocytes are a common side effect caused by cancer treatment and can cause mucosal toxicity. Patients with oral mucositis experience severe pain and are unable to eat, drink and talk and, consequently, their quality of life is impaired[9]. Thirty to eighty-five percent of patients undergoing chemotherapy will experience oral mucositis. Preventing or reducing the incidence of oral mucositis and its severity can help reduce the pain experienced by patients. oral cryotherapy, is a prophylactic intervention. to reduce the incidence and severity of oral mucositis induced by chemotherapy[10].

Research conducted by Svanberg et al. by dividing respondents into 2 groups randomly namely interventions and controls which stated the assessment of mucositis was measured on day 22 after chemotherapy and the result was that oral cryotherapy could significantly reduce the incidence and severity of mucositis and confirmed that oral cryotherapy could prevent induced mucositis chemotherapy with the aim of the mucosal blood vessels undergoing vasocontraction so that chemotherapy drugs do not reach the mucosa[11].

Wilcoxon test results showed there were differences in the pre-post mucositis assessment of gargling with normal saline with a value of p=0.000. The results of the study were the same as the research conducted by Nursalam, Ertawati, and Kristyaningsih, stating that in the normal saline group the p value was 0.012, these results show that normal saline is effective in preventing oral mucositis. Normal saline is a physiological fluid (according to body fluids) that can clean debris, does not irritate, nor does it change the pH of saliva. Because it does not change the pH of saliva, the natural buffer of the mouth will not be disturbed. Physiological mouth will be maintained because there is no irritation [12]. Reducing the number of debris will result in a reduction in bacteria in the mouth. If the patient rinses with normal saline, it is expected that the endurance (oral) of the patient will increase[13].

The value of mucositis before and after the oral cryotherapy action in this study was identified by comparing the post-test values of the degree of mucositis between the intervention group and the control group by using a statistical analysis of the mann whitney test. Based on the results of the analysis it can be interpreted that there are differences in the intervention and control groups with an OAG value, p = 0.003, given p <0.05.

The results of this study are in accordance with Askarifar, Lakdizaji, Ramzi, Rahmani and Jabbarzadeh, which divided the two groups: the intervention group with oral cryotherapy and the control group using

mouthwash with normal saline. The results showed that on the seventh day the severity of mucositis was less in the intervention group (p=0.031) than in the control group. On the fourteenth day mucositis severity was less in the intervention group (p=0.004) than in the control group. The conclusion of the study is that cryotherapy is more effective than mouthwash using normal saline in preventing mucositis [4].

Karagozoglu and Ulusoy showed that the incidence of mucositis in the intervention group was 10% and in the control group 50% using instruments measuring the degree of mukositis Physician-Judged Mucositis Grading. The results of the study confirmed that oral cryotherapy was effective for the prevention of mucositis and reduced severity [13].

Conclussion

The results of this study are described in several sections about: (1) There is a difference in the value of mucositis after being given treatment (post) Oral cryotherapy using ice cubes in the intervention group, where 29 respondents did not experience mucositis and 3 respondents experienced mucositis. Whereas in the control group that experienced mucositis 18 respondents and did not experience mucositis 12. respondents (2) There were mucositis values before and after treatment in the intervention group with oral cryotherapy measures, the results of this study showed there were significant differences in mucositis values. While in the control group there were also significant differences between the values of mucositis.

The Correlation of Neck Circumference with the Metabolic Age of Obesity

Ni Nyoman Sri Yuliani [1], Elsa Trinovita[2]

[1]Department of Nutrition, [2]Department of Pharmacology, Faculty of Medicine, Palangka Raya University, Central Kalimantan, Indonesia

Abstract

Fat accumulation in obesity stimulates an increase in the production of pro-inflammatory mediators in the body chronically, causing the cell's metabolic age to be older than the chronological age. This situation can cause a decrease in metabolic rate; therefore, the body is at risk of cardiometabolic disease. Neck circumference (NC) is known as an anthropometry which is closely related to obesity, visceral fat, and metabolic syndrome. The purpose of this study was to determine the correlation of NC with increasing cell's metabolic age so that it can serve as a simple anthropometry in predicting cell's metabolic age. The study was conducted with a cross-sectional design. The sample of the study was adult male and female with age 30-59 years and following the inclusion and exclusion criteria. The anthropometric examination was carried out in the form of body mass index, neck circumference, and cell's metabolic age using Bioelectrical Impedance Analyzer. Total samples obtained were 94 obese subjects with a mean BMI, NC and metabolic age was 26.9 kg /m^2, NC 34.1 cm, and 50 years. There was a significant positive correlation between NC and cell's metabolic age ($p = 0.001$; $r = 0.42$). In conclusion, NC is useful as simple and practical anthropometry used to predict the increase in metabolic age of cells.

Keywords*: neck circumference; the age of metabolic cells; obesity*

Introduction

Obesity is a serious health problem, and its prevalence continues to increase in many developing countries. World Health Organization (WHO) data shows that the problem of obesity is increasing in developing countries with more than 115 million people suffering. In Indonesia, secondary data analysis from the National Health Survey (Riskesdas) in 2018 depicted an increase in the prevalence of obesity in adults aged > 18 years to 21.8% in 2018, while in 2007 it was only 10.8%.[1] An increase in the prevalence of obesity was also seen in Central Kalimantan Province, which was 15.2% in 2007 to 18.67% in 2018.[1] Obesity is one of the leading causes of metabolic diseases such as insulin resistance which then develops into fatty liver diabetes mellitus, cancer, and cardiovascular disease.[2] Fat accumulation in obesity will increase the basal metabolic rate (BMR) and the deposits of subcutaneous and visceral fat. This situation will stimulate an increase in the production of pro-inflammatory mediators in the body in a chronic manner, causing a cell's metabolic age to be older than chronological age.[3] The more aging cellular metabolic age, compared to the actual age of the patient, indicates a decrease in metabolic rate in the body and implies a risk of experiencing several significant health problems namely cardiometabolic disease.[4]

The gold standard for examining fat accumulation in obesity is computed tomography scans, in addition to indirect methods that are often used, which are anthropometric measurements such as body mass index, waist-hip circumference ratio, skinfold thickness, and upper arm circumference. These anthropometric measurements have advantages and disadvantages of each in predicting fat accumulation in obesity. Neck circumference serves as a relatively new anthropometric measurement.[5–7] Several studies mention that neck circumference is closely related to obesity, visceral fat and metabolic syndrome.[7–10] Examination of metabolic

age of body cells is measured based on the basal metabolic rate which requires sophisticated tools such as indirect calorimetry, dual-energy X-ray absorptiometry (DXA) and bioelectrical impedance analyzer. [11,12]

Based on the previous researches, no research has elicited the relationship of neck circumference with an increasing metabolic age of cells in obesity with the aim of producing an alternative measurement of cell's metabolic age that is practical, simple and minimizes radiation exposure so that it can solidify the prediction of cell's metabolic age which is related to cardiometabolic disease by the primary health workers.

Materials and Method

This research was conducted at the University of Palangka Raya and the working area of the Pahandut Public Health Center in Palangka Raya City, starting from May - July 2019. The sample in this study was male and female adults aged 30-59 years and was following the inclusion criteria ie, not undergoing diet program and not consuming steroids. The exclusion criteria included neck tumors, kyphosis, incomplete extremities, edema, and Cushing's syndrome. The research used a purposive sampling method, and 94 samples were obtained.

The stages in this study were carried out by measuring anthropometrics, namely by using body mass index (BMI) measurements with the formula below. We used WHO Asia pacific adult's cutoff point, BMI ≥ 25 kg/m2 for obesity.[13]

$$\text{BMI} = \frac{Body\ weight\ (kg)}{Body\ height\ (m) x\ Body\ height\ (m)}$$

The neck circumference measurements were then performed on the cricoid cartilage, mid-neck length, between mid-cervical bone and mid-anterior neck using a non-elastic plastic measuring tape with a scale of 1 mm. The circumference of a man's neck was drawn just below the protrusion of Adam's apple. Measurement of cell's metabolic age and BMR were carried out using Bioelectrical Impedance Analyzer (BIA) (Omron Karada Scan professional spec HBF 701, Kyoto Japan).

Analysis of the data used in this study was the Pearson correlation bivariate test using SPSS (Statistical Package for the Social Sciences) version 23 (IBM Corporation, Armonk, NY, USA). Data interpretation based on the value of *r* arithmetic (Pearson correlations) > r table means that this analysis is positive and has a relationship between the two variables.

Findings and Discussion

In this study, 94 subjects with obesity criteria were dominated by the female (72.3%) compared to men (27.7%). In addition, an average body mass index of obese subjects was 29.6 kg / m2 with an age range of 30-57 years. Characteristics of the research subjects can be seen in Table 1 below.

Table 1. Subject characteristics (N = 94)

Variables	Total (%)	Mean ± SD	Min-max
Age (year)		41,6 ± 9,95	30-57
30-40	39 (41,4)	31,8 ± 2,5	30-37
41-50	14 (14,8)	47 ± 2,9	42-50
51-59	41 (43,8)	53,8 ± 1,7	51-57
Sex			
Male	26 (27,7)		
Female	68 (72,3)		
Body mass index (kg/m2)		29,6 ± 3,7	25-41,3
25 – 30	59 (62,8)	26,9 ± 1,2	25-29,1
>30	35 (37,2)	33,2 ± 3,1	30,1-41,3
Neck circumference (cm)	94	34,1 ± 2,6	27,5-39,8
Cell's metabolic age (year)	94	50 ± 13	18-80
BMR (kkal/day)	94	1427,9±241,2	1021-2013

As per Table 2. Data NC and cells's metabolic age was achieved by using Pearson correlation test showed a significant relationship and positive linear correlation on neck circumference variables with cell's metabolic age (p = 0.001).

Table 2. Correlation between neck circumference and cell's metabolic age

Variable	Neck circumference	
	r	p
Cell's metabolic age	0,42	0,001

The results of this study indicate that neck circumference has a positive linear correlation with the cell's metabolic age with moderate correlation strength (r = 0.42, p = 0.001). This correlation indicates that the larger the size of the neck circumference, the metabolic age of cells increases or older than the chronological age in the obese individual bodies. The mechanism that is thought to cause this is the start of a positive energy balance in obesity, which causes an abnormal and excessive accumulation of fat in the body. The fat accumulation is stored mainly in the upper body adipose tissue.[14,15]

The limitations of subcutaneous fat capacity in storing excess fat in obese individuals are causing fat to be stored in visceral tissue and ectopic tissue including the neck in the posterior and subcutaneous compartments, thereby increasing the size of the neck circumference in obese people.[16] Adipose tissue in obesity is known to produce and release pro-inflammatory mediators such as tumor necrosis factor-α (TNF-α), interleukin 6 and reduce adiponectin production which then causes pro-inflammatory conditions and oxidative stress.[17] Extra nutrient stimulation in adipose tissue is responded by performing hyperplasia and hypertrophy of adipocyte cells. Adipocyte cells that continue to grow cause the blood supply to these cells to decrease and trigger hypoxia.[17] This hypoxia is the cause of cell necrosis and infiltration of macrophages into adipose tissue, which then stimulates overproduction of pro-inflammatory mediators. This situation causes local inflammation in adipose tissue which then becomes a systemic inflammation in obesity.[17,18] This ongoing inflammatory condition in obesity is referred to as chronic low-grade inflammation and can change metabolic function.[19,20] However, tissue function restoration does not occur in obese individuals, and it is different from healthy individuals that can occur due to inflammation of tissue restoration. This situation is associated with the elaboration of cytokines and inflammatory mediators that trigger metabolic organ tissue dysfunction.[19]

The increased of adipose tissue in obesity will increase the BMR compared to individuals of normal weight.[21] Increased BMR will increase the metabolic age of cells, rather than chronological age, and it is reflecting the physical health of obese individuals which leads to cell metabolic dysfunction.[4]

Conclusion

A large increase in neck circumference can be a predictor of the cell's metabolic age in obesity, which in line with an increase of fat accumulation in adipose tissue with obesity.

Ethical Clearance: Approval for the study was taken from the Ethics Committee of Faculty of Medicine, Palangka Raya University. Informed consent was taken from adults aged 30-59 years.

Abstract

Heart failure is a clinical syndrome caused by abnormalities in the structure or function of the heart in the myocardium, causing ventricular filling or cardiac output. Calcium and phosphate are metabolic markers that have been linked to the development of the cardiovascular disease. Increased levels of phosphate in patients cause increased production of FGF-23 which induces activation of calcineurin signaling in cardiomyocytes and triggers cardiac hypertrophy. Calcium plays an important role in connecting membrane stimulation with contractions in the myocardium. This study uses a cross-sectional method. Examination of calcium and phosphate levels using serum samples was taken on 57 heart failure patients treated at the Integrated Heart Center Dr. Wahidin Sudirohusodo during the period May to August 2019. Data were analyzed statistically by the Kolmogorov Smirnov test and the Independent T-test.This study showed a significant difference between the calcium levels of the ejection fraction group <50% with a median of 4.67 mg / dL and the ejection fraction group> 50% with a median of 6.06 mg / dL (p <0.01). There was a significant difference between the phosphate levels of the ejection fraction group <50% with a median of 3.62 mg / dL and the ejection fraction group> 50% with a median of 3.04 mg / dL (p = 0.04). It was concluded that calcium levels arehigher in heart failure patients with ejection fraction> 50% & phosphate levels lower in heart failure patients with ejection fraction> 50%.

***Keywords**: Calcium, phosphate, ejection fraction, heart failure*

Introduction

Heart failure is a clinical syndrome caused by structural and functional defects in the myocardium that causes impaired ventricular filling or cardiac output.[1] According to the American College of Cardiology (ACC) and the American Heart Association (AHA), heart failure with a decreased ejection fraction is defined as an ejection fraction ≤40%, whereas heart failure with maintained ejection fraction is defined as an ejection fraction ≥50%.[2]Data from the Atherosclerosis Risk in Communities Study has shown that around 915,000 new cases of heart failure occur annually in the United States. The incidence rate increases with the age of patients of both sexes. Data from the Framingham Heart Study has shown that the annual rate of new heart failure per 1000 people/year is 9.2 for white men aged 65 to 74 years, 22.3 for white men aged 75 to 84 years, and 43.0 for white men ≥85 years.[3]Higher thresholds for case definition, greater severity of the disease, and limited availability of evidence-based therapy can explain this higher death rate in developing countries.[4]

Heart failure is a multisystem disorder in which there is interference with the heart, skeletal muscle and kidney function, stimulation of the sympathetic nervous system and complex neurohormonal changes. In systolic dysfunction, there is a disruption in the left ventricle which causes a decrease in cardiac output. This results in activation of the neurohormonal compensation mechanism, the Renin-Angiotensin-Aldosterone system (RAA system) as well as vasopressin and natriuretic peptide levels that aim to improve the cardiac environment so that cardiac activity can be maintained.[5,6]

Calcium plays an important role in connecting membrane stimulation with contractions in the myocardium. Damaged calcium homeostasis in heart failure can occur due to pathological changes in the expression, and activity of calcium homeostatic binding proteins, ion channels and enzymes. Calcium also plays

an important role in the excitation and contraction of cell membranes, called Excitation-Contraction Coupling (ECC). Cardiac contraction depends on increasing transient concentrations of cytosolic calcium to activate the formation of cross-bridges between the myofilament proteins which ultimately leads to the development of pressure in the heart chambers and provides energy for blood pumps. Cardiomyocytes wrapped in myofibrils are enveloped in tissue storing calcium sarcoplasmic reticulum and mitochondria. The research of Adeniran et al concluded that with calcium disruption and ion channel remodeling in the ejection fraction, the duration of the potential action of ventricular cells becomes prolonged, along with an increase in diastolic calcium concentration.[7]

Increased phosphate levels in patients with heart failure result in increased production of FGF-23, which induces activation of calcineurin signaling in cardiomyocytes, promoting cardiac hypertrophy.[8] Increased phosphate load has been associated with valvular heart disease, with hypertrophic left ventricles, and especially with vascular calcification.[9] Research conducted by Lutsey et al high phosphate concentrations to be associated with an increased risk of heart failure, atrial fibrillation, and a worse prognosis among patients. Framingham's research and post hoc analysis from Cholesterol and Recurrent Events clinical trials have found a positive relationship between serum phosphorus risk and heart failure.[8]

Research on the analysis of calcium and phosphate levels in heart failure patients is still ongoing and continues to be developed. Based in there backgrounds, we were interested in conducting research on the analysis of calcium and phosphate levels in heart failure patients.

Method

This study is a cross-sectional analytic study, analyzing calcium and phosphate levels in patients with heart failure based on ejection fraction. The study was conducted from May to August 2019 at the Clinical Pathology Laboratory of Dr. Wahidin Sudirohusodo Hospital Makassar. The study sample was all patients diagnosed with heart failure by the cardiologist. All subjects were tested for serum calcium and phosphatelevels in. In conducting this research, every action was carried out with the permission and knowledge of patients who were used as research samples through an informed consent sheet and was declared to have met the ethical requirements to be carried out by the Health Research Ethics Commission (KEPK) Faculty of Medicine, Hasanuddin University-UNHAS State University Hospital (RSPTN UH) -RSUP Dr. Wahidin Sudirohusodo Makassar.

Data were analyzed statistically by the Independent T-test is used to assess the difference between calcium levels of heart failure with ejection fraction <50% and ejection fraction> 50% and phosphate levels of heart failure with ejection fraction <50% and ejection fraction> 50%. Hypothesis test results are significant if $p \leq 0.05$.

Results

The study samples obtained were 57 heart failure patients who met the inclusion criteria. The characteristics of study samples can be seen in Table 1 that shows male subjects were more than female. Most study subjects were found in the 40-64 year group.

Table 1. Sample characteristics

Characteristics	n (%)	Mean ± SD	Median (Min-Max)
Gender Male Female	39 (68.4) 18 (31.6)		
Age (year)		52.87±12.06	
Calcium		5.47 ± 1.61	5.66 (2.54-9.23)
Phosphate		4.05 ± 1.90	2.65(1.99–7.60)

Table 2 showed ejection fraction group <50% with mean calcium level 4.72 mg / dL ± 1.06 and ejection fraction group> 50% with mean calcium level 6.41 mg / dL ± 1.62. The results of the statistical analysis in table 2 show that there are significant differences between these two groups with a value of p = 0.00 (p <0.01).

Table 2.The difference between calcium in heart failure based on ejection fraction

Ejection Faction	calcium levels (mg/dL)		P
	Mean ± SD	Median (min-max)	
< 50 %	4.72 ± 1,06	4.67 (2.54 – 6.44)	*0.000
> 50 %	6.41 ± 1.62	6.06 (3.10 – 9.23)	

*Independent T test

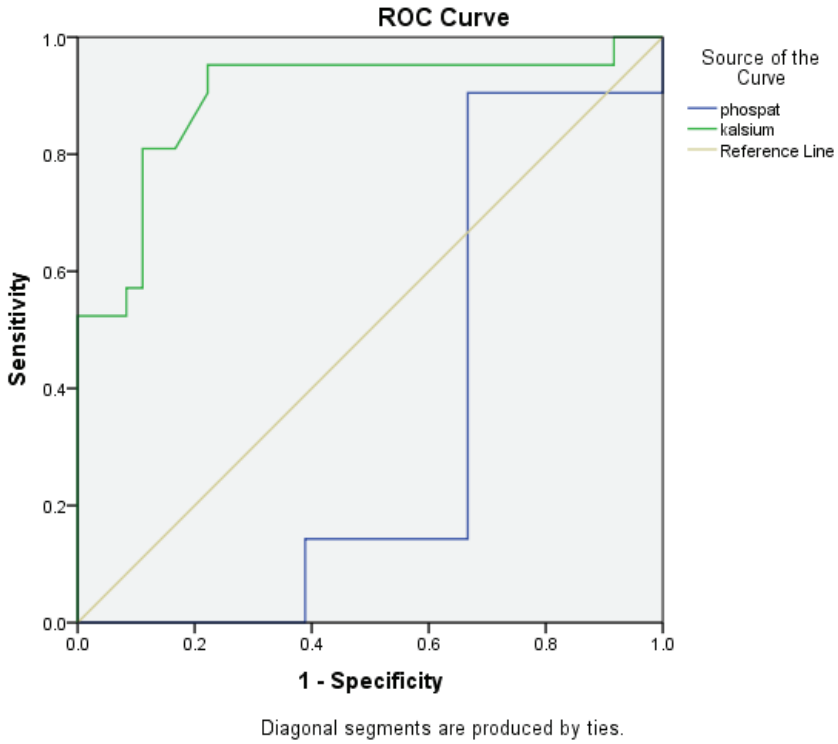
Table 3 shows the ejection fraction group <50% with mean phosphate level of 3.80 ± 1.79 and the ejection fraction group> 50% with a mean phosphate level of 3.44 ± 1.07. Statistical analysis showed that there were significant differences between the two groups with p <0.05.

Table 3. The difference between phosphate in heart failure is based on the ejection fraction

Ejection Faction	Phosphate levels (mg/dL)		P
	Mean ± SD	Median (min-max)	
< 50 %	3.80 ± 1.79	3.62 (1.49-7.60)	*0.047
> 50 %	3.44 ± 1.07	3.04 (1.99-6.30)	

*Independent T test

Pictures 1 shows statistical analysis based on ROC curves shows there is a cutoff in calcium levels in heart failure patients based on ejection fractionis 5.7 mg / dL with ROC = 0.046 (0.011-0.197) with a sensitivity of 87% and a specificity of 76.5%. Pictures 1 shows statistical analysis based on ROC curves shows there is a cutoff in phospate levels in heart failure patients based on ejection fractionis 2.5 mg / dL with ROC = 0.314 (0.077-1.285) with a sensitivity of 87% and a specificity of 32.4%.



Pictures 1. Receiver operating characteristic (ROC) calcium dan phospat levels in heart failure patients based on ejection fraction

Discussion

In this study, subjects were mainly male (68.4%) with a mean age of the subjects 52.8 years. Epidemiological data show that the incidence of heart failure is higher in men than women and the risk increases with age.[10] This study is in line with research conducted by The Netherlands' Rotterdam which found that the majority of heart failure that was obtained was male (33%) compared to women (29%) and the average age of 55 years.[11] In old age and male sex are risk factors associated with atherosclerosis and the occurrence of SCS that cannot be modified.[12]

The results of this study indicate calcium levels in heart failure patients (5.47 ± 1.61 mg / dL). One study reported a patient with hypocalcemia (23%) in heart failure patients (Rozentryt et al., 2015). Other studies have shown calcium levels in heart failure patients to be around 32% with hypocalcemia.[13]

The dysregulation of calcium homeostatic mechanisms are common in heart failure. There have been many studies in patients treated in intensive care units (including those with acute heart failure) showing a high prevalence of hypocalcemia and its association with a poor prognosis. Calcium is an important element for ventricular systolic and diastolic function. During the active process of depolarizing the myocardial membrane, there is a rapid flow of calcium ions through the active membrane calcium channels and the subsequent release of calcium ions from the sarcoplasmic reticulum. Then calcium binds to the troponin-tropomyosin complex, supporting myocardial contraction and fusion of actin-myosin. Relaxation occurs when calcium ions are actively pumped back into the sarcoplasmic reticulum, tropomyosin continues in its shape and myosin returns and releases actin. [14,15]

This study also showed a significant association of calcium levels between the heart failure group and the ejection fraction <50% with> 50%. At the determination of the cut point in calcium in heart failure patients based on ejection fractionis 5.7 mg / dL with ROC = 0.046 (0.011-0.197) with a sensitivity of 87% and a specificity of 76.5%. This is in line with research by Wang et al, 2015 found that low calcium levels are one of the factors that influence the low left ventricular ejection fraction. In another study conducted by Grandi et al, stated that there was a significant correlation between calcium and phosphate levels with a value of p <0.0001.[16] This

is certainly related to calcium phosphate metabolism which is influenced by various factors including the role of parathyroid hormone and vitamin D levels.

The results of this study indicate phosphate levels in heart failure patients (4.05 ± 1.90 mg / dL). Another large-scale study with 977 heart failure patients showed an independent relationship between serum phosphate levels even in the normal range with the severity of disease and prognosis in patients with heart failure. [17]

Hypophosphatemia can cause heart failure. ATP synthesis in muscle cells is decreased in hypophosphatemic patients, indicating that intramyocellular phosphate regulates ATP synthesis. Myocardial and inorganic phosphate keratin phosphate concentrations are significantly reduced during periods of phosphate depletion along with mitochondrial and myofibrillar keratin phosphate kinase activities, which have an important role in contractility of the heart muscle. Stroke volume is increased by administration of phosphate independently of the Frank-Starling effect in patients with severe hypophosphatemia, indicating an increase in myocardial contractility.[18]

Phosphate levels in this study were found to be within normal limits in the heart failure group with ejection fractions <50% and> 50%. At the determination of the cut point in calciumin heart failure patients based on ejection fractionis 2.5 mg / dL with ROC = 0.314 (0.077-1.285) with a sensitivity of 87% and a specificity of 32.4%. A cross-sectional study found high serum phosphate levels were associated with an increase in left ventricular mass and enlarged left ventricular internal dimensions that affected the ejection fraction.

The group with normal phosphate levels was found as many as 26 people. From all research subjects, the mean phosphate value was 4.05. These results are in line with the research of Kamiyama et al, who reported a normal phosphate level of 3.3 mg / dL in heart failure patients. Recent research shows that high serum phosphate levels, even in the normal range, can contribute to an increased risk of cardiovascular diseases such as myocardial infarction and heart failure.[19] Several factors that can affect phosphate levels include diabetic status, albumin levels, smoking history, parathyroid hormone activity, vitamin D levels, history of using beta-blockers, in addition to genetic polymorphism variations that affect FGF-23 production.[20]

This study had some limitations. This study is a cross-sectional study with one-time sampling so it does not see changes in phosphate and calcium levels due to the therapeutic effect and other than that in this study other factors that could affect phosphate and calcium levels were not excluded.

Conclusion and Suggestion

This study concluded that there were differences in phosphate and calcium levels between heart failure patients with ejection fraction < 50% and > 50%. There are significant differences in calcium and phosphate levels in heart failure based on ejection fraction.We recommend further studywith the better distribution of samples in each group, considering therapy received by the patientsand control other risk factors that affect phosphate and calcium levels. We also recommend further study that measures phosphate and calcium levels serially at the beginning and at the end of treatment.

Survival Analysis of Ovarian Cancer Patients based on Age at The Dr. Wahidin Sudirohusodo Makassar Hospital in 2014-2018

Nurul Fitriani[1], Bambang Sutrisna[2], Nugraha Utama Pelupessy[3]

[1]Master of Epidemiology, Faculty of Public Health, University of Indonesia, Depok, [2]Department of Epidemiology, Faculty of Public Health, University of Indonesia, Depok, [3]Department of Obstetrics and Gynecology, Dr. Hospital Wahidin Sudirohusodo Makassar, South Sulawesi

Abstract

Background. Generally, a younger age at diagnosis indicates a better prognosis, with younger women having an average survival of at least 2 years longer than older women. It is estimated that in young women the disease is diagnosed more quickly in the early stages when compared to older women.

Method. A cohort retrospective study. This research was conducted at the Dr. Wahidin Sudirohusodo Makassar Hospital by taking the medical records of ovarian cancer patients from January 2014 to December 2018. The study subjects were 263 patients. The Kaplan-Meier method was used to estimate survival rate and Cox Regression to investigate the effect of variable.

Results. The survival of ovarian cancer patients within 30 months is 78%. Ovarian cancer patients who survived to the 30th month based on age ≤ 60 years were 79% whereas > 60 years to 30th month none had survived with an HR score of 2.74 (95% CI: 1.09-6.88). Multivariate analysis HR values were obtained for age 2.65 (95% CI: 1,07-6,52) after being controlled by stage, and performance status.

Conclusion. Age affects the survival of ovarian cancer patients. Patients aged> 60 years are more at risk of dying compared to patients aged ≤ 60 years

Keywords: *ovarian cancer, survival, age*

Introduction

Globally, the incidence of ovarian cancer was 6.6 per 100,000 population, while the mortality rate was 3.9 per 100,000 population with 300,000 new cases. Based on the same source, the incidence and mortality of ovarian cancer in Asia ranks ninth for cancer diseases suffered by women of all ages. The same situation is also found in Indonesia. Ovarian cancer is still the top ten causes of cancer deaths in women of all ages, with a total of 7,842 or 4.34%.[1]

Ovarian cancer is known as "The Silent Killer". Although the incidence of ovarian cancer is not as high as the incidence of breast and cervical cancer, especially in developing countries, the lethality rate is very high.[2] Ovarian cancer contribute for 2.5% of all malignancies among women. Most cases of ovarian cancer (60-70%) are found at an advanced stage so the treatment results are not as expected. This is due to the absence of specific symptoms (symptomless) in the initial state and the discovery of an approved method of early detection so that the survival rate of patients is low.[3]

For all types of ovarian cancer and ovarian cancer stage under the SEER (Surveillance, Epidemiology and End Results Program) of 2018, the five-year relative survival rate was 47%.[4] If ovarian cancer was discovered and treated before the cancer had spread beyond the ovaries (Stage 1A and 1B), the five-year relative survival rate was 95%. However, only 15% of all ovarian cancers are found in the early stages.[5]

There are many factors that influence the survival rate of ovarian cancer patients. Various factors such as age, grade, FIGO stage, residual disease, CA125, performance status, the presence and absence of ascites, histology, albumin, alkaline phosphatase, race, and various molecular markers are considered to be important prognostic factors affecting the survival of ovarian cancer.[6] The prognosis factors according to Holschneider and Barek (2000) that consistently influence the survival of ovarian cancer patients are stage, tumor histology, grade, age, tumor residues, and ascites.[7]

The age of patient are important prognostic factors in influencing survival rates. It is estimated that in younger age women are more likely to be diagnosed early in the stage than in older women. Also therapy in young women is more aggressive than therapy for the elderly.[8]

The highest age of ovarian cancer is 55-64. The average age at which women are diagnosed is 63, which means that half of women are younger than 63 when diagnosed with ovarian cancer and half are older. The average age of ovarian cancer death is 70.[9] Compared to stages, young women with ovarian cancer are more likely to survive than older women because older women are likely to be in the end stage. Women with stage III-IV ovarian cancer aged 45 years compared to those aged 85 and above are only 8% resistant.[10] Research from Chan (2006) found that overall survival rates of patients with age groups <30, 30-60, and> 60 years, respectively, were 78.8%, 8.8%, and 35.5%.[11] Therefore, the purpose of this study was to determine survival of ovarian cancer patients based on age at the Dr. Wahidin Sudirohusodo Makassar Hospital in 2014-2018.

Method

The design of this study is a retrospective cohort study. This research was conducted at the Dr. Wahidin Sudirohusodo Makassar Hospital obtained medical records of ovarian cancer patients from January 2014 to December 2018 in the hospital information system. The results of the total sample count were obtained in 86 cohort subjects, the minimum sample size in this study was 172. However, in this study we would exclude all ovarian cancer patients who met the inclusion and exclusion criteria. The inclusion criteria were patients with new cases of ovarian cancer and who were receiving treatment only at the Dr. Wahidin Sudirohusodo Makassar Hospital. Exclusion criteria are patients whose medical records are incomplete. The independent variable of study was age. The dependent variable was the survival of ovarian cancer patients. The variables of the covariate were marital status, stage, grade, ascites, albumin, treatment compliance, and performance status. Univariate analysis to see the frequency distribution, the proportion of each variable. To determine survival rate of ovarian cancer patients using the Kaplan Meier test and Log Rank Test. Cox regression analysis is used to investigate the effect of variable.

Results

During this study, a total of 263 patients were studied during the period January 2014 - December 2018. Of the 263 patients event (died) 26 (9.89%) and 237 censored patients (90.11). Patients aged ≤ 60 years were 226 (85.93%) and> 60 years 37 (14.07%). Ovarian cancer patients with marital status were 240 (91.25%) and unmarried 23 (8.75%).

It is known that most ovarian cancer patients who come for treatment in the end stage are 141 (53.61%), while patients with early stages are 122 (46.39%). Patients who had moderate and poor grade were 193 (73.38%), while patients with high grade were 70 (26.62%). Patients who had ascites were 179 (68.06%) and patients who did not have ascites 84 (31.94%). Patients with albumin levels <3.6 g / dl were 191 (72.62%) and patients whose albumin levels were ≥ 3.6 g/dl were 72 (27.38%). Patients with good performance status were 248 (94.30%) and patients with weak performance status were 15 (5.70%). Obedient patients were 257 (97.72%) and non-compliant patients were 6 (2.28%).

The survival rate of ovarian cancer patients within 30 months is 78% with an average survival rate of ovarian cancer patients for 8 months. Based on Figure 1, it was found that ovarian cancer patients who survived to the 30th month based on the age of ≤ 60 years by 79% while> 60 years to the 30th month none had survived with an HR value of 3.82 (95% CI: 95% 1.36-9.51).

Table 1. Frequency Distribution of Ovarian Cancer Patients in RSUP Dr. Wahidin Sudirohusodo Makassar in 2014-2018

Variables	Total		Aged ≤ 60 years		Aged > 60 years	
	n	%	n	%	n	%
Patient Status						
Sensor	237	90,11	207	87,34	30	12,66
Event	26	9,89	19	73,08	7	26,92
Stage						
Early Stage	122	46,39	107	87,70	15	12,30
End Stage	141	53,61	119	84,40	22	15,60
Marital Status						
Married	240	91,25	203	84,54	37	15,42
Unmarried	23	8,75	23	100	-	-
Treatment Compliance						
Obedient	257	97,72	220	85,60	37	14,40
Non-compliant	6	2,28	6	100	-	-
Grade						
High	70	26,62	65	92,86	5	7,14
Moderate and low	193	73,38	161	83,42	32	16,54

No	84	31,94	74	88,10	10	11,90
Yes	179	68,06	152	84,92	27	15,08
Albumin Level						
< 3,6 g/dl	191	72,62	64	88,89	8	11,11
≥ 3,6 g/dl	72	27,38	162	84,82	29	15,18
Performance Status						
Good	248	94,30	214	86,29	34	13,71
Weak	15	5,70	12	80	3	20

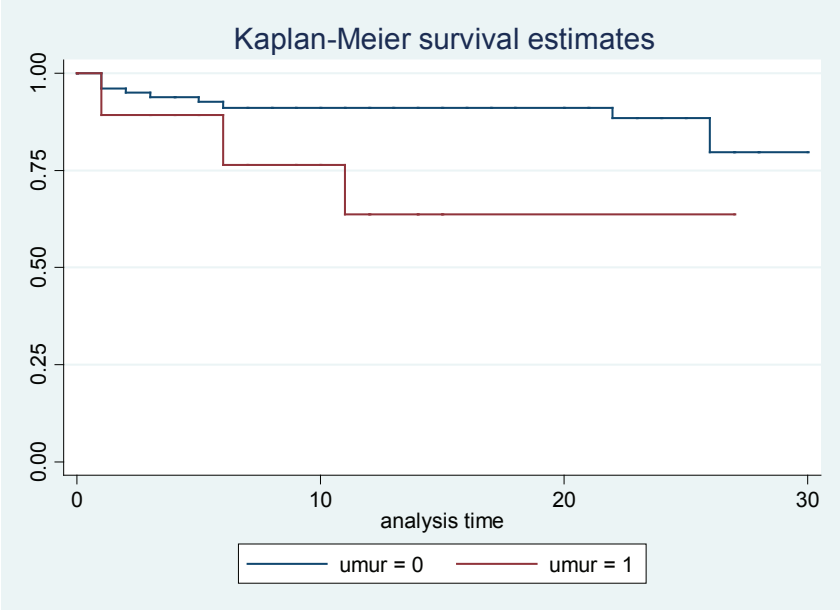

Figure 1. Kaplan Meier's Curve for the Survival of Ovarian Cancer Patients by Age

Table 2. Multivariate Final Models Effects of Age on the Survival of Ovarian Cancer Patients

variables	Coef B	HR	95% CI	p value
Age	0,973	2,65	1,07-6,52	0,032
Stage	0,726	2,07	0,82-5,22	0,132
Performance Status	2,539	12,68	5,67-28,32	0,000

In the bivariate results, the HR value for age was 3.82 (95% CI 1.36-9.51; p <0.0010). This study also conducted stratification analysis to see the variables that interacted, but the results were no interactions and there were confounding on stage, marital status, grade, and performance status. After conducting stratification analysis, all variables were entered then proceed to multivariate analysis and HR values were obtained for age 2.74 (95% CI: 1.09-6.88) after being controlled by marital status, stage, ascites, grade, albumin levels, treatment compliance and performance status. When entering multivariate analysis before entering final modeling, there is no interactions or counfounding were found. From table 2, we get the final model of patients aged> 60 years who have a risk of 2.65 times death compared to patients aged ≤ 60 years after being controlled by variables of stage and performance status.

Discussion

Based on the results of this study conducted at the Dr. Wahidin Sudirohusodo Makassar Hospital with a total of 263 patients, the cumulative probability of survival of ovarian cancer patients was 79% for 30 months. Events (died) occur more frequently in ovarian cancer patients with end-stage (53.61%) compared to ovarian cancer patients with early-stage (46.39%). This survival rate is higher than the Junita Sari study (2008) at Dharmais Cancer Hospital for 36 months by 51%.[12] Research by Aneta et al. (2018) in Podkarpacie province 51.2% .[13] This difference in survival occurred because in this study the lost to follow-up was included in the risk population, as well as differences in sample size, data capture and other factors in each study.

From the results of the analysis found that ovarian cancer patients who survived to the 30th month based on

age ≤ 60 years by 79% while> 60 years to 30th month no one had survived. On average ovarian cancer patients aged ≤ 60 years can survive for 9 months while ovarian cancer patients aged> 60 years can only survive for 5 months. This result is not much different from the results of Chan et al's study where the survival rate of ovarian cancer patients aged <60 years by 84.8% while different for ages> 60 years which obtained by 77.1%.[14] But these results are different from Junita (2007) results in which the survival rate for patients aged ≤ 49 years by 64%, in the 50 to 59 years age group by 34% while those aged ≥ 60 years by only 23% for 3 years.[12] Research conducted by Aneta et al. (2018) also states that as a woman gets older at the time of diagnosis, her survival will decrease. Comparing patient survival in groups> 65 years with women 45-65 years for 3 years by 24.2% .[13] This result may differ due to age category. Although a cut-off age of 60 years has commonly been used, the age criteria have differed among previous studies.

Past research about age as a prognostic factor is very important. Generally, a younger age at diagnosis indicates a better prognosis, with women younger than 65 years having at least 2 years longer median survival compared to women older than 65 years; older women also have an increased risk of recurrence and death. Age remains an independent prognostic factor after controlling for common confounding factors, such as performance status and medical comorbidities. Younger-aged women tend to have less invasive and well differentiated cancers and fewer comorbidities compared to older counterparts, yielding a more favorable overall prognosis.[15] Some studies also find that young women with early-stage ovarian cancer and with good differentiated tumors have good survival higher than older women. However, another study found that age was not the only prognosis factor after adjusting for other variables such as the stage and grade of the disease.[14]

In multivariate analysis it is known that patients aged> 60 years have a risk of 2.65 times of death compared with patients aged ≤ 60 years after being controlled by variable stage and performance status. In contrast to research by Chan et al. where patients> 60 years old have a risk of 1.96 times death compared to patients aged <60 years after being controlled with stage, grade, and citology.[14]

In this study it is also known that staging and general condition affect the survival of ovarian cancer patients. The survival rate of ovarian cancer patients decreases with increasing stage of the disease.[15] Diagnosis of ovarian cancer is often delayed due to lack of early examination and specific symptoms. Only about 25% of women diagnosed with ovarian cancer occur in stage 1.[17] Late diagnosis affects cancer treatment, making it more difficult to effectively fight cancer.[16] Better performance status generally provide greater tolerance for various therapeutic modalities, from surgery to chemotherapy, and might motivate the adoption of more aggressive treatment plans by doctors. Several studies support this reason and confirm the significance of prognosis independent of performance status.[15]

Elderly patients with ovarian cancer may benefit from a multidisciplinary approach, including a comprehensive evaluation by a gynecologist, oncologist, nurse and pharmacist. Comprehensive geriatric assessments have been shown to be able to predict morbidity and mortality in elderly cancer patients.[18] However, the high heterogeneity of elderly patients means that it is not feasible to make treatment decisions based on age alone, and a more objective assessment is required.[19]

Weaknesses in this study are that researchers cannot control the state and quality of data that have been done by others in the past and the research can only rely on secondary data that is already in incomplete medical record records where the possibility of errors in recording or available data is not appropriate with what is needed in research. For this reason, better records are needed for ovarian cancer patients.

Conclusions and Recommendations

From this study it was concluded that age affects the survival of ovarian cancer patients. Patients aged> 60 years are more at risk of dying compared to patients aged ≤ 60 years. It is recommended to do research with more samples to be able to prove other factors that influence the survival of ovarian cancer patients. The research can be continued with different outcomes, categorizing different variables, and including several characteristic variables such as economics.

Ethical Considerations: This Study was approved by Faculty of Public Health University of Indonesia Ethics Committee (No. 370/UN2.F10/PPM.00.02/2019).

Competing Interest: The authors declared that no competing interest exist.

The highest age of ovarian cancer is 55-64. The average age at which women are diagnosed is 63, which means that half of women are younger than 63 when diagnosed with ovarian cancer and half are older. The average age of ovarian cancer death is 70.[9] Compared to stages, young women with ovarian cancer are more likely to survive than older women because older women are likely to be in the end stage. Women with stage III-IV ovarian cancer aged 45 years compared to those aged 85 and above are only 8% resistant.[10] Research from Chan (2006) found that overall survival rates of patients with age groups <30, 30-60, and> 60 years, respectively, were 78.8%, 8.8%, and 35.5%.[11] Therefore, the purpose of this study was to determine survival of ovarian cancer patients based on age at the Dr. Wahidin Sudirohusodo Makassar Hospital in 2014-2018.

Method

The design of this study is a retrospective cohort study. This research was conducted at the Dr. Wahidin Sudirohusodo Makassar Hospital obtained medical records of ovarian cancer patients from January 2014 to December 2018 in the hospital information system. The results of the total sample count were obtained in 86 cohort subjects, the minimum sample size in this study was 172. However, in this study we would exclude all ovarian cancer patients who met the inclusion and exclusion criteria. The inclusion criteria were patients with new cases of ovarian cancer and who were receiving treatment only at the Dr. Wahidin Sudirohusodo Makassar Hospital. Exclusion criteria are patients whose medical records are incomplete. The independent variable of study was age. The dependent variable was the survival of ovarian cancer patients. The variables of the covariate were marital status, stage, grade, ascites, albumin, treatment compliance, and performance status. Univariate analysis to see the frequency distribution, the proportion of each variable. To determine survival rate of ovarian cancer patients using the Kaplan Meier test and Log Rank Test. Cox regression analysis is used to investigate the effect of variable.

Results

During this study, a total of 263 patients were studied during the period January 2014 - December 2018. Of the 263 patients event (died) 26 (9.89%) and 237 censored patients (90.11). Patients aged ≤ 60 years were 226 (85.93%) and> 60 years 37 (14.07%). Ovarian cancer patients with marital status were 240 (91.25%) and unmarried 23 (8.75%).

It is known that most ovarian cancer patients who come for treatment in the end stage are 141 (53.61%), while patients with early stages are 122 (46.39%). Patients who had moderate and poor grade were 193 (73.38%), while patients with high grade were 70 (26.62%). Patients who had ascites were 179 (68.06%) and patients who did not have ascites 84 (31.94%). Patients with albumin levels <3.6 g / dl were 191 (72.62%) and patients whose albumin levels were ≥ 3.6 g/dl were 72 (27.38%). Patients with good performance status were 248 (94.30%) and patients with weak performance status were 15 (5.70%). Obedient patients were 257 (97.72%) and non-compliant patients were 6 (2.28%).

The survival rate of ovarian cancer patients within 30 months is 78% with an average survival rate of ovarian cancer patients for 8 months. Based on Figure 1, it was found that ovarian cancer patients who survived to the 30th month based on the age of ≤ 60 years by 79% while> 60 years to the 30th month none had survived with an HR value of 3.82 (95% CI: 95% 1.36-9.51).

Table 1. Frequency Distribution of Ovarian Cancer Patients in RSUP Dr. Wahidin Sudirohusodo Makassar in 2014-2018

Variables	Total		Aged ≤ 60 years		Aged > 60 years	
	n	%	n	%	n	%
Patient Status						
Sensor	237	90,11	207	87,34	30	12,66
Event	26	9,89	19	73,08	7	26,92
Stage						
Early Stage	122	46,39	107	87,70	15	12,30
End Stage	141	53,61	119	84,40	22	15,60
Marital Status						
Married	240	91,25	203	84,54	37	15,42
Unmarried	23	8,75	23	100	-	-
Treatment Compliance						
Obedient	257	97,72	220	85,60	37	14,40
Non-compliant	6	2,28	6	100	-	-
Grade

< 3,6 g/dl	191	72,62	64	88,89	8	11,11
≥ 3,6 g/dl	72	27,38	162	84,82	29	15,18
Performance Status						
Good	248	94,30	214	86,29	34	13,71
Weak	15	5,70	12	80	3	20

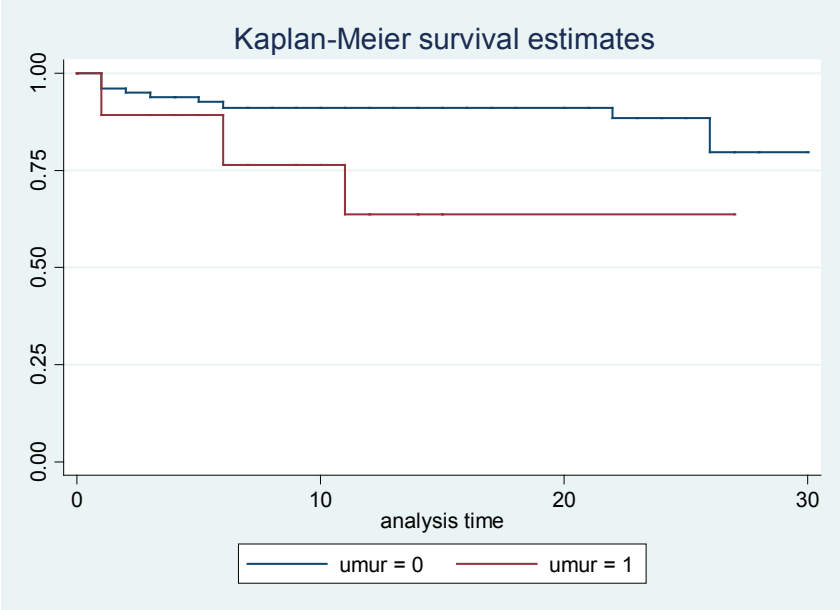

Figure 1. Kaplan Meier's Curve for the Survival of Ovarian Cancer Patients by Age

Table 2. Multivariate Final Models Effects of Age on the Survival of Ovarian Cancer Patients

variables	Coef B	HR	95% CI	p value
Age	0,973	2,65	1,07-6,52	0,032
Stage	0,726	2,07	0,82-5,22	0,132
Performance Status	2,539	12,68	5,67-28,32	0,000

In the bivariate results, the HR value for age was 3.82 (95% CI 1.36-9.51; p <0.0010). This study also conducted stratification analysis to see the variables that interacted, but the results were no interactions and there were confounding on stage, marital status, grade, and performance status. After conducting stratification analysis, all variables were entered then proceed to multivariate analysis and HR values were obtained for age 2.74 (95% CI: 1.09-6.88) after being controlled by marital status, stage, ascites, grade, albumin levels, treatment compliance and performance status. When entering multivariate analysis before entering final modeling, there is no interactions or counfounding were found. From table 2, we get the final model of patients aged> 60 years who have a risk of 2.65 times death compared to patients aged ≤ 60 years after being controlled by variables of stage and performance status.

Discussion

Based on the results of this study conducted at the Dr. Wahidin Sudirohusodo Makassar Hospital with a total of 263 patients, the cumulative probability of survival of ovarian cancer patients was 79% for 30 months. Events (died) occur more frequently in ovarian cancer patients with end-stage (53.61%) compared to ovarian cancer patients with early-stage (46.39%). This survival rate is higher than the Junita Sari study (2008) at Dharmais Cancer Hospital for 36 months by 51%.[12] Research by Aneta et al. (2018) in Podkarpacie province 51.2% .[13] This difference in survival occurred because in this study the lost to follow-up was included in the risk population, as well as differences in sample size, data capture and other factors in each study.

From the results of the analysis found that ovarian cancer patients who survived to the 30th month based on age ≤ 60 years by 79% while> 60 years to 30th month

no one had survived. On average ovarian cancer patients aged ≤ 60 years can survive for 9 months while ovarian cancer patients aged> 60 years can only survive for 5 months. This result is not much different from the results of Chan et al's study where the survival rate of ovarian cancer patients aged <60 years by 84.8% while different for ages> 60 years which obtained by 77.1%.[14] But these results are different from Junita (2007) results in which the survival rate for patients aged ≤ 49 years by 64%, in the 50 to 59 years age group by 34% while those aged ≥ 60 years by only 23% for 3 years.[12] Research conducted by Aneta et al. (2018) also states that as a woman gets older at the time of diagnosis, her survival will decrease. Comparing patient survival in groups> 65 years with women 45-65 years for 3 years by 24.2% .[13] This result may differ due to age category. Although a cut-off age of 60 years has commonly been used, the age criteria have differed among previous studies.

Past research about age as a prognostic factor is very important. Generally, a younger age at diagnosis indicates a better prognosis, with women younger than 65 years having at least 2 years longer median survival compared to women older than 65 years; older women also have an increased risk of recurrence and death. Age remains an independent prognostic factor after controlling for common confounding factors, such as performance status and medical comorbidities. Younger-aged women tend to have less invasive and well differentiated cancers and fewer comorbidities compared to older counterparts, yielding a more favorable overall prognosis.[15] Some studies also find that young women with early-stage ovarian cancer and with good differentiated tumors have good survival higher than older women. However, another study found that age was not the only prognosis factor after adjusting for other variables such as the stage and grade of the disease.[14]

In multivariate analysis it is known that patients aged> 60 years have a risk of 2.65 times of death compared with patients aged ≤ 60 years after being controlled by variable stage and performance status. In contrast to research by Chan et al. where patients> 60 years old have a risk of 1.96 times death compared to patients aged <60 years after being controlled with stage, grade, and citology.[14]

In this study it is also known that staging and performance status affect the survival of ovarian cancer patients. The survival rate of ovarian cancer patients decreases with increasing stage of the disease.[15] Diagnosis of ovarian cancer is often delayed due to lack of early examination and specific symptoms. Only about 25% of women diagnosed with ovarian cancer occur in stage 1.[17] Late diagnosis affects cancer treatment, making it more difficult to effectively fight cancer.[16] Better performance status generally provide greater tolerance for various therapeutic modalities, from surgery to chemotherapy, and might motivate the adoption of more aggressive treatment plans by doctors. Several studies support this reason and confirm the significance of prognosis independent of performance status.[15]

Elderly patients with ovarian cancer may benefit from a multidisciplinary approach, including a comprehensive evaluation by a gynecologist, oncologist, nurse and pharmacist. Comprehensive geriatric assessments have been shown to be able to predict morbidity and mortality in elderly cancer patients.[18] However, the high heterogeneity of elderly patients means that it is not feasible to make treatment decisions based on age alone, and a more objective assessment is required.[19]

Weaknesses in this study are that researchers cannot control the state and quality of data that have been done by others in the past and the research can only rely on secondary data that is already in incomplete medical record records where the possibility of errors in recording or available data is not appropriate with what is needed in research. For this reason, better records are needed for ovarian cancer patients.

Conclusions and Recommendations

From this study it was concluded that age affects the survival of ovarian cancer patients. Patients aged> 60 years are more at risk of dying compared to patients aged ≤ 60 years. It is recommended to do research with more samples to be able to prove other factors that influence the survival of ovarian cancer patients. The research can be continued with different outcomes, categorizing different variables, and including several characteristic variables such as economics.

Ethical Considerations: This Study was approved by Faculty of Public Health University of Indonesia Ethics Committee (No. 370/UN2.F10/PPM.00.02/2019).

Competing Interest: The authors declared that no competing interest exist.

Acknowledgement: The authors would like to

thank the Dr. Wahidin Sudirohusodo Makassar Hospital for sharing the data.

The Relationship between Selling Sex and HIV Status among Transgender in Indonesia
(Analysis of Integreted Biological and Behavioral Survey Data 2015)

Abstract

HIV prevalence in transgender women is increasing compared to previous years. The aim of the Cross Sectional study was to find out the relationship between selling sex and HIV status among transgender in Indonesia. This study used secondary data for the 2015 Integrated Biological and Behavioral Survey (IBBS). Respondents were biologically male; ≥15 years old; recognized by friends of profession, "mami", or NGO workers as a transgender women; answer the questions, having sex partner and results of HIV test. The results showed that transgender who sell sex 1,358 times the risk of having a positive HIV status compared to transgender who do not sell sex (95% CI: 1.045 - 1.766) after being controlled with a variable STIs history.

Keywords *: HIV risk, transgender, transgender women, HIV status*

Introduction

Human Immunodeficiency Virus (HIV) is a retrovirus that damages and destroys the immune system so that the body's defense against infection becomes weak. A weakened immune system makes a person more susceptible to infection and disease.[1] Retroviruses have the ability to use their RNA and host DNA to form DNA viruses and are recognized during long incubation periods. Like other retroviruses, HIV infects the body with a long (clinic-latent) incubation period, and mainly causes signs and symptoms of AIDS.[2]

Based on UNAIDS data in 2017, in the world there were 36.9 million people living with HIV, 1.8 million of whom were new infections. The number of HIV infections in adults is 35.1 million, while in children under the age of 15 the number reaches 1.8 million. Deaths due to AIDS in 2017 were reported as many as 940,000 deaths.[3]

In Asia there are 5.2 million million people infected with HIV, 280 thousand of them are new infections and have caused the death of 170 thousand people in 2017.[4] In Indonesia, in 2016 there were 620,000 people living with HIV, 48,000 of whom were newly infected and there were 38,000 AIDS-related deaths. The key populations in Indonesia most affected by HIV are sex workers with an HIV prevalence of 5.3%, MSM groups with a prevalence of 25.8%, syringe users with a prevalence of 28.76%, transgender with a prevalence of 24.8% , and in prisoners with a prevalence of 2.6%. Since 2010, new HIV infections increased by 22% and AIDS-related deaths increased by 68%.[5]

A systematic review from Asia found that transgender people are 18 times more likely to be infected with HIV than those in the general population.[6] Transgender is one of the groups most affected by the HIV epidemic and 49 times more likely to live with HIV than the general population.[5]

Transgender has unique characteristics in shaping risk factors.[7] The main risk factors for transgender people to become infected with HIV are multiple sexual partners, anal or vaginal sex without using condoms, the use of hormones or drugs with the same syringe, commercial sex work, mental health problems, homelessness, unemployment, and drug abuse, and violence and lack of family support.[8] Transgenders who work selling sex will be at risk of contracting HIV.[9]

The purpose of this study was to determine the HIV prevalence and determinants of HIV status in transgender

transgender people in 5 major cities in Indonesia in 2015.

Material and Method

This study uses secondary data from the 2015 Integrated Biological and Behavioral Survey (IBBS) which was conducted in 5 major cities in Indonesia (DKI Jakarta, Bandung, Semarang, Surabaya, and Malang Raya). This type of observational research with cross sectional study design uses multistage cluster sampling technique which is done in several steps. A detailed description of the research design, sampling and main analysis can be found in the official IBBS report published by the Ministry of Health of the Republic of Indonesia.[10] The population in this study were all transgender respondents who were IBBS respondents in 2015. Whereas the sample was transgender transgender people from 5 major cities in Indonesia who had fulfilled the research inclusion criteria, namely a person who was biologically male; ≥15 years old; recognized by friends, "mami", or NGO workers as transgender; answering questions and there are results of HIV testing and syphilis testing. A total of 1,003 respondents were interviewed, but the number of respondents who entered into this study was transgender who had HIV test results and sex partners was only 867 people. Then, all respondents selected in the 2015 IBBS were included and used as samples in this study (total sampling).

This research was conducted by analyzing interview data based on a structured questionnaire from the 2015 IBBS in transgender transgender groups. The questionnaire contained questions to obtain information about the characteristics of the subjects, sexual behavior, scope of interventions, HIV and STIs testing, knowledge about HIV / AIDS and its prevention. HIV status is diagnosed by a rapid test, a test carried out to see antibodies arising from the presence of HIV infection. If the test shows a reactive (positive) result, then a follow-up test with confirmation is required. Respondents tested positive for HIV if positive results were obtained from the two tests. Syphilis status is determined based on the results of the RPR test (rapid plasma regain) and TP Rapid, which is a blood test to detect the presence of antibodies produced by the body against syphilis infection. While the anal swab is done to check for the presence of Chlamydia trachomatis and Neisseria gonorrhoeae. All IBBS data is officially documented and kept confidential by the Ministry of Health of the Republic of Indonesia.

Data Analysis

The collected data is then performed cleaning, processed and analyzed using univariate, bivariate and multivariate analysis. Univariate analysis was performed to see the frequency distribution of independent, dependent and covariate variables. Bivariate analysis in this study used the *chi square* test to determine the crude Prevalence Ratio (PR). All variables that are substantially related to HIV status were included in the multivariate analysis. Multivariate analysis in this study used a *cox regression* test with a significance level seen based on the value of 95% CI.

The strength of the association between the predictor variable and HIV status was measured using the Prevalence Ratio (PR) and adjusted PR. Confidence Interval (CI) for POR uses 95% CI with a significance value of 0.05..

Findings

Table 1 shows the transgender characteristics that were sampled in this study. Transgender who are HIV positive amounted to 26.1%. The main source of income for transgender from selling sex is 44.5%. Majority of respondents do not have STIs history (77.9%). Most respondents did not consistently use condoms (58.2%). 56.4% had good knowledge of HIV / AIDS transmission, 67.4% had good knowledge of HIV / AIDS prevention, 59.2% had less knowledge of HIV / AIDS misconception and 65.1% had comprehensive knowledge about HIV / AIDS which is good. For ages, some respondents were ≥25 years old (82.8%). Most respondents did not use injecting drugs (99.0%).

Bivariate analysis was performed to determine the *crude* Prevalenc Ratio (PR). All variables that are substantially related to HIV status were included in the multivariate analysis. The results of multivariate analysis of the relationship between selling sex and HIV status among transgender can be seen in table 3.

Transgender who sell sex 1,358 times the risk of having a positive HIV status compared to transgender who do not sell sex (95% CI: 1.045 - 1.766) after being controlled with a variable STIs history

STIs History (Yes vs No)	0,001	1,592	1,202	2,109

Discussion

The results showed that the HIV prevalence in transgender in 5 big cities in Indonesia was 26.1%. This increased if compared to 2011. In 2011, HIV prevalence was 21.85%.[11]

As many as 83.2% of transgender have a history of selling sex. Similar figures were also obtained from UNAIDS data which states that the proportion of transgender people in Indonesia who sell sex is estimated to reach 81%.[12] Then, it was also obtained that 17.4% of respondents had positive syphilis status. The incidence of syphilis in HIV sufferers has clinical implications between HIV infection and syphilis. An HIV test is important for all patients with a new diagnosis of syphilis.[13]

HIV prevalence in trangender who sell sex is 31.1%, whereas in transgender who do not sell sex is 22,0%. This is in line with research Operario et. al (2008) which gives the result that HIV prevalence in transgender sex workers is higher than non-sex transgenders.[14]

Transgender that selling sex has an a-PR value = 1,358 (95% CI: 1,045 – 1,766), this value indicates that respondents who selling sex are 1,358 times more likely to be infected with HIV than those who have no history of selling sex. Operario et al's research (2008) provides consistent results, where the risk of HIV infection in transgender sex workers is 1.46 times greater than transgenders who are not sex workers.[14] According to Altaf et al (2012), transgenders who work sex have a risk of 5 , 5 times more likely to be infected with HIV compared to other occupations.[15] The risk of transmitting HIV and STIs to transgender increases due to the behavior of transgenders who have sexual relations with many partners whose HIV and STIs status are unknown, have unprotected sex, and more often to engage in high-risk sexual activities.[16-18]

HIV prevalence in transgender who have STIs history is 37.5% while in transgender who haven't STIs history is 22.8%. This is in line with Mutmainah's study (2015) which gives the result that HIV prevalence in transgenders who have a positive STIs status is higher than that of transgenders who have a negative STIs status.[19]

The STIs history variable has a-PR value = 1.592 (1.202-2.109), this value indicates that respondents who have STIs history are 1.592 times more likely to be infected with HIV than those with haven't STIs history. This is in line with research conducted by Rompalo, et al (2001) that the median syphilis serology test is higher in patients infected with HIV compared with patients who are not infected with HIV ($p < 0.05$).[20] The results of a study conducted by Lee (2008) in Hong Kong gave the result that a history of STIs had a risk of 1.77 times having HIV (95% CI: 1.09-2.86).[21] Then, Pisani's research (2004) also gave the same result that transgenders who had syphilis had 3.8 times risk to experience HIV positive.[22] Ulcerative and non-ulcerative STIs have been found to increase the risk of sexual transmission of HIV.[23]

Limitations in this study are the use of secondary data with Cross Sectional study design where the associations in this study cannot see causal relationships. Then because risky behavior related to HIV transmission is sensitive enough to be asked of respondents, respondents may not fully answer honestly the questions asked.

Conclusions

Respondents who had HIV positive status were 26.1% and HIV negative status were 73.9%. Based on the final results of the multivariate analysis in table 3, it is known that transgenders who sell sex are 1,358 times at risk of having a positive HIV status compared to transgenders who do not sell sex (95% CI: 1.045 - 1.766) after being controlled with a variable STIs history. HIV status can be prevented by controlling its risk factors.

Conflict of Interest: Both authors declare that there is no competing interest in this paper.

Source of Funding: This research was received no external funding.

Ethical Clearance: This research guarantees the confidentiality of the data and the identity of the respondents. The data usage permit was obtained from Subdirektorat HIV and PIMS of the Indonesian Ministry of Health and written in the letter of approval and stated in the statement letter number PM.02.01/3/3313/2019. This research has also been through the ethics review from Ethical Commite Faculty of Public Health University of Indonesia with Ethical Approval number 717/UN2.F10/PPM.00.02/2019.

Acknowledgment: Author would like to thank the Subdirektorat HIV and PIMS of the Indonesian Ministry of Health for giving permission and providing data.

Prevalence of Demographic Profiles and Loneliness among Elderly Women in Private Care Institution

Nurunsaadah S.[1], Lukman Z.M.[2], Zulaikha M.Z.[1], M.Y. Kamal[1]

[1]Post Graduate Student, [2]Prof, School of Social Work, Faculty of Applied Social Sciences, Sultan Zainal Abidin University, Gong Badak Campus, Terengganu, Malaysia

Abstract

Loneliness among elderly women living in nursing home based on demographic profile become a phenomenon in many developed countries. In most research, loneliness has been identified as a negative feeling that can lead to death. Loneliness among elderly women occur when they are 60 years and above once their children grow up and married. Then, there retired from occupations and their spouse died and make they live alone. Thus, this study aimed to identify the factors of demographic profiles have an impact on loneliness among elderly women. This research was conducted at a private institution in Terengganu, Malaysia with 78 elderly women as respondents quantitatively. The questionnaires from UCLA Loneliness Scale were adopted to analyse the risk of elderly having loneliness in nursing home. The result showed the factors of demographic profile have an impact on loneliness among elderly women in private institution its strength and significant. As a conclusion, the study on loneliness among elderly women in nursing home is important to raise awareness about this alarming issue in the society especially among elderly women.

Keywords: *Loneliness, demographic profiles, elderly women, private care institution.*

Introduction

Loneliness are prevalent among elderly women in the institution [1]. In a cross-sectional study by Barg et al. (2006), it was revealed that in persons 65 years and older, the perceived adequacy of emotional and tangible support was clearly associated with isolation symptoms three years later [2]. According to Adams et al. (2004), the elderly women living in retirement, nursing homes and institution, away from previous homes and neighborhoods and separated from extended families, will continue to increase [3]. There are living in facilities for the elderly women will have to modify to a changed living situation, and this modification can lead to fatal psychosocial problems of loneliness in the absence of positive social networks [4]. The elderly women and depression related when they are 60 years old and above when their children grow up and married [5]. Then, there are retired and their spouse died and make they live alone [6 7].

Material and Method

Population and Sampling: The population of the study was the 78 elderly women in welfare institution in Terengganu, Malaysia during the years 2017.

Instruments: An individual information frame, the UCLA Loneliness Scale were utilized as the information gathering devices in the exploration.

UCLA Loneliness Scale: It was created by Russell, Peplau, and Ferguson and was re-requested in 1980. It is a scale made of 20 things of which 10 are immediate and the other 10 turns around coded. In everything of the scale, a situation that expresses a sense or a pondered the social connection is exhibited and the people are requested to state how frequently they meet this condition, on a four–point Likert scale. The higher score is acknowledged as an indication of depression that is met once in a while. The least scores to be gotten from the scale is 20 and the most astounding is 80. The internal consistency coefficient as 0.96; and the correlation coefficient as 0.94 by the test-retest method.

Findings

Respondent Backgrounds

Table 1 shows the marital status of the respondents who participated in this survey. Among the elderly women in PKWTNS, only 2.6 percent were single, (n=2). Similarly, only 3.8 percent were married, (n=3). The majority of the elderly women were widows at 93.6 percent (n=73). The age distribution of the respondents, the percentage of those who were, 60-64 and 70-74 years old was the same at 30.8 percent, with 24 respondents for each age group. Next, 19.2 percent (n=15) were of 65-69 years old while 17.9 percent (n=14) were between 75-80 years old. The smallest age group was the 80 and above, with only 1.3 percent (n=1). Meanwhile, the level of education of the elderly women participating in this research was low. The majority at 53.8 percent (n=42) only finished lower secondary education (SRP), while 18 percent (n=14) had no education experience whatsoever. Only 28.2 percent (n=22) received basic education (SPM). The working history of respondents in this research were majority of the respondents were self-employed (60.2 percent, n=47). Those who were not working comprised of 26.9 percent (n=21). Out of all of the respondents, only 10.3 percent (n=8) were public workers while 2.6 percent (n=2) were working in the non-government sector. Many of the elderly women interviewed came from small families. Table 1 shows that the majority of the respondents at 46.2 percent (n=36) had only 1-4 children. The next largest group was with 5-9 children that comprised of 37.2 percent (n=29) of the respondents. Only 12.8 percent (n=10) had 10-14 children in their families, 1.2 percent (n=1) had 15-19 children and 2.6 percent (n=2) had no children. Besides, the person(s) whom the respondents spent most their time before coming to PKWTNS are almost half of the respondents (47.5 percent, n=37), lived alone prior to coming to institution. The remaining 52.5 percent were living with someone else, of which 3.8 percent (n=3) was with a husband or spouse while 48.7 percent (n=38) either lived with children, relatives, or others. Below the table shows the reasons to live in PKWTNS. The majority of them want a better life in the institution (21.8 percent) because they lack caretakers (19.2 percent), or because they have a family conflict (14.1 percent). A few respondents mentioned that they live in PKWTNS because they do not want to disturb their children (11.5 percent), or have been abandoned by children (10.3 percent) and lack of energy in doing household chores (6.4 percent). Other reasons for choosing to live in an institution are due to loneliness (10.3 percent) and being poor (6.4 percent). Table 1 shows the level of loneliness among elderly women in PKWTNS as determined using the UCLA Loneliness Scale instrument. It is worth nothing that none of the respondents reported "never" feeling lonely (0-20) and only 5.1 percent (n=4) were feeling minimal loneliness or "rarely" (21-40). A very large majority of respondents at 94.9 percent (n=74) were classified as "sometimes" feeling lonely (41-60). None of the respondents were classified as experiencing high levels of loneliness or "often" (more than 61).

The findings of regression analysis show the impacts of independent variables that are factors of demographic profile on respondents' loneliness. Based on the correlation analysis, only four factors showed insignificant value, network and communication and trust. Only factors with significant correlation value can be measured by the effects of regression analysis.

Table 2: Model Summary

Institution	Model	R	R Square
Private institution	1	0.778	0.689

The r square value in the Model Summary in table 2 shows the amount of variance in the dependent variable that can be explained by the independent variables. In the research, the independent variables together account for 7.78 per cent of the variance in the loneliness scores. The r value (0.778) indicates the multiple correlation coefficient between all the entered independent variables and the dependent variable.

Table 3: Regression

Model B	Std. Error		Beta	T	Sig.
Frequency of visitors	0.367	0.043	1.227	8.516	0.00
Period of stay	-0.248	0.030	-1.005	-8.232	0.00
Level of health	0.005	0.029	0.016	0.183	0.00

The coefficient for period of stay was -0.248 have shown in table 3. Hence, for every unit increase in frequency of visitors score, researcher expect a 0.367 point increase in the depression score keeping the scores for variables period of stay and level of health fixed. The result obtained was statistically significant ($p=0.00 < 0.05$). The coefficient for level of health is 0.05. Hence, for every unit increase in level of health score, researcher expects a 0.05 point decrease in the loneliness score keeping the scores for variables frequency of visitors and period of stay fixed. This is statistically significant ($p=0.03 < 0.05$). The coefficient for frequency of visitors was 0.367. Hence, for every unit increase in frequency of visitors score, researcher expect a 0.043 point increase in the depression score keeping the scores for variables period of stay and level of health was fixed. This result is statistically significant ($p=0.00 < 0.05$). Symbol of t and Sig. was a constant is significantly different from zero at the 0.05 alpha level as in $p=0.00 < 0.05$.These variables statistically significant predicted loneliness, $F = 25.143$, $p < 0.05$, $R2 = 0.716$. All three variables added statistically significantly to the prediction, $p < 0.05$. Furthermore, the researcher will discuss further on the relationship between loneliness and factors of demographic profiles among elderly women in private care institution. Meanwhile, the distribution of frequency of visitors was found that there was a significant relationship between frequency of visitors and loneliness among elderly women in institution. However, in this section, focus will be given on the residents who were never visited by their children, neighbors, friends, and relatives. It is human nature the lack of attention from loved ones could lead to mental illness, especially depression [8 10]. Hence, residents who did not have any visitors were detected as having loneliness. Elderly women who stayed longer in homecare tend to have loneliness [11 12]. In the present research, it was found that most of the residents are staying more than 12 months. Hence, this might be another factor in most of the institution residents having loneliness. This statement is also supported by other researches which indicated that the elderly who are staying at nursing homes tend to have loneliness, regardless of having proper activities because for them, staying with children is more important than staying in the nursing home [13 14 15]. Table 3 shows that the prevalence of loneliness was higher to them who were staying in institutions for longer more than 12 months a (37 people) as compared to those staying for less than 6 months (18 people). The rationale behind the increased prevalence of loneliness with increasing duration of stay could be due to the feeling of loneliness from the outside world especially in an institution [16 17 18]. Thus, there are significant positive relationships between duration of stay with loneliness among elderly women. The relationship between levels of health with loneliness is a well-known issue and has been reported by numerous other researches. The literature suggests that loneliness may increase the risk of the subsequent level of health among them. According [19 20 21], many of them have diabetes and other chronic medical conditions that are associated with an increased risk of depression. The presence of a chronic medical illness may in fact decrease the chances of recognition and therefore treatment of loneliness in the setting. The more severe condition of the illness, the higher the risk of loneliness [22]. A meta-analysis of interventions among elderly women with diabetes and loneliness showed that both psychotherapies and antidepressants were efficacious in treating loneliness among the elderly women with diabetes. In the study, the relationship between financial support and loneliness among elderly women in institution was investigated. According to [23 24] most of them are economically disadvantaged. In those

cases, the economic crisis especially unemployment acts as a precipitant among elderly women. It is therefore especially important to screen for loneliness among them during these periods of economic hardship. In other researches by [25] loneliness among elderly women was found to be related to financial difficulties and poverty where lack of financial support was cited as the most prevalence factors for the occurrence of loneliness.

Conclusion

As a conclusion, the study on the prevalence between demographic profiles and loneliness among elderly women in private care institution is important to raise awareness about this alarming issue in the society especially among elderly women. Hence, the findings of this research will give a better understanding regarding function of the nursing home in reducing loneliness among them.

Prevalence and Risk Factors Associated with Bacterial Food Poisoning in College Students at the Primary Care Unit

Pat Nonjui[1], Wilawan Aunruean[2], Arkhom Bunloet[1]

[1]Lecturer, Department of Community Medicine, Faculty of Medicine, Khon Kaen University, Thailand,
[2]Registered nurse, Primary Care Unit 123, Khon Kaen University, Srinagarind Hospital, Thailand

Abstract

Food poisoning is defined as illness caused by the consumption of contaminated food, of which bacteria is a major cause. Khon Kaen province has the fourth highest rate of food poisoning in Thailand. A previous study in the province found raw meat contaminated with *Escherichia coli*, *Salmonella enterica*, and *Staphylococcus aureus*. The most commonly contaminated meat was pork, followed by beef and chicken. Despite this, there is insufficient awareness and concern regarding fsood poisoning among undergraduate students in the area, more than half of whom had experienced illness caused by consumption of local food. As there have been few studies conducted to examine food poisoning in college students in northeast Thailand, this retrospective descriptive study aimed to determine the prevalence and risk factors associated with bacterial food poisoning in these students at a primary care unit. Data were gathered from outpatient records, outbreak investigation data, and the electronic database at Primary Care Unit 123, Khon Kaen University, Srinagarind Hospital between August 2015 and July 2018.

The data of 155 participants, most of whom were female, were included in the study. The prevalence of bacterial food poisoning confirmed by rectal swab culture was 26.5%. The most common cause of illness was *Vibrio Parahaemolyticus* (39.0%), followed by *Plesiomonas shigelloides* (22.0%), *Vibrio Parahaemolyticus* with *Plesiomonas shigelloides* (12.2%), and *Salmonella* spp. (9.8%). Mucus in the stool (OR=8.40, 95% C.I=1.24-56.81) and consumption of papaya salad (OR=2.77, 95% C.I=1.22-6.27) were statistically significant risk factors for bacterial food poisoning in this group.

Keywords: *food poisoning, college student, primary care, factor, stool culture*

Introduction

Food poisoning is defined as an illness caused by the consumption of contaminated food. Bacteria is the cause of such outbreaks in about 75% of cases[1]. In the United States, most illnesses are caused by norovirus, and 39% are caused by bacteria, including nontyphoidal *Salmonella* spp., *Clostridium perfringens,* and *Campylobacter* spp.[2]. In 2018, there were 122,006 reported cases of food poisoning in Thailand, most commonly in patients aged 15-24, primarily caused by *Vibrio parahaemolyticus* and *Salmonella* spp. Khon Kaen province has the fourth highest rate of food poisoning in Thailand[3,4]. A previous study in the province found raw meat contaminated with *Escherichia coli, Salmonella enterica,* and *Staphylococcus aureus*. The most commonly contaminated meat was pork, followed by beef and chicken[5]. Despite this, there is insufficient awareness and concern regarding food poisoning among undergraduate students in the area, more than half of whom had experienced illness caused by the consumption of local food. Although about 27% of students in the area required medical care because of foodborne illness, approximately 35% continue to eat raw food[6]. As there have been few studies conducted to examine food poisoning in college students in northeast Thailand, this study aimed to determine the prevalence and risk factors associated with bacterial food poisoning

e-mail:patno@kku.ac.th

in these students at a primary care unit.

Method

Study design

This retrospective descriptive study was conducted using data from outpatient documentation at the Primary Care Unit 123, Khon Kaen University, Srinagarind Hospital (PCU 123 KKU), the routine national infectious diseases report (R506 report) and Srinagarind Hospital's electronic database from August 2015 to July 2018. This study was approved by the Center for Ethics in Human Research, Khon Kaen University (Sub office) (Reference No. HE611391).

Participants

We included data from 155 participant's in the study. The inclusion were as follows: 1) the patient was a college student 18 years of age or older, 2) the patient was clinically diagnosed with bacterial food poisoning, and 3) rectal swab culture results were available. Any cases in which there were insufficient data were excluded from the study

Data collection

Outpatient documentation from PCU 123 KKU, data from the routine national infectious diseases report (R506 report), and data from the Srinagarind Hospital electronic database were reviewed. Microsoft Excel 2016 was used to record the data.

Statistical analysis

SPSS Statistics version 26.0 was used for data analysis. Descriptive analysis was presented as percentages, medians, and interquartile ranges. A Chi-square Test and Fisher's Exact Test were used to examine the relationship between each independent variable and rectal swab culture results by crude OR with 95% confidence interval. The significance level was set at 0.05.

Results

The 155 patients included in the study. All were from 18 to 26 years old with a median of 21 years old. Most (65.8%) were female, and 12.3%, 11.0%, and 10.3% belonged to the Faculty of Science, Faculty of Agriculture, and Faculty of Humanities and Social Science, respectively. Most experienced abdominal pain (85.8%) and fatigue (71.0%). Watery stool (58.1%), mushy stool (53.5%), strong-smelling stool (19.4%), and mucus in the stool (3.2%) were common fecal symptoms. A total of 9.0%, 3.9%, and 3.2% of patients had previously used acetaminophen, Salol et Menthol Mixture, and activated charcoal, respectively. Only 3.2% of patients had taken antibiotics before visiting the primary care unit. Patients reported having eaten high-risk foods including papaya salad (20.6%), Thai barbecue (18.7%), and noodles (18.1%). Approximately 112 patients (70.0%) had moderate dehydration.

The prevalence of bacterial food poisoning was 26.5%. The most common causes of illness were *Vibrio Parahaemolyticus* (39.0%), *Plesiomonas shigelloides* (22.0%), *Vibrio Parahaemolyticus* with *Plesiomonas shigelloides* (12.2%), and *Salmonella* spp. (9.8%), as shown in Table 1.

Table 1 Rectal swab culture results in college students at the primary care unit

Results of rectal swab culture (n = 41)	No. (%)
Vibrio Parahaemolyticus	16 (39.0)
Plesiomonas shigelloides	9 (22.0)
Vibrio Parahaemolyticus with Plesiomonas shigelloides	5 (12.2)
Salmonella spp.	4 (9.8)
Aeromonas spp.	3 (7.3)
Vibrio cholera	2 (4.9)
Shigella Flexneri group B	1 (2.4)
Plesiomonas shigelloides with Salmonella spp.	1 (2.4)

One hundred twenty patients were prescribed antibiotics (77.4%; 78.8% of those with negative rectal swab cultures 75.6% of those with positive cultures), all of whom received norfloxacin. Durations of antibiotic treatment were five days (45.8%), three days (18.1%), and seven days (8.4%).

Mucus in stool and consumption of papaya salad were significantly associated with bacterial food poisoning. Students with mucus in their stool were about eight times more likely to have bacterial food poisoning than those without (OR=8.40, 95% C.I=1.24-56.81). And students with history of consumption of papaya salad were about three times more likely to have bacterial food poisoning than those without (OR=2.77, 95% C.I=1.22-6.27).

Discussion

In 2018, 1,230,314 patients were diagnosed with food poisoning without confirmation via diagnostic test in Thailand, the majority of whom were female. The mortality rate was approximately 0.01 per 100,000 population[7]. We found that most cases were caused by *Vibrio parahaemolyticus*, a common cause of seafood-borne illness in many Asian countries[8], which is consistent with the findings of another study conducted in Khon Kaen. However, the second and third most common causes in the previous study were Escherichia coli and Salmonella spp.[9], respectively, whereas those in our study were Plesiomonas shigelloides and Vibrio parahaemolyticus with *Plesiomonas shigelloides*, respectively, followed by *Salmonella* spp. This may have been due to the fact that the previous study included all patients, including those in the inpatient department, where ours only included college students in the outpatient clinic of the primary care unit. In the previous study, diarrhea was the most common symptom for *Vibrio parahaemolyticus* infection and was associated with abdominal cramps, nausea, and vomiting. The food vehicle for *Vibrio parahaemolyticus* infection was seafood or cross-contamination with seafood, especially raw fish or shellfish.[8,10,11]

The second most common cause of bacterial food poisoning in our study was *Plesiomonas shigelloides.* Plesiomonads can colonize in cows, pigs, poultry, and – in tropical areas – fish and shellfish[12]. The consumption of raw and undercooked food is common in Southeast Asia[13,14]. In our study, the consumption of papaya salad statistically significant increase the risk of bacterial food poisoning. Although we did not find an association between the consumption of seafood and bacterial food poisoning, some types of papaya salad contain seafood. Moreover, previous studies found that the microbiological quality indices for *Staphylococcus aureus* and *Escherichia coli* contamination in green papaya salad exceed the standard limits and that coliform bacteria was most-commonly found in this type of food[15,16] Another study found the consumption of chicken rice, food containing coconut milk, fried rice, and leftover food to be associated with food poisoning. [4].According to the Thailand treatment guidance of acute diarrhea for community pharmacist, antibiotics should be prescribed when patients have mucous or blood in the stool with a history of fever (higher than 38.5 °C). A 3-5 day course of 400 mg of norfloxacin b.i.d. is recommended as first-line treatment[17]. However, only 62.1% of patients were prescribed three-to-five-day antibiotic treatment. All of the patients who did undergo antibiotic treatment received norfloxacin.

Bacterial enteropathogens produce acute watery diarrhea, so this condition is clinically nonspecific. However, the passage of bloody stools suggests possible bacterial colitis, which is often caused by *shigella*, *campylobacter*, nontyphoid *salmonella*, and Shiga toxin-producing *E. Coli*[18]. Diarrhea, abdominal cramps, nausea, vomiting, headache, fever, and chills are symptoms of *Vibrio parahaemolyticus* infection. In the most severe cases, watery diarrhea is associated with mucus, blood, and tenesmus[11]. Although a previous study found that stool with visible mucous and did not indicate a specific infecting agents, stool examination is still useful in the diagnosis of patients with diarrhea[19].

Conclusion

About one-fourth of the clinical diagnoses of bacterial food poisoning were confirmed via rectal swab culture. A history of consumption of papaya salad and mucus in the stool were associated with bacterial food poisoning.

Acknowledgments: The authors would like to a thank the staff at the PCU 123 KKU for their assistance in our study.

Abstract

Background: Thailand has been deployed the health coverage policy which integrated into the activities of health promotion hospitals and the local administrative organization to provide the health promotion program for Thai people. Due to the population aging in Thailand had been increasing and expanding the number which experiences aging process incorporate with underlying diseases.

Objectives: This study aims to assess sources of information and experiences of participated proportion in health promotion programs among the elderly funded by the National Health Security Local Fund (NHSLF) in Northeastern Part of Thailand.

Methods: A descriptive study was conducted. Sample size calculation to estimate a proportion and systematic sampling was used. The sample included 577 elders 60 or more years of age, registered at 54 Primary Care Unit (PCU) and health promotion hospital in Khon Kaen and Kalasin province, Thailand. A structured questionnaire was used to collect the information which reviewed and tested by experts and Cronbach's alpha was 0.81.

Results: The response rate was 97.57%. The elders comprised more females than males (mean age 64.82, SD 1.36). The proportion of the elderly who perceived information on elderly health promotion services program funded by the NHSLF was 79.2%. The highest source of information proportion that the elderly perceived elderly health promotion services program were village health volunteers (80.3%), public health personnel (60.5%) and community leader announce via community broadcasting program (50.9%). This study also found the highest experience of participating in the elderly health promotion program was nutritional assessment screening, joined the community elderly club, and trained for appropriate exercise. In addition, this study also found having caregivers related to the elderly health promotion services program funded by NHSLF with statistically significant.

Conclusion: The humanize communication by community health volunteers and public health personal were good sources for access to health information among the elderly. In addition, the nutritional assessment joined the community elderly club and trained for appropriate exercise were popular activities among the elderly. The two-way communication technique and family caregiver made the elderly can access health information and participated in the health promotion program.

Introduction

According to the Thai government's policy created universal health coverage for the people since 2001 to make people access the medical services and public health by equal quality standards cover all areas as

well as promote encouraging health accessibility. In the universal coverage program, the NHSLF was an important part to enhance the participation of the sector in the management of community health systems by the cooperation between the local government organizations, health promotion hospitals, and the community. The important principles of the NHSLF were to support the budget for health promotion operations, disease prevention, medical treatment, and rehabilitation, as well as building a collaborative learning process between related organization-level and community level.

The elderly are the one special group that must be cared for inevitably due to the aging process dealing with the life events and social change that made the elderly fall into the high risk of diseases and disability. The Thai elderly health status found about three in five respondents (56%) reported that their health was either fair or very bad/bad [1]. In addition, three in four of Thai elderly had underlying diseases and mostly experienced at least one symptom in the past six months [2]. Therefore, the NHSLF supports health promotion programs for the elderly to improve their overall well-being. Understanding the health promotion project accessibility and involvement among the elderly of the health promotion program would be beneficial for policy and planning the project regard the elderly health in the community and another similar community context in Thailand.

Objectives

This study aims to assess sources of information and experiences of participated proportion in health promotion programs among the elderly funded by NHSLF in the Northeastern part of Thailand.

Materials & Method

A descriptive study was conducted in Khon Kaen province and Kalasin province, located in the Northeastern part of Thailand. The inclusion criteria were the elderly aged 60 years and over, living in the community where the provided the health promotion program and registered at 54 Primary Care Unit (PCU) or health promotion hospital in Khon Kaen and Kalasin province, Thailand. The exclusion criteria were the elderly who had severe health problems and were unable to communicate and participate. The sample size calculation was calculated based on a pilot study as assumed proportion = 0.40. The Win Pepi program was used for a sample size calculation with a confidence level of 95%, Acceptable difference = 0.04. Therefore, the sample size required 577samples.

The study tool was a questionnaire, comprising 3 parts: socio-demographic characteristics, source of information and participation in elderly health promotion programs funded by the National Health Security Local Fund. The questionnaire was reviewed and tested by experts and the reliability test found the Cronbach's alpha was 0.81.

Data were collected through the well-trained interviewers. The data was entered and transferred into the SPSS of Khon Kaen University licensed for data analysis. The data were analyzed using frequency, percentage, mean, SD and 95%CI, chi-squared.

Results

The response rate was 97.57%. The elders comprised more females than males (59.88%) and the mean age was 64.82 (SD 1.36) years old. had completed primary school (91.70%), half of the respondents were married (56.97%).

The highest proportion of the elderly experience in participated in the health promotion program funded by NHSLF were nutritional assessment (71.7%), joined the community elderly club (60.1%), and trained for appropriate exercise (50.0%) respectively.

The proportion of the elderly who perceived information on elderly health promotion services program funded by the NHSLF was 79.2%. The highest source of information proportion that the elderly perceived health promotion services program were village health volunteers (80.3%), public health personnel (60.5%) and community leader announce via community broadcasting program (50.9%) respectively. The lowest source of information proportion that the elderly perceived elderly health promotion services program were leaflet (4.0%), newspaper (4.7%), and radio (10.1%) respectively. (Table1)

Table 1 Source of information proportion that the elderly perceived elderly health promotion services program

Variables	Number	Percentage
Perceived information on elderly health promotion services program funded by the National Health Security Local Fund (n=563)		
Yes	446	79.2
No	117	20.8

Discussion

This study found nearly eighty percent perceived information on elderly health promotion services program funded by the NHSLF. Health promotion has long been recognizing as a tool and strategy for prevention of functional decline and improving the health and quality of life among the elderly [3]. Similar to the study of Booranarek et al [4] found most of the elderly reported easily and conveniently accessible to health services (91.19%). The information that the elderly perceive might be a protective factor that increases control with affect to the elderly health behavior and become even more important, particularly with regard to maintaining functional independence and improving quality of life (QoL) [5].

Regards nearly eighty percent that the elderly perceived health promotion information, the most source of information that the elderly accessed was from their social networks such as community health volunteers, public health personals, and community leaders. The social network influences the elderly as a primary factor in the adoption of health behaviors and their quality of life [6, 7]. The social interaction between the elderly and their social network were communicated by the two-way communication which the sender transmits a message to another person, who is the receiver. When the elderly get the message, they send back a response, acknowledging the message was received. This technique was effective to the elderly people who are the functional decline, facing with the hearing problems and poor eyesight. The two-way communication made the elderly easy to send back the response, and ask for more information. In addition, the health volunteers and public health personals working closely with the elderly, therefore, the elderly easily access those other sources of health promotion information.

Health promotion programs for the elderly funded by NHSLF includes health promotion activities, health screening, and prevention activities for decrease complications of the diseases and rehabilitation program. The most frequent that the elderly joined were nutritional assessment, joined the community elderly clubs, and trained for appropriate exercises. Due to functional decline may be the main reason for the high risk of malnutrition and increases the risk of multi-morbidity, and disease-related malnutrition [8]. The nutritional screening might be benefits to the elderly to meet the nutritional needs of people at old age.

The elderly joined the community elderly club benefit for social interaction with other peoples including the community health volunteers and public health personals that consequently the information in health promotion program [9]. Piriyakunkit et al [10] stated the elderly persons who were members of the elderly club had significantly higher knowledge about the elderly club activity than those who were not members. This study also found more than half of the elderly trained and joined exercise for the elderly club activities, similar to Ethisan et al [11] found 58.7% of the elderly performed exercise such as brisk walking, housework, and aerobic exercise which the elderly easily to perform by themselves no sporting equipment and practicing at their residence.

In part of factor related to perceived information on elderly health promotion services program, the elderly caregiver plays an important role to assist the elderly in psychological support, financial support, information support, and support the elderly in daily life [12], and also assistant to accessibility to the source of health promotion information.

Conclusions

The highest source of health promotion information among the elderly were community health volunteers, public health personnel and the elderly participated in the nutritional assessment, joined the elderly club, and trained for appropriate exercise regards the health promotion project funded by NHSLF. Two-way communication by close up people and the family caregiver made the elderly accessed health information and participated in the health promotion program.

Identification of Norovirus Infection in Adults with Acute Gastroenteritis in Jambi, Indonesia

Putri Sari Wulandari[1], Rury Mega Wahyuni[2], Mochamad Amin[2], Laura Navika Yamani[2,3], Takako Utsumi[4], Maria Inge Lusida[2,5], Juniastuti[1,2,5]

[1,5]Master Program of Tropical Medicine and Department of Microbiology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [2]Institute of Tropical Disease, Universitas Airlangga, Surabaya, Indonesia, [3]Department of Epidemiology, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [4]Center for Infectious Diseases, Kobe University Graduate School of Medicine, Kobe, Japan, Uniastuti

Abstract

Background: Norovirus (NoV) infection is the most common cause of non-bacterial acute gastroenteritis (AGE), which affects both adults and children. However, study of NoV in adults with AGE in Indonesia is still limited.

Objectives: This study aimed to investigate the incidence and clinical characteristics of NoV infection, and also genotype distribution of NoV in adults with AGE in Jambi, Indonesia.

Methods: Stool samples were collected from adults (≥18 years of age) with AGE at 3 participating hospitals in Jambi from February to April 2019. The detection of NoV and its genotyping were carried out by Reverse Transcriptase PCR and direct sequencing.

Results: Of the 44 stool samples collected, 4 (9.1%) were positive for NoV. Four different genotypes were identified, namely GI.2, GII.3, GII.6, and GII.20. All adults with AGE and NoV-positive showed abdominal pain and no dehydration, most of them experienced watery diarrhea (75%) for <5 days and half of them showed vomiting for 1 day.

Conclusion: NoV was detected in 9.1% of adults with AGE. The various rare genotypes of NoV in Indonesia were identified in Jambi. The common symptoms in AGE infected with NoV included abdominal pain and watery diarrhea with a short duration. Further surveillance is needed to complete the database of circulating NoV strains for its control.

Keywords *: Norovirus, genotype, acute gastroenteritis, adult, Indonesia*

Introduction

Acute gastroenteritis (AGE) is one of the most common illnesses and a major public health problem worldwide. Approximately 1.7-5 billion cases and nearly 1.7 million AGE-associated deaths still occur each year.[(1)] Over the eight-year study period, gastroenteritis-associated deaths from all causes increased from nearly 7,000 to more than 17,000 per year. Adults over 65 years old accounted for 83% of deaths. Norovirus (NoV) was one of the most common infectious causes of gastroenteritis-associated deaths.[(2)]

Noroviruses have been recognized as the leading cause of epidemics of gastroenteritis and an important cause of sporadic gastroenteritis in individuals of all ages in both developed and developing countries.[(3)] It is estimated that NoVs account for 12% of severe

gastroenteritis cases (hospitalized) among children under-5 years and 12% of mild and moderate diarrhea cases (outpatient) among persons of all ages.[4] Clinical infection with NoV generally has an incubation time of 12 to 48 hours, with nausea, vomiting, watery diarrhea, and abdominal pain.[1]

Norovirus, a member of the family Caliciviridae, is a non-enveloped, positive-sense, single-strand RNA virus. Its genome contains approximately 7.7 kb in length, which is organized into three open reading frames (ORFs): ORF1 encodes non-structural proteins including the RNA-dependent RNA polymerase (RdRp), ORF2 encodes the major capsid protein VP1, and ORF3 encodes the minor structural protein VP2. NoV is classified at least into 7 genogroups, GI–GVII. GI, GII, and GIV genogroups have been found in humans[5,6,]. More than 30 genotypes were characterized within the 7 genogroups[7,8].

Acute gastroenteritis is one of the most common public health problems in Indonesia and other countries. During the past several years, most studies of NoV infection in Indonesia focused on the role of human NoV in AGE in children, while the study of NoV in adults with AGE is still limited. In Jakarta, Indonesia, Norwalk-like viruses (NLV) were detected in 9.7% from patients >12 years of age with acute AGE.[9] Another study in Surabaya, Indonesia reported that the prevalence of NoV in asymptomatic adult population was 2.7%.[10]

Jambi is a capital and the largest city of Jambi province, located on the east coast of cental part of Sumatra island, Indonesia. Ministry of Health of Indonesia reported 96,397 diarrhea cases in all ages in Jambi[11] with the prevalence about 4.1%,[12] however the causative agents have not been reported. This study aimed to investigate the incidence and clinical characteristic of NoV infection, and also genotype distribution of NoV in adults with AGE in Jambi, Indonesia.

Methods

Sample and clinical data collection

Stool samples were collected from adults (≥18 years of age) with AGE at 3 participating hospitals in Jambi, Indonesia between February to April 2019. They were collected within the first 48 hours after admission according to the World Health Organization (WHO) protocol[13] and examined in Institute of Tropical Disease, Universitas Airlangga, Surabaya, Indonesia. Acute gastroenteritis was defined by the diarrhea (≥3 loose stools or liquid stools within a 24 hours period) and lasts no longer than 14 days, possibly accompanied by vomiting, fever, and abdominal pain. The level of dehydration were classified according to WHO.[14] The characteristics (age and sex) and clinical data of the patients were retrieved from medical records.

RNA extraction and reverse transcriptase polymerase chain reaction (RT-PCR)

A 10% (w/v) stool suspension of each sample in distilled water was prepared, then the supernatant was subjected to RNA extraction using QIAamp Viral RNA Mini Kit (Qiagen, Valencia, CA). The extracted RNA was reverse transcribed and amplified using Superscript III reverse transcriptase (Invitrogen, New York, NY) and random primers (Takara Bio, Kyoto, Japan). Polymerase chain reaction (PCR) amplification was subsequently performed to detect NoV GI and GII in the capsid gene (VP1) using the previously published primer pair of G1SKF/R and G2SKF/R, respectively.[15]

PCR products were electrophoresed on a 2% agarose gel containing ethidium bromide and visualized under UV illumination.

Sequencing and sequence analysis

Amplified cDNA fragments were sequenced by a direct sequencing method with the BigDye terminator cycle sequencing kit using an Applied Biosystems 3500XL Genetic Analyzer (Applied Biosystems, Foster, CA).

Nucleotide sequences were aligned with the reference strains by the program Molecular Evolutionary Genetic Analysis (MEGA) X (http://www.megasoftware.net). Phylogenetic trees were constructed by the Neighbor Joining method and bootstrap resampling was performed 1000 times.

Results

Study population

A total of 44 stool samples were collected from adults with AGE at 3 participating hospitals in Jambi city. The age of patients ranged from 19 to 78 years (median, 45 years). More patients were female (56.8%), with the sex ratio (female/male) was 1.3.

Virus detection rate and clinical characteristics

Of the 44 stool samples collected, 4 (9.1%) were positive for NoV. Noroviruses were identified mostly in adults 36-64 years of age group (ranged 34-70 years, median 45 years, mean 48.5 years) and more frequently in female patients (75%) of cases.

Most of adults with NoV-positive had watery diarrhea (75%) for <5 days, while half of the adults showed vomiting for 1 day. Abdominal pain and no dehydration were observed in all adults with AGE and NoV-positive (Table 1).

Genogroup and genotype of NoV

Among 4 NoV-positive stool samples, most of them was classified as GII genogroup (75%) and the rest was GI. Four different genotypes were identified, namely GI.2, GII.3, GII.6, and GII.20 (Figs. 1-2).

Table 1. Clinical characteristics among adults with AGE

Clinical characteristics	**NoV-positive (n = 4)**	**NoV-negative (n = 40)**
Fever (>38ºC)		
• Yes	1 (25%)	22 (55%)
• No	3 (75%)	18 (45%)
Vomiting		
• Yes	2 (50%)	25 (62.5%)
Frequency of vomiting (episodes/day)		
1-4	1 (50%)*	10 (40%)*
≥5	1 (50%)*	15 (60%)*
Duration of vomiting (days)		
1	2 (100%)*	17 (68%)*
≥2	0 (0%)*	8 (32%)*
• No	2 (50%)	15 (37.5%)
Diarrhea		
• Stool type		
Watery	3 (75%)	17 (42.5%)
Mushy	1 (25%)	23 (57.5%)^
• Frequency of diarrhea (times/day)		
3-9	2 (50%)	23 (57.5%)
≥10	2 (50%)	17 (42.5%)
• Duration of diarrhea (days)		
1-4	4 (100%)	34 (85%)
≥5	0 (0%)	6 (15%)
Abdominal pain		
• Yes	4 (100%)	36 (90%)
• No	0 (0%)	4 (10%)
Dehydration		
• No dehydration	4 (100%)	32 (80%)
• Mild to moderate dehydration	0 (0%)	8 (20%)

* The percentage was calculated using the number of patients with vomiting only as a denominator ^ 1 patient have mushy and bloody stool type

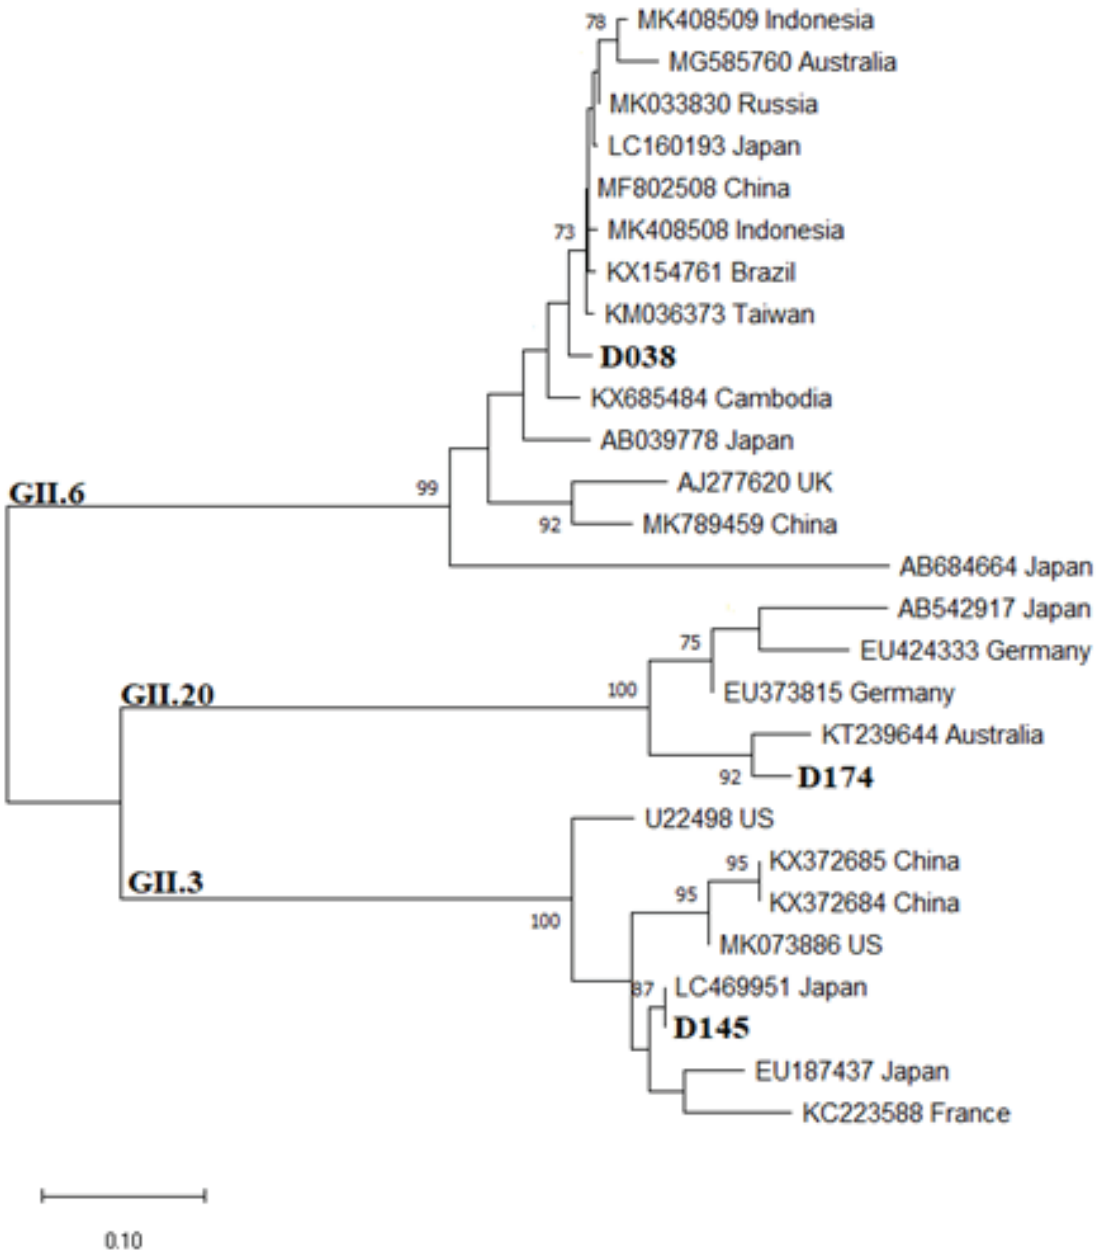

Fig 2. Neighbor-joining phylogenetic tree of partial sequences of the capsid (VP1) of 3 NoV GII isolates from Jambi (shown in bold) and 24 reference strains

Discussion

In this study, the proportion of NoV in adults with AGE was 9.1% in Jambi, quite similar to that in the ≥12 years with AGE in Jakarta, Indonesia (9.7%)[9], but more than that in asymptomatic aduls in Surabaya, Indonesia (2.7%)[11]. However, the rate was lower than the previous studies in China, United States, and France (17.0%-49%).[16-18]

The percentage of GII NoV (75%) strains detected was greater than GI NoV (25%). It confirmed the previous report that GII NoV was the most prevalent (96%) of all sporadic AGE worldwide.[19] Our study identified GI.2, GII.3, and GII.20 genotypes which have never been reported in Indonesia, and GII.6 genotype which has already been reported previously in children <5 years of age hospitalized with AGE in other cities in Indonesia.[20]

In other countries, NoVs with genotypes GI.2, GII.3, GII.6, and GII.20 have been reported. Norovirus GI.2 emerged in Singapore in 2014 causing outbreaks of NoV AGE in military camps.[21] This genotype was also reported in ice-associated NoV outbreak in Taiwan, 2015. Norovirus GI was reported more predominant in waterborne outbreaks.[22] Genotype GII.3 is a major cause of sporadic gastroenteritis, particularly in children[23] and it was identified also as a causative agent of gastroenteritis outbreaks in China [24] and Australia. [25] Genotype GII.20 was reported in a small number among gastroenteritis cases in Thailand in 2007 and Australia during 2013-2014.[26,27] GII.6 is one of the common agents of gastroenteritis.[28] An AGE outbreak caused by NoV GII.6 was first reported in China in 2013. [29] In 2015, GII.6 accounted for 10% of NoV infections, whilst before 2014 it was identified only sporadically. Circulation of GII.6 has also been reported elsewhere in recent years.[30,31] These findings suggest that this genotype has an important epidemiological role in NoV incidence.[28] Our finding of rare genotypes in Indonesia is interesting, however it needs further surveillance on a larger scale.

The predominant symptoms of NoV infection were vomiting and diarrhea, generally of a short duration.[32] Diarrhea occurred more frequently in people aged >18 years infected by NoV, whereas in the ≥65 years age group, the predominant symptom was diarrhea (87.9%) and vomiting (52.9%).[33] In 4 outbreaks over 3 years in an inpatient psychiatric unit in Taiwan that affected 172 patients and 7 health care workers, the most common symptom was diarrhea (87.5%), followed by vomiting (25.5%), abdominal pain (4.4%) and fever (2.2%).[34] In our study, watery diarrhea for <5 days was common in adults with NoV-positive, while vomiting for 1 day was found in half of the patients. Abdominal pain and no dehydration were observed in all adults with AGE and NoV-positive (Table 1). Generally, they showed mild symptoms with a short duration, which is quite similar with the previous studies.

Conclusion

Norovirus was detected in 9.1% of adults with AGE in Jambi, Indonesia, with various genotypes of NoV. The common symptoms in the adults with AGE and NoV-positive included abdominal pain and watery diarrhea with a short duration. Norovirus genotyping should be performed continuously to provide databases of circulating NoV strains for its control.

Acknowledgment: The authors are grateful to all participants who provided stool specimens for supporting the specimen collection.

Conflict of Interest: There was no conflict of interest in this study.

Ethics Statement: The ethical clearance was obtained from the Ethics Committees of Faculty of Medicine and Health Science, Universitas Jambi, Indonesia (No. B/248/UN21.8/PT.01.04/2019). Informed consent was provided by the parents or guardians of each child' to patients.

Source of Funding: This study was supported by a grant from Faculty of Medicine, Universitas Airlangga.

Classification of Neonatal Mortality Risk Factors

Raesita Aliefa Sekardira[1], Sulistiawati[2], Risa Etika[3]

[1]Clinical Student at Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [2]Head of Department of Public Health-Preventive Medicine, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [3]Lecturer at Department of Child Health, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background: The efforts to reduce neonatal mortality were not optimal as targeted by MDGS's 2015. The number revealed, seen from the mortality rate of neonatal, is still quite high. This study aims to determine and to classify the risk factors of neonatal mortality in Situbondo district based on neonatal factors, maternal factors, and health care factors. **Method:** a retrospective descriptive research with survey research design and secondary data was used. The population of this study were neonates who died at RSUD Dr. Abdoer Rahem Situbondo period 2015-2016 in total sampling according to inclusion and exclusion criteria. The number of samples that fulfilled the inclusion and exclusion criteria was 50 people. **Result:** The results showed that of 50 neonatal mortality consisted of 46 (92%) early neonatal mortality and 4 (8%) late neonatal mortality. Neonatal mortality were most common in neonates of male sex, low body weight, premature, and asphyxia. Based on maternal factors, neonatal mortality occurs in mothers of <20 and> 35 years of age, primary education, housewives, less family income, less or more nutritional status, abdominal massage history, incomplete ANC, women with no previous birth (nulliparous) and deliver normally. **Conclusion:** Factors affecting neonatal mortality are classified into three components, namely neonatal factors, maternal factors and health service factors.

Keywords: *risk factors, neonatal mortality, classification, maternal, health service.*

Introduction

Neonatal mortality constitute 2/3 of infant deaths.[1,2] Based on the results of the 2012 Indonesian Demographic and Health Survey (IDHS), the Neonatal Mortality Rate (NMR) was 19 per 1,000 live births.[3]

Neonatal mortality is perinatal disorders as a result of high-risk pregnancies such as asphyxia, low birth weight babies, and birth trauma. The degree of neonatal health itself is also closely related to the health of the mother during pregnancy, knowledge of the mother and family about the importance of antenatal care delivery and new-born care and the availability of health facilities. [4] Factors affecting infant safety include age, parity and birth spacing. In addition, many factors influence it, among others, mothers rarely check the content to health facilities, pregnant at a young age, distance that is too close, pregnant at old age, lack of nutrition for mothers and infants, food consumed by unclean mothers, sanitation facilities and inadequate hygiene.[5]

In 2014, the number of infant mortality in Situbondo was higher (53.06 per 1,000 live births) than the total infant mortality in East Java province. This figure was not insignificant and requires serious treatment from the local health service system to overcome the incident.[6]

Method

This study aims to analyse the description of classification of neonatal mortality risk factors. Retrospective descriptive using primary data from interview surveys and secondary data, namely medical records was used in this study.

Sample, Research Instrument and Data Analysis

The research samples were neonates who died in Dr. Abdoer Rahem Situbondo District Hospital starting from January 2015 to December 2016. The instrument checklist included the recorder condition of patients who experienced neonatal mortality in secondary data or medical records and confirmation of data using structured questionnaires. The data collected was analysed based

on the formulation of the research problem using the Microsoft Excel 2013 program.

Result

Neonate Factor (Table 1)

Male neonates mortality were had higher percentage (56%) than women. Neonatal birth weight in the moderate or normal birth weight group was 20 neonates, while 60% were outside the normal group either in the group of underweight or more. The highest gestational age was in the preterm group with 35 neonates and the lowest was in the serotines/postdate group with 1 neonate. The most common cause of neonatal mortality was asphyxia with a percentage of 32%. The majority of neonates were in the age category of early neonatal mortality with a percentage of 92% neonates.

Maternal Factors (Table 2)

It is known that the age of most mothers was in the high risk group of 27 mothers, the highest level of education of mothers was elementary school with a percentage of 40% mothers. Mother's work was a housewife with a percentage of 60% mothers, family income was less by 52% families, mothers with normal nutritional status was as much as 38%, while mothers with less nutritional status and more was as much as 62%.

History of consumption of herbal medicine was about 16% mothers. History of abdominal massage during pregnancy was 72% mothers, mothers who did antenatal examinations <4 times were 54% mothers, most were nulliparous with a percentage of 52% mothers. The majority of parturition process was spontaneous (80%). The most complications of parturition was premature rupture of membranes as many as 7 mothers and there were 29 mothers who did not experience childbirth complications.

About 90% of mothers do not experience medical problems during pregnancy. Meanwhile, the most obstetric problems experienced by mothers were anaemia by 12%, mothers.

Health Service Factor (Table 3)

The most neonatal childbirth places were in the Hospital of Dr. Abdoer Rahem as many as 19 neonates and the least in primary care (Polindes/Poskesdes) was 1 neonate. Distance of home to the place of delivery was the most in the close group as much as 80%.

Discussion

More neonates are male than female with a ratio of 1.2: 1. Biological factors involved with an increased risk of neonatal death in male infants are delayed immune system maturity which increases the risk of infectious diseases,[7] also results in high respiratory diseases[8] and congenital malformations of the urogenital system in male infants.[9]

Neonates with lower birth weight are more likely to die, as many as 56%. Low birth weight is universally recognized as a major risk factor for major neonatal mortality. It is known in other studies that 52% of neonates who die have a birth weight <500 grams.[10]

The most gestational age was in the range of 28-36 weeks or preterm gestational age (70%). The risk of infection and sepsis increases in premature births which will result in mortality if proper medical care is not sought as early as possible.[11] The most common cause of mortality was asphyxia (32%). Asphyxia is a condition in when a new-born baby or shortly after birth is the failure to start and continue breathing spontaneously and regularly.[12]

The age range of 0-7 days or often referred to as early neonatal mortality was 92%. The risk of neonatal mortality has increased during the early days of their lives.[13, 14] The high risk of neonatal mortality occurs in mothers under the age of 20 years and more than 35 years. This period is the safest for giving birth because the reproductive organs have developed perfectly.[15, 16]

This study was found that 62% of neonatal mortality occur in mothers with low education levels. This shows that mothers with low education pay less attention to the conditions of pregnancy and childbirth.[17, 18] The majority of mothers were 60% housewives. The dominance of housewives as maternal occupation can be related to factors that influence neonatal mortality due to low income families is not tended to spend their income for health care costs.[11, 19,20-22]

Neonatal mortality occurred in mothers with under and over nutritional status (62%). The nutritional status of the mother before and during pregnancy greatly affects the growth of the fetus. Babies born with low weight and premature are generally less able to reduce new environmental stresses which can cause stunted growth and development and can even interfere with their survival.[23-29]

There were 16% of respondents who consume herbal medicine during pregnancy. Mothers who during pregnancy consume herbal medicine have 7 times the risk of giving birth to asphyxia babies compared to mothers who did not consume herbal medicine during pregnancy. This is due to the deposition of medicinal material in the amniotic fluid which causes the amniotic fluid to become turbid so that the baby's hypoxia and respiratory tract will be disturbed.[30]

It was found that the majority of respondents (72%) had a history of doing abdominal massage during pregnancy which is usually done in trimester 3 or after 7 months of gestation.[31] In the abdomen there is direct contact with the fetus in the womb which can affect the position of the fetus into abnormal, the umbilical cord can be wrapped around so that the compression occurs in the umbilical cord blood vessels, consequently the blood

supply containing oxygen and nutrients is reduced, and the fetus experiences hypoxia.

Neonatal mortality occurred at parity 0 and more than 3 times (54%). At parity 0, the birth canal has not been tested besides that the mother has not been trained in fetal care efforts. Similarly, parity of more than 3, because in labour can cause a risk that is damage to blood vessels in the uterine wall which will affect the circulation of nutrients to the fetus.[18 32]

It was found that 80% of neonates were born spontaneously or normally through the vagina.[33, 34] This is because the normal parturition process without tools has a high percentage of asphyxia birth events (89.2%), whereas in parturition section caesarean total incidence of asphyxia was 4.8%.[16, 35] Parturition complications such as antepartum haemorrhage, malpresentation, eclampsia, prematurity, and premature rupture of membranes increase the risk of neonatal mortality 8-fold.[36]

Neonatal mortality occurred in women who do not experience problems during parturition because the majority of respondents (62%) were referral patients from other health facilities so there may be incomplete information received by the hospital from the referral letter.

Conclusion

Factors affecting neonatal mortality are classified into three components, namely neonatal factors, maternal factors and health service factors.

Elevated Corticosterone Level Due To Chronic Stress on Hb-Egf Expression as a Marker of Endometrial Receptivity Disorder in *Rattus norvegicus*

Risya Secha Primindari[1], Ashon Sa'adi[2], Reny I'tishom[3]

[1] Master degree of Reproductive Health Science, [2] Department of Obstetrics and Gynecology, [3]Departemen of Biomedical Science, Faculty of Medicine Universitas Airlangga, Surabaya, Indonesia

Abstract

Endometrial receptivity is a physiological state in which the endometrium obtains an adhesive phenotype that allows embryo implantation and have a role in the problem of implantation failure. Endometrial receptivity disorders can be caused by interference with the Hypothalamus-Pituitary-Gonad (HPG) axis due to the activation of the Hypothalamus-Pituitary-Adrenal (HPA) axis by stress. HB-EGF is a biomarker of endometrial receptivity that plays a role in the decidualization of endometrial stromal cells to reach the receptive state and initiation of implantation. Corticosterone is the dominant glucocorticoid hormone in rodents, as is cortisol in humans. High corticosterone due to chronic stress triggers disruption of homeostasis in the endometrium by resulting in decreased levels of HB-EGF. This study aims to find out the effect of increased corticosterone levels due to chronic stress on HB-EGF expression in endometrium *Rattus norvegicus*. This research has obtained ethical eligibility from the Research Ethics Commission of the Faculty of Medicine Airlangga University. The samples on this study were 34 rat (*Rattus norvegicus*) which were divided into 2 groups, the control group and the stress treatment group using the Chronic Unpredictable Mild Stress (CUMS) method. Corticosterone level were obtain from blood serum detected via ELISA and HB-EGF expression was obtained from endometrial in diestrus phase was evaluated by immunohistochemical methods. Corticosterone levels in the stress treatment group were higher (72.84 ± 64.03) than in the control group (23.29 ± 8.42). HB-EGF expression in the stress treatment group was lower (82.06 ± 5.91) than in the control group (118.76 ± 13.20). Statistical tests showed significant differences in HB-EGF expression in endometrium Rattus norvegicus p = 0,000 (p <0.05). Elevated level of corticosterone can decrease HB-EGF expression in endometrium *Rattus norvegicus.*

Keywords : *chorticosterone, chronic stress, HB-EGF expression, endometrial receptivity*

Introduction

Endometrial receptivity is a physiological state in which the endometrium obtains an adhesive phenotype that allows embryo implantation and occurs over a period of time known as the implantation window in the middle phase of endometrial secretion. In this phase endometrium is very dependent on the presence of endogenous or exogenous progesterone and stimulation of 17β-estradiol. Implantation can only occur when the endometrium is in its receptive phase[1,2].

A study shows that endometrial receptivity has a 60% role in the incidence of implantation failure [3]. Another study conducted in India found that 25% of implantation failures are known to be caused by endometrial receptivity[4]. As many as 30% of secondary infertility in women is caused by implantation failure and endometrial receptivity disorders being one of them[5,6,7]. One factor that can interfere with endometrial receptivity is stress[8].

Endometrial receptivity disorders can be caused by several factors, such as interference with the

Hypothalamus-Pituitary-Gonad (HPG) axis due to the activation of the Hypothalamus-Pituitary-Adrenal (HPA) axis by stress. Excessive activity of Corticotrophine Releasing Hormone (CRH) in the hypothalamus, in response to stress, is a mechanism for suppression of GnRH. Furthermore, as the body's effort to adapt to stress causes the production of a glucocorticoid hormone, cortisol, by the adrenal glands. Increased cortisol levels can indirectly cause interference with GnRH pulsation, causing a decrease in the amount of gonadotropin hormone produced by the anterior pituitary[9]. Increased cortisol results in impaired levels of the hormones estrogen and progesterone in the ovary. Decreased levels of the hormones estrogen and progesterone in the ovary also have an impact on estrogen and progesterone levels in the endometrium[10].

One of the biomarkers that plays a role in determining endometrial receptivity is Heparine Binding Epidermal Growth Factor (HB-EGF) which affects cell-to-cell interactions and is a dependent estrogen progesterone[1]. HB-EGF is needed for normal decidualization of endometrial stromal cells to reach the receptive state in the endometrium and for the initiation of implantation. HB-EGF has been identified as an initial mediator of embryo-uterine interactions during implantation and is expressed both in the blastocyst and in the endometrium during implantation and plays a role in stimulating embryonic development during hatching. The high cortisol hormone due to chronic stress triggers homeostasis in the endometrium due to the inhibition of the formation of the hormone progesterone which results in decreased levels of HB-EGF[6]. When HB-EGF levels decrease, the number of mature ErbB4 and HB-EGF receptors released in the endometrium decreases. ErbB4 has an important role in stimulating blastocyte implantation. ErbB4 in endometrium will communicate in juxtacrine with ErbB1 contained in blastocytes. Communication between these two receptors is an important key in mediating implantation[10,11].

Chronic stress in this study uses the Chronic Unpredictable Mild Stress (CUMS) method. Chronic Unpredictable Mild Stress is giving various treatments as a stressor and resembles a stressor of everyday life that is not too heavy but continuously[12]. This method has been shown to significantly increase corticosterone levels (cortisol in mice) within 20 days[13]. In Rattus, cortisol secretion is replaced by corticosterone[14]. Chronic stress increases glucocorticoid synthesis and secretion (cortisol in humans and corticosterone in rodents). Increased glucocorticoids are biomarkers for stress and depression disorders[15]. Based on this background, this study was aim of to find the effect of increased corticosterone on HB-EGF expression as a marker of interference with endometrial receptivity.

Material and Method

This study was true laboratory experimental designs with randomized post test only control group design. The study was conducted from April to June 2019 at the Experimental Animal Laboratory, Department of Biology, Faculty of Science and Technology, Universitas Airlangga. The samples of this study were female rats *(Rattus norvegicus)* Wistar strains aged 5-6 months, have ever given birth to the consideration of mice in fertile conditions, never been used as an object of research before, and in healthy condition. All animals are injected with PGF2α at a dose of 25 µg / g body weight intraperitoneally to synchronize the lust cycle. The purpose of synchronizing the lust cycle is to equalize and obtain the diestrus phase during surgery. Female rat was taken randomly into 2 groups, each group consisting 17 female rat. The control group (K1) consisting rat with negative treatment were mice that were not given a stressor and the treatment group (K2) consisting rat with stressors treatment. Stressors treatment in rat using Chronic Unpredictable Mild Stress (CUMS) method for 20 days.

Corticosterone level were obtain from blood serum detected via ELISA and HB-EGF expression was obtained from endometrial in diestrus phase was evaluated by immunohistochemical methods. HB-EGF was assessed semi-quantitatively on the scale of Rammele-Stegner using the Immuno Reactive Score (IRS). Statistical analysis uses IBM SPSS Statistic 25. Data with normal distribution was tested by Independent T test. If the data was not normally distributed, the data was tested by the Mann Whitney test. This study uses a significance level of 0.05 with a confidence level of 95%.

Findings

1. Corticosterone Levels

Table 1. The mean and standard deviation of corticosterone levels in serum *Rattus norvegicus*

Group	n	Corticosterone Levels
		Mean ± Standard Deviation
K1	15	23.29 ± 8.42
K2	16	72.84 ± 64.03

The results showed a mean of corticosterone levels in the treatment group was higher (72.84 ± 64.03) than control group (23.29 ± 8.42).

Table 2. Mann Whitney analysis results of corticosterone levels in serum *Rattus norvegicus*

Group		P Value	Different test analysis
K1	K2	0,000*	Mann Whitney Test

*Significantly different $P<0,05$

Analysis of the Mann Whitney test showed that there were significant differences in the corticosterone levels between the control and treatment groups with a value of $P= 0,000$ ($P<0.05$).

2. HB-EGF Expressions

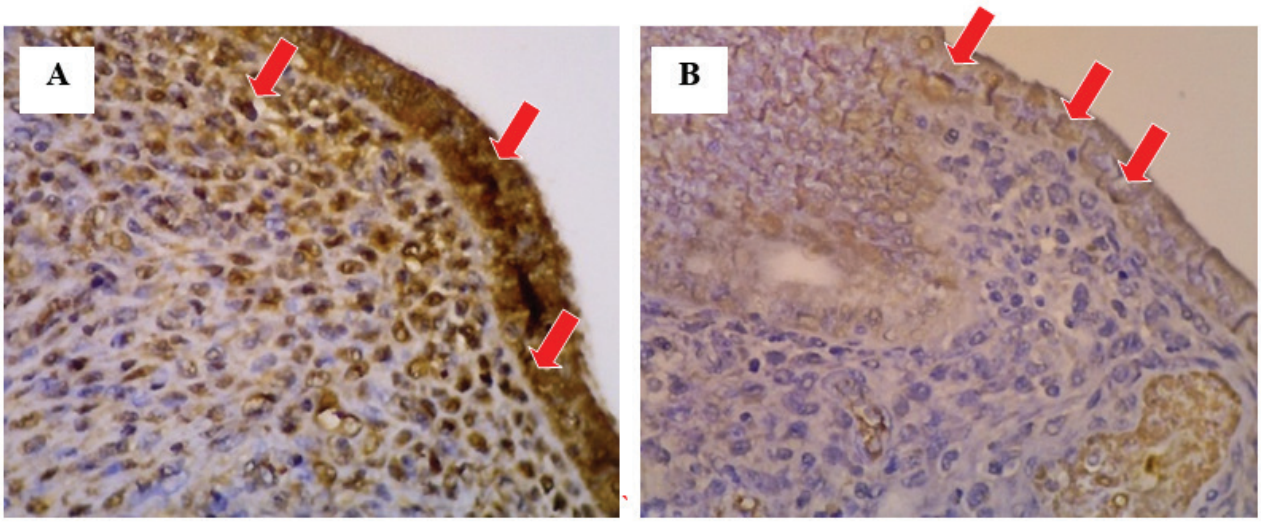

Figure 1. Comparison of HB-EGF expressions represented by chromogen brown color on the endometrial tissue, red arrows showing the maximum expression area using immunohistochemical staining, 400x magnification; Miconos microscope MCX50LED; Optilab Plus camera. (A) HB-EGF expression in the control group (B) HB-EGF expression in the treatment group.

Table 3. Mean and standard deviation of endometrium HBEGF expression

Group	n	HBEGF expression (IRS)
		Mean ± Standard Deviation
K1	15	118.76 ± 13.20
K2	16	82.068 ± 5.91

The examination results of the endometrium HBEGF expression showed a mean and deviation standard in the stress treatment group (82.068 ± 5.916) lower than the control group (118.76 ± 13.208).

Table 4. Results of Independent T analysis of endometrium HBEGF expression

Group		P Value	Different test analysis
K1	K2	0,000*	Independent T

*Significantly different $P<0,05$

The results of the Independent T test showed that there was a significant difference in the HBEGF expression between the control and treatment groups with a value of $P= 0,000$ ($p<0,05$).

Discussion

Chronic stress increases glucocorticoid synthesis and secretion (cortisol in humans and corticosterone in rodents). Increased glucocorticoids are biomarkers for stress and depression disorders[15]. Corticosterone is the dominant glucocorticoid hormone in rodents, as is cortisol in humans[14].

In normal conditions, glucocorticoids will provide negative feedback by suppressing CRH secretion to prevent excessive stress responses, but this does not occur in chronic stress where the activity of the HPA axis continues[13]. Increased of glucocorticoids also affects the HPO axis directly by releasing GnRH release from the hypothalamus and suppressing the release of the gonadotropin hormone from the pituitary which can interfere with various mechanisms that occur in the ovaries so that it can lead to reproductive disorders[9].

There are many theories that present the mechanism of chronic stress on changes in reproductive function. Apart from the activity of CRH and glucocorticoids, which will be discussed next with the effect on the gonadotropin hormone, the disturbed circadian cycle also becomes the mechanism used in this study. The sample unit in this study is Rattus norvegicus which is a nocturnal animal[16], while all treatment activities are carried out in the morning - afternoon so that it changes the circular cycle of Rattus norvegicus. Disorders of sleep patterns that are applied to experimental animals cause disruption of the circandian rhythm in the central arrangement of the circandian rhythm in the hypothalamus, the Supra Chiasmatic Nucleus (SCN). Circandian rhythm is the body's biological clock 24 hours a day. This system regulates hormone secretion, and one of the physiological processes of the sleep cycle is awake[17]. Disorders of sleep patterns that are not sought to overcome it will fall in a state of psychosocial stress. In addition to the physical stress that is given, the change in circular rhythm also has an impact on the psychological stress of the experimental animal, thereby increasing the existing stress. The circadian cycle is an integral part of the reproductive system, when the 24-hour program is irregular the endocrine system can be disrupted. The high corticosterone levels in Rattus norvegicus in this study are in line with the Lopez-Lopes *et al*. study which states that CUMS can increase corticosterone levels with a minimum of treatment for 20 days[13].

HB-EGF has been identified as an initial mediator of embryo-uterine interactions during implantation and is expressed both in the blastocyst and endometrium during implantation and is a dependent estrogen and progesterone[1,6]. Chronic stress causes elevated serum corticosterone levels, resulting in impaired estrogen and progesterone levels in the ovaries. Decreased levels of the hormones estrogen and progesterone in the ovary also have an impact on estrogen and progesterone levels in the endometrium[10]. Increased cortisol has an impact on homeostasis disruption in the endometrium resulting in decreased levels of HB-EGF which is a dependent estrogen and progesterone [6]. HB-EGF is expressed in luminal endometrial epithelial cells and on the surface of pinopods. Disregulation in HB-EGF expression in the endometrium has been associated with infertility whose causes cannot be explained (unexplained infertility). HB-EGF is needed for normal decidualization of endometrial stromal cells to reach the

receptive state in the endometrium and for the initiation of implantation[1,18].

HB-EGF performs two simultaneous functions during the human implantation as an attachment factor and a growth factor. It was reported that HB-EGF plays an important role in the preparation of the uterine luminal epithelium for blastocyst attachment at the beginning of pregnancy. HB-EGF, as a growth factor, accelerates the development of human embryos to the blastocyst stage and their subsequent hatching from the zona pellucida. HB-EGF, as an attachment factor, upregulates many important proteins expressed from a uterine luminal epithelial surface such as integrin β3, leukemia inhibitory factor (LIF), and HOXA10. Integrin αvβ3 serves for osteopontin to mediate the embryo attachment. LIF stimulates human embryo development to the blastocyst stage and is required for embryo implantation. HOXA10 was found in the human endometrium during the mid-secretory phase abundantly and may be involved in implantation and decidualization of endometriumduring early pregnancy. HOXA10 induction by progesterone during the window of implantation leads to a blockage in the stromal cell cycle, facilitating decidualization[19].

HB-EGF induces endometrial cell proliferation through activating the cascade of ERK1 / 2 signals in epithelial cells and increasing DNA synthesis and cyclin D3 in stroma cells[10,20]. Decreased levels of HB-EGF have an impact on disruption of endometrial proliferation and angiogenesis, this can have an impact on the inability of the endometrium to reach its receptive phase. The sequence of endometrial proliferation and angiogenesis disorders can be interpreted as a disturbance in endometrial receptivity.

Conclusion

Elevated level of corticosterone can decrease HB-EGF expression in endometrium *Rattus norvegicus.*

The Determinant Factor Premariral Sexual Behavior in Female Student Migrant Workers

Sri Susanti[1.2], Asmadi Alsa[3], Akif Khilmiyah[3]

[1] Islamic Education Psychology Doctoral Program, Posgraduate of Universitas Muhammadiyah Yogyakarta, [2]Lecture at the Faculty of Health Sciences, Muhammadiyah University of Ponorogo, [3]Islamic Education Psychology Doctoral, Program Posgraduate of Universitas Muhammadiyah Yogyakarta

Abstract

This research is a qualitative phenomenological approach, aims to analyze the factors that trigger the student premarital sexual behavior in children of migrant workers. Data collected by the snowball technique and purposive through observation, interviews, and documentation. The validity of the data using triangulation confirmation. Analysis of the data used is an interactive model of Miles and Huberman. The findings of this study indicate: (1) a permissive attitude towards dating; (2) lack of knowledge and information that is not true of reproductive health; (3) lack of self-control on mahasisianak migrant workers; (4) conformity peers makes the subject tends to follow the custom of peergropnya; (5) social and cultural conditions of permissiveness towards modernization and globalization; (6) family background and lack of moral education from an early age from family; (7) lack of good role models and a lack of parental supervision. Further studies should be done on a pornographic media exposure variables, and modeling of the environment.

Keywords: *determinants, sexual behavior, female student, phenomenology.*

Introduction

Social phenomenon which is currently rife is premarital sexual behavior that leads to abortion, where most of the perpetrators and the victims are teenagers. For some teens, Pre sexual behaviormarriage is regarded as a natural thing with the change of times today, so it was perceived as a lifestyle that can be consumed by anyone[1]. Women as actors is the most suffer the consequences of the current behavior, ranging from physical, psychological and social. for those who initially only dabble intercourse or sexual contact, tend to be hooked and will do again, because they get enjoyment from this illicit relationship[2].

An initial survey conducted by the author with the observation and interviewing student revealed that most of them have a serious relationship with a boyfriend. In fact, their behavior there is shown directly incompatible with the norms of ethical, moral, and religious, have a picture as seen from the display screen laptop or her WhatsApp profile. In fact, they deliberately skipped college and went to entertainment venues or clubs with their partner.

Problem.

Premarital sexual behavior into cultural issues in everyday student life of children of migrant workers. The main problem in this study is the number of factors that encourage student of child labor migrants committing premarital sexual behavior, include: factors attitude towards dating, a factor of knowledge about reproductive health, factors of self-control and self-efficacy, factors conformity peers, social environmental factors of culture community, family background factors, and factors of parental supervision.

Literature Review

Premarital sexual behavior that becomes a social problem for society and the state because it is done outside of marriage is legitimate and legal. Notoatmojo say that premarital sexual behavior is an act committed by juveniles associated with sexual urges that come both from within and from outside himself[3]. Soetjiningsih define premarital sexual behavior is any sexual behavior that is driven by sexual desire in the opposite sex performed before marriage[4]. Meanwhile, according to Ajzen, premarital sexual behavior is closely related to

a permissive attitude toward premarital sexual behavior. Attitudes and behaviors can be consistent when attitudes and behavior in question is specific and of no relevance to each other. Because the permissive attitude toward premarital sexual relations is relevant with each other, then that attitude can be a predictor for behavior[5].

Based on some sense it can be concluded that premarital sexual behavior is the behavior that leads to intimacy heterosexual, which is a manifestation of their sexual drive in the stages of sexual behavior ranging from dating, holding hands, kissing to intercourse involving a pair of teenagers without going through the process of marriage legitimate according to religious and legal according to the law. According Sarwono, stages and forms of sexual activity can be categorized into four activities, namely kissing, necking, petting and intercouse[6].

Methods

This research is a phenomenological study with a qualitative approach, the source of the data obtained through interviews with respondents that female student of migrant workers who perform premarital sexual behavior, which is obtained through the snowball technique and purposive. The technique of collecting data using interviews, observation and documentation. The validity of the data using triangulation confirmation of the source, where the researchers matched the findings of the data obtained by confirming the findings with the data source. Data analysis techniques using interactive analysis of Milles and Hubberman.

Results and Discussion

The result showed that most of the subjects had sexual intercourse before marriage originated from trial and error when they are going through high school, and some other subjects in premarital sexual intercourse because of sexual urges and desires wanted to achieve pleasure and satisfaction in dating. This is supported by data interviews with the subject as follows: *"..... I do it before marriage bond because of the insistence of lust I wanted to try, and I think that sexual intercourse should be performed by young people, the interaction free and we were in college may not have to get married first because not ready to become husband and wife. We still want to have fun like other children"*, According to Freud's theory of "Psychoanalysis" on instinct, suggested that a person with libidinal instincts have destructive impulse that ensures the survival of reproduction. In this case the subject get satisfaction related to the sexual organs, namely erogen areas on the body that are sensitive to excitation. The subject will feel satisfaction and can relieve strain on her after having sexual intercourse.

For those subjects who have never had sexual intercourse at the time of dating, he was able to facing challenges and improve a strong commitment to her. The results showed that, apparently subjects with high self-efficacy, they have the ability to control themselves to abstain from sexual relations before marriage. Whereas subjects with low self-efficacy, they do not have the ability to resist a challenge when it invited the couple to have sexual intercourse. According to Bandura's theory of "self-efficacy", that individuals who have high self-efficacy will feel confident that they are able to deal effectively with their situation, and enhance a strong commitment to her, whereas individuals who have self-efficacy poor feel helpless, and quickly give up when faced with challenges and a commitment to the objectives to be achieved.

Regarding things that encourage premarital sexual behavior, the subject reveals that there are several factors, both internal and eksterenal, among others:

(1) factors attitudes toward premarital sexual behavior. Based on the findings that almost all subjects permissive attitude toward dating. Attitudes toward premarital sexual behavior that is typical in adolescents usually begins with freshly interested, dating, making out until the desire for sexual intercourse. The results of this study indicate that, Subject permissive to have a chance of dating a high enough toward premarital sexual behavior. As pointed out by the subject as follows: "*I am dating since junior grade 3 was initially just to find a friend to confide in, because I see friends that others also had a boyfriend then I also want to have a boyfriend, for support in learning, sharing and commitment so*". This fact is in line with research by Rony, et al. showed that there is a positive correlation between courtship with premarital sexual behavior (Cc = 0.433). This positive relationship means that the courtship is done teenagers will increasingly lead to premarital sexual behavior, teenagers who do not reverse the lower dating leads to premarital sexual behavior. In Erik Erikson's psychosocial theory, states that adults beginning is ready to form a new relationship of trust and intimacy with another person, a partner in friendship, sex, competition, and cooperation. They were not looking for intimacy or failure, may withdraw into isolation. The most important

social agent at this stage is the friend (boyfriend) to be faithful to their commitment to pasangannya[7].

(2) factors subject knowledge about premarital sexual behavior, on average, they have a good knowledge. This is because they claimed while in high school never received counseling on sexuality and reproductive health collaboration whith the National Family Planning Agency and other institutions providing extension at the school. This fact is in line with research conducted by Rahmawati, showed that the level of knowledge of students at the National High School Semarang on premarital sexual behavior mostly have good knowledge, it is evident that out of 70 respondents there, as many as 41 students or as much as 58.6% have good knowledge, and only very few of the 70 respondents were knowledgeable about as many as seven students or 10.0%, and knowledgeable enough as many as 22 students or 31.4%. Students who have a good knowledge of this is because of the counseling on sexuality and reproductive health, and easy access to imternet around sekolah[8]. According Notoatmojo in education and health behavior theory, saying that knowledge is influenced by the experience of someone who can be expressed and believed that lead to motivation, as well as other factors, namely the environment, both physical and non-physical environment, including socio-cultural. So it is desirable to improve the knowledge of the younger generation, by providing outreach activities in order to better understand the theory obtained by the fact that there[9].

(3) The factor of self-control and self-efficacy. Low self-control and self-efficacy subjects in this study are shown in the attitude of their inability to hold and control his lust when dating. They feel helpless,and quickly give up and a weak commitment in the face of the challenges that come from the couple. As disclosed subject as follows: "..... *if lust is urgent and can not longer hold back, finally we make a pact to do it. And it is always we do because we've been married fiance where the latter will become husband and wife*". In line with research from Iga & Goddess, that there is a correlation between self-control sexual behavior before marriage, with a significance value of 0.042 <0.05, it can be said that between premarital sexual behavior with self-control relationship exists linier[9]. Inability adolescents in control of himself is what can lead to a tendency to sexual behavior pranikah[11]. In the "low self-control theory" Travis Hirschi said that individuals with low self-control have a tendency to be impulsive, risky behavior and thinking happy sempit[12].

(4) The conformity factors peers. Based on the results of research in the field, conformity to peer very closely associated with premarital sexual behavior on the subject, because more time with friends than with family. And the influence and pressure from the peer group is greater than the influence of the family. It's like saying the subject when asked about the status of a girlfriend in conformity peers, as follows: *"..... courtship that has become a trend for teens right now, if not have a boyfriend so like being buillied whith our friends, arguably not slang so I adherents trend alone"*, According Sarwono, the strong emotional bond and group conformity in adolescents, is usually considered as a factor that led to the emergence of bad behavior in adolescents[13]. If the adolescent peer environment that supports toward premarital sexual behavior, as well as the conformity of teenagers who are also high on his peer, then a teenager is very likely to commit other forms of sexual behavior before marriage. While in the "social learning theory" Bandura said that the process of observing and imitating the behavior and attitudes of others as a model of action learning. If teenagers live in an environment of peers who have a habit of sexual behavior before marriage, then he is likely to behave in the same[14].

(5) factors of social and cultural environment. Ponorogo is well known for the largest Indonesian Workers in East Java, after two other cities that Blitar and Malang. The results showed that the number of Labor Migrant Workers has an impact on social change Ponorogo, as well as a negative impact especially on the internal family left behind; from the problem of disharmony in the family, divorce, abandoned children, until the child delinquency cases. As disclosed subject matter that: "..... *the parents did not know anything about it, because at home there is only my father and grandmother are old while the mother is a migrant worker in Malaysia, I feel the loss of a mother figure and affection of a mother, threrefore I was more comfortable staying at the boarding house with boyfriend without anyone caring*". The workers will leave their families for months or even years, as a result the child loses a parent figure in the long term. They lost the role and function of parents is very important for children's growth both physically, and socially.

(6) family background factor. The family is the first social environment that provides a huge influence to the growth and development of children and adolescents. Ideally adolescent development will be optimal if they

shared a harmonious family, so that the various needs required can be met and have positive role models from their own parents. As revealed by Bandura in "modeling" is one important step in learning, most human behavior is influenced by others, people will learn to imitate the behavior tungkah or in certain cases to make someone else as a model for him[15]. The family lacks the function of socialization which is expected to instill the values and norms on children. There has been a shift in the role and function of the family in terms of socialization. Lack of parental supervision and lack of cultivation of religious values will impact on promiscuity which results in adolescent premarital sexual intercourse.

(7) the factors parents. Parents as primary socialization agent who first role is to introduce the values and norms applicable to children both in the family and in society. This socialization of values and norms cannot possibly be fulfilled perfectly when parents go to become migrant workers. Even children whose parents are left behind are migrant workers experiencing many psychological problems such as emotional disturbances, problems with behavioral disorders and hyperactivity. Often parents think only of his external needs by working hard regardless of how children grow and develop. Parental supervision is absolutely necessary as a filter for children to prevent negative influences of social. Unfavorable conditions often experienced by subjects as child workers. They live separately with their parents in a long period of time so that less supervision and prone to deviant behavior. Even some of them must feel the role of parents is replaced by the grandmother as caregivers. The grounds are a single parent because of work a migrant worker or both parents are divorced. This will impact on the formation of the personality of children and adolescents to be more influenced by the social environment, even the role of the mass media might replace the role of the other.

Conclusions and recommendations.

Premarital sexual behavior that occurs in a student's child labor migrants originated almost entirely from courtship in which they live since junior high school or senior high school, and partly since the beginning of college. Courtship is one of the reasons they commit acts of premarital sexual behavior. In addition triggered by several factors, among others, the factors of knowledge and attitudes toward premarital sexual behavior, self-control factor, conformity peers, social and cultural conditions, family background and parental factors. Among the factors that most influence is a factor family and parents. Many of those who came from a family full of conflict and division (broken). This is due tothe lack of intensity of communication between members of the family, because parents become migrant workers abroad so rarely communicate intensively with her son. Conditions parent who is a migrant worker makes the subject to lose the need for love and comfort of the family, which then makes the student look for meeting those needs to others who can serve as the outpouring of all the problems of life faced.

It is recommended that all parties to make efforts to address premarital sexual behavior and for further research may make observations and thoughts as well as the development of models and strategies for the handling of premarital sexual behavior through stages that are arranged in a systematic and applicable.

Abstract

Personal hygiene which should be started from childhood and having proper knowledge and practice during this time period will help to attenuate the infectious disease, thus increase the productivity of an individual in his or her life cycle. Investigating the knowledge, attitude and practice regarding personal hygiene among primary school going children was the aim of this study. A school based cross sectional study involving 408 children by probability proportionate was carried out in eight government and private primary schools at Sadar Upazilla, Noakhali District. The mean age of the respondents were 9.77±1.62 years with equal numbers of boys and girls. Overall 78.4% (N=320) respondents had good knowledge regarding hygiene and the percentage was higher among girls (79.4%) compared to boys and there have been also significant correlation among knowledge, attitude and practice about personal hygiene (P= 0.000). The study also revealed that respondents having adequate knowledge of proper hygiene were more likely to have clean clothes and clean teeth (AOR 2.37, CI 1.2-4.6 and AOR 2.51, CI 1.4-4.5 respectively). Thus continuous health education and behavioral change program are essential and should be conducted frequently to improve overall hygiene situation.

Keywords *– Knowledge, Practice, Attitude, Children, Primary School, Hygiene.*

Introduction

Hygiene is the discipline which helps in maintaining the health and is one of the determinants of good health which varies according to one's moral and practices [1]. In Greek mythology, the meaning of Hygiene is derived from "Hygiea" which means goddess of health [2]. Personal hygiene is art of wellbeing living of individual and it can be defined as the science of health and it embraces all the factors that will help for a healthy living such as bathing, washing hands before a meal and after using toilet, cleaning the face, eye, feet, washing hair, trimming nail, wearing clean clothes etc.

Children in their primary schooling age can learn specific health-promoting behaviors, even if they do not fully understand the connections between illness and behavior [3]. As a socializing institution, school plays an important role for the children and as well as for the adolescent to develop a healthy citizen and after introducing about the knowledge of personal hygiene and life style in school, when they will mature, they will in better position as an adult to maintain their own health and also to maintain the health of their family [4].

Having lack of awareness of health benefits of personal hygiene can result poor health outcomes among school children especially infectious diseases such as diarrheal diseases, skin diseases, worm infestations and dental diseases [5]. About 50% gastrointestinal and respiratory infections can be reduced significantly

by improving awareness and hand hygiene practices especially among children, which are two leading causes of childhood morbidity and mortality around the world [6-8]. Thus personal behavior are discrete and independently modifiable, individuals can voluntarily alter such behavior and can maintain good personal hygiene.

Hence the present study was conducted aiming in to investigate the knowledge, attitude and practices concerning personal hygiene among primary school going children in Sadar upazila, Noakhali District, Bangladesh and also to find out the association of socio-demographic characteristics with KAP of the respondents regarding hygiene.

Materials and Method

The descriptive cross sectional study was conducted among primary school going students of class I to class V in eight government and private primary school in Noakhali region, Bangladesh. The schools were selected randomly and the respondents were also included by randomization. Total 408 students were included by probability proportionate in the study from four government and four private primary school. An interviewer administered questionnaire was used to collect all the information including demographic data, morbidity data and KAP regarding personal hygiene from the respondents. Face validity and content validity of the questionnaire were done and the value for the Cronbach alpha was 0.68. After validation the questionnaire was translated to Bangla and a pilot study was conducted in three primary schools. Then the questionnaire was modified and finalized for the final data collection.

Consent from the authority of the school was taken before the study was conducted and also from the guardians of the children. Data were collected by face to face interview and physical appearance and hygiene were observed directly and carefully and recorded in the check list in the questionnaire.

All the collected data were checked, verified and edited and then analyzed (Chi square test, logistic regression) using statistical package for social science (SPSS version 23.0) with 95% level of confidence. There were 12 questions for assessing knowledge, 9 questions for attitude and 14 questions for practice. Each questions were scored according to the options and the category of the KAP was done according to Elsabagh HM (2016) [9].

Results

The study was conducted among the primary school (Class I to V) children and the mean age of the children were 9.77±1.62. Most of the respondents (94.1%) of the study are Muslims and male and female ratio was 1:1. In the study it was seen that there were huge difference regarding personal hygiene between government and private school. Most of the fathers of the respondents (99.75%) are employed where about 86.8% of the mothers are unemployed and most of them are housewife. About 16.17% mothers are illiterate or can sign, read and write where 38.16% fathers are illiterate or can sign, read and write. Fathers have done higher studies (38.65%) more than the mothers (31.63%).

According to the BMI for age, about 77% of the respondents are underweight and only 17.4% are normal. Approximately 6% students fall in the overweight and obese group.

The present study also found that, girls had have higher knowledge and practice than that of the boys but attitude was seen higher in the boys than girls. According to categorization of the KAP, about 78.4% and 64.7% students have good knowledge and practice but only 35.3% students have positive attitudes on personal hygiene (figure 1) and there have significant correlation among knowledge, attitude, and practice (table 1). Table 2 shows the significant association between category of knowledge and attitude (p=0.000) and category of knowledge and practice (p=0.000). Table 3 shows the association of KAP with various demographic variables such as types of school, sex, education and occupation of the parents of respondents. From the table 3, it is seen that, type of schools is significantly affect the knowledge, attitude and practice (p=0.000) of the respondents, in where the sex is statistically significant with practice only (p=0.036). The level of education of the parents also statistically signifies with KAP (p= 0.000 and p=0.001) but the occupation has no significant effect on KAP of the students. About 78.4% students have adequate knowledge of personal hygiene (figure1). Those who have adequate knowledge about personal hygiene as more likely to have clean cloths and clean teeth (AOR 2.37, CI 1.2-4.6 and AOR2.51, CI 1.4-4.5 respectively) though the other factor such as clean eye, clean hand, cleanliness of hair, trimmed nail and clean face did not have statistical significant association.

Discussion

The study focused on the KAP about personal hygiene and sanitation of the primary school going children (Grade I to V) and helped to find out the association between knowledge, attitude and practices with different socio demographic variables and also the correlation between knowledge with attitude and practice. Among all the respondents, 78.4% had have proper knowledge of personal hygiene though about 64.7% respondents had have the positive attitude and good practice. Appropriate knowledge is necessary for the practice of proper hygiene in their daily life but the findings from the author Vivas et al (2010) reported that approximately half of the students did not have adequate knowledge of proper hygiene[10] in Angolela, Ethiopia.

It was found from the present study that the students from private schools had greater knowledge, attitude & practice than that of the government school students. The percentage of students for knowledge, attitude & practice of government schools were 64.53%, 53.96% & 50% respectively, in where the findings for private were 91.7%, 75.12%, 79.02% respectively, which was quite higher, however to the best of our knowledge, no published report have assessed KAP between government and private schools in Bangladesh.

As the literacy rate and educational status of women in Bangladesh is growing up gradually due to ongoing awareness among government and NGOs [4], in the current study, it was found that girls had significantly better knowledge and practice than male ones though the boys had greater attitude than girls. A study which was conducted in Iran, has also reported that females had better knowledge, attitude and practice scores than males [11]. Whereas in another study males had shown significantly higher scores compared to females [12]. This dissonance in results may be explained by the cultural and social differences from different regions of the world between male and female.

As the children spend most of the time with their mother and she is typically the primary caretaker of the family, that's why she has to charge with teaching her children proper health and hygiene practices[10]. Due to illiteracy of mother, may have less knowledge to teach their children about proper hygiene practices and it would lead to increase rates of infectious disease amongst her children [13]. In our study it was seen that children whose mothers was literate and who studied up to college or university had a good knowledge in hygiene practices and was almost similar to another study carried out in Gambia in 1996 [14]. The findings also found that father's education significantly related to the children's knowledge, attitude and practice of personal hygiene.

According to this study, the children who had adequate knowledge regarding personal hygiene were more likely to have clean clothes and clean teeth and the study from Ethiopia also found that except clean teeth[10]. A study conducted in Munshigonj, Bangladesh reported that 93.33% children trimmed their nail

[15] in where our study found only 66.9% and found insignificant association with knowledge about proper hygiene (AOR 1.31, CI 0.7-2.1). Another study which was also conducted in Mymansing, Bangladesh revealed that almost 77% secondary school students trimmed their nail[4], which was quite near to our study result.

Conclusion

Childhood is the best period in which one can easily adopt the behaviors that they have seen around their environment. If hygiene education and information would give in this early stage of life, the prevalence of communicable diseases can be reduced in a significant level. So that more health education is needed concerning personal hygiene to ensure that all children would aware of the hazardous effect of poor hygiene and this can be implemented through formal (as a part of the curriculum) and informal health education messages.

Acknowledgement: Authors are thankful to all the children, teachers and the authority of the schools for their cooperation and participation in the study, without them, the study would not have been possible.

Conflict of Interest: Nil

Source of Funding: The study was funded by Research cell, Noakhali Science and Technology University, Bangladesh.

Ethical Clearance: The Ethical approval was taken from the Ethical Board of Noakhali Science and Technology University.

Relationship of Mothers' Parenting and Stunting in Toddlers Aged 12-36 Months in Bogor Regency, West Java Province, Indonesia in 2019

Sakina Makatita[1], Ratna Djuwita[2]

[1]Master of Epidemiology, Faculty of Public Health, University of Indonesia,
[2]Department of Epidemiology, Faculty of Public Health, University of Indonesia

Abstract

Background: Stunting is a nutritional problem in toddlers who experience growth failure due to long-term malnutrition so that the z-score is less than -2SD / standard deviation (stunted) and less than - 3SD (severely stunted). According to the 2016 Global Nutrition Report, the prevalence of stunting in Indonesia shows that Indonesia ranks 108 out of 132 countries. Based on previous reports, Indonesia is included in 17 countries that experience problems with nutrition, both excess and malnutrition. For the Southeast Asian region, the prevalence of stunting in Indonesia is the highest in the world, after Cambodia. In addition to nutritional factors, stunting is also caused by indirect factors, namely parenting. Therefore the aim of the study is to assess the relationship between mothers' parenting and stunting in toddlers aged 12-36 months in Bogor Regency, West Java Province, Indonesia in 2019.

Method: Cross-sectional study design from primary data with a total sample of 500 toddlers aged 12-36 months taken in Bogor Regency, West Java Province, Indonesia in 2019. Stunting status was assessed based on the TB / U indicator <-2 z-score, while categorizing variables Mothers' parenting was done scoring. Analysis of the relationship between mothers' parenting with stunting in this study using multivariate cox regression analysis and the magnitude of the effect expressed in the prevalence ratio (PR) with confident interval (CI: 95%.)

Results: This study shows the prevalence of stunting in toddlers aged 12-36 months in Bogor Regency in 2019 of 39.2%. The result of cox regression test of the relationship between mothers' parenting and stunting showed PR 1.47 (95% CI: 1.09-1.97) meaning that mothers with poor parenting had a prevalence of stunting toddlers 1.47 times higher than mothers with good parenting after controlling for the variable "Mothers' Education".

Conclusion: Mothers' parenting is one of the factors that causes the high prevalence of stunting in toddlers aged 12-36 months in Bogor Regency, West Java Province, Indonesia in 2019. The efforts to prevent stunting are very important, one of which is based on mothers' parenting factors, therefore it needs to be increased education for expectant mothers, and especially adolescent girls as well as increasing knowledge of pregnant women who have low education about parenting in toddlers in accordance with aspects of parenting that are good and right. So that hopefully mothers have enough knowledge about parenting, and it can be applied during parenting.

Introduction

Nutritional status plays an important role in the development of a child's body weight or height which is strongly influenced by nutrition(1). Stunting is a situation

where children under the age of five fail to grow due to lack of chronic nutritional intake caused by long-term malnutrition so that the child's height does not match the age of the child or the child can be said too short when compared to his age[2]. According to the WHO Child Growth Standard, stunting is based on a body length index compared to age (PB/U) or height compared to age (TB/U) with a z-scoring limit of less than -2SD / standard deviation (stunted) and less than -3SD (severely stunted)[2][3].

In 2017, the world experienced 150.8 million stunting, or 22.2%. This figure has decreased when compared with the stunting rate in 2000 which was 32.6%. In 2017, more than half the stunting toddlers in the world came from Asia (55%) while more than a third (39%) lived in Africa. Of the 83.6 million stunting toddlers in Asia, the largest proportion came from Asia (58%) and the lowest proportion in Central Asia (0.9%)[4]. According to the 2016 Global Nutrition Report, the prevalence of stunting in Indonesia shows that Indonesia ranks 108 out of 132 countries. Based on previous reports, Indonesia is included in 17 countries that experience problems with nutrition, both excess and malnutrition[4][5]. For the Southeast Asian region, the prevalence of stunting in Indonesia is the highest in the world, after Cambodia[4][6]. Results of Basic Health Research (RISKESDAS) 2018 stunting prevalence fell to 30.8% from the previous 37.2% (2013)[2]. While for toddlers who have normal height increased to 57.8% (2018) from 48.6% (2013)[4][2]. Even so, West Java Province is a province in Indonesia that still has a high prevalence of stunting, even a significant increase in cases from 25.1% in 2016 to 29.2% in 2017. Meanwhile the Districts in West Java with Stunting cases are still high, one of which is Bogor Regency 28.5%[7].

Mothers' parenting plays an important role in the occurrence of growth disorders in children. To support good nutritional intake needs to be supported by the mothers' ability to provide good care for children in feeding practices, personal hygiene practices and the environment[8]. According to the United Nations Children's Fund (UNICEF) parenting is one of the indirect factors related to the nutritional status of children including stunting[10][11]. Mothers when caring for children with affection, spending time with children such as playing storytelling, teaching children discipline, giving praise or appreciation if the child succeeds in doing well, and implementing a clean and healthy lifestyle (PHBS) can indirectly affect growth and development children[9]. This is because the pattern of parenting from the psychological side of the child is also one of the factors that play an important role in the growth and development of children under the age of five. At this age children are still very dependent on the parenting of their mothers[12].

Venny research on factors related to stunting among toddlers aged 24-59 months in Wawatu Village, North Moramo District, South Konawe Regency in 2017 shows that out of 35 toddlers (100%) who have unfavorable mothers' parenting patterns there are 23 toddlers (65.7%) who experienced stunting and there were 12 toddlers (34.3%) who did not experience stunting (normal). Whereas out of 45 toddlers (100%) who have good mothers' parenting, there are 11 toddlers (24.4%) who experience stunting and 34 toddlers (75.6%) who do not experience stunting (normal). This shows that there is a relationship between mothers' parenting and stunting among toddlers aged 24-59 months in Wawatu Village, North Moramo District, South Konawe Regency, 2017[13].

Based on the description above, the researcher is interested to see "The Relationship of Mothers' Parenting and Stunting in Toddlers Age 12-36 Months in Bogor Regency, West Java Indonesia in 2019".

Method

The research design used in the study is a cross-sectional study using primary data taken in Tamansari District, Bogor Regency in 2012. Tamansari District has the highest stunting prevalence in Bogor Regency. The target population in this study are all toddlers under the age of 12-36 months in Bogor Regency in 2019, where based on data from the Public Health Sector of the Bogor District Health Office in 2019 there were 10,447 toddlers. The selected sample is the inclusion criteria of all toddlers aged 12-36 months, living with parents, has complete data according to the variables to be studied and has lived for one year in the area of 500 samples, while the exclusion criteria are toddlers with abnormalities or defects that can hinder the process of anthropometric measurement and mothers who refuse to be interviewed. In the research, 111 posyandu (integrated service post) were sampled using the probability proportional to size method.

Data collection was carried out on 02 to 18 July

2019 using questionnaires by recruiting enumerators of Nutritionist and Epidemiology Masters Students who were trained in advance. The data that has been collected is edited by checking the instrument that has been filled in, encoding the data, then entering the data into the data processing system, and cleaning up the data by checking the completeness and correctness of the data.

The dependent variable is stunting while the independent variable is mothers' parenting with mothers' education, income, URI, diarrhea, number of children, protein intake and calorie intake covariate. Stunting data was obtained by measuring the length of a toddler aged 12-24 using the Length Measuring Board (LMB) and the height of a toddler over 25-36 months using microtoise. The age data is obtained by reading the birth certificate or the child MCH book. Other data were obtained by filling in the questionnaire.

Data analysis was performed using the STATA 13 program. To determine stunting based on TB/U z-score value using WHO Anthro software, while categorizing data for Mothers' parenting variables the composite method was performed by scoring the questions from Mothers' parental variable from questionnaire, as well as for variables Other covariates are mothers' education, income, number of children, diarrheal disease, URI, protein intake and calorie intake. Analysis of the relationship between independent and dependent variables in this study was influenced by the prevalence ratio (PR) with a 95% confident interval (CI) using multivariate analysis of multivariate cox regression.

Results

Table 1. Frequency Distribution based on Research Characteristics in Bogor Regency, West Java Province in 2019

Variable	Frequency	Percentage
	n=500	%
Stunting		
Stunting	196	39.20
Normal	304	60.80
Mothers' Parenting		
Bad	277	55.40
Good	223	44.60
Mothers' Education		
Low (<12 years)	376	75.20
High (≥12 years)	124	24.80
Income		
<2 million	177	35.40
≥ 2 million	323	64.60
URI		
Yes	213	42.60
No	287	57.40
Diarrhea		
Yes	139	27.80
No	361	72.20

Cont... **Table 1. Frequency Distribution based on Research Characteristics in Bogor Regency, West Java Province in 2019**

Number of Children		
> 2 Children	111	22.20
≤ 2 Children	389	77.80
Protein Intake		
Poor	293	58.60
Satisfactory	207	41.40
Calorie Intake		
Poor	287	57.40
Satisfactory	213	42.60

Table 1 shows that toddlers in Taman Sari District of Bogor Regency in 2019 mostly had stunting problems which was 39.20%. The proportion of mothers' parenting to toddlers with poor parenting is 55.40%. Mothers with low education have a greater proportion of 75.20%. While income ≥ 2 million has a greater proportion of 64.60%. The proportion of those who do not have URI is 57.40%, while the proportion of those who do not diarrhea was 72.20%. For the number of children ≤ 2 people have a greater proportion of 77.80%. In poor protein intake has a greater proportion of 58.60%, while poor calorie intake has a greater proportion of 57.40%.

Table 2. Relationship of Mothers' Parenting and Stunting in Toddlers Age 12-36 Months in Bogor Regency, West Java Province in 2019

Mothers' Parenting	**Stunting Situation**				**Total**	**PR**	**95% CI**	**P-Value**
	Stunting		**Normal**					
	n=500	**%**	**n=500**	**%**				
Bad	128	46.21	149	53.79	277			
Good	68	30.49	155	69.51	223	1.96	1.35-2.83	0.0003
Total	196	39.20	304	60.80	500			

Table 2 shows the results of the analysis of the relationship between mothers' parenting with stunting obtained that there were 128 (46.21%) Mothers with poor parenting had stunted toddlers. While mothers with good parenting, there were 68 (30.49%) having stunted toddlers. Chi-Square test results obtained p = 0.0003, it can be concluded that there is a difference in the proportion of stunting between mothers who have poor parenting and mothers who have good parenting means that there is a significant relationship between parenting mothers with stunting in toddlers Aged 12- 36 months in Bogor Regency, West Java Province in 2019. From

the analysis results also obtained PR 1.96, meaning that mothers with poor parenting have a prevalence of stunted toddlers 1.96 times higher than mothers with good parenting.

Table 3. Full Multivariate Initial Model

Stunting Prevalence Factors	PR	95% CI	P-Value
Mothers' Parenting	1.40	1.03-1.90	0.030
Mothers' Education	1.47	1.00-2.17	0.050
Income	1.30	0.97-1.74	0.078
URI	1.27	0.95-1.71	0.097
DIARRHEA	1.22	0.90-1.66	0.188
Number of Children	1.35	0.98-1.85	0.062
Protein Intake	0.79	0.52-1.18	0.250
Calorie Intake	1.05	0.70-1.56	0.807

Table 3 shows the results of the selection of all variables produce p value <0.25, there are only two variables whose value> 0.25, namely the variable protein intake and calorie intake. However, the two variables are still analyzed by multivariate because substantially protein intake and calorie intake are very important variables related to stunting status in toddlers.

Table 4. Final Multivariate Model

Stunting Risk Factors	PR	95% CI	P-Value
Mothers' Parenting	1.47	1.09-1.97	0.010
Mothers' Education	1.63	1.12-2.39	0.011

Table 4 shows the results of the final multivariate model. Where there are no variables that are confounding variables. This is due to the difference in PR crude and PR adjust which is still <10%, but mothers' education is still included in the final model because in substance mothers' education is related to mothers' parenting. Cox regression test results obtained a PR value of 1.47 with 95% CI 1.09-1.97 meaning that mothers with poor parenting have a prevalence of stunted toddlers 1.47 times higher than mothers with good parenting after being controlled by the variable "Mothers' Education ".

Discussion

The results of this study indicate that mothers' parenting is one of the causes of stunting in toddlers aged 12-36 months in Bogor Regency in 2019 after being controlled by the mothers' education with a PR value of 1.47 (1.09-1.97). This is in line with research from Venny which shows that there is a significant relationship between mothers' parenting and stunting (p = 0.001)[13].

Parenting is one of the indirect factors related to the nutritional status of children one of which is stunting[14]. Mothers with good parenting will tend to have toddlers with optimal growth[13]. Mothers with good parenting patterns are also related to mothers' education level[10]. Mothers with low levels of education are more difficult

to receive information than Mothers with high levels of education, causing mothers' knowledge to be lacking which can make mothers' parenting bad. This can affect the nutritional intake of toddlers to be not optimal[14]. It also affects the emotional and social development of children so that it can cause stunting in toddlers. Whereas the main principle in a positive parenting pattern other than optimal nutritional status is that children must be treated with appreciation, free from acts of violence, love and affection, and provide a comfortable and friendly environment for children's growth and development[9].

Research from Irdawati and Dewati shows that there is a significant relationship between the level of knowledge and mothers' behavior in fulfilling nutritional needs and child health monitoring patterns[15], and Taufiqurrahman's research shows that there is a significant relationship between the level of mother's knowledge about nutrition and parenting behavior in toddlers[1]. Research from Judith and Stand in their study in Filipina concluded that mothers' education also affected the incidence of stunting[16][17]. In line with this, Semba et al showed that mothers' education was a determinant of stunting in Indonesia and Bangladesh[18] [17].

Conclusions

From the results of the analysis it can be concluded that the relationship between mother's parenting style and stunting status after being controlled by mothers' educational variables showed significant. Prevalence of stunting shows that nutritional problems in Indonesia are chronic problems that are directly related to factors, one of which is education and indirectly is mother's parenting. Therefore, the Health Office and the Local Health Services Unit need to make efforts to increase knowledge about positive parenting patterns for toddlers targeting pregnant women through routine socialization conducted with village midwives and posyandu (integrated service post) cadres. This effort is expected to be able to improve optimal parenting patterns in toddlers from before birth until the next life so they do not experience stunting.

Ethical Considerations: This study was approved by The Research and Community Engagement Ethical Committee Faculty of Public Health Indonesia University (Ket-560/UN2.F10/PPM.00.02/2019).

Competing Interests: The authors declared that no competing interests exist.

Association of Immature Platelet Fraction and Trombopoietin Levels Based on the Grades of Sepsis Severity

Steven Tiro[1], Uleng Bahrun[1], Mansyur Arif[1]

[1]Department of Clinical Pathology, Faculty of Medicine, Hasanuddin University-Dr.Wahidin Sudirohusodo Hospital Makassar, Indonesia. Jl. Perintis Kemerdekaan Tamalanrea, Makassar, Telp. (0411)581226.
Corresponding author: Steven Tiro, Jl. Sumba no 34b, Makassar

Abstract

Sepsis is one of the major causes of morbidity and mortality around the world. Organ dysfunction in sepsis can be identified using *Sepsis-related Organ Failure Assessment*. The dysfunction of the coagulation cascade, the number of pro-inflammatory cytokines, and endothelial dysfunction promote the consumptive thrombocytopenia in sepsis patients, which triggers a compensatory response in the body by increasing thrombopoietin release. As a result, it increases platelet production which can be assessed by immature platelet fraction (IPF). This study is a preliminary research to see the relationship between IPF values and serum thrombopoietin (TPO) levels in terms of the clinical severity of patients with sepsis based on SOFA scores. A cross-sectional design was performed in this study with 49 samples of patients with sepsis, collected during June-July 2019, at Dr. Wahidin Sudirohusodo Hospital in Makassar. The study was conducted in August 2019. IPF values were measured by the fluorescent flow cytometry method. Meanwhile, serum thrombopoietin levels were calculated by the enzyme-linked immunosorbent assay (ELISA) method using human Thrombopoietin ELISA (RayBioTech, Australia). The results showed that the IPF value increased along with the SOFA score, followed by a decrease in platelet ($p = 0.014$). TPO levels presented an upward along with SOFA scores with a decrease in platelet ($p = 0.008$). There was a significant correlation between IPF values and TPO levels ($r = 0.606$, $p < 0.001$) where the Immature Platelet Fraction score and thrombopoietin levels increased with SOFA scores. In addition, there was also a positive correlation between IPF values and TPO levels in sepsis patients.

***Keywords**: Sepsis, SOFA score, immature platelet fraction, thrombopoietin, platelets*

Introduction

Sepsis is a systemic inflammation as a response of the body to infection, potentially leading to organ dysfunction or death. Sepsis is one of the major causes of morbidity and mortality around the world. In 2013, the World Health Organization (WHO) reported that the number of sepsis cases worldwide reached 30 million cases with mortality rates in developing countries at 60-80%. Subroto and Loehoeri (2003) stated that the incidence of sepsis in several referral hospitals in Indonesia was around 15-37.2% with a mortality rate of 37-80%.[1-4]

Disorders of hemostasis in sepsis are caused by several things: malfunctioning of the coagulation cascade, the number of pro-inflammatory and anti-inflammatory cytokines released by mononuclear cells and endothelial cells, thrombus formation in the advanced stages, and stimulation of plasminogen and antithrombin-III activation that cause fibrinolysis. As a result, it causes clot formation and bleeding associated with disseminated intravascular coagulation (DIC). Disseminated intravascular coagulation results in increased consumption of platelets, causing thrombocytopenia in patients with sepsis.[5,6]

Consumptive thrombocytopenia in sepsis triggers a compensatory response from the body. The liver increases thrombopoietin release, stimulating the production and differentiation of megakaryocytes in the bone marrow which increases platelet production. The increased platelet production promotes an increase in the number of immature platelets in the peripheral characterized by

high RNA in the cytoplasm of platelets.[7]

Immature platelet fraction (IPF) is a recent parameter that measures immature platelets in peripheral blood by staining RNA in the cytoplasm of immature platelets and measured through laser light. IPF examination is used to distinguish thrombocytopenia due to bone marrow failure from consumptive thrombocytopenia.[8]

Many studies of organ malfunction in sepsis are still being carried out especially in the failure of hematopoiesis. This study aims to analyze the correlation of IPF values and thrombopoietin levels with clinical severity based on SOFA scores in patients with sepsis.

Method

A cross-sectional study was performed to analyze the value of IPF and thrombopoietin levels in patients with sepsis at the Inpatient Installation of Dr. Wahidin Sudirohusodo General Hospital, Makassar. This research was conducted during June-July 2019. The samples in this study were the adult patients diagnosed with sepsis based on the clinical symptoms and examinations. Excluded criteria were those with incomplete laboratory data, hematological malignancies, bone marrow failure before the diagnosis of sepsis, and those with lysis/ lipemic that could not be re-sampled. All samples were examined for IPF values by using the Sysmex XN-1000 automatic hematological analysis device and for TPO levels by the ELISA (Enzyme Linked Immunosorbant Assay) method in the research unit of the medical faculty of Universitas Hasanuddin/Hasanuddin University Hospital. The study subjects were observed during inpatient at Wahidin Sudirohusodo General Hospital to investigate the patient outcomes.

The study subjects were divided into 3 groups based on the SOFA scores: group 1 with the score at 2-6, group 2 at 7-9, and group 3 at >9. The data were statistically analyzed using the *Kruskal-Wallis* Test to assess the differences in IPF values and TPO levels based on the SOFA scores. *Spearman* correlation test was performed to assess the correlation between IPF values and TPO levels. The results of the analysis were significant with a p value at <0.05.

Results

Table 1. The characteristics of the subjects of the study

*Source: Primary data

49 subjects met the inclusion and exclusion criteria with a median of age at 57 years old. There was no difference in the category of gender. 33 subjects had SOFA scores at 2-6, while 11 subjects were at 7-9, and 5 of them were at >9. The median of platelet rates from all samples was 158,000/mm3 with the lowest platelet rates of 8,000/mm3 and the highest platelet rates of 501,000/ mm3. The median of IPF values was 6.6% with the lowest IPF value of 0.6% and the highest of 23.5%. The median of TPO levels in the study subjects was 792.9 pg/mL with the lowest levels of 447.1 pg/mL and the highest levels of 4893.5 pg/mL.

2 out of 49 patients requested termination of care at the request of the family. The number of deaths in the study population was 31 of 47 patients (66%). The mortality rate for the three groups reached more than 60%.

Table 2. The comparison of IPF rates based on the SOFA scores

Groups	SOFA scores	IPF (%)	PLT (103 /mm3)	p*
I	2-6	6,8±4,8	205,55±115,37	
II	7-9	8,3±5,7	130,09±112,39	0,014
III	>9	13,9±2,8	34,20±11,21

* *Kruskal-Wallis* test

Table 2 shows the IPF rates in the three groups of study subjects based on SOFA scores. The Kruskal-Wallis test indicated that there were significant differences (p = 0.014) of the mean of IPF values in the three groups of the research subjects. The mean of IPF values increased along with SOFA scores, while the platelet rates decreased with an upward in SOFA scores. The increase in IPF value was inversely proportional to the platelet rates; the lower the platelet rates, the higher the mean IPF value. The results indicated a significant association of increased SOFA score with platelet rates and IPF values. The difference in IPF values based on SOFA scores is shown in Figure 1.

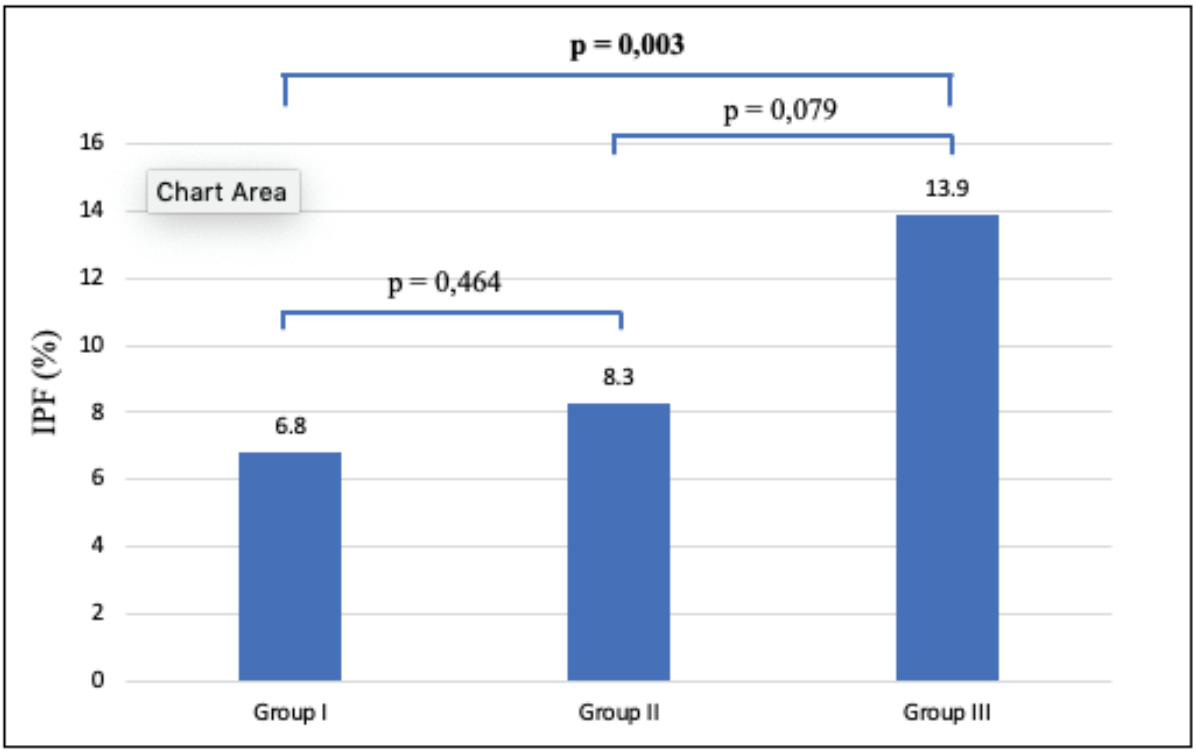

Figure 1. The comparison of IPF rates based on the groups of SOFA scores

On the post hoc test, the IPF value was significantly different between group I (mean IPF value = 6.8 ± 4.8%) and group III (mean IPF value = 13.9 ± 2.8%) with a value of p = 0.003. Meanwhile, IPF values between groups I and II and between groups II and III did not show significant differences (p = 0.464 and p = 0.079).

Table 3. The comparison of TPO levels based on the SOFA scores

Groups	SOFA scores	TPO (pg/mL)	PLT (10^3 /mm^3)	p*
I	2-6	976,4±804,1	205,55±115,37	
II	7-9	1166,1±494,8	130,09±112,39	0,008
III	>9	1638,3±94,7	34,20±11,21

* *Kruskal-Wallis* test

Table 3 presents the levels of TPO in the three groups of study subjects based on SOFA scores. The *Kruskal-Wallis* test indicated that there were significant differences (p = 0.008) of the average TPO levels in the three groups of study subjects. The mean of TPO levels rose along with SOFA scores. The increase of TPO levels was inversely proportional to the platelet rate; the lower the platelet rate, the higher the mean of TPO levels. These results indicated an association of increased SOFA scores with platelet rate and TPO levels. The difference in TPO levels based on SOFA scores is shown in Figure 2.

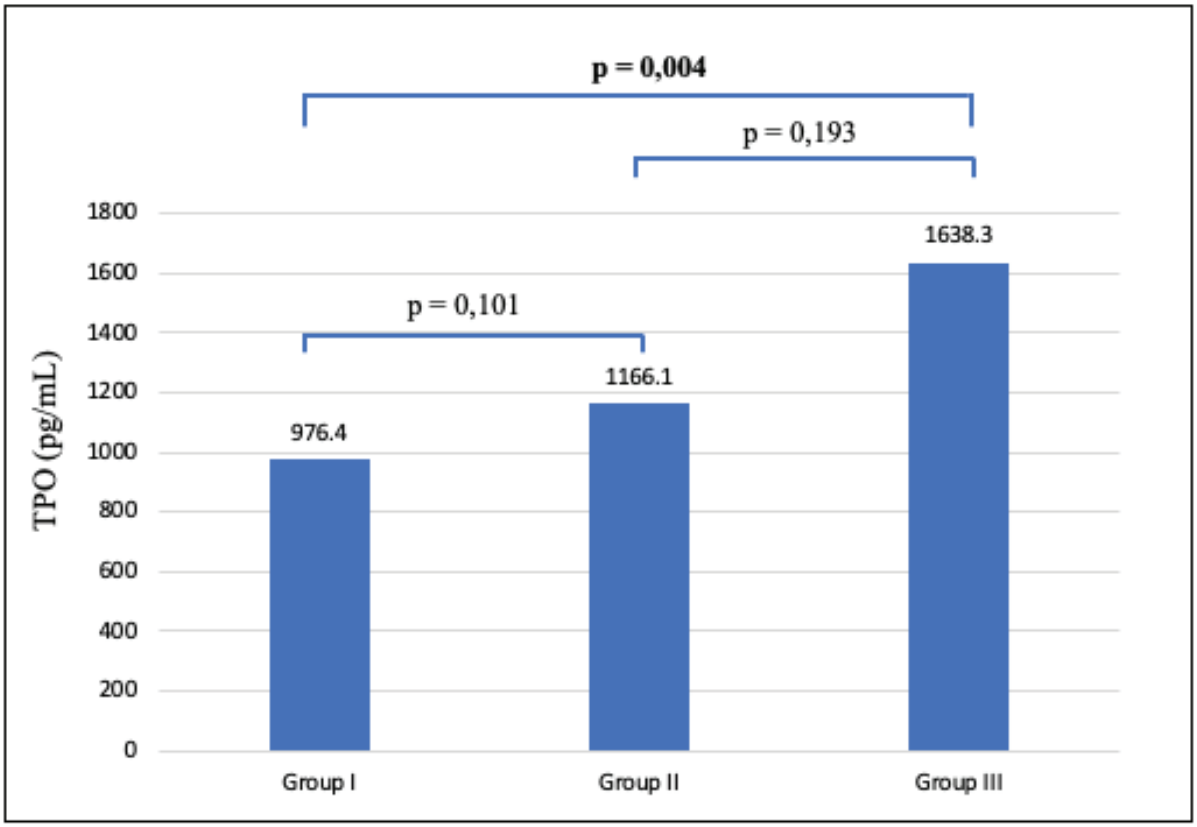

Figure 2. The comparison of TPO levels based on SOFA scores

Post hoc test showed that TPO levels were significantly different between group I (mean TPO level = 976.4 ± 804.1 pg/mL) and group III (mean TPO level = 1638.3 ± 94.7 pg/mL) with a p value = 0.004. Meanwhile, TPO levels between groups I and II and TPO levels between groups II and III did not show significant differences (p = 0.101 and p = 0.193).

Table 4. The correlation of IPF rates and TPO levels

	IPF		
	n	r	p*
TPO	49	0,606	<0,001

Source : Primary data

* Spearman Test

Measurement of correlation with IPF values and TPO levels showed a significant association. Spearman correlation test results indicated a strong positive correlation between IPF values and TPO levels (r = 0.606, p <0.001); the higher the TPO level, the higher the IPF value. The correlations of IPF values and TPO levels are shown in Table 4.

Discussion

This study showed that there was no significant difference between men (48.9%) and women (51.1%) with an average age of 54.9 years old. In 2005, an epidemiological study reported that sepsis was more frequently found in men than women with a relative risk of 1.28 in men. This difference may be caused by abnormalities of comorbid conditions in the study subjects and different lifestyles according to demographic conditions. Some comorbid conditions and lifestyle are related to sepsis in the form of immune status, heart disease, and alcohol intake.[9]

The mean of the IPF values increased with increasing SOFA scores. The mean of group I IPF was 6.8 ± 4.8%, while group II was 8.3 ± 5.7%, and group III was 13.9 ± 2.8%. The *Kruskal-Wallis* test showed that there were significant differences in the mean for the IPF of the three groups. Platelet rates are low with increasing SOFA scores. Both of these results provide a description of the condition of thrombopoiesis in the state of sepsis. Endothelial dysfunction which promotes a decrease in platelet count causes a compensatory mechanism in the body to increase thrombopoiesis characterized by an increase in IPF value. A research by Hubert et al (2015) reported the same thing as an increase in IPF values and decreased platelet rates in patients with sepsis shock compared with severe sepsis and sepsis without complications.[9]

Post hoc test showed significant differences in IPF values between group I with SOFA score 2-6 (mean IPF value = 6.8 ± 4.8%) and group III with SOFA score 9-15 (mean IPF value = 13.9 ± 2.8%). Meanwhile, the mean of group I IPF value is higher than group II, and the mean of group II IPF value is higher than group III, but there was no significant difference. These results differ from studies by Hubert et al who reported an increase in IPF values in study subjects with higher SOFA scores (SOFA ≥ 6) compared to study subjects with lower SOFA scores (SOFA <6). This difference may be due to differences in the assessment of SOFA scores and IPF scores. The assessment of SOFA scores and IPF scores in the study by Hubert et al was performed 24 hours after the subjects received intensive care while in this study the assessment of SOFA scores and IPF values was obtained when the patient was diagnosed with sepsis.[9]

The highest IPF value in this study was 23.5% in patients with congestive heart failure with complications of pulmonary edema. TPO levels in these patients were 2,291 pg / mL, platelet rates at 100,000 / mm3, and SOFA scores at 6. Despite the highest IPF values compared to other patients, TPO levels and SOFA scores in these patients were not the highest in the study sample. This might occur because thrombopoiesis was influenced by several other cytokines that were not examined in this study such as IL-3, IL-6 and IL-11.[10]

The mean of TPO levels increased along with SOFA scores and was inversely proportional to platelet rates. The mean of TPO levels in group I was 976.4 ± 804.1 pg / mL, while group II was 1166.1 ± 494.8 pg / mL, and group III was 1638.3 ± 94.7 pg / mL. The Kruskal-Wallis test showed that there were significant differences (p = 0.008) of the average TPO levels in the three groups of study subjects. This is in line with previous research by Zakynthinos et al (2004) and Segre et al (2014) who reported elevated TPO levels in sepsis shock compared with severe or uncomplicated sepsis.

Research comparing TPO levels based on SOFA scores has never been conducted.[11,12]

In line with the post hoc IPF test, differences in TPO levels were only found to be significant between group I and SOFA scores at 2-6 (the mean of TPO levels = 976.4 ± 804.1 pg / mL), and group III with SOFA scores of 9 -15 (mean TPO level = 1638.3 ± 94.7 pg / mL). There were no significant differences in TPO levels between groups I and II and between groups II and 3, but IPF values and TPO levels increased along with the SOFA score.

The correlation test results between IPF values and TPO levels in adult sepsis patients showed a positive correlation between IPF values and TPO levels (r = 0.606, p = 000). The condition of consumptive thrombocytopenia in sepsis caused the response from the body to compensate by increasing thrombopoiesis by increasing TPO production (Hitchcock IS & Kaushansky K, 2014; Larkin CM et al., 2016). The increase in TPO production promoted an increase in immature platelets in circulation with the elevation in IPF value. Significant correlation between IPF value and TPO level showed that there was no bone marrow failure in the process of thrombopoiesis in the state of sepsis.[13,14]

This research has several limitations: the lack of subjects in the study in patients with higher SOFA scores (group III) which could affect the mean of IPF values and TPO levels in this group, the assessments of IPF and TPO levels which were only performed at the beginning of diagnosis without a description of the function of thrombopoiesis in the bone marrow throughout the course of sepsis, and the absence of therapeutic analysis in research subjects that might affect the value of IPF and TPO levels.

Conclution and Suggestion

This study concludes that the value of Immature Platelet Fraction and thrombopoietin levels increases along with the SOFA scores. In addition, there is a positive correlation between the value of Immature Platelet Fraction and thrombopoietin levels in patients with sepsis. Further research is needed with better distributed research subjects in each group regarding the grades of sepsis, followed by analyses of the therapy and examinations towards the value of serial IPF and TPO following the course of sepsis.

Abstract

Radio-chemotherapy of the head and neck area can cause mucositis in cases of nasopharyngeal cancer that is felt as swallowing pain, dry mouth and loss of taste. This condition is often exacerbated by the onset of candidiasis on the oral mucosa. The aim of the case report was to inform the side effects of chemotherapy and radiotherapy treatments in nasopharyngeal cancer patients that occur in the oral cavity include angular cheilitis, acute pseudomembranous candidiasis and oral mucositis type 1 and their management. Case report, a 69 year old-man, came to the dental clinic of the Sardjito hospital with complaints of pain to swallow food, and his mouth had many white spots. Complaints were felt one week after the 3rd chemotherapy and 9th radiotherapy. The patient was diagnosed with nasopharyngeal cancer (NPC) with T2N3M0 classification. Clinical examination showed the presence of a white layer on the mucosa of the tongue, cheeks, palate and lip mucosa. The entire oral mucosa was dark red, and angular cheilitis on both corners of the lips was found. Treatment of this case by eliminating the necrotic tissue and debris by 3% hydrogen peroxide solution mouth rinse and administration of drugs, including candystin droops and betadine mouth rinse for 1 week. The patient can swallow and eat a little hard without any more pain after 1 week treatment. Clinical examination found that the white spots on the tongue, palate, cheeks and lips were gone. The color of the oral mucosa appeared the same as the surrounding tissue. The oral hygiene and general conditions were good. In conclusion, oral mucositis and acute pseudomembranous candidiasis due to chemo-radiotherapy treatment in nasopharyngeal cancer patient were disappearing, and the oral condition has improved. Patients can chew and swallow food without any pain.

Keywords*: nasopharyngeal cancer, oral mucositis type 1, candidiasis, angular cheilitis, chemotherapy, radiotherapy*

Introduction

Radiotherapy and chemotherapy in the head and neck area in case of nasopharyngeal cancer involves a large portion of the oral mucosa and the parotid gland. As a result, there will be side effects on the oral mucosa in the form of radiation mucositis in acute circumstances that the patient feels as swallowing pain, dry mouth (hyposalivation) and loss of taste. This condition is often exacerbated by the emergence of candidiasis infections in the mucosa of the tongue, cheeks and palate.[1] Oral mucositis can affect a patient's quality of life, increase the risk of infection, and cause failure of cancer treatment itself. The incidence of oral mucositis is estimated at 40% in patients receiving chemotherapy, 70% -90% in patients undergoing blood transplants and bone marrow stem cells, and 80 -100% in patients undergoing radiotherapy involving the oropharynx

region.[2] Mukositis is an ulceration and pain-causing inflammation in the mucous membrane layer caused by the effects of cancer treatment using chemotherapy and radiotherapy.[3] It was reported that 100% oral mucositis occurs in patients receiving high-dose chemotherapy and hematopoietic stem cell transplantation, while 80% occur in cancer of the head receiving radiotherapy.[4] Diagnosis of oral mucositis is based on symptoms that arise in oral tissue due to chemotherapy, spinal cord transplantation or radiotherapy. Ulceration with the appearance of red burn-like sores in the mouth is sufficient to diagnose oral mucositis.[5]

Oral candidiasis is a fungal infection that often occurs together with oral mucositis on radiotherapy treatments. Oral candidiasis is caused by Candida albicans species which can be acute or subacute, the infection is seen as a white layer on the mucosa of the cheeks, tongue, lips and palate. If the layer is lifted, the mucosa will bleed, the mouth feels dry and burning, and the taste sensitivity on the tongue decreased.[6]

In the present case, the side effects of chemotherapy and radiotherapy treatments in nasopharyngeal cancer patients that occur in the oral cavity in the form of acute pseudomembranous candidiasis (thrush), angular cheilitis and oral mucositis and their management were informed.

Case Report

A 69 year old man came to the Dental clinic in the reference from the Internal Medicine Department, Dr. Sardjito Hospital. He was complaint of pain to swallow food, and his mouth had many white spots. Complaints were felt one week ago with the mouth feeling dry and difficult to swallow food, so patients rarely consumed food. A few days later, white patches appeared on the edge of the tongue and other mouth areas (Figure 1).

Figure 1. The oral condition of the patient at the first visit

Medical history showed the patient had nasopharyngeal cancer (NPC) with T2N3M0 classification or grade 3. The patient had received the 3rd chemotherapy treatment using carboplatin 100 mg in a 500 cc 0.9% NaCl solution in 90 minutes, and the 9th radiotherapy. During the treatment at the Internal medicine department, the patient received vomceran injection 8 mg/24 hours intravenous (i.v) and dexamethasone injection 2 ampules / 24 hours i.v. Past dental history, the patient had ever extracted and filled teeth in Dr. Sardjito hospital, 4 years ago. Clinical examination found a white layer on the lateral right and left tongue, posterior dorsum of the tongue, right and left cheek mucosa, hard and soft palate, and mucosa of the upper and lower lips. Gingivitis appeared at all oral regions, oral mucosa was dark red, and cheilitis angular at both corners of the lips (Figure 2).

Figure 2. Patients with acute candidiasis pseudomembran, mucositis and angular cheilitis

Based on clinical examination and oral mucositis classification according to WHO,[5] patient was diagnosed with degree 1 radiation mucositis. Examination of vital signs showed blood pressure 130/80 mmHg, pulses 84 times/minute, respiration 20 times/minute, temperature 38.5^0C, and general condition: thin and weak.

Treatment was done by removing the necrotic tissue and debris using mouth rinse of 3% hydrogen peroxide solution for 1 minute 3 times a day. Medication consisted of candystin droops and betadine gargle for 1 week. Control patient at 1st visit, he can swallow and eat a little hard food, including meat, soft vegetables and side dishes that were not fried without any pain. Objective examination found a white layer on the tongue, palate, cheeks and lips had disappeared. Mild gingivitis at the anterior lower area still exists. Furthermore, the oral hygiene and general conditions were good. The color of the oral mucosa was the same as the surrounding tissue (Figure 3). Vital signs at 1st control revealed the blood pressure 120/60 mmHg, pulse 80 times/min,

respiration 20 times/min, and afebrile. Suggestions for patient included maintaining oral hygiene, continuing mouthwash, cleaning tartar and calculus, and finally making dental prostheses.

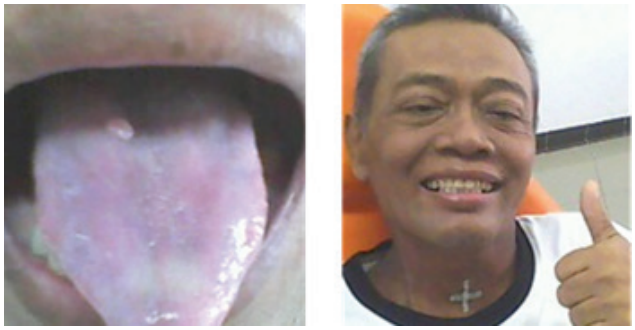

Figure 3. The oral mucositis and acute pseudomembranous candidiasis have healed, the patient did not feel pain and can swallow solid food. Finally, the patient looks happy.

Discussion

Treatment of the head and neck cancer includes nasopharyngeal cancer has a variety of problems that require careful handling by considering many factors that will affect the final outcome of treatment. Patients with smoking habits or heavy alcohol drinkers have a tendency to fail in radiation therapy followed by the lower tolerance of mucosal tissue to radiation.[7] Head and neck cancers have a type of histological anaplastic carcinoma that is sensitive to radiation. Other types such as squamous carcinoma and transitional carcinoma have lower levels of radiation sensitivity compared to anaplastic carcinoma. Nasopharyngeal cancer has the property of rapid propagation through the lymph channels to the neck lymph nodes and infiltratively to the skull base which can result in paralysis of some cranial nerves, especially the optic nerve.[8] It was reported that based on the radiation field area and radiation dose given to the neck region, the parotid gland can be ensured to have a disorder that causes hyposalivation and radiation mucositis.[7]

In this case, nasopharyngeal cancer patients had a T2N3M0 classification with complaints of pain when ingesting food. The oral mucosa was covered with fungi and angular cheilitis on both corners of the lips. Patients consumed less food so that the patient's body weight drops dramatically. This complaint was felt after receiving the 9th radiation therapy and 3rd chemotherapy. Moreover, the patient had undergone radiation mucositis with symptoms as described above,[1] namely pain due to dry mouth (xerostomia), the entire mucosa experiences erythematous, and loss of taste. According to WHO classification,[5] patient suffered from grade 1 oral mucositis, with the criteria that there was widespread erythema, and the patient cannot swallow solid food. These symptoms are compounded by the onset of candidiasis in the mucosa of the tongue, cheeks and palate. Interestingly, the patient's oral mucosa had experienced increased sensitivity due to radiation therapy in the nasopharyngeal irradiation. It was proven that radiotherapy was effective and successful because tissue sensitivity increased after chemotherapy.[1]

Oral mucositis is one of the most complications of chemotherapy and radiotherapy treatments. This result was produced from the cytotoxic effects of chemotherapy materials and the local effects of radiation on the oral mucosa. Oral mucositis is an oral mucosal inflammation with reddish-colored mucosal symptoms to severe ulceration. The mucositis symptoms are vary from pain to discomfort to the taste and mastication of food. Severe oral mucositis can cause treatment to be longer so that the secondary infection is easy to arise.[4] Patients who have the risk of developing oral mucositis need to get good and correct oral care with the aim of maintaining oral hygiene and preventing opportunistic infections through damage to the oral mucosa. Pull-out and treatment of dental caries must be done before radiation therapy, as well as education about the importance of oral hygiene and dental health.

Oral candidiasis is established based on clinical features supported by laboratory examination.[9] White patches that can be removed with the basis of erythema on the tongue, cheeks, palate and buccal mucosa show a picture of acute pseudomembranous candidiasis, while cracked lip angles describe angular cheilitis. It was reported that the most common infection in patients undergoing head and neck radiotherapy was candidiasis, and the most frequently involved candida species were Candida albican which is an opportunistic infectious agent.[10] Patients with decreased oral mucosal damage and immunity due to radiotherapy tend to occur opportunistic infection in his oral cavity. In this case, various factors that can increase susceptibility to oral candidiasis were decreased salivary production, changes in mucosal epithelium, nutritional deficiencies, and poor oral health.[11] Saliva is important in maintaining normal oral microflora. Saliva dilutes pathogenic antigens and mechanically cleanses the mucosa. Salivary antibodies (sIgA) and nonspecific antimicrobial factors are

important to reduce fungal attachment and colonization, therefore decreased salivary flow due to radiotherapy spurs candida infection in this patient. Radiation to the head-neck region can change the speed of normal epithelial replacement, causing a direct cytotoxic effect that can change the integrity of oral epithelium and promote secondary infection. Nutritional deficiencies can cause a decrease in body resistance and loss of cell integrity, which will facilitate candida invasion and infections.[2] Poor oral hygiene helps a conductive environment in increasing colonization and attachment of candida. It has been reported that oral mucositis can be aggravated by candidiasis because the infection aggravates mucosal epithelial damage.[12]

Treatment of oral mucositis, angular cheilitis and acute candidiasis as a side effect of irradiation in nasopharyngeal cancer patient was by removing necrotic tissue and debris by 3% hydrogen peroxide solution mouth rinse, and giving medication of candystin droops and betadine gargle for 1 week. Perhydrol (hydrogen peroxide) 3% solution is a strong oxidizer, used as a disinfectant, antiseptic, and includes bacterial agents that have generally recognized as safe (GRAS).[13] Nystatin is an antifungal drug that is effective and sensitive to candida infections, and safer if given orally like topical administration because of its minimal absorption through mucocutaneous membranes. The mechanism action of nystatin is by binding to ergosterol, a major component of the fungi cell membrane. Nystatin can cause membrane leakage of fungal cells which results in the release of K + ions and the death of these fungi cells.[14] Betadine gargel is a mouthwash containing 1% povidone iodine, one of the strongest antiseptics in the oral cavity. Betadine also has an antiviral and antibacterial effect that is widely used for inflammation of the oral cavity. Betadine can overcome throat and mouth problems such as itching, sore throat, phlegmon, tonsillitis, hoarseness, canker sores to bad breath.[15]

Based on the treatment that had been given it was known that patients can already swallow and eat a little hard food including meat, soft vegetables and side dishes that were not fried, without any complaints of pain. White spots on the tongue, palate, cheeks and lips were gone, angular cheilitis had disappeared, although mild gingivitis in the lower anterior area still exists. Interestingly, the general condition of the patient was good and he can eat a lot.

In conclusion, acute pseudomembranous candidiasis and oral mucositis type 1 as a result of combination of chemotherapy and radiotherapy treatments in nasopharyngeal cancer patients had disappeared and oral conditions had improved. Current clinical management of oral mucositis and acute candidiasis is largely focused on palliative measures such as pain management, nutritional support and maintenance of good oral hygiene. However, several promising therapeutic agents are in various stages of clinical development for the management of oral mucositis and acute candidiasis. In this case, the results of treatment given to patient was in accordance with the expectations of the operator.

Correlation of *Bla*$_{shv}$ And *Bla*$_{tem}$ Genes in Extended-Spectrum Beta-Lactamase (Esbl) - Producing *Acinetobacter Baumannii* With Patient's Outcome at Dr. Wahidin Sudirohusodo Hospital, Makassar

Tenri Esa[1], Nursin Abd Kadir[1], Rahmawati[1]

[1]Department of Clinical Pathology, Faculty of Medicine, Hasanuddin University-Dr.Wahidin Sudirohusodo Hospital Makassar, Indonesia. Jl. Perintis Kemerdekaan Tamalanrea, Makassar

Abstract

Acinetobacter baumannii causes the high morbidity and mortality. *Acinetobacter baumannii* has ESBL enzyme that makes it resistant to the mostly beta-lactam antibiotics. Some ESBL – coding genes are *bla*$_{SHV}$ and *bla*$_{TEM}$. The purpose of this study was to evaluate correlation *bla*$_{SHV}$ and *bla*$_{TEM}$ genes in Extended-Spectrum Beta-Lactamase (ESBL) - producing *Acinetobacter baumannii* with outcome (length of stay and death) at Dr. Wahidin Sudirohusodo Hospital, Makassar. The study used cross-sectional method conducted on *Acinetobacter baumannii* isolates and medical record at Dr. Wahidin Sudirohusodo, Makassar. ESBL was detected with automated culture, *bla*$_{SHV}$ and *bla*$_{TEM}$ genes was detected with PCR. Statistical analysis used Chi Square, Fisher Exact, Independent-t and Pearson's Correlation tests. Significance of test if $p<0.05$. Research of 57 *Acinetobacter baumannii* isolates, ESBL was found in 20 isolates (35%). Average length of stay (LOS) in positive ESBL (26.3 days) was significantly longer than in negative ESBL (16,5 days)(p = 0,016). Mortality rate was higher in positive ESBL (55%) than negative ESBL (35,1%), but statistically not significant ($p = 0.147$). The *bla*$_{TEM}$ gene found in 53 isolates (93%) and there was no isolate bringing *bla*$_{SHV}$ gene. In positive ESBL, average length of stays (LOS) in positive *bla*$_{TEM}$ was 25.4 days while in negative *bla*$_{TEM}$ was 42 days; Mortality rate was higher in positive *bla*$_{TEM}$ compared to negative *bla*$_{TEM}$ (57.9%, 0.0%, consecutively), but statistically not significant ($p>0.05$). It was concluded that *bla*$_{TEM}$ gene was found 93% and *bla*$_{SHV}$ was not found. The LOS in positive ESBL was significantly longer.

***Keywords**: Acinetobacter baumannii, ESBL, bla$_{SHV}$, bla$_{TEM}$, Outcome*

Introduction

Acinetobacter baumannii is an opportunistic bacterial pathogen primarily associated with a high morbidity and mortality.[1,2] It is an important agent of nosocomial infections worldwide, such as urinary tract infections, septicemia, pneumonia, burns, meningitis, and wound infections in hospitals.[3-5] *Acinetobacter baumannii* infection causes duration of stay in hospital becomes longer, increases burden of cost and difficult to treat.[6] *World Health Organization* (WHO) had published list of bacterias that needed urgently new antibiotics in 2017 and placed *Acinetobacter baumannii* in the first row critical priority group. National Nosocomial Infections Surveillance (NNIS) System found that there was an significant increase *Acinetobacter* infection between 1987 and 1996 in United State of America about 54%.[7] Studies in Indonesia showed that one of pathogens in late onset Hospital Acquired Pneumonia infection was *Acinetobacter baumannii* with prevalence 23,2%.[8,9]. Data in 2019 at Wahidin Sudirohusodo Hospital Makassar showed prevalence *Acinetobacter baumannii* infection about 19,6% of all Gram-negative bacterial infections in recent last eight months. Resistance mechanism of *Acinetobacter baumannii* can be through several ways such as production enzyme that able to hydrolyze drugs component, drug *efflux*, failure to reach target or change in drug target.[10,11]

Extended-spectrum beta-lactamase (ESBL) is an enzyme that has resistance to the most beta-lactam antibiotics including penicillin, cephalosporin and

aztreonam monobactam.[12,13] *Acinetobacter baumannii* is one of pathogens that capable to produce ESBL. Genes that encodes ESBL is located in plasmid that is easily transferred to another pathogen and therefore resistence is spreading.[14,15] First publication about genes that encoding beta-lactamase was found in 1983. Some of these genes are *Temoniera* (bla_{TEM}) and *sulfhydril variable* (bla_{SHV}). Prevalence bla_{SHV} gene in China 30,7% during 1998-1999. Korea, Japan, Malaysia and Singapore reported prevalence 5-8% while Thailand, Taiwan, Filipina and Indonesia reported prevalence 12-24% with bla_{SHV} gene was the dominant gene.[14] Enzymes of ESBL that are resistant to the third generation cephalosporin antibiotics are encoded by bla_{SHV} gene 58%, bla_{TEM} gene 20% and *Cefotaxime Munich* (bla_{CTX-M}).[10] The purpose of this study was to evaluate correlation bla_{SHV} and bla_{TEM} genes in Extended-Spectrum Beta-Lactamase (ESBL) - producing *Acinetobacter baumannii* with patient's outcome at Dr. Wahidin Sudirohusodo Hospital, Makassar.

Method

This study is a cross sectional study detecting bla_{SHV} and bla_{TEM} genes in ESBL producing - *Acinetobacter baumannii* isolates and evaluating correlation these genes with outcome length of stays and mortality. The study was conducted during August 2019 at Clinical Pathology Laboratory of Dr. Wahidin Sudirohusodo Hospital and Microbiology laboratory of Hasanuddin University, Makassar, Indonesia. The study sample was all *Acinetobacter baumannii* isolates that had been confirmed using Vitek 2 Compact. Contamined samples were excluded. All isolates were tested for ESBL and Polymerase Chain Reaction for bla_{SHV} and bla_{TEM} genes.

Data were analyzed statistically by *Chi Square*, *Fisher Exact*, *Independent-T* and *Pearson's* tests using SPSS version 25. The results were considered significant if $p<0.05$.

Results

Table 1. General Characteristics

Variables		***n***	**%**	***Mean±SD***
Age (years)	<20	12	21,1	
	20-39	9	15,8	
	40-59	23	40,4	
	>=60	13	22,8	
Sex	Men	38	66,7	
	Women	19	33,3	
ESBL	Positive	20	35,1	
	Negative	37	64,9	
bla_{SHV}	Positive	0	0	
	Negative	57	100	
bla_{TEM}	Positive	53	93	
	Negative	4	7	
Death	Yes	24	42,1	
	No	33	57,9	
Length of Stay(days)				20±15

The study samples obtained were 57 isolates which met the inclusion criteria. The characteristics of study samples can be seen in Table 1 that shows male subjects were more than female. Most study subjects were found in the 40-59 year group. PCR of bla_{SHV} and bla_{TEM} of the study are shown in Figure 1.

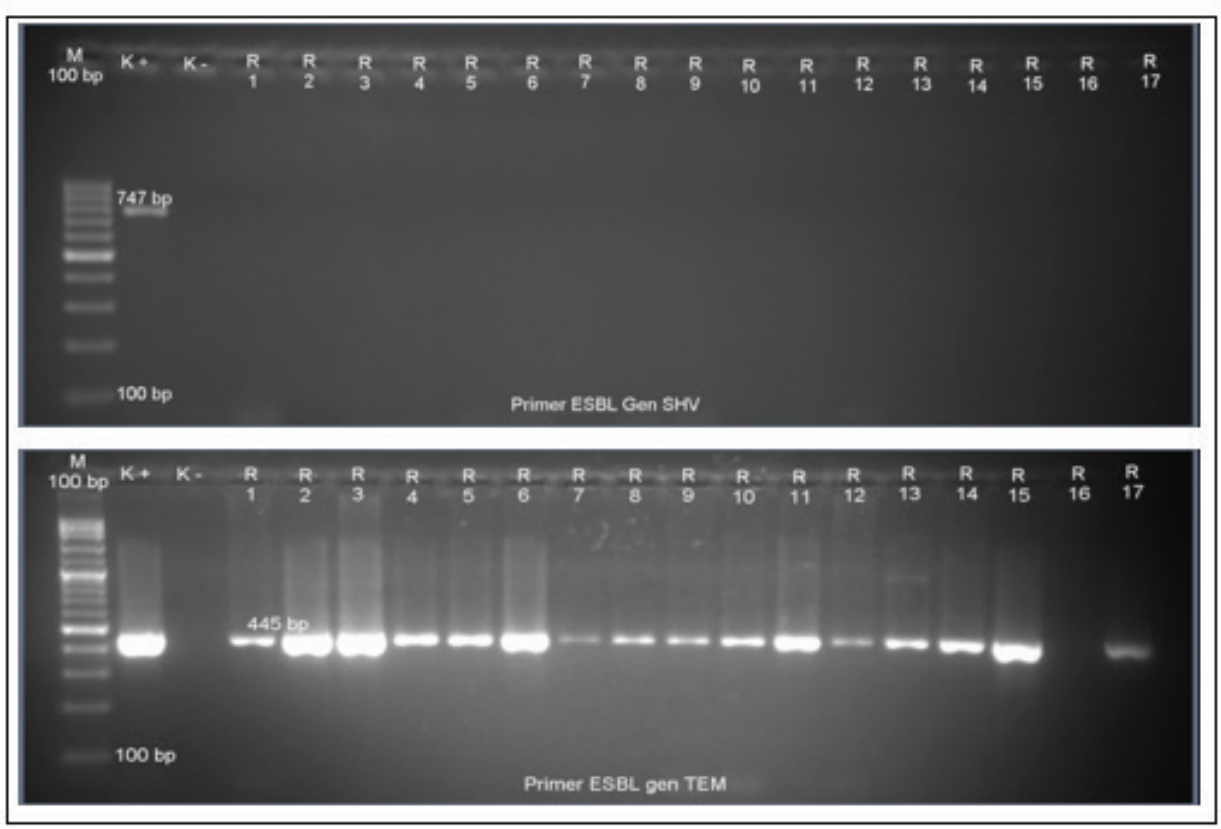

Figure 1. PCR of bla_{SHV} and bla_{TEM} of the study.

Table 2. Correlation Length Of Stay Based On ESBL

ESBL	*n*	LOS(days) *Mean±SD*	*p
Positive	20	26,3±17,5	0,016
Negative	37	16,5±11,9	

**Independent-t test*

Table 2 showed the mean length of stay in positive ESBL was higher than in negative ESBL. Statistical analysis showed significant correlation between ESBL and LOS (p = 0.016).

Table 3. Correlation Mortality Based On ESBL

ESBL		Mortality		*p
		Yes	No	
Positive	*n*(%)	11(55)	9(45)	0,147
Negative	*n*(%)	13(35,1)	24(64,9)	

**Chi Square test*

Table 3 showed that mortality rate was higher in positive ESBL (55%) than in negative ESBL (35,1%), but statistical analysis result was not significant (p>0,05).

Table 4. Comparison bla_{TEM} Based On Outcome

Group			N	Outcome				
				LOS (days)		Mortality		
				(mean±SD)	*p	Yes n(%)	No n(%)	**p
ESBL								
	bla_{TEM}	Pos	19	25,4±17,6	#	11 (57,9)	8 (42,1)	0,450
		Neg	1	42,0±17,6		0 (0)	1 (100)	
NonESBL								
	bla_{TEM}	Pos	34	17,0±12,2	0,439	12 (35,3)	22 (64,7)	1,000
		Neg	3	11,3±7,8		1(35,3)	2 (66,7)	

*Independent-t test
**Fisher Excat test
Could not be analyzed because negative bla_{TEM} was only one isolate

*Independent-t test

**Fisher Excat test

Could not be analyzed because negative bla_{TEM} was only one isolate

Table 4 showed that presentation mortality in ESBL group was found higher in positive bla_{TEM} (57,9%) than in negative bla_{TEM}, but statistical analysis was not significant (p>0,05). Presentation mortality in nonESBL group was found higher in positive bla_{TEM} (35,5%) than in negative bla_{TEM}(33,3%), but statistical analysis was not significant (p>0,05).

Discussion

Acinetobacter baumannii is an opportunistic Gram-negative pathogen that is able to produce ESBL. Extended-spectrum β-lactamases are the main cause of bacterial resistance to beta-lactam antibiotics. In this study, positive ESBL was found 35% of all *Acinetobacter baumannii* isolates. The results obtained in this study were not consistent with Abdar *et* al in Iran that found 59% of 100 *Acinetobacter baumannii* were positive.[16] Sharif *et al* also found detection rate ESBL was 51%.[17] This difference was caused by the high use of the third generation cephalosporine antibiotics in hospital and home care in that country.[16] Overuse antibiotics and *hand hygine* were factors that caused adalah higher incidence ESBL in hospital setting. Abdar *et al* and Sharif *et al* used diffusion test agar while our study used automated culture method.[16,17] Automated culture method has sensitivity 98,1% and specificity 99,7%. The method needs 6 - 13 hours (mean 8.2 hours) and therefore this method can be a choice for detecting isolates of ESBL producing- bacteria.[18]

This study found significant difference statistically between length of stay and positive ESBL and negative ESBL. *Acinetobacter baumannii* that has ESBL causes antibiotic resistance and therefore infection is difficult to treat and duration stays in hospital is longer and increase burden of hospitality costs. The results obtained in this study found that mortality in *Acinetobacter baumannii* was high (42%). Higher mortality rate was found in isolates with positive bla_{TEM} and also found higher in positive ESBL although statistical analysis is not significant. *Acinetobacter baumannii* is the most pathogen from *Acinetobacter* genus. This pathogen often causes infection in compromised subject, especially in ICU with invasive support. *Acinetobacter baumannii* causes *ventilator associated pneumonia* (VAP), meningitis, septicemia, urinary track infection, and burn infection.[17] *Acinetobacter baumannii* infection causes severe sepsis. High mortality also increases with invasive procedure such as mechanical ventilator and central venous catheter.

Acinetobacter baumannii produces ESBL through role of plasmid such as bla_{SHV} and bla_{TEM} genes. The study which we did in Wahidin Sudirohusodo Hospital revealed that there was no isolate containing bla_{SHV} gene while bla_{TEM} gene dominated most of all samples (93%). The results obtained in this study were consistent

with Abdar *et al* who did not find any bla_{SHV} gene in ESBL producing-*Acinetobacter baumannii* isolates.[16]. Koo *et al* also did not find any bla_{SHV} gene in Korea.[19] The result of this study were consistent with Chaudhary *et al* who found prevalence of bla_{TEM} in positive ESBL was 87%.[20] Adams-Haduch *et al*, also found prevalence bla_{TEM} gene about 73,5%.[21] The results obtained in this study were different with Sharif *et al* who found 56% bla_{TEM} and 63% bla_{SHV} of ESBL isolates.[17] Other studies in the world show variation result. The difference of our study and others indicates that type of ESBL genes can be variable from one place to another place. Bla_{TEM} gene that encodes ESBL is located in integron 1 of plasmid and therefore that gene is easily tobe transferred from one *Acinetobacter baumannii* to another *Acinetobacter baumannii*.[16] Genotype detection method used PCR technique that has high specificity and sensitivity therefore this technique was able to detect 93% bla_{TEM} gene in *Acinetobacter baumannii* isolates in this study. The difference between prevalence of bla_{TEM} gene and ESBL in this study could be caused by *Acinetobacter baumannii* had already had bla_{TEM} resistant gene in the plasmid but this gene was not transferred yet to the chromosome or the bla_{TEM} resistance gene had been in the chromosome but synthesis ESBL was not happened. Bla_{TEM} gene that was found in *Acinetobacter baumannii* isolates indicates that this gene can be a candidate for molecular skrining from positive ESBL samples in our hospital and can be an important concern because that *Acinetobacter baumannii* can further produce ESBL if antibiotics are not used rationally.

This study had some limitations. This study did not analyze the type and duration antibiotics that had been used by the patients and also diagnosis of the disease. These factors might cause bias for length of stay in this study.

CONCLUSION AND SUGGESTION

This study concluded that there were 35% positive ESBL of all *Acinetobacter baumannii* isolates. Bla_{SHV} gene was not found and bla_{TEM} gene was dominant 93%. Prevalence positive ESBL was higher in positive bla_{TEM} gene. Length of stay positive ESBL was significant statistically in positive ESBL. Mortality rate was high (42%) in *Acinetobacter baumannii* infection. We also recommend further study that evaluates factors related to the outcome (length of stay and mortality) in subjects with ESBL producing *Acinetobacter baumannii* infection.

Abstract

Retinectomy has been so far the most effective method to eliminate the retinal traction caused by proliferative vitreo-retinopathy (PVR) in retinal detachment. There are several methods of retinectomy applicable to different situation on surgeons' personal preferences, cirfumferential, radial, or combined. However, there is no clear evidence explaining whether one method is superior than the other. Radial retinectomy has been less commonly performed, yet is speculated to be more effective methods in certain cases of severe PVR. Whilst there is no scientific and geometrical analysis or formula for radial retinal cutting (retinectomy of radial relaxation) in retinal detachment with severe PVR, the authors proposed to developed a two-dimensional projection of the retina following Cartesian rules and apply geometrical projection to analyze the optimal radial cutting assuming retinal detachment with severe PVR is present.

***Keywords**: Two-dimension, Radial retinectomy, Retinal Detachment*

Introduction

Proliferative Vitreo-retinopathy (PVR) has been classified by The Retinal Society into grade A, B, C1, C2, C3, D1, D2, and D3 based on the level of severity and its extension in the retina.[1] Grade A PVR is the most minimal and grade D is the most severe form of PVR. In previous years, the surgery done in rhegmatogenous retinal detachment (RRD) with severe PVR (grade C or worse) involves vitrectomy with retinectomy and silicon oil tamponade.[2-6] The method of retinectomy applied in most cases of RRD with higher degree of PVR was circumferential. Unfortunately, this technique demonstrated considerable rate of re-detachment because of the traction of the remaining tissues.[7]

Previous report has suggested that radial retinectomy might also be useful in cases of RRD with severe PVR, as an alternative to circumferential retinectomy.[8] Our empirical data of all radial retinectomy for RRD patients with PVR of at least grade C indicated a considerably high rate of anatomical success with less post-surgical complication without the need of silicon oil tamponade (unpublished data). However, there has been no precise method or formula (geometrical formula) on how to perform optimal radial retinectomy.

In this paper, we presented the two-dimensional analysis of the retina and extend this in the context of radial retinectomy for RRD.

Method

The Cartesian coordinate system with x and y-coordinates are used to define the exact position of a point in a plane. It is also employed to describe a curve line as well as two-dimensional (2D) surfaces.[9]

The horizontal axis is labeled x, and the vertical axis is labeled y. In the three-dimensional (3D) coordinate system, another axis is added and often labeled by z-axis. The axis is orthogonal to one another and all are appendicular to each other. The intersection of the points is as the origin and labeled 0. Each axis has a unit length and each length is marked then forms a grid. To describe a particular point in 2D spaces, the x-value is written (abscissa), followed by y-value (ordinate). Thus, it is always (x,y). Since two axes are perpendicular to each other, the xy plane is divided into four regions called quadrants as in Figure 2.46 which often numbered with Roman numeral I, II, III, and IV. According to the common convention, the four quadrants are ordered starting from the top right (quadrant I), circling counter-clockwise. In quadrant I, both coordinates (x and y) are positive. In quadrant III, both coordinates are negative and in quadrant IV, the x coordinate is positive while the y-value negative (Figure 1).

In contrast to the Cartesian coordinates which denote the points on x and y coordinate, the polar coordinates determine the position of a point based on an angle on positive x-axis and a distance from a reference point.[10]

On the chart above, the P-point is delineated in two coordinates, the Cartesian coordinates (x, y) which indicate its relative position to x and y-axis, and the polar coordinates showing a distance to the 0 reference point and α angle formed by OP line segment to the positive x-axis (Figure 2).

Results

Geometrically, 2D Cartesian and polar coordinates can be applied to the eyeball depicted by following fundus photograph. Figure 3 illustrates polar coordinates projected on a fundus photograph of a detach retina. To find the linear equation of the blue and green lines, we assume that the two points of the end line are determined. The general linear equation for both points is as follow.

$$\frac{y-y_n}{y_{n+1}-y_n}=\frac{x-x_n}{x_{n+1}-x_n} \quad (1)$$

where for quadrant I

$$x_n=r\cos\theta_n;\ y_n=r\sin\theta_n \quad (2)$$

$$x_{n+1}=r\cos\theta_n;\ y_{n+1}=R\sin\theta_n \quad (3)$$

For Quadrant II: $\theta_n=180^\circ-\alpha_n$ (4)

For quadrant III: $\theta_n=180^\circ+\alpha_n$ (5)

For Quadrant IV: $\theta_n=360^\circ-\alpha_n$ (6)

$$\frac{y-r\sin\theta_n}{R\sin\theta_n-r\sin\theta_n}=\frac{x-r\cos\theta_n}{R\cos\theta_n-r\cos\theta_n} \quad (7)$$

$$\frac{y-r\sin\theta_n}{(R-r)\sin\theta_n}=\frac{x-r\cos\theta_n}{(R-r)\cos\theta_n} \quad (8)$$

$$y-r\sin\theta_n=\frac{(R-r)\sin\theta_n}{(R-r)\cos\theta_n}(x-r\cos\theta_n) \quad (9)$$

$$y-r\sin\theta_n=\frac{\sin\theta_n}{\cos\theta_n}(x-r\cos\theta_n) \quad (10)$$

$$y=\tan\theta_n(x-r\cos\theta_n)+r\sin\theta_n \quad (11)$$

$$y=x\tan\theta_n-r\cos\theta_n\tan\theta_n+r\sin\theta_n \quad (12)$$

when equation (12) is simplified, it becomes

$$y=x\tan\theta_n-r\cos\theta_n\frac{\sin\theta_n}{\cos\theta_n}+r\sin\theta_n \quad (13)$$

$$y=x\tan\theta_n \quad (14)$$

So, the equation of the line is a straight line with a gradient (m) of $\tan\theta_n$.

By the trigonometric identity formulas that $\tan(n\pi-\beta)=-\tan\beta$ *(even quadrants)* and $\tan\theta=\tan(\theta+n\pi)$ *(odd quadrants)* with= 0,1,2,...

Then if it is defined $\theta_1=45^\circ$; $\theta_2=60^\circ$; $\theta_2=120^\circ(\alpha_2=60^\circ);\theta_4=135^\circ(\alpha_4=45^\circ);\theta_3=150^\circ($ $\alpha_3=30^\circ$) the equation of the line will be

Line 1: $y=x$ (15)

Line 2: $y=\sqrt{3}x$ (16)

Line 3: $y=-\sqrt{3}x$ (17)

Line 4: $y=-x$ (18)

Line 5: $y=-\frac{\sqrt{3}}{3}x$ (19)

We considered the rule that it is forbidden to draw a line crossing two red circles with some radius (r) due to its vital function, defining and determining the line must be started from quadrant I, II, III, and last IV respectively. Then, if the equation (2) and (3) are substituted into equation (1), we will get equation as follow.

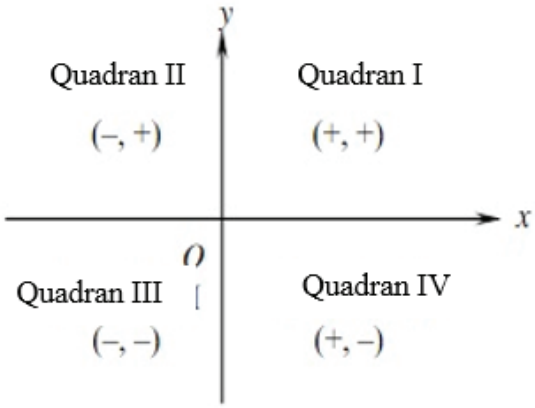

Figure 1. The Cartesian Coordinate System (Paul Ryclear *et al.*, 1977)

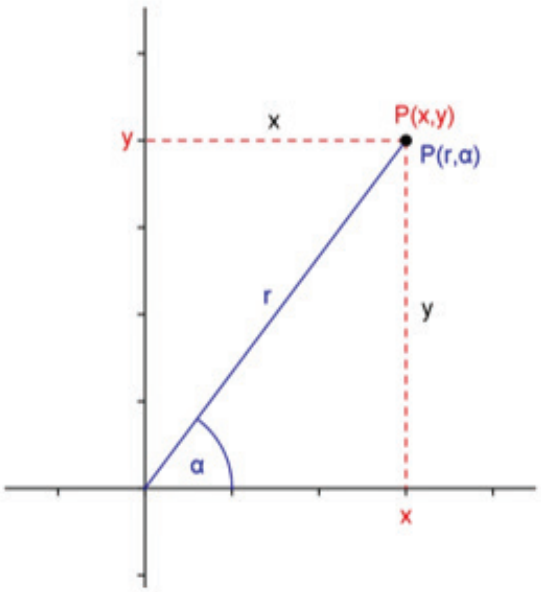

Figure 2. Delineation of polar coordinates

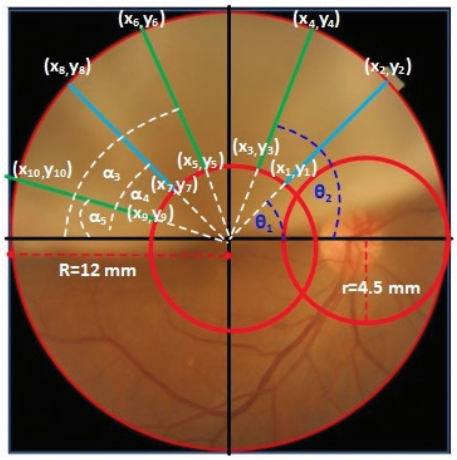

Figure 3. The application of polar coordinates (2D) on a fundus photo.

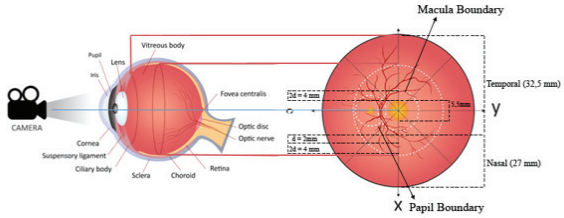

Figure 4. Cutting boundaries in the retina

Discussion

Two-dimensional projection of a three-dimensional object may dissolve the accuracy of information related to the actual distance and direction between two points. However in this paper, we provide a geometric analysis of radial retinectomy when applied on two-dimensional retinal photograph of a detached retina, which may possibily help to guide the application of radial cutting on the detached retina during the surgery.

With the advancement of retinal photography, the retina can be accurately portayed and thus offer retinal surgeon significant advantages. Assuming that the two-dimensional plane of the retina is projected from a microscope or camera, detached and PVR portion of the retina can be depicted easily from the retinal images and potential retinal cutting can be constructed considering the the border and angle of retinal cutting prior to the surgery. Figure 4 below is the example of two-dimensional projection of the retina with cutting border. In the future, further application of this two-dimensional projection may allow automatic detection of PVR lesion on detached retina and generate the outline of the cutting boundaries automatically using computer generated software.

In conclusion, the two-dimensional projection of radial relaxation retinectomy has been made possible with the advancement of retinal photography, allowing retinal surgeons to precisely plan the radial cutting of the retina prior to the surgery. This two-dimensional analysis is a significant basis to make a general formulation which is further will be completed by the physical condition of eyeballs (elasticity and crimp) as well as a 3D model of radial retinectomy relaxation.

Identification of Acute Rotavirus Diarrhea and Analysis of its Risk Factors in Children Under-5 Years in Surabaya, Indonesia

Yunita Ratri Adhiningsih[1], Alpha Fardah Athiyyah[2], Juniastuti[3]

[1]Undergraduate Program for Medical Doctor, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [2]Department of Pediatrics, Faculty of Medicine, Universitas Airlangga/ Dr. Soetomo General Hospital, Surabaya, Indonesia, [3]Department of Microbiology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia.

Abstract

Background: Diarrhea is the most common disease among children and still a major cause of morbidity and mortality. Among the various causes of acute diarrhea in children, rotavirus is the most frequent one, especially in developing countries where universal rotavirus vaccination has not been introduced, including Indonesia.

Objectives: This study aimed to determine the percentage of acute rotavirus diarrhea in children and analyze its risk factors in Tanah Kali Kedinding Primary Health Care, Surabaya, Indonesia.

Method: Stool specimens were collected from a total 116 children under-5 years visiting Tanah Kali Kedinding Primary Health Care in Surabaya, Indonesia due to acute diarrhea during September 2018 – January 2019. Rapid stool antigen immunochromatograhic test was used to identify group A rotavirus antigen. Some potential risk factors were analyzed.

Results*:* Among 116 samples from children with acute diarrhea, 67 (57.8%) were identified group A rotavirus positive. Samples with rotavirus positive were obtained mostly form male (p=0.008). Malnutrition was associated with an increased risk of rotavirus infection (p=0.025). Male and malnutrition were about 3 times more likely to have rotavirus infection. Other risk factors including children' age, history of exclusive breastfeeding, mothers' education and the amount of income were not statistically associated with rotavirus diarrhea.

Conclusion: The occurence of children with acute rotavirus diarrhea in this study was 57.8%. Some risk factors for rotavirus infection were gender and malnutrition. Control measures such as anticipating its risk factors need to be adapted, according to the further epidemiology investigation.

***Keywords** : rotavirus, acute diarrhea, risk factors, children under-5 years*

Introduction

Diarrhea is the most common disease among children with approximately nearly 1.7 billion cases and kills around 525,000 children every year worldwide.[1] In Indonesia, the incidence of diarrhea was very high, with 270 new cases per 1,000 persons and its prevalence in children under-5 years was 12.3% in 2018.[2]

Acute diarrhea is an inflammatory disease on intestine caused by various agents like viruses, bacteria and parasites. Among the causative agents, rotavirus is the most frequent one in children. Rotavirus is primarily spread via the fecal-oral route, either by person-to-person contact or through ingestion of food or water that has been contaminated with the stool of infected

persons.[1] Rotavirus is a viral infection that depends on seasonal changes, with the highest its prevalence occurs in cooler months.[3] Symptomatic presentations of rotavirus infection which are more visible at the age of 6- 24 months include fever, vomiting, and acute watery diarrhea.[4,5] There is no specific treatment for rotavirus other than fluid and electrolyte replacement to prevent several complication such as dehydration, sepsis, gastrointestinal (GI) bleeding, respiratory infections, myocarditis, hepatic abscess, hepatitis, seizures and meningoencephalitis.[6,7]

Studies of rotavirus infection in children under-5 years previously have been conducted in some cities in Indonesia. In Jakarta, rotavirus infection was detected in 42%, twice more than norwalk like viruses (prototype of norovirus) infection in 1997-1999.[8] In Bali, rotavirus infection was reported 49.8% in 2009-2011.[9] Nirwati et al reported the prevalence of rotavirus in Yogyakarta was 57% in 2009 and in Mataram was 65.47% in 2015.[10,11] The prevalence of rotavirus infection among hospitalized pediatric patients in Surabaya during 2015-2018 was 31.7%.[12] Proportion of rotavirus infection in the community (primary health care) in Bandar Lampung was 74.3%, and no potential risk factor was found to be associated with the disease.[13] Many studies showed the high prevalence of rotavirus infection in Indonesia, however rotavirus vaccination has not been included in a national immunization program (still included in an optional immunization).[14]

In East Java province, the prevalence of diarrhea in children under-5 years increased from 6.6% in 2013 to 10.7% in 2018.[15] Surabaya is a capital of East Java province, and Tanah Kali Kedinding Primary Health Care was ranked fourth for the highest case number of diarrhea (1,460 cases) in Surabaya in 2018.[16]

Only a few studies have reported acute rotavirus diarrhea in cities in Indonesia including its risk factors. This study aimed to determine the proportion of acute rotavirus diarrhea in children and analyze its risk factors in Tanah Kali Kedinding Primary Health Care, Surabaya.

Materials and Method

Stool specimens were collected from children under-5 years visiting Tanah Kali Kedinding Primary Health Care in Surabaya due to acute diarrhea during September 2018 – January 2019. Acute diarrhea is defined as passage of ≥3 of abnormally loose or watery stools in the preceding 24 hours or as a new onset of diarrhea in a patient without a history of diarrhea in the previous 14 days. Rapid stool antigen immunochromatograhic testing by using SD rotavirus BIO LINE (SD Bioline Rotavirus Rapid; Standard Diagnostics, Inc, Yongin, Korea) was performed to identify VP6 antigen of group A rotavirus according to the manufacturer's instructions. The sensitivity and the specificity of this test were 100% and 92.4%, respectively. Data of socio-economic and history of breastfeeding was collected using a standard questionnaire by interview. Nutritional status was collected from raw data (medical record) which then analyzed using cut off Z-Score WHO 2006 and recommendation of Indonesian Pediatric Society.[17] All data were analyzed using SPSS 20 with chi-square or fisher's exact test for categorical variables.

Ethical clearance for this study was obtained from the Ethics Committee of Faculty of Medicine, Universitas Airlangga, Surabaya. Informed consent for participation in this study was obtained from parents of each individual.

Results

Among a total of 116 enrolled children, most of them (57.8%) were rotavirus-positive and the rest (42.2%) were rotavirus-negative. More boys (59.7%) were infected with rotavirus infection than girls. Most of both children with and without rotavirus infection were 1-2 years old, had mothers with tertiary education and parents who earned income under city minimum wage (Table 1). All children have not been vaccinated with rotavirus vaccination.

Some potential risk factors of rotavirus infections were analyzed in this study, including age, gender, history of exclusive breastfeeding, nutritional status, maternal education, parents' income. Among those factors, only gender and nutritional status were statistically significant. Male and malnutrition were about 3 times more likely to have rotavirus infection (OR=2.789, CI=1.298-5.989, p=0.008 and OR=3.05, CI=1.120-8.304, p=0.025, respectively).

Discussion

One hundred and sixteen children with acute diarrhea in a community (a primary health care) in Surabaya were enrolled in this study. Sixty seven (57.8%) children were infected with rotavirus. This result was in agreement with previous studies in hospitalized children in other cities in Indonesia, ranged 31.7%-65.5% of rotavirus infections, however it was less from the prevalence reported in a primary health care in Bandar Lampung (74.3%).[8-13] All of those studies presented high number of rotavirus infection, however a rotavirus vaccination has not been included in a national immunization program yet. [14] Compared with the result of the previous study in a referral hospital (31.7%) in the same city (Surabaya), our study in the community found the higher number of rotavirus infection. Hospitalized patients at tertiary health care tend to have more severe disease. It looks like that the number of milder rotavirus infection in community was more than that in hospital. Salim et al (2014) reported among 327 cases with rotavirus infection, 91.4% (299) presented mild dehydration and 11 (3.4%) presented severe dehydration.[9]

In our study, children with male gender were about 3 times more likely to have rotavirus infection (*p<0.05*). It confirmed the previous report that ratio of male and female with rotavirus infection was 1.6 : 1.[9] However, Fidhow et al (2017) reported that gender was not a significant factor associated with rotavirus infection.[18]

Although age was not a significant factor, most children under-2 years (55.3%) were infected with rotavirus. This result was supported by previous studies in other cities in Indonesia and also in India.[8,12,19,20] The incidence of rotavirus infection rarely occurs in children less than 6 months and more than 2 years. It might due to passively mother's anti-rotavirus antibodies through exclusive breastfeeding, while after 2 years of age the children have already developed antibodies against repeated infection.[21]

A previous study showed that clinical infants who were breastfed presented milder symptoms of shorter duration than infants who were bottle-fed.[22] Breastfeeding reduces gastrointestinal infections as breast milk contains lactadherin that is protective against symptomatic rotavirus infection. Human milk also contains anti-rotavirus antibodies that seem to play a smaller role against pathogens.[23] In our study, children with history of exclusive breastfeeding were less likely to have rotavirus infection (OR 0.67), although the history of exclusive breastfeeding was not statistically significant as its risk factor ($p>0.05$). This result was in line with the Shen et al' finding.[24]

Malnutrition was associated rotavirus infection ($p<0.05$). Children with malnutrion had a 3 times increased risk of rotavirus diarrhea. Epidemiological studies suggested a strong association between childhood malnutrition and increased risk of infectious diarrhea. The increased incidence and severity of infections in malnourished children is largely due to the deterioration of immune function; limited production and/or diminished functional capacity of all cellular components of the immune system have been reported in malnutrition.[25] However, certain infectious diseases, including rotavirus infection also cause malnutrition, which can result in a vicious cycle. Among all causes of childhood diarrhea, rotavirus is one of the most significant attributable one[26] and cellular attachment with healthy cells in the brush border of the intestine is fundamental in the pathophysiology of the rotavirus infection.[27-29] Malnutrition with the possibility of shortening of villi in malnourished infants may inhibit rotavirus entry and replication.[30]

Children with rotavirus diarrhea whose mothers had tertiary education were predominant (52.2%). It was suggested that mothers with higher education were more likely to be aware of health condition of their children. Unfortunately, in this study, most of them had a low household income. Parashar et al (2003) showed from the median 2.1 million deaths due to diarrhea, 85% occurred in children from low-income countries. The proportion of deaths in infants with diarrhea shows a declining trend with increasing income levels.[31]

The finding of high number of acute rotavirus diarrhea needs a great attention and anticipation. The earlier detection of the infection could prevent the greater severity in those children. Improving nutritional status and implementation of rotavirus vaccination as a national immunization program might be considered to lower the incidence of acute rotavirus diarrhea.

Conclusion

The occurence of children with acute rotavirus diarrhea in Tanah Kali Kedinding Primary Health Care, Surabaya was 57.8%. Interestingly, it was higher than that in hospital reported previously in Surabaya. Some risk factors associated with rotavirus infections were gender and malnutrition. Control measures such as anticipating its risk factors need to be adapted, according to the further epidemiology investigation.

Conflict of Interest: There was no conflict of interest in this study.

Ethical Clearance: The ethical clearance was obtained from KEPK, Faculty of Medicine, Universitas Airlangga No. 84/EC/KEPK/FKUA/2019.

Source of Funding: This study was supported by the authors.

Analysis of Patient Safety and Occupational Health Safety in Surabaya Haji Hospital

Rusmina

Faculty of Public Health, Airlangga University, Indonesia

Abstract

Introduction: Safety standards are one of the important indicators of hospital services. But so far there have been no studies that discuss safety efforts in the Surabaya Haji Hospital. This study aims to study and understand the management in the Intensive Care, Central Surgery and Inpatient Installation of the Surabaya Hajj Hospital, especially the standards of patient safety and occupational health safety in the hospital. **Method:** The study used primary data from observation, in-depth interviews, and secondary data from each unit. Study location were in Intensive Care Unit, Central Surgery Installation and Inpatient Installation. **Results:** This study shows the efforts of the Surabaya Haji Hospital in ensuring patient safety and work safety in the hospital environment. In general, the steps of hospital management were right. Patient safety procedures referred to service quality standards at JCI hospitals. While work safety efforts in hospitals have also received attention because a special team has been formed that regulates hospital health and safety. **Conclusion:** To ensure patient safety and occupational health safety in the hospital runs according to established procedures, hospital management needs to conduct regular supervision.

Keywords: *patient safety, occupational health, hospital, services quality*

Introduction

Hospital is the center of specialist and subspecialist medical referral services, with the main function of providing and organizing healing (curative) and recovery (rehabilitative) as the health efforts for the patients[1,2]. According to those main functions, it needs an arrangement so the hospital can utilize its resources more efficiently and effectively.

The future hospital should be prepared by following the new paradigm where people start to perceive hospital as the center of excellence, hence hospital cannot perform unprofessional and underperform quality of services, considering the constant increase of people awareness for the satisfying health service needs, not merely focus on medical services system alone, but also doing an improvement in managerial system. The improvement effort of hospital managerial needs innovation, creativity, development, and a broaden mind to be able to compete fairly and give an optimal advantage for the external customer (the health service user) as well as the internal customer (the hospital workers).

A quality health service was one of the basic needs of all people. It has been realized long time ago, therefore every policy of health development by the government always aimed to increase the health quality services to the people. A lot of efforts have been made to increase the quality of health service through accreditation or institution specification of health service provider. The hospital growth as the center of the health service was rapid because of the role and function of the hospital in giving the complete health service to the people either promotion, prevention, medication and rehabilitation[3,4,5]. The hospital should compete fairly, its service should follow the current demands. Hospital should improve itself in technological development, quality of human resources, including the health services provider resources and administrative resources.

This study aimed to learn and understand the management in Intensive Care Unit, Central Surgery Installation, and Inpatient Installation of Surabaya Haji Hospital especially on patient safety standard and occupational health safety in hospital[6,7].

Method

This study used direct observation in Intensive Care Unit, Central Surgery Installation, and Inpatient Installation in Surabaya Haji Hospital. The data obtained by direct interviews and the existed data in Intensive Care Unit, Central Surgery Installation, and Inpatient Installation in Surabaya Haji Hospital.

Result and Discussion

Patient Safety

Hospital patient safety standard referred to "*Hospital Patient Safety Standards*" which published by *Joint Commission on Accreditation of Health Organization*, Illinois, USA, in 2002 which was adopted to the hospital situation and condition in Indonesia. Those patient safety standards consisted of seven points, i.e: patient rights, educate the patient and their family, patient safety and service balance, the use of performance improvement methods to do evaluation and safety improvement programs, leadership role in patient safety improvement, communication is a key for the staffs to achieve the patient safety.

According to patient safety standard, therefore Surabaya Haji Hospital designed a new process or fixed the existing process, monitored and evaluated the performance through data collection, intensively analyzed the Unexpected Event, and did a change to improve quality performance and patient safety. The designed process should refer to the Surabaya Haji Hospital visions, missions, and goals, patient needs, health service providers, actual clinical principle, healthy business practice, and other factors which potentially risking the patient[8,9,10].

The Seven Steps of Hospital Patient Safety are: (1) raise the awareness of patient safety value, (2) lead and support your staff,

(3) integrate risk management activity,

(4) develop reporting system,

(5) involve and communicate with patient,

(6) learn and share the patient safety experience, (7) prevent injury through the implementation of patient safety system.

Related with the attempts to increase the patient safety specifically. These targets highlighted the troubled area in health service and elaborate the solutions of a consensus based on proof and skill towards the problem. With the recognition that a good system design was intrinsic/merge in delivering of a safe and high-quality care, generally the goal targets focused on systemic solution, if possible[11].

The 6 patient safety targets are:

1. Accuracy of patient identification

2. Enhancement of effective communication

3. Enhancement the drug safety of high alert medication

4. Certainty of precise-location, precise -procedure, precise-operated patient

5. Reduction the infection risk related to health service

6. Reduction of fall risk

To support the patient safety achievement, thus Surabaya Haji Hospital will do the patient safety monitoring and evaluation program. The monitoring and evaluation steps which will be done are [12,13]:

1. All management staffs of Surabaya Haji Hospital will periodically be doing the patient safety monitoring and evaluation program which conducted by the Surabaya Haji Hospital Safety and Quality Committee.

2. Surabaya Haji Hospital Patient Safety Committee periodically (maximum in 3 years) do the patient safety guidelines, policy, and procedure which used in the hospital.

3. Surabaya Haji Hospital Patient Safety Committee do the monitoring (supervised the services unit) once in a month. Surabaya Haji Hospital Patient Safety Team do the activities evaluation every three months and make the follow-up.

Occupational Safety

Occupational health and safety were the effort to give a safety assurance and increase the workers health degree by preventing work related disease, workplace

hazard control, health promotion, medication, and rehabilitation.

The hospital occupational health and safety programs were:

1. Occupational health and safety service standard

2. Do the health check before work for the worker

3. Conduct the occupational health and safety education and promotion/workshop and provide help to the hospital workers in self adaptation either physically or mentally with their job

4. Do health examination periodically at minimum once in a year

5. Improve worker's body health, mental condition, and physical ability (additional nutrition, exercise, recreation and mental/spiritual coaching)

6. Provide medication and rehabilitation for the workers which suffer from illness (free basic medication, provide medication and bear the medication expenses for the workers with work related disease)

7. Conduct work environment monitoring and ergonomic which related to occupational health (physical, chemical, biological, psychosocial, and ergonomic monitoring/measurement)

8. Occupational health and safety standard for infrastructure, facilities, and work tools

9. Coaching and supervision for the infrastructure, facilities, and health equipment (operational permit, calibration, operational SOP)

10. Coaching and supervision or adjustment of work equipment to the workers (identification and risk measurement)

11. Coaching and supervision of the working environment (working environment meet the physical, chemical, biological, ergonomic, and psychosocial requirements)

12. Coaching and supervision of the sanitation (food, beverage, water, laundry, waste and rubbish, insect and rat control, sterilization/disinfection, radiation protection)

13. Coaching and supervision of work safety equipment (safety sign, provision of work safety equipment)

14. Occupational safety promotion/workshop

15. Coaching and supervision of fire countermeasure system management (fire prevention and countermeasure infrastructure and facilities, SOP, socialization, and fire drill)

16. Reporting and follow up system

17. Evaluation, recording, and reporting occupational safety activities.

Through their activities Surabaya Haji Hospital provided secure, functional, and supportive facilities for the families, staffs, and visitors. In the book of Hospital Occupational Health and Safety, Surabaya Haji Hospital determined to conduct hospital occupational health and safety as follow [11,12]

1. Reducing and controlling hazard and risk

2. Preventing accident and injuries

3. Maintain the safety condition

As for the facilities provided by Surabaya Haji Hospital for the staffs in Inpatient Installation were:

1. Workshop and refreshment on disaster and fire management

2. Provide a proper work safety equipment

3. Provide the health examination facilities

4. Provide the fire extinguishers facilities in each policlinic waiting room

5. Provide written evacuation sign facilities for the fire/disaster incident.

6. Do the calibration for the health equipment

Conclusion

This study showed Surabaya Haji Hospital efforts to ensure the patient safety and occupational safety in hospital environment. In general, hospital management steps have been done properly. The patient safety procedure has referred to the JCI standard quality of services [12,13]. While the hospital work safety has been a concern which proved by the establishment of a special

team which organize the hospital health and safety. In order to ensure the patient safety and hospital work safety could be functionate according to the established procedure, the hospital management should routinely perform supervision.

Abstract

Background: Gastroesophageal reflux disease (GERD) is a pathological condition as a result of gastric contents reflux into the esophagus. Acid reflux is the major irritant for the esophagus in the development and progression of GERD. A number of theories have developed regarding the correlation of gastric acid secretion and the development of GERD, one of which has attracted attention and controversy is the effect of *Helicobacter pylori* (H. Pylori) infection on acid secretion. This study aims to look at the correlation of the GERD degree with H Pylori infection.

Methods: This was an observational study with a cross-sectional approach in GERD patients who were diagnosed based on endoscopic examination at the Gastro Center of Wahidin Sudirohusodo Hospital and histopathology examination was performed to determine the presence of H. pylori infection from July 2017 to December 2018. Statistical analysis was performed by descriptive and frequency distribution with Chi Square test statistics using SPSS 25

Results: There were 151 subjects, 85 male subjects (56.3%) and 66 female subjects (43.7%), 20 subjects (13.2%) of whom had H. pylori infection. In this study the GERD degree was more mild with H. pylori infection than with negative H. pylori infection, but the correlation was not statistically significant.

Conclusion: The degree of GERD in H. pylori infection is more mild though there is no significant correlation.

Keywords: *Gastroesophageal reflux disease, Helicobacter pylori, degree*

Background

Gastroesophageal reflux disease (GERD) is a pathological condition as a result of gastric contents reflux into the esophagus with a variety of symptoms that arise due to involvement of the esophagus, pharynx, larynx and airway.[1] GERD is a condition that occurs due to reflux of gastric contents that cause disturbing symptoms or complications caused.[2,3] Based on Los Angeles (LA) classification of endoscopy examination, eGERD is divided into 4 degrees, A to D with degrees of C-D as complications in the form of Barret's oesophageal and strictures.

The prevalence of population-based GERD worldwide is 13%. The prevalence of GERD was previously found to be highest in South Asia and Southeast Europe (> 25%), and lowest in Southeast Asia, Canada, and France (<10%), but since the mid-1990, the prevalence of GERD symptoms in North America, Europe and Asia southeast increased 50% from the previous prevalence.[4]

Pathophysiology of GERD is multifactorial and often associated with the cause of *Helicobacter pylori* (H. pylori) infection.[5] Population prevalence in developed countries is around 30-40%, while in developing countries it reaches 80-90%.[6] The prevalence of H.

pylori infection from 5 major tribe groups in Indonesia is around 22.1%, with the Bugis tribe found in 11 of 30 dyspeptic patients infected with H. pylori. Ethnic Papuans, Bataks and Bugis have a higher risk for H. pylori infection than Javanese, Dayaks and Chinese with risk factors are age, religion, and water source.[7]

Polat FR et al, provides significant evidence of the role of H. pylori infection in the development of GERD. The effect of infection on acid secretion is determined by several factors including the location and extent of the infection, inflammation severity, which is partly determined by the strain of H. pylori, and gastric atrophy severity.[8]

Several reports on the correlation between the severity of reflux esophagitis and H. pylori have been widely reported.[9] In Indonesia research on the correlation betweeen H. pylori infection with GERD degree has not been widely reported. Therefore, this study was conducted.

Method

This is an observational study with a cross-sectional approach. Study was conducted at Gastroenterohepatology Center Wahidin Sudirohusodo Hospital Makassar from June 2019 to August 2019. Study population was obtained from the medical record data of GERD patients who underwent treatment at the Gastroenterohepatology Section of Wahidin Sudirohusodo Hospital. The sample was taken from populations that met the study criteria. Inclusion criteria consisted of patients diagnosed with GERD and had endoscopy, age ≥ 18 years, complete medical record data, nonpregnant patients. Exclusion Criteria consisted of upper gastrointestinal malignancy, Hiatus Hernia. Statistical analysis was performed by descriptive and frequency distribution with Chi Square test statistics using SPSS 25.

Results

In this study, 151 subjects with GERD were identified through endoscopy, 20 subjects (13.2%) of whom had H. pylori infection, age between 18-83 years with mean 46.0 ± 14.5 years, where male 85 subjects (56.3%) and women 66 subjects (43.7%).

Table 1. Baseline Characteristics of The Study Subjects (n=151)

Variable		H. Pylori (+) n (%)	H. Pylori(-) n (%)	Total n
Gender	Male	11(12,9)	74(87,1)	85
	Female	9(13,6)	57(86,4)	66
Age	<30 years old	3(11,5%)	23(88,5)	26
	30-39 years old	3(16,7)	15(83,3)	18
	40-49 years old	9(17,0)	44(83,0)	53
	50-59 years old	0(0)	23(100)	23
	>=60 years old	5(16,1)	26(83,9)	31
Tribe	Bugis	12(17,1)	58(82,9)	70
	Makassar	0(0)	21(100)	21
	Toraja	6(24,0)	19(76,0)	25
	Mandar	0(0)	8(100)	8
	Others	2(7,4)	25(92,59)	27
GERD Q score	<8	4(12,5)	28(87,5)	32
	≥8	16(13,4)	103(86,2)	119
GERD Degree	NERD	3(12,5)	21(87,5)	24
	GERD A	16(14,5)	94(85,5)	110
	GERD B	1(5,9)	16(94,1)	17
NSAID	No history	18(20,2)	71(79,8)	89
	Present	2(3,2)	60(96,8)	62
Smoking	No history	13(11,0)	105(89,0)	118
	Present	7(21,2)	26(78,8)	33
BMI	Underweight	1(4,3)	22(95,7)	23
	Normal	15(9,7)	61(80,3)	76
	Overweight	3(13,0)	20(87,0)	23
	Obese	1(3,4)	28(96,6)	29

The age range of 40-49 years is the most research subjects, 53 subjects (35.1%) and the age range 30-39 years is 18 subjects (11.9%) as the fewest, with the majority of Bugis 70 subjects (46.4%). H. pylori infections were 20 subjects (13.2%). Based on the GERD score, the GERD score ≥8 is the most, 119 subjects (78.8%) and for the GERD score <8, 32 subjects (21.2%). For the positive H. pylori infections found in the Bugis tribe mostly 12 subjects (60%).

Table 2. Correlation Between H. pylori Infection with GERD Degree Based On Endoscopic Results

H. pylori Infection			GERD Degree			Total	P
			NERD	GERD A	GERD B		
	Positive	N	3	16	1	20	0,614
		%	15,0%	80,0%	5,0%	100,0%	
	Negative	N	21	94	16	131	
		%	16,0%	71,8%	12,2%	100,0%	
Total		N	24	110	17	151	
		%	15,9%	72,8%	11,3%	100,0%	

Chi Square test

Table 2 shows that the percentage of GERD A was found to be higher in positive H. pylori (80.0%) than in negative H. pylori (71.8%) infection, whereas GERD B was found to be higher in negative H. pylori (12.2%) compared to H pylori positive (5.0%) infection, but statistically not significant (p> 0.05).

Table 3. Correlation Between GERD Q Score with GERD Degrees

GERD Q score			GERD Degree			Total
			NERD	GERD A	GERD B	
	<8	n	4	26	2	32
		%	12,5%	81,3%	6,3%	100,0%
	>=8	n	20	84	15	119
		%	16,8%	70,6%	12,6%	100,0%
Total		n	24	110	17	151
		%	15,9%	72,8%	11,3%	100,0%

P = 0,451

P = 0,451

Table 3 shows the percentage of GERD A was found to be highest at a score of <8 (81.3%) while the percentage of GERD B was found to be highest at a score of ≥8 (12.6%) but statistically not significant (p> 0.05).

Table 4 shows that the percentage of GERD A was found to be highest in normal BMI (78.9%) and lowest in obese 2 (25.0%), while GERD B was found highest in obese 1 (28.0%) and lowest in normal BMI (5.2%).

Table 4. Correlation Between BMI with GERD Degrees

BMI			GERD Degree NERD	GERD A	GERD B	Total	P
	Underweight	N	4	16	3	23	
		%	17,4%	69,6%	13,0%	100,0%	
	Normal	N	12	60	4	76	
		%	15,8%	78,9%	5,3%	100,0%	
	Overweight	N	4	17	2	23	
		%	17,4%	73,9%	8,7%	100,0%	0,051
	Obese 1	N	2	16	7	25	
		%	8,0%	64,0%	28,0%	100,0%	
	Obese 2	N	2	1	1	4	
		%	50,0%	25,0%	25,0%	100,0%	
Total		N	24	110	17	151	
		%	15,9%	72,8%	11,3%	100,0%	

Table 5 shows that the percentage of GERD A was found to be higher in the nonsmoking group (72.9%) than in those who smoked (72.7%), likewise GERD B was found higher in nonsmokers (11, 9%) compared to smoking (9.1%), but not statistically significant (p> 0.05).

Table 5. Correlation Between Smoking with GERD Degrees

Smoking			GERD Degree NERD	GERD A	GERD B	Total	P
	No	n	18	86	14	118	
		%	15,3%	72,9%	11,9%	100,0%	
	Yes	n	6	24	3	33	0,854
		%	18,2%	72,7%	9,1%	100,0%	
Total		N	24	110	17	151	
		%	15,9%	72,8%	11,3%	100,0%	

Table 6 shows that the percentage of GERD A was found to be higher in subjects with a history of NSAID use (79.0%) compared to subjects without NSAID users (68.5%), whereas GERD B was found to be almost the same between those with history and those without history (about 11%), but not statistically significant (p> 0.05).

Table 6. Correlation between NSAIDs with GERD Degrees

NSAID			GERD Degree NERD	GERD A	GERD B	Total	P
	No	N	18	61	10	89	
		%	20,2%	68,5%	11,2%	100,0%	
	Yes	N	6	49	7	62	0,211
		%	9,7%	79,0%	11,3%	100,0%	
Total		N	24	110	17	151	
		%	15,9%	72,8%	11,3%	100,0%	

Discussion

Increased prevalence of GERD may be caused by several factors such as older age, male gender, race, analgetic intake, consumption of certain types of food and drinks, decreased prevalence of *Helicobacter pylori* infection, smoking, family history of GERD, high Body Mass Index (BMI), and limited physical activity. These risk factors are mostly related to the patient's lifestyle.[10]

In Indonesia, several studies also found that the percentage of GERD incidence was higher in males than females. Arif et al found a higher prevalence in males than females.[11] Man Wang et al, reported a higher proportion of GERD in males compared to non-erosive.[12]

This study found that the percentage of GERD A was found to be highest at the age of 40-49 years (77.4%) and the lowest at the age of 30-39 years (66.7%), while GERD B was found to be highest at the age of 50-59 years (21.7%) and the lowest at age <30 years (3.8%), but not statistically significant (p> 0.05).

Huang et al in found that in elderly patients the degree of gastroesophageal reflux and esophageal lesions was more severe, compared with younger patients.[13] Gastric dysmotility with delayed gastric emptying and duodenogastric bile reflux play an important role in the pathogenesis of GERD in elderly patients.[14]

This study found the most prevalent in the Bugis tribe were 12 subjects (60%). Syam AF et al found that ethnic Papuans, Bataks and Bugis had a higher risk for H. pylori infection than Javanese, Dayaks and Chinese. It is still unclear why there is a difference in the prevalence of H. pylori infection in Sulawesi. The possibility of differences in prevalence is due to differences in the phenotype of H. pylori.[7]

The percentage of GERD A was found to be higher in positive H. pylori (80.0%) than in negative H. pylori (71.8%), whereas GERD B was found to be higher in negative H. pylori (12.2%) than in Positive H. pylori (5.0%) Although there was no significant correlation, this study illustrates that the tendency of patients with positive H. pylori has more mild GERD degree compared to patients with negative H. pylori.

Fatin Polat et al found significant evidence of the role of H. pylori infection in the development of GERD.[15] Aswathy et al found an association of H. pylori infection in endoscopy and histological features of GERD where the prevalence of GERD severity increased, found positive H. pylori decreased.[16] Chaurasia et al found that H. pylori infection was associated with a reduction in gastric acidity and a less severe GERD degree. Mohameed S et al found there was no statistically significant correlation between H. pylori infection and oesophagitis reflux.[17] Manes et al concluded that the presence of H. pylori had no effect on esophageal motility, lower esophageal sphincter pressure, or gastro-esophageal reflux.[18] Kuipers et al concluded eradication of H. pylori using a proton pump inhibitor did not show a significant correlation with GERD severity.[19]

This study found that a greater GERD Q score did not reflect the degree of damage to the esophageal mucosa. Wang et al, found the higher GERD Q score, the more severe the erosion of the esophageal mucosa.[12] Pace et al reported no correlation between GERD Q score and the erosive degree. In NERD patients where the pathogenesis underlying the complaint arises not only because of mucosal damage, but is caused by 3 mechanisms: the incidence of reflux itself, esophageal hyperalgesia, and psychological disorders.[20]

Obesity is associated with a significant 1.5 to 2-fold increase in the risk of symptoms of GERD and erosive esophagitis, compared to individuals with a normal BMI.[21] This study also showed a higher percentage of patients with Obesity compared to patients with normal BMI which was found in patients with GERD B, where the highest percentage was found in obese 1 (28.0%) and lowest in normal BMI (5.2%). While the percentage of GERD A was found to be highest in normal BMI (78.9%) and lowest in obese 2 (25.0%).

Ruzniweski et al shows that GERD symptoms are significantly more common in GERD patients who use NSAIDs and the same results are found in those who take aspirin. Medicaid Study in the United States on 163,000 patients, the risk of GERD was twice as high in NSAID patients, as well as community-based studies in the United Kingdom finding common GERD symptoms in those with NSAIDs.[22] Markku V et al found that the use of NSAIDs is a risk factor for GERD. However, the effect of prostaglandins on the use of NSAIDs on oesophageal motility remains controversial so that the mechanism of damage to the esophageal mucosa due to the use of NSAIDS is unknown.[23]

This study also found no significant correlation between GERD degree and NSAIDs use. The percentage of GERD A and GERD B was found to be almost the same in existing patients with no history of NSAID use. The results of this study have not specifically differentiated groups of patients based on the type of NSAID used or the length of use of NSAID.

Conclusion

The degree of GERD in H. pylori infection is more mild though there is no significant correlation.

Original Article

Analysis of Dengue Infection Severity among Ethnics in Surabaya, Indonesia

Sulistiawati, Suharto[2], Harianto Notopuro[3], Abyan Irzaldi[4], Adikara Pagan Pratama[5]

[1]Senior Lecture / Associate Professor, Department of Public Health and Preventive Medicine, Faculty of Medicine, Universitas Airlangga, [2]Professor of Tropical Disease, Department of Internal Medicine, Dr. Soetomo Teaching Hospital-Faculty of Medicine, Universitas Airlangga, [3]Professor of Biochemistry Medicine, Department of Biochemical Medicine, Faculty of Medicine, Universitas Airlangga, [4]Staff Internship, [5]Junior Lecturer, Faculty of Medicine Universitas Airlangga

Abstract

Background: Dengue infection prevalence remains high in tropical countries, including Indonesia, whereas the government had struggled to overcome the disease. Indonesia has very diverse ethnicities living across the archipelago, there might be a wide variety of susceptibility and severity.

Objective: This research was aimed to analyse ethnicity as a risk factor for dengue infection severity in Surabaya, Indonesia.

Design and Methods: This research observed Dengue Hemorrhage Fever (DHF) or Dengue Fever (DF) patients aged over 12 years, who were hospitalized in three private hospitals in Surabaya. Data collection was conducted from March 20, 2013 to May 20, 2013 with a sample size of 95 patients. Ethnicity, dengue infection severity, clinical findings, and relevant laboratory information data were obtained. This was a cross-sectional study design with consecutive sampling. All data were analysed using SPSS 17.00 software. The statistical analysis was performed at a significance level of p-value <0.005 using the chi-square test.

Results: The majority of patients who suffered from severe dengue infection based on WHO classification and bleeding symptoms were Chinese patients (82.1%). The laboratory results pointed out Chinese patients had the highest hemoglobin concentration (15.62 ± 1.70 %), highest PCV (44.90 ± 4.23 g/dl), and the lowest platelets (31.42 ± 22.05 x 103µl). There were significant dengue infection severity difference (p=0.015), hemoglobin increase (p=0.004), PCV (0.024), and platelets (p=0.006) between Chinese, Javanese, and other ethnicities.

Conclusion: Chinese ethnic had the highest risk of suffering severe dengue infection in Surabaya.

Keywords: *dengue infection severity; ethnicity; Indonesia; Chinese; Javanese*

Introduction

Dengue Hemorrhagic Fever (DHF) and Dengue Fever (DF) prevalence remain high in the tropical countries, include Indonesia. By 2008, the spread of DHF reached ± 69 countries in Southeast Asia, Western Pacific and the USA. The number of cases increases from 479,848 in 1990-1999 to 1,656,870 in 2000-2008 worldwide.[1] In Indonesia the incidents of DHF and DF in Indonesia reached 51 per 100,000 in 2007 with the Case Fatatily Rate (CFR) 1.8% and in 2009 reached 66.48 per 100,000 with the CFR 0.89%.[2] All sub-districts in Surabaya have become dengue endemic areas, the data from 2007 to 2011 are 113; 75.6; 78.43; 116; 36.22 per 100,000 while CFR are 0.7%; 0.46%; 0.26%; 0.4% and

0.69% respectively.[3]

Interaction of host-agent-environment affects the disease. Previous studies showed that the factors from host that could affect the manifestation of the disease are race/ethnic, sex, age, nutrition status, secondary infection and immune response.[4]

Ethnic or race might determine the manifestation of dengue. The Chinese who live in Singapore were found higher in attack rate of DHF than the Malay and the Indian.5 A study in Brazil showed that African people are more protective than the whites toward dengue virus. Indonesia is a country with diverse ethnicities and cultures, there might be a wide variety of susceptibility to dengue infection.6 In Indonesia, the Javanese is the largest ethnic group, the second is the Sundanese (15.51%), the third is the Malay, Batak and Madurese contribute 3.70%, 3.58% and 3.03%, respectively. There are another 10 ethnic groups, each contributing between 1.2% and 3.0%, with the Chinese as the lowest (1.20%) in this group.[7]

Manifestation of dengue infection varies which is characterized by bleeding symptoms and leakage of plasma, measured by Hematocrit (Hct) or Packed Cell Volume (PCV), hemoglobin and trobocytes depletion. DHF according to WHO (2011) is classified into 4 grades and added with expanded dengue syndrome.[1]

Finding out the description of the dengue infection severity based on the ethnicity could be used as a basis to create an effective model of prevention and management of the dengue infection. The model is created based on the ethnicity as its approach, thus the result is expected to be more effective and could indirectly help reducing the number of patients and death rate due to dengue infection in Indonesia, especially in Surabaya.

This study aims at analyzing the severity of dengue infection based on the ethnicity in Surabaya; Javanese, Chinese and other group ethnics.

Methods

The study was analytic observational with a cross sectional design. The sample was IgM and/or IgG dengue positive DHF/DF patients. With inclusion criterias were: not in a state of suffering from other severe infections and aged above 12 years old. Patients were hospitalised at 3 private hospitals in Surabaya between March 20th until May 20th 2013. Total sample was 95. Independent variable was ethnicity, while dependent variable was DHF severity based on WHO criteria in 2011.

Immnochromatography dengue strip test, PanBio™ duo cassete, was used to confirm the diagnosis with dengue IgM and IgG. Data of Hb, PCV and platelets were analyzed by the hospitals using hematology analyzer tool, products from Sysmex™ and Celltac™.

Results

Based on the ethnicity, most of patients identified themselves as Javanese (42.1%), while Chinese and other ethnic groups occupy almost the same (Table 1). Majority of patient suffered from severe category of DHF (62.1%). Laboratory data showed that Hb increase, platelets and leucocyte count decrease were severe in the most patients, 51.6%, 61.1%, 58.9%, respectively (Table 2).

Based on the bleeding symptoms that, in this study, are categorized into 3: severe (hematemesis, melena, epistaxis), moderate (*echimose*, spontaneous *petechia*) and mild (positive RL without bleedings), the study showed that severe and moderate bleedings are more commonly found among Chinese patients than Javanese and other group ethnics. The symptoms of mild bleedings are mostly found in among Javanese patients.

Table 3 showed that Chinese patients had highest mean of Hb and PVC and lowest mean of platelets compared to others. While other ethnic groups category showed lowest mean of leucocytes compared to Javanese and Chinese.

Chi-square statistical test shows that there are differences in the severity of dengue infection based on those indicators, except for leucocytes decrease, between Chinese, Javanese and other ethnic groups. (Table 4)

Table 1. Characteristic of patients

Variable	N (%)
Sex	
- Male	52 (54.7)
- Female	43 (45.3)
Age	
- Adolescence (12-16 years)	21 (22.1)
- Young adult (17-25 years)	32 (33.7)
- Midle age (26-45 years)	36 (37.9)
- Older adult (>45 years)	6 (6.3)
Ethnic	
- Chinese	28 (29.5)
- Javanese	40 (42.1)
- Others / mixed	27 (28.4)

Table 2. The diagnosis of dengue infection severity

The diagnosis of dengue infection severity	N (%)
• WHO criteria for DHF (2011)	
- Mild (DF & DHF grade I)	36 (37.9)
- Severe (DHF grade II, III, IV and DHF exp.)	59 (62.1)
• bleeding symptoms	
- Mild	36 (37.9)
- Moderate	46 (48.4)
- Severe	13 (13.7)
• PCV/haematocrite increase	
- Mild	49 (51.6)
- Severe	46 (48.4)
• Hb increase	
- Mild	46 (48.4)
- Severe	49 (51.6)
• Platelet decrease	
- Mild	37 (38.9)
- Severe	58 (61.1)
• Leucocytes decrease	
- Mild	39 (41.1)
- Severe	56 (58.9)

Laboratory (PCV, Hb, platelets, and leucocyte) were classified into two categories, mild and severe. Mild was when the laboratorial result is below the mean of all patients' results while severe was when the result is higher than the overall patients' results.

Table 3. Laboratory examination

Laboratory examination	**Mean ± SD**
• Highest PCV - Chinese - Javanese - other ethnics	44.06 ± 4.87 % 44.90 ± 4.23 % 43.27 ± 4.17 % 44.37 ± 6.28 %
• Highest Hemoglobin (Hb) - Chinese - Javanese - Other ethnics	15.14 ± 1.75 g/dl 15.62 ± 1.70 g/dl 14.62 ± 1.45 g/dl 15.44 ± 2.05g/dl
• Lowest Platelets - Chinese - Javanese - other ethnics	41,540 ± 27,940 /µl 31,420 ± 22,050 /µl 52,980 ± 29,790 /µl 35,110 ± 25,120 /µl
• Lowest Leucocytes - Chinese - Javanese - other ethnics	2,930 ± 1,360 /µl 2,810 ± 1,490 /µl 2,890 ± 1,150 /µl 2,120 ± 1,540 /µl

Table 4. Comparison of dengue infection severity based on ethnicity

Comparison of dengue infection severity based on ethnicity	**P value**
Severity based on WHO dengue classification and ethnicity	0.015
Severity based on hemoconcentration of Hb increase and ethnicity	0.004
Severity based on PCV/haematocrite increase and ethnicity	0.024
Severity based on platelets decrease and ethnicity	0.006
Severity based on leucocyte decrease and ethnicity	0.493

Discussion

Characteristics of Patients with Dengue Fever

Sex

Ratio of DHF/DF patients over the age of 12 years between male and female was slightly higher in male (54.7%). The finding also similiar with another research on dengue infections at Hasan Sadikin Hospital, Bandung, where the percentage of male patients was 50.7%.8 Another study conducted in Singapore showed that the ratio of male:female was 1.9:1, whereas in India was 1:0.57, respectively.5 These conditions might indicate that the proportion of DHF/DF incidents between men and women were almost equal.

Age

Group of 26-45 years old (37.9%) was higher than any other groups. Some studies in Latin America and Southeast Asia in the early 1980 showed that many dengue cases were suffered in older adult. In Singapore, the mortality alteration of dengue infection occurred at the older age, proved by the case of death in 1982 which 50% higher among > 15 years old (the age group of 15-34). In Bangladesh, the proportion of hospitalized dengue infection patients aged 18-33 years old was higher than any other age groups (82%).5 In Malaysia, dengue cases were suffered more in 13-35 years old people since 1982.9

Diagnosis of Dengue Infection Severity

According to WHO criteria for DHF, the most hospitalized patients were categorized as DHF grade II rather than DHF grade I, Dengue Fever or Dengue Shock Syndrome.1 This facts happened due to spontaneous bleeding symptoms on DHF grade II, which were not shown on grade I or dengue fever. Many of dengue fever patients usually not to go to hospitals because the symptoms are milder than DHF. This situation is also similar to a study in Iran that showed the highest inpatient case was DHF II (92%).10

The study of prognostic indicators of dengue infection severity showed a significant relationship between the value of PCV, platelets and leukocytes to the severity of dengue infection.11 In addition, a meta-analysis study showed that thrombocytopenia and PVC hemoconcentration were strongly associated with DSS.12 Moreover, another study found a significant relationship between dengue severity with thrombocytopenia (p: 0.002) and leukocytes (p: 0.067). The results of this study indicate that the severity of Hb, PCV, platelets and leukocytes is almost the same as shown by the percentage data from mild, moderate to severe.13

Based on the severity of bleeding symptoms, Chinese were suffered more serious bleeding symptoms compared to other ethnic groups. Based on the severity of Hb, PCV hemoconcentration and trombositopenia, Chinese have more severe symptoms as well. This condition showed that Chinese were more susceptible to severe clinical symptoms when they are infected by dengue compared to Javanese or other ethnics. The results of this study are similar to study conducted in Cuba showed the DHF/DSS ratio risk for the whites:blacks:mixed-race = 5.5:1:1.8, and also there was a tendency that a certain ethnicity become more susceptible than other ethnic groups.14 Chinese genetically have lighter skin color compared to Javanese, consequently they have more severe clinical symptoms. In addition, study in Singapore found the attack rate of Chinese was higher than Malay and Indian ethnic.5

The Differences of Dengue Infection Severity Based on Ethnicity

The ethnicity was mostly Javanese, eventhough the study was conducted in hospitals near Chinatown and area where the Arabian or Madurese live together. It happens as the larger number of Javanese descent (83.68%) lives in Surabaya compared to other ethnics, 7.5% Madurese, 7.25% Chinese, 2.04% Arabian and the rest is for other ethnic groups.

Based on Chi-square analysis, there was a significant difference of dengue infection severity between those 3 ethnic groups. Therefore, the difference of ethnicity can lead to the difference of infection response, which means there is a tendency of greater genetic difference in controlling the immune response in different ethnic groups compared to the same ethnic groups.

There were several studies discussing about the relation between genetic and the response to dengue infection; including HLA, HPA, vitamin D receptor,

etc. According to HL. Blum, someone's health status is influenced by the environment, genetic (heredity), and lifestyle as well as health services. The theory stated that the genetic is one factor contributing to health status.

This study showed different severity of dengue infection in different ethnicity. Ethnicity is a unique human population that differ from another due to frequency of particular gene and in its development are some variations in both genetic and phenotypic variation. There were some previous studies that showed differences of dengue infection severity between phenotypes whites, blacks or mixed-races. One of them showed that the whites have more risk than the colored ones. Those researches had same results with this study which is suggesting that Chinese is clinically more affected than Javanese or other ethnic.14 Another research conducted in Cuba showed that the percentage of DHF II and III in adults patients were 81% whites, 13% Caucasians-mixed and 6% blacks respectively. The mortality case was found in whites 77%, colored 14% and blacks 9%. These conditions happened due to a stronger specific immune response of whites to dengue virus, hence cytokine increased that led to more severe clinical manifestation.15

Study in Cuba showed that factor of varying severity of dengue infection in different ethnics due to the personalized immunological reaction, more specifically T-lymphocytes activation and cytokines. On the other hand, the polymorphism of human leukocyte antigene (HLA) region which encode specific protein roled in immune response. The variation of HLA has been known in several viral diseases, such as delayed progression of HIV and Hepatitis B carriage. Furthermore, T cell receptor which is directly response to dengue virus antigen might be vary in number distributed between different ethnics. The last is the role of monocytes expressing FCγ receptor which is main target of dengue infection antigen forming dengue virus-dengue antibodies immune complex.16 Beside the serotype of dengue virus also determine the severity of the disease.17

Conclusion

Chinese suffered the most severe dengue infection compared to Javanese and other ethnic groups. It is essential, when health professionals deal with dengue infected patients, to obtain information regarding the exact origin and ethnicity of the patient. Previous studies revealed that each ethnicity has different susceptibility on dengue virus. Thus, on this point forward doctor are going to treat Chinese patients of DHF / DF more intensively and to arrange a new procedure that increases the doctors' awareness in dealing with Chinese patients with dengue infections.

This paper also underlines the importance of preventing dengue infection by giving environmental intervention to reduce mosquito breeding sites, especially in Chinatowns.

Research Article

Determinant Factors Related Word Fatigue in Workers at PT. Makassar Indonesian Ship Industry

Suharni A Fachrin[1], Alfina Baharuddin[2], Samsualam[3]

[1]Assistant Professor in Departement Public Health (OSH), University Muslim of Indonesia, Makassar, [2]Research Scholar in Departement Environmetal Health, University Muslim of Indonesia, Makassar, [3]Research scholar in Public health, University Muslim of Indonesia, Makassar

Abstract

Work fatigue is one of the occupational health and safety issues that can be a risk factor for accidents at work. fatigue can be caused by several factors both internal and external factors, including body work attitude, neck work attitude, leg work attitude, upper arm work attitude, forearm work attitude, wrist work attitude. This type of research is observational analytic with cross sectional study design. the target population in this study all workers who work in the hull, engine and shaft, dock and pipe at PT. Makassar's Indonesian ship industry with a total of 61 people. the method of taking samples in this study uses total sampling. Data analysis method uses the chi-square test. The results showed that there was a significant relationship between the variable work attitude (body) with p value = 0.01, while there was no relationship in the variable work attitude (neck) with a value of p value = 0.898 while the variable work attitude (feet) with a p value value = 0.002 has a relationship with work fatigue and work attitude (upper arm) p value = 0.030, and work attitude (forearm) p value = 0.424 has no relationship with work fatigue, work attitude (wrist) with a value of p value = 0,000 , has a relationship with work fatigue in workers in the hull, engine and shaft, dock and pipe at PT. Makassar Indonesian ship industry. Further research is suggested to be able to examine other factors suspected to be related to work fatigue and not examined in this study, and is expected to use better and more accurate measurement tools for further research so that the results of the research can be more accurate and better.

Key word: *Engine, Saft, Dock And Pipe, work fatique, workers.*

Introduction

According to the International Labor Organization (ILO) every year as many as two million workers die due to work accidents caused by changing factors. In this study excluded from 58,115 samples, 32.8% in coverage was better, while problematic workers were related to an increase factor, so it would increase directly at the level of income increase[1,2]. PT. ArwanaAnugrah Ceramics with the Chi-Square statistical test results obtained a p-value = 0,0001, which means related to work relationships by increasing work for employees of the production department of PT. Arwana Anugrah Keramik, Tbk. As many as 41 employees of PT. Arwana Anugrah Keramik, Tbk has a risky work attitude[3,4,8.]

Based on this background, the researcher is interested in conducting research "Effect of Work Attitude (Body, Neck, Legs, Upper Arm, Forearm, Wrist) on factors related to work effort at PT. Makassar Indonesian Ship Industry in the Hull, Engine and Shaft, Dock and Pipe sections[5,6]. Occupational Safety and Health (K3) is a program created by a company to prevent work-related accidents and occupational diseases, analyze work that causes accidents and illnesses caused by work caused by disasters and occupational diseases[7,10]. The work accident data is based on preliminary data collection at PT. The Indonesian Ship Industry (Persero) Makassar number of work accidents in 2014 were 3 people, in 2015 there were 8 people, in 2016 1 person, in 2017 there were 6 people and in 2018 1 people and in 2019

(March) 1 person[8,11].

Based on work accident data at PT. During the period of 2014 to 2019, the Indonesian Ship Industry experiences work accident incidents in every unit, namely in the Hull, Engine and Axle, Dock and Pipe sections. Work accidents show a number that is not too large but needs to be evaluated for PT. Makassar Indonesian Ship Industry in order to achieve Zero Accident[12]. Based on the results of preliminary data obtained at PT. The Indonesian Ship Industry in the Machinery and Axle section has 12 workers, 22 in the Hull section, 12 in the Dock section and 15 in the Pipe section. In addition, working time at PT. Makassar Indonesian Ship Industry starts at 07.00 am to 17.00[13,18]. The average age of workers there ranges between 30-60 years, where as said Tarwaka (2014) that physical strength from the age of 25 years will begin to decline. And their tenure is 10 to 20 years. While the level of education of workers there starting from elementary, middle, and high schoo[l4,20]. From the results of observations in the hull, machinery and shaft in PT. The Indonesian Ship Industry level of fatigue of workers there is quite high, because workers there work for 8 hours minus 1 hour of rest, praying, and eating[15,16,17]. It is said to be quite high because, the workers work nonstop because of the hull section. Therefore, workers when they want to take a break to eat, or pray must be carried out alternately.

Method

This type of research is observational analytic with cross sectional study design. the target population in this study all workers who work in the hull, engine and shaft, dock and pipe at PT. Makassar's Indonesian ship industry with a total of 61 people. the method of taking samples in this study uses total sampling. In this study the measurement of work fatigue is done by measuring the feeling of fatigue using the Fatigue Measurement Tool Quizzer (KAUPK2)[4.8,11]Data analysis method uses the chi-square test.

Result

Table 1: Relationship between Work Attitude and Work Fatigue in Workers at PT. Makassar Indonesian Ship Industry 2019

Work Attitude of the Agency	Work Fatigue				Total		p Value
	Not Tired		Tired				
	N	%	N	%	N	%	
No Risk	14	70,0	6	30,0	20	100	
At Risk	13	31,7	28	68,3	41	100	0,011
Total	27	44,3	34	55,7	61	100	

According Table 1, shows that 61 workers with no risky body work attitude who are not tired as many as 14 workers (70.0%) and tired as many as 6 workers (30.0)%, while for work attitude risky bodies are not tired 13 workers (31.7%), and tired of 28 workers (68.3%).

Table 2 : Relationship between Neck Work Attitude and Work Fatigue in Workers at the at PT. Makassar Indonesian Ship Industry 2019

Neck work attitude	Work Fatigue				Total		*p Value*
	Not Tired		Tired				
	n	%	N	%	N	%	
No Risk	9	40,9	13	59,1	22	100	
At Risk	18	46,2	21	53,8	39	100	**0.898**
Total	**27**	**44,3**	**34**	**55,7**	**61**	**100**	

Table 3: Relationship between Working Legs and Work Fatigue in Workers at PT. Makassar Indonesian Ship Industry 2019

foot work attitude	Work Fatigue				Total		p Value
	Not Tired		Tired				
	N	%	N	%	n	%	
No Risk	19	67,9	9	32,1	28	100	
At Risk	8	24,2	25	75,8	33	100	0.002
Total	27	44,3	34	55,7	61	100	

According table 3 about the relationship between working attitude of the feet with work fatigue in workers in the Hull, Machine and Axle, Dock and Pipes at PT. Makassar Indonesian Ship Industry, shows that 61 workers with no risk foot work attitude who are not tired as many as 19 workers (67.9%) and tired as many as 9 workers (32.1)%, while for the attitude of working leg legs who are not tired as much as 8 workers (24.2%) and tired as many as 25 workers (75.8)%.

Table 4: Relationship of Forearm Work Attitude with Work Fatigue in Workers at PT. Makassar Indonesian Ship Industry 2019

Forearm Work Attitude	Work Fatigue				Total		*p Value*
	Not Tired		Tired				
	n	%	n	%	n	%	
No Risk	8	57,1	6	42,9	14	100	
At Risk	19	40,4	28	59,6	47	100	**0.424**
Total	**27**	**44,3**	**34**	**55,7**	61	100	

According Table 4 about the relationship between forearm work attitude with work fatigue in workers in the hull, machinery and shaft, dock and pipe at PT.

Table 5 : Relationship of Upper Arm Work Attitude with Work Fatigue in Workers

at PT. Makassar Indonesian Ship Industri 2019

Upper Arm Work Attitude	Work Fatigue				Total		p value
	Not Tired		Tired				
	N	%	N	%	n	%	
No Risk	23	54,8	19	45,2	42	100	
At Risk	4	21,1	15	78,9	19	100	0.030
Total	27	44,3	34	55,7	61	100	

Table 5 shows that 61 workers with an upper arm work pose no risk who are not tired as many as 23 workers (54.8%)

Table 6 : Relationship between Wrist Hand Attitude and Work Fatigue in Pipes at PT. Makassar Indonesian Ship Industry 2019

Wrist Attitude	Work Fatigue				Total		p value
	Not Tired		Tired				
	N	%	N	%	n	%	
No Risk	19	76,0	6	24,0	25	100	
At Risk	8	22,2	28	77,8	36	100	0.000
Total	27	44,3	34	55,7	61	100	

Table 6 shows that 61 workers with no risky wrist work attitude who are not tired as many as 19 workers (76.0%) and tired as many as 6 workers (24.0%), while for the wrist work attitude are at risk who are not tired as many as 8 workers (22.2%) and tired as many as 28 workers (77.8%).

Discussion

Work fatigue is a process of decreasing efficiency, work performance and reduced strength or physical endurance of the body to continue the activities that must be carried out[18,19,22]. In this study the measurement of work fatigue is done by measuring the feeling of fatigue using the Fatigue Measurement Tool Quizzer (KAUPK2)[4.8,11]. Based on bivariate analysis, it can be described as follows: Relationship between Work Attitude and Work Fatigue: Work attitude on the part of the body is measured using the REBA method.

Relationship between Neck Work Attitude and Work Fatigue With the statistical test results using the chi-square obtained p value = 0.898 because the value> 0.05 then Ha is rejected and H0 is accepted, which means there is no influence between Neck Work Attitudes towards work fatigue in workers in the Stomach, Machine and Axle, Dock and Pipe at PT. Makassar Indonesian Ship Industry.Relationship between Leg

Work Attitudes and Work Fatigue With the results of statistical tests using the chi-square obtained p = 0.002 because the value <0.05 then Ha is accepted and Ho is rejected, which means there is a relationship between working attitude of the feet to work fatigue in workers in the hull, machine and shaft, dock and Pipe at PT. Makassar Indonesian Ship Industry[23].

Relationship between Upper Arm Work Attitude and Work Fatigue Statistical test results using chi-square obtained p value = 0.030 because the value <0.05 then Ha is accepted and Ho is rejected, which means there is a relationship between the Upper Arm Work Attitude towards Work Fatigue in workers in the Stomach, Machine and Axle, Dock and Pipe at PT. Makassar Indonesian Ship Industry.

Relationship between Forearm Work Attitude and Work Fatigue Next is the assessment of the position of the forearm. Forearm positions that have the lowest risk at a flexion position of 60 ° -100 ° are given a value of 1 and a risky position at a flexion position <60 ° or flexion> 100 ° are given a value of 2. This is evidenced by the greater score for each risky posture. With the statistical test results using chi-square obtained p value = 0.424 because the value <0.05 then Ha is rejected and Ho is accepted, which means there is no relationship between the Forearm Work Attitudes towards work fatigue in workers in the Stomach, Machine and Shaft, Dock and Pipe at PT. Makassar Indonesian Ship Industry. Relationship between Wrist Attitude and Work Fatigue. The final working attitude on the use of the REBA method is the wrist. The position of the wrist that has the smallest risk is in the position of flexion or extension at an angle of 0-150 that gets a score of 1. The position at risk is the position of the wrist flexion or extension at an angle of> 150.

The results of the study using the chi-square test found that the value of p value = 0,000 (p <0.05) showed that there was a significant relationship between wrist work attitude and work fatigue.The results of this study are in line with research conducted by Ekawati (2014), which states that there is a significant relationship between work attitude (wrist) with work fatigue, with a p value in the study of 0.043 (p value <0.05).

Conclusions

1. There is a significant relationship to work (body) attitude with work fatigue =p value = 0.011 (<0.05).

2. There is no significant relationship to the work attitude of the neck with work fatigue as seen from 61 workers, p value = 0.898 (<0.05).

3. There is a significant relationship to the work attitude of the feet with work fatigue as seen from 61 workers, p value = 0.002 (<0.05).

4. There is a significant relationship to upper arm work attitude with work fatigue p value = 0.030 (<0.05).

5. There is no significant relationship to the forearm work attitude with work fatigue p value = 0.424 (<0.05).

6. There is a significant relationship to wrist work attitude with work fatigue as seen p value = 0,000 (<0.05).

The Effects of PNF Exercises by a Special Device of Develop the Hip Joint Flexibility and Perform some Kicking Skills of Young Taekwondo Players

Ali Jasim Kareem[1], Hamid Abdul Shaheed Hadi[2], Abbas Mahdi Saleh[3], lman Okab Sarhan[3]

[1]Assist. Prof. University of Basra / College of Physical Education and Sport Sciences, [2]Lecturer, Ministry of education/Najaf Education Directorate /IRAQ, [3]Prof., University of Kufa/College of Physical Education/ Theoretical Science Branch

Abstract

The problem of research focused on increasing the flexibility of the hip joint and measuring it according to advanced scientific standards is important for Taekwondo, which most of the workers in this game did not care, because its skills depend on the opening the legs and any weakness has effects on the motor extent of skills and then be difficult to reach the goal, the research objectives is prepare PNF exercises by using a special device to develop and measure the flexibility of the hip joint, to identify on the effect of these exercises by the device in the development of hip joint flexibility and kicking skills of young Taekwondo players, the researchers hypothesized that there are significant differences in post measurements in the development of hip joint flexibility and kicking skills. The researchers used the experimental method by designing (the two equal groups) and the research population was determined as the young players of Al Furat Al Awsat, number of (45) players and the sample was chosen randomly and number of (16) players, the results in post and pre –measurement were significant differences in the hip joint and motor skills of the experimental group, The post measurement was significant differences in all the studied variables, the researchers concluded that PNF exercises on the used device had a large effect on the development of working muscles of the hip joint, PNF exercises use according to the device which was close from the performance similar to the skills performance under study which helps to develop these skills, the most important recommendations use these exercises in accordance to the used device to develop the hip joint flexibility and the skill performance, diversification and change in exercise performance leads to the development the level.

Keywords*: PNF Exercises, Flexibility, Joints, Health.*

Introduction

The development of any field of sports science contributes in one way or another to the development of physical education and sports through use of ways, methods and modern scientific techniques in various fields of knowledge as effective means in the process of training, measurement and evaluation to reach the development of the planning and skill aspects of sports [(1)]. Taekwondo game has abundant share of research, analysis and development at the game level and the player, and it is characterized by the performance nature of the changing and rapid positions, which depends on the motor extent of the joints and this requires effective measurement and this helps to give a clear picture of the players levels, especially when it is based on codified objective tests by new devices[(2).] Hence the importance of research of PNF exercises by using a measuring device to develop the hip joint flexibility and perform some kicking skills that contain in its performance on the joints flexibility.

Corresponding author:

The Research Problem:

One of the important things in the Taekwondo game

is to increase the flexibility of the hip joint and measure it according to advanced scientific standards, which most workers did not care about this game, because a lot of game skills depends on the opening the legs and any weakness effects on the motor extent of skills [3]. It is also possible to measure this joint through a device that measures the angle of flexibility of the hip joint, so researchers tried to study the effect of exercise PNF by a special device to measure the angle and joint flexibility in the development of some skills that are characterized by opening during motor performance[4].

Research Objectives:

1. Preparation of PNF exercises by a special device to develop and measure the hip joint flexibility.

2 - Identify the effect of exercise by the device in the development of hip joint flexibility of young Taekwondo players.

3 - Identify the effect of exercise in the development of some kicking skills among the young Taekwondo players.

Research hypotheses:

1 - There is a significant difference between the pre and post measurements in the development of hip joint flexibility and kicking skills of young Taekwondo players and in favor of post measurements.

2 - There is a significant difference in the post measurements in the development of the hip joint flexibility of and kicking skills of young Taekwondo players between the two research groups and in favor of the experimental group.

1Research Fields:

1-4-1 **Human field:** Al Fruat Al Awsat Taekwondo players for 2019 season.

1-4-2**Time Field**: 10/2/2019 to 25/8/2019

1-4-3 **Spatial Field**: Taekwondo hall in NajafAlAhraf.

Research methodology and field procedures:

Research Methodology

The researchers used the experimental method to suit the nature of the research problem.

Research population and sample

The research population determined as Al Furat Al Awsat players (total of 45 players),the sample was chosen by simple random number (16) players and the percentage (35%),the parity and homogeneity in the variables(length, mass, age of training, and skills under study) as in tables (1):

Table (1) shows the homogeneity of the variables under study

variables	Measurement unit	S-	Mean	A	Sprains	Significance
Length	CM	165.12	164.3	6.45	0.38	homogeneous
weight	KG	64.67	63.2	5.51	0.80	homogeneous
Age of training	Month	26	25	3.36	0.89	homogeneous

Table 1 shows that the two homogeneous research groups in all variables, the results showed that the sprains coefficient values are between (1±)

Table (2) shows the equivalence of the variables under study

variables	measuring unit	Experimental		Control		Calculated (T) value	Significance level	Type of significance
		S	A	S	A			
Angle of hip flexibility	CM	122.53	11.67	121.07	11.49	1.54	0.09	Non - moral
Apollo Jacky (Vocal solo kick)	Degree	6.14	2.43	12.6	1.23	2.13	0.14	Non - moral
Jikojki (Kick Hammer Front)	Degree	6.47	1.09	6.21	1.16	2.21	0.24	Non - moral
Higujki (Round Kick)	Degree	6.34	1.59	6.13	1.36	1.23	0.17	Non - moral

Tools and Means:

-Test and measurement.

- Statistical means.

- (hip) Joint Flexible device.

-Medical balance.

-stopwatch.

- Unloading and data collection form.

- Computer brand (DEEL).

Main research procedures:

Skills under study:

Some of attacking skills of legs adopted by the researchers because the importance of these skills in the Taekwondo sport, Hapatolyogki (single-kick Alotawip), Jikojki (front hammer kick), Hijojki (round kick).

Evaluation skills under study:

The researchers evaluate the skills by showing the skills to three arbitrators, the score (10) degrees and extracted the arithmetic mean of the scores for each skill.

Measurement Test of hip joint flexibility on the device :

- Name of the test: measurement test the extent of the angle of the hip joint.

- **Objective of the test:** to measure the angle of the hip joint.

- **Performance method**: The player lying on his back so that the hip at the end of the mastaba and his back base on the device and the legs are stretched on the device arms and when the player stabilizes on the device is lifting one of the legs through the lifting machine, which is close to the upper side of the arm to the maximum and pain in the back thigh muscles[4]. The angle is measured by the angle measure on the device.

- **Recording method**: is done by the angle measurefixed on the device, recording the measurement of the hip joint angle[5].

- **Number of attempts**: the player has one attempt.

Exploratory Experience

The researchers conducted the Exploratory Experience on Monday 15/3/2019 on the sample of (5) players:

- Knowing the required time for tests when applied to take advantage of this when conducting the main experiment.

- Check the accuracy and safety of the devices and used tools and how to record the results.

- Inform the assistant team on how to conduct the tests.

- Extract the scientific standers of the tests and the method of measurement on the device[6].

Scientific standers for the tests:

Validity of the test:

The apparent validity of the test was result from showing the designed device on a group of experts and specialists and confirmed the validity of the device to measure the hip joint angle

Test stability:

The test method was used and re-tested, the test was re-applied after seven days and processing results of two tests by using Correlation coefficient (Pearson) reached (0.88) and its represents high correlation value which indicates to the stability of the test

Objectivity of the test:

The correlation coefficient was extracted from the results of the exploratory experimental sample by testing the elasticity of the hip joint at the same time and the correlation coefficient was evaluated (0.89) which indicates too objective the test.

Pre-testing:

The pre-test tests were conducted on 25/3/2019, where the hip joint flexibility measured and PNF exercises were applied to the research sample and all the conditions which performed of these tests[7].

Preparation and implementation of PNF exercises:

PNF exercises were prepared by the researchers using the hip joint flexibility device[8,9] and were implemented on the experimental group which included (16) training units at rate of two units per week. the duration of the educational unit lasts 120 minutes and the application of educational units lasted for (8) weeks from 18/4/2019 until 20/6 / 2019.

post -tests:

The post-measurement of kicking skills applied after perform the PNF exercises by using the hip joint flexibility device prepared by the researchers on 27/6/2019 and on the same conditions as the pre-test.

Statistical Methods: The researchers used the statistical bag (SPSS) in analyzing the data

• Arithmetic mean.

• Mediator.

• Standard deviation.

• Torsion coefficient

• T-test for associated samples.

• T-test for independent samples.

• Pearson.

- show, analyze and discuss the results.

-show the results of kicking skills and hip flexibility:

Table 3: Shows the arithmetic means and the standard deviations of kicking skills and hip joint flexibility in the pre- and post-test of the two groups

Discuss the tests results of kicking skills and the hip joint flexibility

Through what show in the table (4) shows the significant differences in the angle of hip joint flexibility, the researchers know the reason for the device which used for exercise by clearly effect on the performance and hip joint flexibility by increasing the efficiency of muscles and ligaments surrounding the joint and according to performance requirements which requires presence of perfect motor control when performing to score a point on the opponent and requires from the player a good knowledge of the mechanical laws to the extent of movement and development. The lower limbs are at best to maintain the edition of some physical abilities when the player extends his leg during the direction of a certain kick and the participation of all joints of the body must be the maximum speed and then achieve control through the contraction of muscles working on the joints at the end of the movement to reach the goal and this is confirmed by (Nawal Obeidi and Fatima al-Maliki), as the more flexible the appropriate degree the faster the rotation. This is confirmed by the device, which measures the angle of flexibility of the hip joint (1),

and on this basis has been divided skills kicking Taekwondo and hip joint into its parts according to mechanical foundations and the increase of the extent of the hip joint in the corner is through the first two stages is to accelerate the ground strike man and this is from During the dynamics of the movement and the second is the dynamic relationship between the end of the movement and score points ie it is to reach the goal and achieve a point by pushing the man strongly and speed within the required range requires a large mechanical force useful in the control to perform skills properly and this requires high flexibility Count on the expansion of the motor range of the joint, which is reflected positively in the development of muscles involved in the performance, as the device designed to measure the flexibility of the joint under the influence of an external factor, the device and this is called negative lengthening (1) and this is what researchers used for the exercises prepared on the device in order to Increase the angle of the hip joint and focal point easily.

Also, the following table shows the presence of significant differences in the performance of motor skills and the researchers attribute this reason to the fact that the members of this group has been trained in these exercises (PNF) and through the device that was used and given time and linking them to performance led to the emergence of significant differences as these exercises It works to stretch the muscles and ligaments surrounding the knee and hip led to the development of the skills under discussion in addition to it helped to improve the overall shape of the movement and basic positions. The researchers also believe that these exercises and their compatibility with the requirements of the effectiveness of Taekwondo determine the level of motor performance and this is confirmed (Mehdi 2008) (must be integrated exercises (PNF) with the form of motor skill on the device as well as these exercises positively affected the performance of kicking skills, especially working muscles However, this is related to the development of the flexibility of the hip joint, which helps freedom of movement in various directions without feeling any particular pain (2), and this is what tests were done through the device and considered the starting line for the beginning as well as the angle gauge Connect the hip and then do the exercises that were prepared in the correct scientific form.

Conclusions and Recommendations

Conclusions

1- The researchers concluded that PNF exercises on the system used have a significant impact on the development of working muscles of the hip joint.

2 - Diversification and change through the device helped to develop the skill performance of kicking skills.

3- The use of exercises (PNF) according to the device was close to the performance similar to the performance of the skills in question helped in developed these skills.

Psychometric Properties of the Pain Self-Efficacy Questionnaire Using Nigerian University Students with Chronic Pain

Christian S. Ugwuanyi[1], Chinedu I.O. Okeke[2]

[1]Postdoctoral fellow, [2]Host, Professor and Head, School of Education Studies, Faculty of Education, University of the Free State, Bloemfontein, 9300, South Africa

Abstract

This study was set to determine the psychometric properties of the pain self-efficacy questionnaire among Nigerian university students with chronic pain. A sample size of 256 Nigerian university students with chronic pains was used. The construct validation of the PSEQ was done using exploratory factor analysis while the internal consistency and stability reliability indices were estimated using Cronbach Alpha method. The study found that the items of the PSEQ correlated positively with each other (r = 0.72) and PSEQ is a unidimensional instrument with good internal consistency reliability. By implication, the Nigerian version of PSEQ demonstrated good psychometric properties as already indicated in English language, Portuguese and Dutch versions. Thus, usage of the PSEQ on Nigerian university students with chronic pain will help then to find out the level of adjust in their academic pursuit.

Keywords: *Psychometric, Properties, Pain, Self-efficacy, Chronic, Validation.*

Introduction

Pain, also known as a musculoskeletal disorder, is common among undergraduate students, particularly those with chronic cases and has remained a major concern of public health professionals and researchers worldwide.[1-3] Pain can restrict daily activities, decrease appetite, impair sleep and lead to depression, anxiety[4]. Pain is a common and major public health problem which impact an individual's quality of life from different aspects including physical, psychological and social negatively.[5-8] The ability of a patient to manage the painful condition is usually based on his/her pain self-efficacy level. As a psychological construct, pain self-efficacy is seen as one's confidence regarding his/ her ability to function effectively while in pain.[9] Available research has shown that pain self-efficacy is linked to positive pain-related outcomes in children with chronic pain.[1]

Corresponding author:
Dr. Christian S. Ugwuanyi
Email:ugwuanyics@ufs.ac.za

Self-efficacy beliefs are defined as convictions that one can successfully execute behaviours that are required to produce outcomes[10]. According to a previous study[11], efficacy beliefs determine whether coping behaviour will be initiated, how much effort will be expended, and how long this behaviour will be sustained in the face of obstacles and aversive experiences. Bandura proposed that efficacy expectations determine how much effort people will expend and how long they will persist in the face of obstacles and aversive experiences. This concept has been applied to chronic pain patients and several reviews[12] have concluded that self-efficacy beliefs, along with other psychological constructs, are related to adjustment to chronic pain. Self-efficacy beliefs have been found to explain a range of behaviours and aspects of pain experience in chronic pain situation.

Self-efficacy beliefs play an important role in functioning and coping with chronic pain.[12, 13] Converging lines of evidence support the importance of self-efficacy beliefs in adopting coping strategies[14], reducing avoidance behaviour[15], and predicting pain-induced fear.[16] Moreover, self-efficacy belief is a more

important determinant of disability than pain intensity, pain duration and anxiety.[17] Studies show that increases in functional self-efficacy are strongly related to positive treatment outcome.[18, 19] Self-efficacy beliefs are therefore important psychosocial determinants of pain behaviour and treatment outcomes. Several questionnaires have been employed to measure self-efficacy in chronic pain patients.[20-22]

Despite the prevailing/continuous pain experiences in many patients, only two questionnaires validated using English language speaking countries, Portuguese and Dutch patients had specifically investigated patients' confidence in performing general or more specific tasks in the presence of pain.[2,21] Thus, the study determined the psychometric properties of PSEQ using Nigerian university students with chronic pain.

Methodology

Participants

Chronic pain patients in different medical centres in Southeast universities in Nigeria were purposively selected for the study. A sample of 256 University students with chronic pain patients of different age cohorts were selected from 72 hospitals in the South-Eastern part of Nigeria. 43 of the participants are of ages within 15-25 years; 167 of the participants are of ages within 26-45 years, while 46 participants are of ages within 46-70 years.

Instrument

Pain Self-efficacy Questionnaire (PSEQ).[2] The PSEQ consists of 10 items. Each item is scored on a 7-point scale ranging from 0 "not at all confident" to 6 "completely confident". Higher scores on the PSEQ imply stronger self-efficacy beliefs while lower scores imply weaker SEB.

Procedure

At the first instance, copies of the informed consent letter were sent to 324 undergraduate students in the 5 medical centres in Southeast universities but 256 of them with chronic pain responded positively to the request. After that, copies of the PSEQ were administered to the chronic pain patients who responded positively to the request.

Construct Validation

The instrument was construct validated by subjecting it to confirmatory factor analysis using the principal component matrix. This was done after the completion of the questionnaire items by the chronic pain patients. After that, the data collected were coded and factor analysis was done. A criterion factor loading of 0.50 was used in the selection of pure items. That was based on the recommendation[23] that any item that loads 0.5 or above in only one of the factors should be considered a pure item.

Table 1:Correlation matrix of the items of PSEQ

		item1	item2	item3	item4	item5	item6	item7	item8	item9	item10

	item8	.093	.209	.277	.369	.261	.487	.720	1.000		
	item9	.109	.112	.152	.115	.166	.264	.434	.396	1.000	
	item10	.098	.190	.100	-.066	.130	.194	.312	.192	.471	1.000
a. Determinant = .034											

Table 1 shows that the items of the PSEQ correlated very positively with each other. This means that the items are related to a particular construct.

Table 2: KMO and Bartlett's Test for the Adequacy of the sample for the factor analysis of PSEQ

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		**.693**
Bartlett's Test of Sphericity	Approx. Chi-Square	845.141
	Df	45
	Sig.	.000

Table 2 shows that the KMO measure is 0.693 which shows that the sample for the factor analysis of the PSEQ was very adequate. From the same Table 2, the **Bartlett's test** of sphericity is significant. That is, its associated probability (0.000) is less than 0.05, and is small enough to reject the null hypothesis. This means that the correlation matrix for the PSEQ is not an identity matrix

Table 3: Communality values for the items of PSEQ

Item Statement		**Initial**	**Extraction**
1.	I can enjoy things	1.000	.696
2.	I can do most of the household chores	1.000	.751
3.	I can socialise with my friends or family members as often as I used to do	1.000	.537
4.	I can cope with my pain in most situations	1.000	.585
5.	I can do some form of work	1.000	.470
6.	I can still do many things I enjoy doing	1.000	.608
7.	I can cope with my pain without medication	1.000	.450
8.	I can accomplish most of my goals in life	1.000	.662
9.	I can live a normal lifestyle	1.000	.646
10.	I can gradually become more active	1.000	.773

Table of communalities (Table 3) shows how much of the variance in the variables have been accounted for by the extracted factors. It shows that item 1 which says "I can enjoy things" had communality value of 0.696 meaning that over 69% of the variance in *I can enjoy things* is accounted for. Also, item 2 with communality value of 0.75 means that 75% of the variance in *I can do most of the household chores* is accounted for. This follows of other items in Table 3. However, item 7 had the smallest communality value of 0.45 meaning that 45% of the variance in *I can cope with my pain without medication* is accounted for while the highest in communality value is 10 with communality value of 0.77 meaning that 77% of the variance in *I can gradually*

become more active is accounted for.

Table 4: Component Matrix for the items of PSEQ

Item Statement	Component		
	1	2	3
I can enjoy things		.682	
I can do most of the household chores	.535	.634	
I can socialise with my friends or family members as often as I used to do	.558		
I can cope with my pain in most situations	.513		
I can do some form of work	.588		
I can still do many things I enjoy doing	.743	.657	
I can cope with my pain without medication	.739	.567	
I can accomplish most of my goals in life	.739		
I can live a normal lifestyle	.543		
I can gradually become more active			.682

Extraction Method: Principal Component Analysis.
a. 3 components extracted.

Table 4 above shows the loadings of the ten variables on the three factors extracted. The higher the absolute value of the loading, the more the factor contributes to the variable. The gap on the table represents loadings that are less than 0.5. In order words, the benchmark for the selection of the items was 0.5 and we suppressed all loadings less than 0.5. Table 4 also shows that items 2, 3, 4, 5, 6, 7, 8 and 9 loaded more than 0.5 on factor 1, items 1, 2, 6, 7 loaded more than 0.5 on factor 2 while only item 10 loaded more than 0.5 on factor 3. This implies that items 2, 3, 4, 5, 6, 7, 8 and 9 are more related to factor 1, item 1 is more related to factor 2 while item 10 is more related to factor 3. This result shows that items 1, 3, 4, 5, 8, 9 and 10 are factorially pure items out of the items of PSEQ because they loaded above 0.5 in only one factor. Items 2, 6 and 7 are factorially complex items because they loaded above 0.5 in more than one factor. Thus, 7 out of the 10 items of PSEQ were found to be pure items after the confirmatory factor analysis.

Internal Consistency Reliability of PSEQ

Table 5: Reliability analysis of the PSEQ

Cronbach's Alpha	N of Items
.838	7

Table 5 shows the internal consistency reliability of the 7 items of PSEQ was estimated as 0.838 using Cronbach alpha method. This value confirmed that PSEQ is a reliable instrument for the management of pains by patients.

Stability Reliability of PSEQ

The stability of PSEQ was estimated through test re-test method. Pearson correlation between the first and second administration of PSEQ is 0.866, $p<.001$. This shows a high correlation of the first administration and second administration of PSEQ after two weeks interval. This indicates that PSEQ is stable

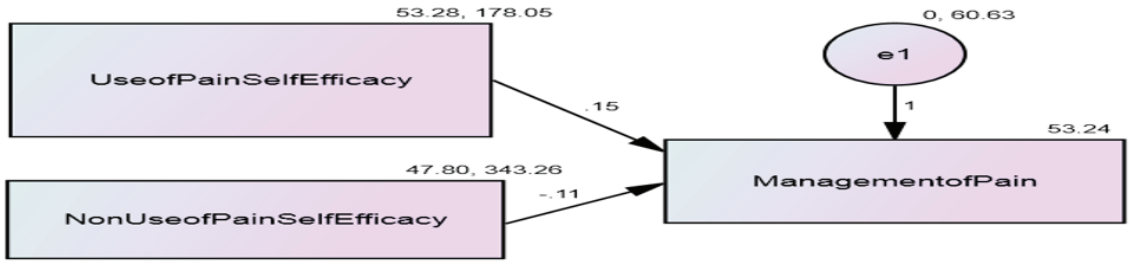

Figure 1: Path diagram of the use of PSEQ in the management of pains

The figure 1 represents the model diagram for the impact of the use of PSEQ in the management of pains. It reveals that the use of PSEQ has a positive impact on the management of pains among Nigerian university students. The model fit for the recursive model developed was tested using Chi-Square goodness of fit test and Root Mean Square Error of Approximation (RMSEA). The developed model had a Chi-square value of 28.34 with a probability value of 0.72. The Chi-square value of 28.34 and RMSEA value of 0.00 showed that the data used for the study fitted the model.

Discussion

This study has been able to establish the psychometric properties of PSEQ using Nigerian university students. The PSEQ had good psychometric properties in the sense that the items of the PSEQ correlated highly with each other and as well loaded above 0.50 majorly in one factor. This implies that the PSEQ is a unidimensional instrument with good internal consistency reliability as well as stability reliability for determining the self-efficacy of patients with chronic pain. These findings are similar to the findings.[2, 21, 11] Study[11] found that the exploratory factor analysis demonstrated that the Dutch version of the PSEQ is a unidimensional instrument with adequate internal consistency which is also in accordance with the original English language version[2] and the Portuguese version.[21] This by implication shows that the Nigerian version of PSEQ demonstrated good psychometric properties as already indicated in English language, Portuguese and Dutch versions.

However, the 10-item English version of PSEQ developed by Nicholas in 1989 was reduced to 7 items through the exploratory factor analysis. The variation in the number of items may have been because of the difference in the area of the study. Thus, further validation of the instrument is recommended for future research in Nigeria or any of the African countries.

In conclusion, the Nigerian version of the PSEQ is a unidimensional instrument with good internal consistency and stability reliabilities. This implies that the Nigerian version also demonstrated good psychometric properties just like those of the English language, Portuguese and Dutch versions. The implication of this finding lies in the fact that Nigerian university students with chronic pain can be diagnosed from time to time ascertain their level of management of their pains for optimal academic performance.

Call for Papers / Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialities. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper: A general invitation is extended to authors to submit papers papers for publication in IJPHRD.

The following guidelines should be noted:

- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or back ground
- Material and Methods
- Findings
- Conclusion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: **editor.ijphrd@gmail.com**

CALL FOR SUBSCRIPTIONS

About the Journal

Print-ISSN: 0976-0245 **Electronic - ISSN:** 0976-5506, **Frequency:** Quarterly

Indian Journal of Public Health Research & Development is a double blind peer reviewed international Journal. The frequency is half yearly. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, Public Health Laws and covers all medical specialities concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and south east Asia.

The journal has been assigned international standards (ISSN) serial number and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases.
