Indian Journal of Public Health Research & Development

Print-ISSN: 0976-0245-Electronic-ISSN: 0976-5506, Frequency: Quarterly (Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare. The journal is now part of DST, CSIR, and UGC consortia.

The Cancer Principle-I: Introducing Cancer as a Fundamental Principle of Nature

Asima Tripathy[1], Rajat Kumar Pradhan[2]

[1]Post Graduate Department of Zoology and Microbiology, [2]Post Graduate Department of Physics, Bhadrak Autonomous College (Department of Higher Education, Govt. of Odisha), Bhadrak, Odisha, India

Abstract

In a series of five articles we put forth and establish a new principle, namely the cancer principle which we propose as a fundamental principle of nature. Cancer is an agent of the principle of disorder and is at the root of origin of life, evolution of species and may be, is also the determinant of the ultimate fate of all life. We introduce and motivate this principle and provide arguments in favor of its being at the origin of all evolution. Cancer is defined as the tendency for unrestrained proliferation that is operative in both inanimate and animate worlds and that has given rise to the phenomenon of life from the nonliving background.

Keywords: *cancer, disorder, order, evolution, self-replication*

Introduction

Cancer is unrestrained proliferation. The unicellular organisms evolved as the primary life-forms on earth at least around 3 to 3.5 billion years ago[1,2]. The multiplication rate in them is no doubt high, but the average time taken for each division is typical of the species and is constant. In multicellular organisms, the cells stop dividing when the respective organs reach their appropriate size, but in case of cancer, the cells go on dividing indefinitely. The cancerous cells are having remarkable adaptive ability for survival. They work on the surrounding cells and destroy them and create space for their own accelerated multiplication and growth[3,4].

Hippocrates (460-370BC) used the ancient Greek name *carcinos* (meaning crab), pronounced *karkinos*, which has its origin in the proto-indo-european word *korkros*, or may be, even pre-dated by the corresponding original Sanskrit word *karkata* (also meaning crab), possibly due to the finger-like projecting spiculations from the sore which make a crab-like appearance[5] and it may also be related to angiogenesis[6]. This most ancient name also surprisingly indicates that cancer is a living organism and not just a disease[7]. Perhaps, no other disease has such a name. Interestingly, the analogy with crab also catches the other prominent characteristics of cancer: the crab makes several holes for its residence by digging out lumps of mud which dry up to harden, and which do look like tumors on earth (Tumorigenesis)! If its hole is closed in one place, it digs out a lump at another place, exactly as does cancer in post-operative metastasis[8].

The increased virulence of harmful pathogens is because of their adaptive evolution in course of time. The drug resistance in the pathogens is part of the mechanism of survival fitness in terms of evolutionary advantage[9]. Insecticide resistance in a vector is an adaptation for the evolutionary advantage of the vector species for its survival and reproductive success[9,10,11]. In the chain of vigorous competition, cancer-causing pathogens have gone much ahead. In recent works, carcinogenesis has been proposed to be a form of speciation and cancer development as an evolutionary process in which nature selects some cells that can develop new metabolic pathways of aggression and resistance[12,13].

Cosmic origins of molecular Self-replication

Each elementary particle (*e.g*. an electron or a proton or even a photon) has the ability to store information and to interact in specific ways with other particles depending on their quantum numbers. When such particles come together to form larger aggregates such as nuclei in stellar

Corresponding author:
Asima Tripathy
Email ID: asimatripathy09@gmail.com

interiors and atoms in relatively colder regions such as planets, the information-storing ability increases and gets encoded in the quantum states of such composite systems[14]. In course of time and in suitable conditions such as the earth's, long chains of carbon atoms with different functional groups forming biomolecules can come up with their definite information and interaction capacities. The possibility of self-replication is inherent in long chains of carbon atoms because of the self-similarity of the chain over long segments, the reason for self-similarity being the availability of particular kind of radicals in a particular environment. Fragments of such chains of carbon atoms can become ligand as well as receptor for the formation of larger biomolecules that can replicate themselves. A chain of carbon atoms thus holds within itself the most important possibility of self-replication[15]. Too long a carbon chain may easily break into similar and smaller fragments which is the basis of self-replication of complex biomolecules such as nucleic acids and proteins[16].

Evolution and Cancer

As per the Darwinian evolution paradigm, the mutations are random and nature selects the fittest under the circumstances to survive and therefore, the individual organism seems to have very limited personal, willful choice in its evolution because it is nothing but a colony of its genes which gets propagated down the generations, presumably with naturally selected mutations[17]. Natural selection is often credited with the power to bring up complex adaptations in nature[12]. We may ask: What is the urgency in the cells to divide so rapidly as to become cancer cells? What is the origin of oncogenes? What is the active principle of natural selection of these cancer cells here? What is the purpose of the complex adaptations of a cell to be cancerous? Why natural selection is unable to drive out or kill these cancer cells from the body in order to ensure survival of the organism? Or, is there some other more powerful natural process which, in its own course, will be able to wipe out the cancer cells from the body of the organism, or is it the contrary: *Is all life going to merge in Cancer*?

Existing theories of cancer such as the SMT (Somatic Mutation Theory) and TOFT (Tissue Organization Field Theory) are partial in their success since most of the cancers remain untraceable to their underlying causes[18]. SMT holds that cancer is a disease of cell proliferation while TOFT holds that it is a disease of tissue organization. The SMT, TOFT and other such approaches are mere plausible mechanisms of cancer and don't completely address the fundamental causes thereof[19,20]. In the integrative approach, metabolic imbalance and immunologic response in the host are taken along with genetic causes as determining cancer formation as well as growth lading to eventual mortality[21]. Analysis of bioenergetics of cells lends further support to such an integrative theory of cancer as to its molecular basis in living cells, though it is yet unclear how driver mutations and passenger mutations are related and why such huge numbers of driver mutations are there in the uncogenic landscape[22,23] of the same type of cancer even.

The atavistic theory of cancer proposed by Davies and Lineweaver views it to be a return to the preferential expression of ancient genes that were present during the transition from unicellular to multicellular species[24]. This pre-dates the origin of cancer to about a billion years back when metazoan life was present which acted as an intermediate stage between unicellulars and more complex multicellulars.

All the characteristics of cancer were nicely paraphrased as the six hallmarks by Hanahan and Weinberg as: (1) self-sufficiency in growth signals, (2) insensitivity to growth-inhibitory (antigrowth) signals, (3) evasion of programmed cell death (apoptosis), (4) limitless replicative potential, (5) sustained angiogenesis, and (6) tissue invasion & metastasis[25]. There are, no doubt, natural defense mechanisms in the individual organism to fight against cancer[26]. Then what evolutionary advantage do the cancer cells gain by overpowering the defense mechanisms of the individual *i.e.* by working against the survival of the organism itself, whose constituents they actually are? Is it not the intense urge for unrestrained proliferation ingrained somehow in each cell to acquire the greatest reproductive success since the time when it was but a unicellular organism? And, since that time, it has been the organism's continuous effort to gain the ability to multiply as rapidly as possible to establish its maximum potentiality to gain reproductive and survival fitness but, only that it took its time to come to the multicellular organism? Or, is the root of cancer somewhere else?

On the other hand, there is increasing realization among biologists that cancer has played a major role in the evolution of multicellularism, cellular defenses, apoptosis, cancer suppressor genes, tumor suppressor mechanisms and epigenetic mechanisms, all in the

direction of naturally combating cancer only[27]. In the process, diversifications of many species as well as of the many viral strains of the oncovirus have all occurred and are still continuing. Thus, susceptibility to cancer seems to be a possible key selection pressure on organisms, thereby determining their evolution. Therefore, what are stated to be the causes of cancer are actually its effects[19]. We therefore envisage cancer as a fundamental principle of nature, namely the principle of unrestrained proliferation following from the principle of disorder (POD), rather than as a mere disease.

The cancer principle

We thus propose:

Cancer is at the origin of life; the incessant struggle against it is the evolution of species and finally, succumbing to it is the ultimate fate of all life.

Hugely surprising it may seem, but which fact about cancer is not surprising! Defined as *unrestrained proliferation*, it is indeed what perfectly captures the phenomenon of life. Cancer, as the tendency for unrestrained proliferation, has taken the form of life. This is the proposal of "origin of life in cancer". In fact, the astrobiological theory of cancer proposes on certain evidences that it must have been a universal phenomenon in all life in the cosmos, including alien life and those in exoplanets, because any star that supports such life must have UV radiation predominant in its spectrum against which in case of life on the earth there evolved the tumor suppressor genes P53/P63/P73, whose primary function in those early times was to protect the DNA against damage due to UV radiation[28].

The next three essays in this series will deal with the role of cancer in evolution and evolution of cancer itself since the beginning. There are many factors that try to limit the propensity of life for unrestrained proliferation, and hence comes evolution[29]. In the last decade or so, it has been increasingly realized that cancer itself has an independent evolutionary path through the expert adaptation of the oncoviruses to outcompete all others in the fray. On the other hand, tools of evolutionary biology have also been increasingly getting used for studying cancer and dealing effectively with it[30,31].

Finally, in the last two articles we deal with the last part of the principle i.e. the inevitability, invincibility and immortality of cancer, which sounds like doom-saying. But going by the rampaging trend of unstoppable march of cancer as a phenomenon (about 70% to 80% of all cancer is of unknown etiology), we feel that it can be amply justified. Davies opines, "In that sense, cancer is an accident waiting to happen"[32]. It is as certain as that! The cancer principle thus seeks to invert the argument that cancer is the product of evolutionary processes[33]; rather it is cancer that causes all evolution! What concerns us in this series is the ontology of cancer rather than its epistemology as a multistage process[34,35] or as an effect of evolution.

Conclusion

Different points of view on cancer that we have outlined here only point to its multi-facetedness and we have not exhausted all the views that have so far been proposed by way of theorizing. Cancer as a fundamental principle determining all evolution, from the origin of life itself to the dissolution, is of course a startling proposition. What we have motivated in this first article is that, if we define it as the urge for unrestrained proliferation instead of being just a disease, then it does indeed turn out to be an all-potent determining agency which, by its collusion and conformity with the principle of disorder(POD) that is universally operative, has led to all evolution by opposing the cosmic ordering principle(COP). This continuous see-saw between the ordering principle and the disorder agent (cancer) is at the root of all evolution, and even, of the origin of life itself. From the low entropy initial pre-big-bang state to the expanding universe, from structure formation to radiating stars, from abiogenesis to tumorigenesis – all are processes brought about by the principle of disorder against the cosmic ordering principle that ever acts to organize, regulate and systematize.

In trying to counteract the tendency to move towards the maximally disordered state of thermodynamic equilibrium of non-living components of the universe, the compromise obtained by COP is what we call "life". But it too is not free from the operations of the disorder principle, as it is inherent and inbuilt into the very fabric of the universe, and hence is present in all the constituents of living organisms. The living organisms are far-from-equilibrium systems which are complex dissipative structures. They maintain homeostasis, order and organization by continuous exchange of matter, energy and entropy with the surroundings, ever striving for an organized steady-state rather than sliding down to maximally disordered thermodynamic equilibrium, which is nothing but death of the organism. The COP

strives to bring forth and maintain order and organization in all systems in opposition to the POD.

The Cancer Principle-II: Cancer as the Origin of All Life on Earth

Asima Tripathy[1], Rajat Kumar Pradhan[2]

[1]Post Graduate Department of Zoology and Microbiology, [2]Post Graduate Department of Physics, Bhadrak Autonomous College (Department of Higher Education, Govt. of Odisha), Bhadrak, Odisha, India

Abstract

Life is the urge for perpetuation and cancer as the agent of disorder is the force that drives this urge in the direction of unrestrained proliferation. The oncovirus strains like HPV and HCV are as old as life itself from its initial incipient stages and the evolution of such viruses has determined the course of evolution of species from within in a bottom-up manner purely through this urge for unrestrained proliferation. The cosmic ordering principle(COP) acts in the direction of arresting the increase of disorder (cancer) by evolving various cancer suppression or evasion mechanisms and thus both contribute to the evolution of all life.

Keywords: *Cancer, Evolution, Oncovirus, Oncogenes, abiogenesis, cosmic ordering principle (COP) and the principle of disorder (POD)*

Introduction

In the previous essay we have motivated cancer as a fundamental principle of nature that is as old as the universe itself. We wish now to establish it as an agent of the principle of Disorder (POD) that is continuously operating along with the cosmic ordering principle (COP) to give shape to all evolution[1]. Abiogenesis of life on earth can be seen in light of the cancer principle to shade light on pre-cellular evolution. Up to the formation of methane and ammonia etc. which led to the synthesis of amino acids with the help of the energy from lightening and ultraviolet radiation or from hydrothermal vents in the primordial ocean-atmosphere system there was increase of disorder as per the second law in a global sense[2]. But simultaneously, there was also the increase of local order in the formation of larger molecules and molecular aggregates gradually going to form the lithosphere[1]. Wherever the conditions favored the formation of macromolecules, there was rapid growth of such formation as long as catalytic support to the reactants was there. This process could halt only if the catalysts were withdrawn or all the reactants were exhausted, assuming no other inhibiting factors. When this primitive system favored formation of long-chained molecules such as proteins and nucleotides there were aggregates of such molecules which filled large portions of the oceans[3].

The exact number of hydrothermal vents, the extent of oceanic surface with proper catalytic conditions are matters of debate and therefore nothing definite can be said about the locations where biomolecules came up, but the ubiquitous presence of life in the form of Archea and bacteria all over the earth points to the fact that large portions of oceanic belts must have had identical suitable catalytic conditions for synthesis of biomolecules. The recent discovery of extremophiles (thermophiles and cryophiles) in uninhabitable regions on earth, hitherto considered barren for life, lead us to propose that even prior to the formation of lithosphere the entire hydrospheric envelop was filled with such biomolecules as would support evolution of life[4,5]. We may call it the Global Biomolecular Envelop (GBE). This GBE, regional climatic variations notwithstanding, must be taken as the basic substrate for life to manifest[6]. Once the biomolecules started getting synthesized, there could have been no stopping of such synthesis till different regional thresholds were reached in different belts forming the GBE. The inherent tendency in the GBE to pervade ever larger regions by proliferation is the fundamental defining feature of all life[7].

The tango between order and disorder

Upon the emergence of membrane-bound pre-cellular organisms, this fundamental feature of life became converted to *proliferation-by-invasion*. This conversion is due to the operations of the cosmic ordering principle (COP) that tried to curb this inherent tendency of life to pervade by proliferation. The appearance of life on earth is due primarily to a cancerous disorder-producing force which has at its core the characteristics of proliferation and invasiveness and which has little concern for the consequences thereof. The COP has continuously acted to resist and to channelize such irresponsible tendencies as is evidenced by the gradual condensations, and also by the synthesis of macromolecules. These biomolecules started self-replicating under the action of the principle of disorder (POD) without any restraint. The information about interdependent proliferation (Protein synthesis by nucleic acids) of these macromolecules stored in the nucleic acids by the COP was encapsulated within proteinous or lipoproteinous membranes. But the tendencies for proliferation and invasiveness hid themselves within those encapsulated "individuals" as their core characters and these are nothing but the oncogenes in segments of the nucleic acids (DNA and RNA). The protein encapsulated nucleic acids were the viruses and those with lipoproteinous encapsulation were the bacteria and archea[8,9].

The tendencies for proliferation and invasiveness remained most potently with the viruses but were patent in the archea and bacteria. Invasion into one another with a view to rapid irresponsible proliferation (Cancer again!) was the operating principle among them[7]. Primordial endosymbiotic mechanisms among archea and bacteria led to the eukaryotes as the result of such invasiveness and proliferation and then on to multicellular complexity[10,11]. By endosymbiosis the COP ensured the survival of the host as well as that of the endosymbiont.

It has been found by phylostratigraphic analysis of emergence of cancer related protein domains that there was a peak at the emergence of the first living cell corresponding to caretaker cancer genes in tumor progression[12]. Thus it is that the Cancer principle is at the very origins of life through abiogesis. Davies' remark, "Cancer can give us important clues about the nature and history of life itself" is thus justifiable[13].

Origins of Oncovirus

The viruses on their part were always on the lookout for entering others to proliferate which led first to the lytic mode of virulence. Thus the fundamental traits of invasiveness and proliferation due to the POD are present in them as their such virulence factors. The COP intervened to bring about a less virulent alternative in the shape of the lysogenic mode of viral proliferation. The viruses, driven by their irresponsible core characteristic of proliferation and invasion, get attached to the DNA of the host and ensure the perpetuation of virulence[14,15,16]. Thus the endosymbiotic compromise brought about by COP against the rampaging virulence held sway for survival of both the species. The POD then makes the endosymbiont integrate its genetic material into that of the host for its perpetual proliferation utilizing the cellular mechanisms and the resources of the host. The character of proliferation got ingrained in the organisms as the genes responsible for reproduction. To curb unrestrained proliferation the COP brought about various mechanisms such as longer duration reproductive cycles, programmed cell death and also changeover from asexual to sexual reproduction which necessitates dependence on third party pollinators in case of plants and mate availability in case of animals.

The invasiveness following from POD was initially in a highly virulent mode, but the COP made it symbiotic. It is precisely in this manner that the highly detrimental lytic mode became converted to the lysogenic mode. The cancerous urge for unrestrained selfish proliferation by invasion into other organisms is so strong in the viruses that they have co-evolved alongside all known species beginning with prokaryotes right up to the humans and there are viruses specializing in infecting particular tissues of particular species. The species have also co-evolved to counter such virulence but no species has ever been able to free itself from viral infections. Thus the entire evolutionary process can be seen to be a continuous struggle to counter the core characteristics of proliferation, invasiveness and virulence. The viral strains have evolved to adopt the most unavoidable living processes as their mode of transmission e.g. respiration, reproduction etc. which increase their virulence as well as fitness factors. The most evolved of the viruses are double stranded DNA type which can attach their genetic material to that of the host and by that ensure their proliferation. The HIV, for example, is capable of completely paralyzing the immune system as if having specifically developed the ability to target

human immunoglobulins[17]. The oncovirus, on its part, appears to have specialized in silencing the tumor suppressor genes.

The oncovirus evolved, preserving within itself the original disorder-producing traits viz. proliferation, invasiveness and virulence all along, to finally be able to activate the human oncogene by producing mutations so that it can completely incapacitate and overpower the highest evolved species by attaching its double stranded DNA to that of the humans[18,19]. In this perspective it is not surprising that virulence in some form or the other has always been on the rise through the entire course of evolution to achieve a sort of invincibility even in their continuous battle against human intelligence, finally landing in the genetic mode of transmission[20].

Bacterial Origins of Cancer Cells

The fact that no exact mechanism is known behind (1) the transformation of normal cells to the primary cancer cells (PCC) that initiate cancer and (2) the transformation of PCCs to the secondary cancer cells (SCC) that are responsible for progress of cancer, has led Dong and Xing to propose the hypothesis of bacterial origins of cancer cells[21]. They base their proposal on the fact that (a) newly formed PCC and SCC are devoid of organelles and look like bacteria (2) Organelle biogenesis of cyanobacterium TDX16 to transform into TDX16-DE by acquiring the DNA of its algal host is similar to the transition of normal cells to PCC and PCC to SCC. The PCC are hypothesized to be intracellular bacteria that take up and hybridize the DNA of senescent or necrotic normal cells, while the SCC are proposed to be the PCC that take up such DNA and hybridize. This view supports the idea that cancer cells are single-celled eukaryote organisms, to which our above analysis does also point.

Cancer cells as a species

The cancer cell line HeLa has been observed to live in vitro for 50 years[22] while canine sarcoma cells known as canine transmissible venereal tumors (CTVT) evolves as a unicellular pathogen outside any host and has developed appropriate immuno-resistance to survive in the wild for decades, as if these cells were a new species[23]. Such transmissible cancers showing inter-individual metastasis prove that cancer cells are indeed living organisms having their own evolutionary adaptations for achieving maximum replication efficiency[24]. Intra-tumor genetic diversity of the cancer cells qualifies them to be called a species rather than an individual.

This schematic figure below represents the successive actions of the cosmic ordering principle (COP) and the principle of disorder (POD) in the evolution of life and species and depicts how the latter has manifested as the cancer principle and has directed evolution all along.

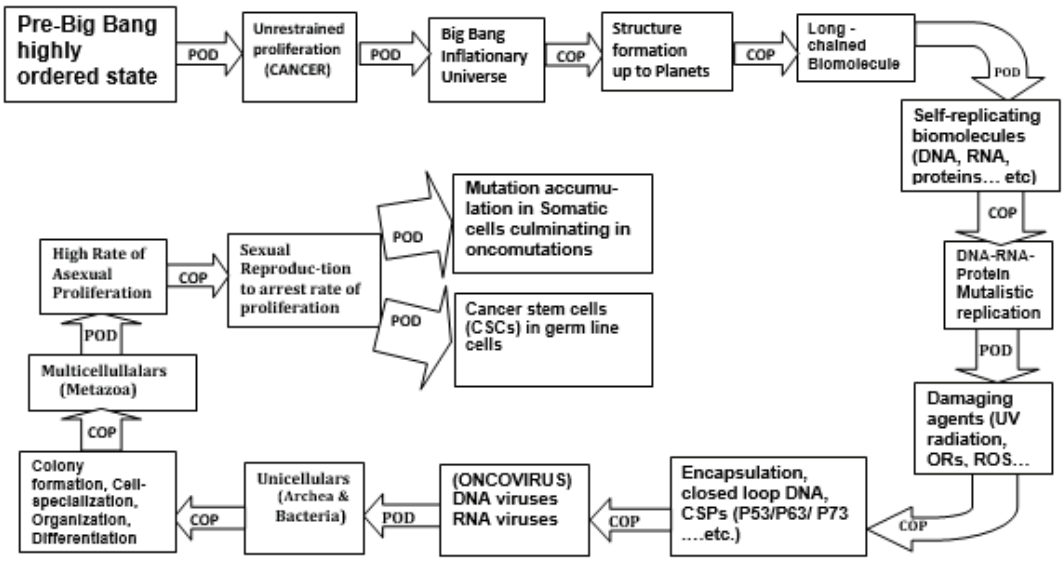

Fig.1. Schematic of Evolution from the highly ordered pre-big bang state up to prokaryotes through the actions of COP and POD

Starting from a highly ordered pre-big-bang state of the universe we have depicted the actions of COP and POD as if competing with each other, and cancer is the agent of disorder and stands for all kinds of irresponsible proliferation that is detrimental to the overall order and organization. As cancer tried to spread its deadly tentacles to engulf all life, the organisms evolved various strategies correspondingly to defend themselves against the menace. The more cancer tried to take the unavoidable routes to manifest, the more specific became the microscopic cellular defenses against it. As per the cancer principle this is the key to understanding all evolution.

Conclusion

With time our knowledge of cancer incidence and progression has entered the genetic domain and oncogenes have been identified. Some oncogenes are isomorphic to the DNA fragments of the early viral strains and which are now identifiable as either the oncoviruses or their precursors. The mtDNA as well as the vast non-coding sector of the DNA have been implicated as having the triggers for the switching on of oncogene expression by the mediation of non-coding RNAs such as mcRNA, circRNA, lncRNA, siRNA and asRNA etc[25,26].

Thus cancer can be understood as the underlying force behind the emergence of life through abiogenesis as well as the progress of life through viral and then bacterial evolution. The road from viruses onwards can be surmised to have been a series of endosymbioses that brought about the evolution of prokaryotes and then the eukaryotes. In the third essay we will argue that it is cancer that has determined the evolution of multicellularism and of all the species. This gives strength to the hypothesis that cancer is at the origin and is the cause of evolution of life in its variety.

Also there are numerous mechanisms which seem to have been designed to limit the ability of the organism to disobey the decentralized tissue principle in order to reduce the risk of getting cancer. All these important processes in evolution can thus be seen to have come up only to resist undifferentiated cell growth, which is nothing but "cancer". There seem to be two distinct forces pitted against each other: the force of cancerous growth versus the resistance to cancer. What we see as evolution of life is but the ongoing contest between these two opposing forces of order and disorder, each operating to defeat the other in multifarious ways. More about this tussle will be discussed in the next essay.

The cancer principle arose out of such musings on its character as unrestrained proliferation, as an undaunted and tenacious march towards immortality as if, it alone were immortal, while all else is mortal.

The Cancer Principle-III: Evolution by Cancer

Asima Tripathy[1], Rajat Kumar Pradhan[2]

[1]Post Graduate Department of Zoology and Microbiology, [2]Post Graduate Department of Physics, Bhadrak Autonomous College (Departmentment of Higher Education, Govt. of Odisha), Bhadrak, Odisha, India

Abstract

Cancer evolves to make all else evolve along with it. Each cancer cell is the result of a huge number of mutations undergone till the point of activation of uncogenes by some kind of natural selection. The uncovirus evolved all along entering the primitive cellular life as an endosymbiont through the mitochondrial route and got itself thoroughly entrenched in the very life process of each living cell, waiting for the appropriate moment to trigger tumor genesis. We propose that multicellularism evolved to arrest cancerous proliferation i.e. overgrowth of single cell types. Afterwards specialized tumor suppression mechanisms, cancer suppressor proteins, lymphoid organs with immune cells evolved to protect the organism against carcinogenesis. It seems as if only to not fall into cancer's deadly trap, all creatures have evolved definite mechanisms and in the process have not only gotten their diversified morphologies, but also their specific physiological systems.

Key Words: *Cancer Principle, oncovirus, oncogenes, Cosmic ordering principle, Principle of Disorder, CSP, VEGF*

Introduction

Unrestrained proliferation of any one category is always opposed by the emergence of effective control mechanisms evolving alongside it to counter such canker. The unrestrained growth is a tendency towards disruption of order and organization in the system and thus the counteracting agency must be an ordering principle or agency that always works to restore or maintain order and organization by adopting as many means and methods as would be suitable to counteract the force of cancer. Evolution of cancer cells by mutation and selection are exactly like evolution of species by such processes[1].

Mutation risk increases with age and with number of cells of an organism. Correspondingly cancer risk too must increase, since carcinogenic mutations become more probable with increasing mass and age. It means that higher mass animals such as elephants and whales compared to humans (or humans compared to mice) should have more susceptibility to cancer, while it is not observed to be so. This is Peto's paradox[2]. There must have been selection for definite protection against cancer with evolution of new morphological and biological characteristics such as larger body size and longer life[3]. The killer capacity of cancer has been highlighted by Lichtenstein as an additional hallmark and this must have had its selection agency in the evolution of various species, their mutation rates, body sizes, longevity, susceptibility to mutagens and so on[4]. Evolution of malignant tissues has been seen to be similar to evolution of drug resistance in bacterial communities[5]. Evidences are there that skin acted as a selection agent in the evolution of black pigmentation in early hominin[6].

Species-specific and cell-specific requirements for malignancy has been studied all through, but there has also been corresponding evolution of resistance against the disease[7]. Klein has emphasized studying the genetics of cancer resistance rather than of cancer attack which is clearly an evolutionary perspective[8]. For example the P53 family of genes including P63 and P73 has its common ancestry in the P63/P73 genes found in fish and sea anemones. They have later diversified in their functions in higher vertebrates though their sole function is to protect the germ-line from genomic instability following from various stresses[9].

The contribution of cancer to evolution all along the history of life on earth is so deep that Greaves has echoed Dobjhansky's famous statement in regard to it-

"Nothing in cancer makes sense …"[10].

Multicellularism

Cancer has been branded as a disease of the multicellular organisms where multicellualrity has failed[11]. How cancer permeates the entire landscape of multicellular life forms has been reviewed by Aktipis *et al*[12]. Note that cancer, in this series of essays, is an evolutionary force of unrestrained proliferation and not just a disease.

The autonomous unicellular became multicellular only to resist cancer. Is that autonomy somehow stored in the highly complex and organized multicellular organisms? Are the individual cells incessantly endeavoring for selfish reproductive success resulting in this tug-of-war for reproductive success between the organism and its "would-be-cancer-cells"? Indeed, the reproductive success of the organism might be the explanation for the late-age appearance of cancer[13]. Nature in this manner gives a chance to the organism to propagate itself by struggling and maximizing its reproductive success against its individualistically endeavoring "would-be-cancer-cells". Success of cancer cells proves that nature favors them or they have molded nature successfully so that oncomutations get inherited thereby. Further, competition among cancer cells leads to the faster dividing cells overpowering and outcompeting the comparatively slower dividing cells. Nature thus favors the cellular over the organismic reproductive success! Cellular reproduction has overpowered natural selection[14] !

Evolution of sexual reproduction

Reproduction as a process of fulfilment of the instinct for perpetuation is the common characteristic of all life[14]. However, no life-form has been able to proliferate indefinitely. The emergence of multicellularism from unicellularism is one such stage where unrestrained growth of unicellular life was halted in favor of complexity. Indeed, phylostaratigraphic tracking of oncogenes suggests that multicellularism in metazoa emerged as a micro-evolutionary transition following a complex multi-level selection[15]. Further, divergence of species occurred at different epochs of evolution owing to various selection pressures. Such diversification effectively controlled unrestrained proliferation of any one species by competition. For this reason, cancer is seen to be a failure of multicellularity[16]. Similarly sexual reproduction evolved from the asexual mode to drastically reduce asexual proliferation of the particular type.

Differentiation of cells in an organism is similar to diversification of species in the sense that both can be seen as an effect of a regulatory force that restricts undifferentiated growth of a particular kind. A tumor in an organism is just such an undifferentiated growth, which may become cancerous. The cancer suppressor gene, apoptosis, autophagy and such other cellular mechanisms have evolved only to suppress or eliminate the possibility of such undifferentiated cell growth or tumor formation. The existence of the definite times for cell division in different tissues is also such an effective mechanism[17].

Cancer Suppression Mechanisms

Cancer suppressor proteins(CSP) are part of the defense system of the body against cancer cells. If there is any abnormality or deviation in the cell multiplication, then these CSPs cause the cell to die or lead to its senescence. Thus CSPs are the reason for normal growth and make us fittest for survival[17]. Then how does CSP fail to halt the success of normal cells and give in to the cancerous mode? Is it only to gain higher uncontrolled reproductive success or it has some other deeper meaning?

For example, among the CSPs, P^{16} is one which causes senescence of abnormally multiplying cells. Contrary to this, VEGF (Vascular Endothelial Growth Factor) stimulates blood vessels to supply the cancer cells with sufficient nutrients for successful growth and multiplication. Here which one competes with which? The P^{16} competes with VEGF or nature competes with the supreme conscious evolutionary force? While nature's objective is reproductive success, the evolutionary force has for itself the role of ultimately monitoring nature's forces and consequences and takes care of things by endowing the organism with P^{16} against VEGF. Or, do both operate simultaneously on both P^{16} and VEGF to compete among themselves and finally it is the achievement of the beneficial one (P^{16}) to win? It has been found that the tumors become refractory and then become resistant to any antibodies tried against the VEGFs[18]. Similarly Tumor suppressor protein P53 is pitted against MDMX and MDM2 (or HDM2 in case of humans) that inactivate them[19]. Cancer seems to be winning in this battle of evolutionary competition!

Similarly, the genes responsible for facilitating the human fetus to form placenta in to the womb, normally remain silent in adult tissues. In cancer cells these genes become active and trigger aggressive growth of blood vessels to ensure energy supply for their growth and multiplication. It seems as if a cancer cell were the knower of all advantageous set-ups of the body and specializes in employing them for its own purpose! Indeed recent studies indicate that ancient retroviruses had a significant contribution in the development of placental gene regulatory networks in mammals[20]. The huge variation in mammalian placental form and function across species as well as phenotypic plasticity may be linked to the evolutionary diversifications of the retroviruses themselves[21,20].

Lymphoid organs and immune cells

In both vertebrates and invertebrates antigen-specific immunity serves the purpose of defense against virus, bacteria and other pathogens and primarily they protect the organism against pre-cancerous and cancerous cells and thus they contribute towards tumor suppression[23]. Immune system is comparatively more developed and complex in vertebrates[24,25]. The design of the whole lymphoid system such as primary lymphoid organs (bone marrow, thymus), secondary lymphoid organs (lymph nodes, spleen, mucosa associated lymphoid tissue, skin associated lymphoid tissue and lymph cells) and immune cells such as B cells, T cells and NK cells; phagocytes i.e. monocyte-macrophage system and neutrophils; antigen presenting cells (APCs), granulocytes, mast cells, platelets is to defend the body[26]. The cell-mediated and humoral (antibody) responses of the immune system result from the coordinated activities of all the immune cells, organs and tissues found throughout the body and they combinedly function to defend the body against antigens.

The whole micro-system of the body is protected by a cascade of defense mechanisms including Tertiary Lymphoid organs (TLOs) and Ectopic Lymphatic Organs (ELOs), but still cancer can easily take its place successfully[27,28]. It seems as if cancer were already there and in response to it the body has tried to develop some successful mechanisms but finally could only develop these defense systems which are but too feeble to defend against cancer so much so that even if cancer is detected and treated at an early stage and in an early age, premature ageing of the survivors starts[29].

Enucleation of RBCs in mammals

RBCs are pivotal to the life of many higher organisms and in the mammals, they are bereft of nucleus and hence are devoid of DNA. The increased oxygen carrying capacity, the flexibility of having a biconcave shape after the ejection of the nucleus and mitochondria are definitely potent reasons for the enulcleation. But the more important reason seems to us to be to not have any genetic material which can possibly become cancerous, from which there would be no escape from certain death[30,31]. The greatest advantage of getting rid of mitochondria and nucleus on the part of the mature RBC is thus to avoid cancer by getting rid of all genetic material, since it is seen that (Nucleated RBC) NRBC appear in adult patients just 2 to 3 weeks before death.

We tabulate below the cancer inhibitory and the cancer supportive processes respectively brought about by the actions of the cosmic ordering principle(COP) and the principle of disorder(POD)[32]. Therapeutic approaches to counter cancer are merely the actions of COP acting through our intelligence to restore order in the system affected by cancer(POD). This lets us put them under COP, though it may be said to be artificial while the systemic defenses are natural. But the natural-artificial divide here is itself quite artificial since intelligence-based therapeutic approaches are only too natural for human beings to take recourse to!

Table 1: Action of COP in cancer inhibition and POD in Cancer progression:

Processes	**Cosmic Ordering Principle(COP)**	**Principle of Disorder(POD)**
A. Cellular Processes	1. Growth inihibition signals	Self-sufficiency in growth signals
	2. Limited Replicative potential	limitless replicative potential
	3. Apoptosis	Evasion of Apoptosis
	4. Autophagy	Inhibition of Autophagy
	5. Necroptosis	Inhibition of Necroptosis
	6. Anoikis	Anoikis resistance
	7. Oxydative Phosphorilation	Glycolysis (Warburg effect)
B. DNA related processes	1. Chromatin remodeling 2. Histone modification 3. Epigenetic Control 4. Transcription factors 5. RNAi 6. DNA damage sensors 7. Non-homogeneous end-joining path way (Repair mechanism)	DNA damage:- adducts and lesions Mutation accumulation. oncogenes Mutational inactivation of Tumor suppressor genes. DNA Repair failure. Intra tumor heterogeneity
	8. Antioxidant defense system	Over-production of oxyradicals and ROS.
	9. Telomere erosion	Telomere preservation/reactivation
C. Immune system	1. Immune cells of different kinds 2. Immune editing 3. Lymphoid organs	Immune suppression
	4. Cancer suppressor proteins	VEGF (Vascular Endothelial Growth factor), sustained angiogenesis, Lymphangiogenesis
	5. Macrophages	Anti-inflammatory immune suppressor
D. Extra-cellular processes	1. Cell-cell adhesion	Metastasis
	2. Tumor progression inhibitory microenvironment	Tumor progressive adaptations, Degradation of extra-cellular matrix to create new passages for metastasis
E. Therapeutic intervention	1. Surgical intervention 2. Ancillary clinical strategies such as anaesthetics, analgesics and anti-inflammatory drugs 3. Other therapeutic approaches	Post-operative accelerated metastasis and peri-operative immuno-suppression, All round Systemic dysfunction, multiple organ failure and the resultant appearance of host of other diseases

Conclusion

We focused on how cancer has shaped up evolution in crucial stages and in decisive ways, out of which we explicitly dealt with evolution of multicellularism, reproduction, immune system and a few other aspects. Multicellularism arrests unicellular proliferation but, the organization of tissues and decentralization of responsibilities by their spatially limiting the urge for proliferation of the cells create a pressure on the somatic cells to react and become cancerous. Cancer is thus a fundamental factor in evolution of multicellulars with all kinds of tumor-suppression mechanisms. In the extracellular niche, the cells proliferate and are continuously under competition pressure for nutrition, survival and space. Thus, the cell may reach a competing state to acquire high ability to grow, divide and gain strength to attain immortality, by acquiring an oncomutation. Though tumor-suppression mechanisms are in place, cancer has its ways to wade around them and metastasize. Indeed, nothing in evolution makes sense except in the light of cancer.

Abstract

The inevitability and invincibility of cancer despite the evolution of various systemic strategies such as apoptosis, senescence and autophagy etc. over millennia in all species, point to its fundamental ingrainment in all existence as the principle of unrestrained proliferation. Cancer is in real command of all cellular and organismic processes and can reorient and modulate them all to its advantage. It seems reasonably clear that all life, whether unicellular or multicellular, individual or species, is destined to end in a cancerous boom. It has found ways to evade all suppression mechanisms and strategies and can stem from many sources and causes such as external chemical and viral carcinogens and also internal genetic reasons.

Key words: *apoptosis, oncovirus, oxyradicals, immortality*

Introduction

Cancer has defeated all our attempts to control any of its hallmarks precisely because neither its pathology nor its biology completes its etiology[1,2]. It seems that it has some inbuilt strategy to counteract any attempt from outside for prevention, intervention, treatment and eradication by multipronged therapeutic approaches. This strong never-say-die character of cancer hints at the deepest principle of immortality which is operative in all organisms as the struggle for survival.

Continuously occurring mutations in a cell lineage over a length of time increase the chances of hitting upon an oncomutation provided mutations are truly random. In contrast metaevolutionary transencoding of urges and instincts into the genes through epigenetic channels may suffice to give more definite routes for oncomutations to occur. In particular long term impact of stress and repercussions of acute shock induced by accidents and bereavements may be sufficient to produce oncomutations in the DNA by over-production of ROS. Inevitable exposure to environmental carcinogens (UV radiation, chemical mutagens etc.) leads to a faster rate of cellular proliferation which leaves little scope for the DNA repair mechanisms to heal the damages caused. Our approach to cancer prevention has to be modified by a suitable shift of attitude since cancer is not a disease but a living force that has proved its mettle for survival since times immemorial.

Cancer as a late age phenomenon

Generally, cancer is the disease in late ages[3,4]. The delay is possibly because the cells should gain multiple variations before they become cancerous as if the cancerous cells know and remember that multiple variations are required for being selected to survive to the next generation unfailingly. The multicellular organisms are equipped with efficient tumor suppressive mechanisms, otherwise it would have been impossible for them to develop into a well coordinated organized organism[5]. Recently, by Monte Carlo simulation of the effect of key somatic evolutionary parameters on carcinogenesis, ageing-dependent somatic selection and evolution of species-specific tumor suppression mechanisms have been demonstrated to have played significant roles in cancer incidence across tissues as well as species[4]. Similarly Xu and Taylor studied epigenetic changes by DNA methylation that lead to a lowering of threshold for malignant transformation that partly explains the increased incidence of cancer with age[6]. In our view, all these fundamentally imply that in

addition to the urge for reproduction, the urge to avoid becoming a tumor cell was also a primary objective for the unicellular in the primordial stages of evolution.

Cell senescence and apoptosis

Cell suicide (Apoptosis) and cell senescence and autophagy are mechanisms in the cells to get rid of carcinogenic mutations[7]. These mechanisms can also be seen as having developed to achieve tumor suppression[8]. Suppression of rogue cell growth was thus a primary objective of the primordial living cell. It implies that though unrestrained cancerous proliferation is at the origin of life, the whole process of origin and evolution of complexity of life can be seen as a continuous struggle only to enhance the tumor suppressive mechanisms to limit cancer. In fact, cancer treatment by exploiting cell senescence mechanisms have long been proposed since by the early onset and acceleration of senescence in the tumor cells, they can be made to die before proliferating too much[9]. Similarly, if massive autophagy can somehow be triggered in the cancer cells in a targeted manner, tumors can be effectively eradicated.

Apoptosis is the natural design for the cell for its death in fixed time. Apoptotic mechanisms are highly regulated to ensure such programmed cell death[10]. It is the process of elimination of unnecessary and unwanted cells. The information for apoptosis is encoded in every gene but the process gets activated, if there is DNA damage or uncontrolled proliferation[11]. There is loss of apoptotic regulation in cancer[12]. The apoptotic pathway is regulated by intracellular (mostly mitochondrial) and extracellular (death receptor) mechanisms. The signals generated at intracellular level are DNA damage, deprivation of growth factors and deprivation of cytokine. The signals which are generated from extracellular level are by toxic T cells for the damaged cells for death of infected or impaired cells[13].

We observe that apoptosis is designed specifically for the prevention of cancer[14]. Because of loss of apoptotic regulation the tumor cells survive longer, as a result of which mutations get accumulated, thereby increasing invasiveness and virulence and thus angiogenesis is stimulated which enhances cell proliferation and negatively affects cell differentiation[15]. The mitochondrial pathway of apoptosis may be seen as the initial action of the COP to make mitochondria endosymbiotic in bacteria for multicellularism to come up and restrict the unrestrained proliferation of unicellulars, but afterwards resistance mechanisms to it developed leading to apoptotic deregulation by which cancer thrives. Now researchers are focusing to effect apoptosis by targeting such pathways so that cancer cells will become apoptotic to eradicate cancer cells[16]. But who can guarantee that cancer is not already in the know of such attempts and can easily find its way out?

Stem cells and Telomeres

As per Darwinian view, cancer might be the attempt of a cell to adapt to a changing and unsuitable environment. Thus it supports our hypothesis of primal role of cancer in the first emergence of life since during that time the environment was changing and not suitable. This answers the question: Why cancer targets stem cells for initiation and why are stem cells situated in highly shielded locations[17-19]? It seems that only to evade cancer only stem cells have a highly shielded niche. Stem cell mechanism is in place in the organism in such a way that it must prevent somatic cell division through divergence, as if it were suspected pretty prior to the multiplication of somatic cells that they will definitely grow cancerous if left differentiated! All the stem cells of the respective tissues are positioned in well planned locations which guarantee protective niches for them, but almost all cancers with more than two mutagens have been observed to have some link to mutations at the level of corresponding stem cells, though the transit cells are more prone to replication errors than the average stem cell[17].

The chromosomes are capped by telomeres to maintain the DNA codons which thus act as part of the tumor suppressive mechanisms. In unicellular organisms and the germ cells, telomeres are maintained to ensure exact propagation of the original genetic code. But in case of adult tissue, the somatic cells cannot maintain telomeres since they get reduced in length by repeated cell division. The shortened telomere causes cell death and this might be the reason for decline of tissues during aging[20]. The cancerous urge of the somatic cells to acquire immortality in spite of telomere erosion by possible reactivation mechanisms leads to tumors[21].

Invincibility of oncovirus

Cancer occurs through mutations and these mutations make them grow faster, survive better and reproduce faster[25]. As the organisms grow in complexity and organization, this particular instinct in each individual cell is suppressed by the corresponding evolution of

the cancer suppressor genes whose only function is to control the rate of multiplication in specific manner. On the contrary, the viral strains continue to increase their virulence by becoming more and more specific to their hosts and were always looking for infecting any organism which would guarantee their fastest rate of multiplication. This they achieve by disabling the cancer suppressor gene in a particular infected cell. The most dominant factor of evolution has been the instinct for multiplication right from the stage of the peptides and nucleotides. When mitotic cell division became the prominent mode of multiplication, this particular instinct drove organisms towards the fastest possible multiplication in their existing environments but when multicellularism evolved, this particular instinct in every cell for the fastest rate of multiplication could not be fulfilled because of specificity of their functions for ensuring survival of the multicellular organism. Cancer cells acquire immortality by gaining the ability to divide for ever (Infinite reproduction fitness). This is how tumors arise as a consequence of the most dominant instinct for fastest multiplication in every cell.

Biotic interactions may be having their role in the evolution of the individual to divide faster than others, which is responsible for origin of cancer. This is similar to the competition occurring between somatic and germ cells. As per ecological theory, species extinctions may have a role in preventing cancer. Along with species extinction cancer elimination occurs either by their habitat destruction[26] or competition or resource limiting factors that disrupt their life. So, this unavailability of resource may be one reason for metastasis of the cancer cells exactly as in case of organisms, resource unavailability leads to diversification of the population (dispersal). So it seems nature selected cancer cells first and cancer suppression mechanisms came in after such selection.

Stress, Oxyradicals and the inevitability of cancer

The eventual expression of the oncogenes is so inevitable that so far only unsuccessful suppressor mechanisms of different kinds have evolved against it through the entire course of evolution of life on earth. Therefore, no single cancer suppressor mechanism has proved itself effective enough to eradicate cancer as if the cosmic ordering agent acting against it were certain about the invincibility of cancer and hence the suppression mechanisms are only to continuously improve in an unending succession.

One of the reasons for the inevitability of cancer is its relation to mental and physical shock and stress, both of which can lead to tumors. The mechanism has to do with stress induced oxy-radicals in the cellular level which damage DNA and thereby increase chances of carcinogenesis[27,28]. Overproduction of ROS leads to mitochondrial malignancy[29]. For example, bereavement of a loved one can cause such a melancholic vacuity in the mind that it can act in a psycho-somatic way on the physical body and form tumor in a specific organ[30,31]. Similarly, an accidental physical injury (Such as a burn injury) suffered in any organ leading to a fibrosis (Scarring) may turn malignant in course of time[32]. And, who on earth can be completely free from shocks, stress and accidents in life!

Mitochondrial DNA as the Uncogenome

The role of mtDNA mutagenesis in cancer initiation and progression has recently been in focus[33,34]. Oxidative damage is one of the primary causes of such mutagenesis though replicative polymerase error is also proposed to be the next possible reason. Free oxy-radicals in the mitochondria are abundant as it is the site of cellular respiration and these free radicals can cause oxidative damage to the mtDNA. About 60% of all solid tumors have more than or equal to one mtDNA mutation, though not all are caused by oxidative damage[35,36]. Still, the fact that the damaged mtDNA lead to cancer, only shows its inevitability since respiration is an unavoidable cellular process and this happens in the mitochondria and is associated with oxidative damage to mtDNA. Further, it could be surmised that it might be cancer that drove the mitochondrion in the first place to become endosymbiont in the process of evolution of the eukaryotes.

Conclusion

Each cell in an organism has a different history, and hence a different life, specific to itself. For this reason oncogene expression in a particular cellular lineage is specific to that lineage having its own evolutionary time scale to become manifest. This is the reason why successful treatment of cancer of one affected tissue does not protect the organism against cancer of other tissues. Continuous exposure to organic and inorganic carcinogens increases the stress and thus pro-tumorigenically alters the cellular processes such as redox homeostasis and makes the oncogenes expression more probable and hastened.

Faster growing populations are thus more favored by the cancer principle to survive as species and indeed the lower organisms such as viruses and bacteria, having faster growth rates are the ones that are seen to be vastly outnumbering the higher organisms in nature. They, like cancer cells, not only multiply faster but also adapt at a faster pace to changing selection pressures in the biotic and abiotic environments. Faster multiplication and expert adaptation are key characteristics of the cancer cells as well as of the favored species in nature. Somatic cells try to become immortal by outcompeting the reproductive cells which have conditional immortality (if they take part in reproduction) and thus become cancer cells. Immortality seems to be a fundamental feature of life and all life is striving for immortality only. "Survival of the fittest" cannot mean survival till a certain death occurs, even for that fittest of organisms or species. Cancer points to this fundamental fact of immortality beyond the death of the organism.

Review of Statistical Analysis and Effects of Meditation on Mental Health and Cognitive Skill Development

A.Kamaraj[1], J.Senthil Kumar[2], C.Kalyana Sundaram[1]

[1]Asst. Prof.(Sr.G), [2]Asso. Prof., Department of ECE, Mepco Schlenk Engineering College, Sivakasi

Abstract

Study of brain wave signals and proper analysis of them helps us to understand the impact of meditation in much more broader extent. This review paper examined various practices like Mindfulness, Full Attention, Open Meditation, Jhana, Yoga asanas, Mind Body Intervention and Heartfulness. It also extended to the study of effects of meditation on practitioners and narrates the cases with better cognitive skill development. Every meditation process analysis included with number of persons involved in the process along with the study of affected region in the brain due to the continuous practice of meditation. It is observed that signal frequency of communication from heart to brain is improved by Heartfulness meditation. This strengthens brain rewiring of a continuous meditation practitioners and its effects are visualized from the characteristics of EEG and fMRI signals. Analyzes from different literatures, it is evident that cognitive skills, contextual memory, attention, logical thinking, and problem solving capability are highly improved in the practitioner. Also, emotional and behaviour characteristics of the meditation practitioners are greatly improved, in turn life style enhanced.

Keywords: *Meditation, Cognitive skills, fMRI, Heartfulness.*

Introduction

The human brain has Left and Right hemispheres. The Left is for Analytic thoughts, Logical thinking, and Reasoning. The Right is for creativity, intuition, holistic thoughts. The brain signals are classified as α, β, θ, δ and γ based on the frequency of operation of the signals[1]. The network can be re-organized by External or Internal Stimulation called as Neuro-plasticity[2].

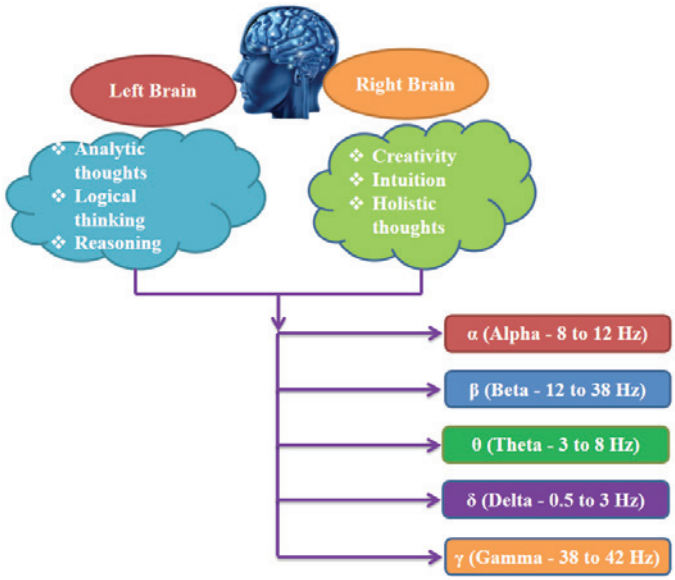

Fig. 1. Classification of Brain Signal

Fig. 1 shows the general classification of the left and right brain activities and brain signal frequency range. The researches are done based on Mindfulness Meditation (MM), Zen Meditation and few are addressing the other meditation techniques[3]. The meditation is classified as Full Attention (FA) and Open Monitoring (OM)[4,5]. The working memory (WM) capacity can be improved by adaptive and extended cognitive training[6]. The classification of medical data has been classified using Deep Learning Neural Network (DLN)[7, 8]. The MRI and fMRI data of the Alzheimer's persons are effectively classified using DLN[9].

Mind is full of thoughts; it is generating thoughts each and every moment. The regulation of thoughts creates better environment inside and outside[10,11]. The most popular meditation practices are Mindfulness, Zen Meditation[7], Vipassana Meditation, and Heartfulness. Patanjali states that, yoga has 7 steps; starts with purification of mind as a first step to Samathi (Liberation) via meditation as the last step[12].

Dr. Masaru Emoto proven that the words and thoughts are having impact on the crystal structure of the water[13]. The human body consists of around 70% of water; thus the mood, thoughts and the out spoken words have more impact on the human both mentally and physically. The Heart communicates to the entire body through nervous system through control signals. Therefore the electromagnetic (control) signals generated by the Heart affects the thoughts produced in the mind[14].

There are many articles stating and and proving the benefits of Meditation with experiments on Children, Students, Adults and family[15,16]. Few researchers extended their contribution on Meditation effects on disease cure[17]. The number of articles dealing with the meditation is increasing over the years as shown in Fig.2. More than 31,000 are conducted on various meditation techniques and its effects. Heartfulness technique is gaining popular for the last couple of years which provides positive results in a very short span of practice [18].

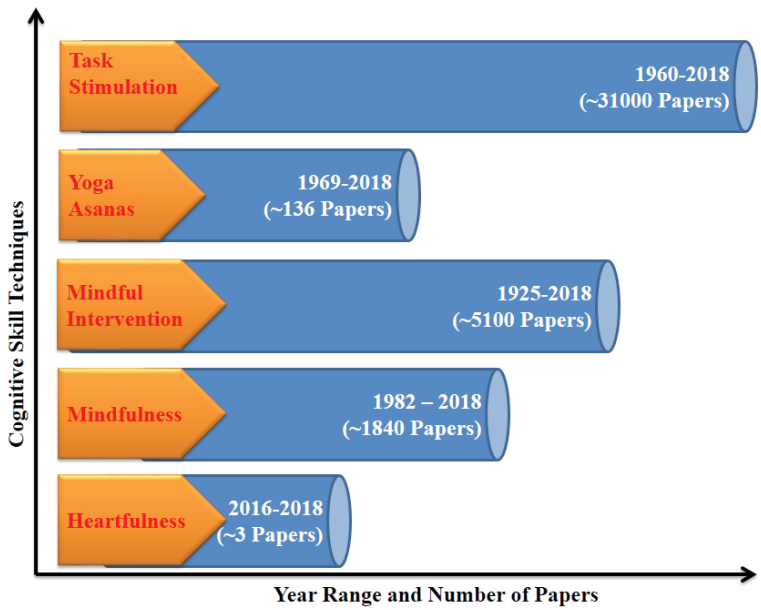

Fig.2. Number articles published in Meditation

Mindfulness Meditation

Mindfulness meditation has a positive impact on various parts of the brain; which are anterior, cingulate, thalamus, insula, amygdala, hippocampus and Gyrus[19]. Mindfulness meditation alters the rs-FC in the brain[20]. The EEG shows the positive reflection of meditation on theta wave[21]. These are scientific proofs of Mindfulness meditation. Standard tests like KIMS, Stroop[22], CAT[23], COWAT, SDMT[24] and d2 tests[25] prove the improvements in the cognitive skills. The analysis of the effects of meditation is estimated using Analysis of variance (ANOVA)[26,27]. Thus the Mindfulness meditation produces good positive life changing

characteristics in the practitioners which improve their life in the society[28]. It has very positive impact on the Dementia / Alzheimer patients[29].

HTKS and Ten-Sticker Sharing Tasks are used for testing the emotional change in kinder garden school children[30]. MAAS, SCS and EF are used for evaluate and improve the mind regulation cognitive intelligence of School Students[15]. MOT methods are applied for adults for mind regulation observations[31]. SART is developed as computer based software testing system using SPSS-21 Software for estimating Self-sustain mindfulness capability of the practitioners[32]. BOLD testing was performed on stressed unemployed adults and the changes in the Gyrus and right parietal cortex area are observed[33].

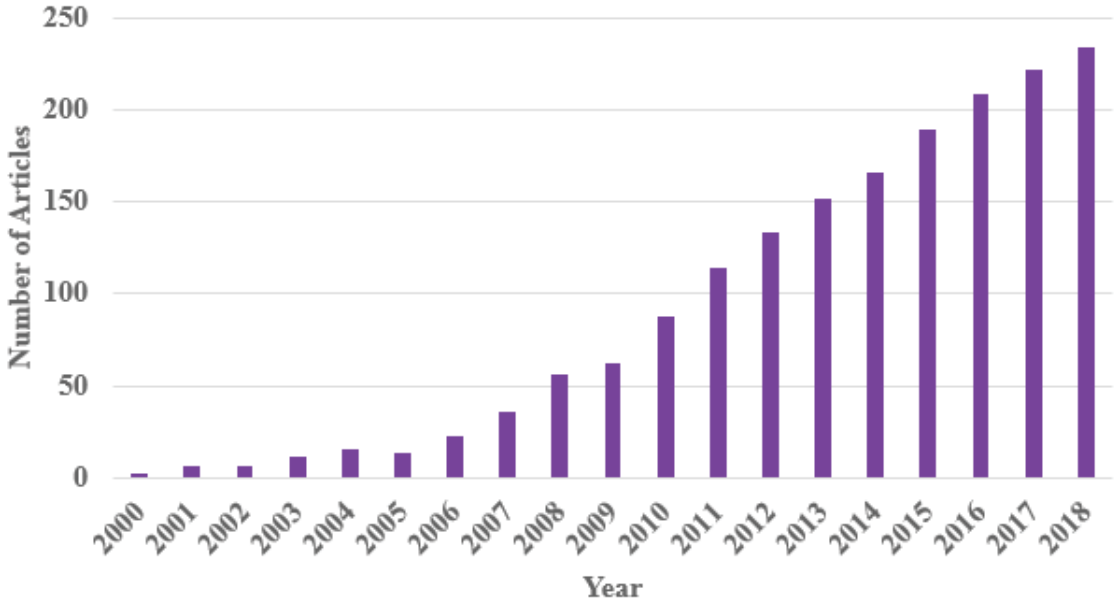

Fig.3. Mindfulness research articles

Fig.3 shows the statistics of mindfulness related research articles published for past two decades. The effects of mindfulness meditation practiced with different set of control group and members are listed in Table 1. Other impacts of Mindfulness meditation techniques are, reduction of Mind Wandering [32] and increase in functional connectivity[24,34] and Volume change in various parts of brain.

Table 1: Mindfulness

Ref. No.	Affected region	Analysis			No. of practitioner

[29]	Dementia Patients		Yes			

Full Attention and Open Meditation

The research on Full Attention and Open Meditation are carried over the last decade. The research data are analysed using EEG, fMRI and other standard tests. It has been found that, gamma and alpha wave activity are increased[35], functional connectivity and reorganization of brain is improved, and reduced mind wandering are some of the positive impacts of the meditation practitioners.

Table 2: Full Attention and Open Meditation

S. No.	Type of Practice	Affected region	Analysis			No. of practitioner	
			EEG	fMRI	Other	Control	Meditation
[4]	FA (Samatha) and OM (Vipassana)	Anterior Insula.	Yes	Yes		-	8
[3]	FA on Tanden	Pre-frontal cortex	Yes + ECG		BOLD, POMS	-	15
[36]	FA – Meditation	Cingulate		Yes		-	14

Heartfulness Meditation Techniques

Recently, Heartfulness meditation technique[38] is popular among the seekers. The research is carried on COPD patients[17], Students, novices, Teachers[39] and normal human. The research platforms for this meditation technique are varying across Schools, Colleges and Hospitals. It has very positive results on them in a very short span of time across all platforms[40]. Telomeres length improvement[41], Heart Rate and RR[49] regulation, brain coordination[43] and Stress reduction[44] are the changes observed on the practitioners. Most importantly, it brings out and develops the emotional balance on the practitioners; which is very much essential in today's living environment for the youngsters[45]. Recent literatures started elaborating the effects of Heartfulness meditation and it is gaining highly popular because of its large positive effects in cognitive skill development. Table 3 lists the effects of Heartfulness meditation practiced observed from various recent literatures. It is studied that it drastically reduces the stress level of students[46] and thereby making them emotionally stable and be skilled with better cognitive skills[47].

CRT and RAT are used for analyzing the effect of Heartfulness. It is observed that increased alpha in brain[43]. DASS 42 questioners based testing is used for estimating the stress scale with observations on 42 symptoms for a Heartfulness practitioners[45].

Table 3: Effects of Heartfulness Meditation

Ref. No.	Affected region	Analysis			No. of practitioner	
		EEG	fMRI	Other	Control	Meditation
[41]	Telomeres length	-	-	-	12	35
[42]	HR, RR and SBP.	-	-	-	-	134
[43]	Alpha wave	Yes	-	CAT, RAT		60
[45]	-	-	-	DASS 42 and stress scale.	80	80
[46]	-	-	-	Questionnaire		848
[39]	-	-	-	INSPIRE		90
[49]	HRV, BP and HR	-	-	ANOVA	-	30
[44]	Stress reduction in Students			Stress Questionnaire		120

Heartfulness also develops their emotional intelligence to a larger extent. The statistics it is also observed that it improves heart rate, blood pressure[48] and cognitive function. Hence, Heartfulness meditation technique provides the very positive impact on the practitioners in a very short span (3 hours); both mentally and physically. So, we can say that Heartfulness meditation has good score of Intelligent Quotient (IQ), Emotional Quotient (EQ) and Spiritual Quotient (SQ)[49].

Conclusion

Human beings are daring to have a better world and safeguard themselves from other fellow beings with their improved Cognitive skills. This survey analyzed the effects of different meditation techniques like Mindfulness, FA and OM, MBI and Heartfulness practiced by experts and novices. The impact of the meditation practices are evaluated using EEG, fMRI and Standard Questionnaire processes. It is commonly observed that the meditation practice improved the functional connectivity and neural plasticity. It is

practically visible that practitioners had improved mind regulation, characteristic changes and Cognitive level. Recently, Heartfulness meditation is popular and its communication between heart and brain is effective. It has positive impact on sleep pattern, stress reduction and disease control in a short span. From the survey on different literatures, it is obvious that Cognitive skills and Life Style behaviour of the meditation practitioners are highly improved by consistent meditation.

The Cancer Principle-V: Cancer Prevention and Therapeutics

Asima Tripathy[1], Rajat Kumar Pradhan[2]

[1]Post Graduate Department of Zoology and Microbiology, [2]Post Graduate Department of Physics, Bhadrak Autonomous College (Departmentment of Higher Education, Govt. of Odisha), Bhadrak, Odisha, India

Abstract

Organisms evolve in attempting to evade cancer while they perish ultimately by succumbing to it because cancer, being at the very core and source of life and evolution is simply undefeatable and is destined to win in the long run. Rather, due to the depth and versatility of cancer that they aim to counter, they end up causing many other diseases due to wholesale systemic dysfunction in the organism. Every cancer cell therefore has its own independent aberration profile and as such can be treated as an independently evolving organism with its own inbuilt mechanisms of survival and perpetuation. There is as fundamental feature of immortality associated with cancer which is its primordial origin. Therefore therapeutic strategies fail invariably to contain cancer progression and metastasis.

Keywords: *Cancer therapeutics, Cancer prevention, meditation, Immortality*

Introduction

Cancer as a killer disease seems to be but the tip of the iceberg that lies hidden from our view because of an error in our perception of the true causes behind any phenomenon. A gross physiological effect such as a tumor has its origins not just at the genetic levels but beyond the submicroscopic physical, at the metaphysical level of a principle. The rational quest ingrained in the curiosity of human intelligence truly rests satisfied when it reaches the metaphysical realm of the fundamental principles behind all observed phenomena. We elevate cancer to the status of a fundamental principle that serves to increase disorder and opposes the cosmic ordering principle (COP) in its operations at every moment everywhere. The survival of cancer cells *in vitro* and *in vivo* that has been observed experimentally is thus only a negligible facet of its immortality.

Cancer progression has been likened to asexual proliferation of micro-organisms[1]. Was evolution of life up to the asexually reproducing micro-organisms any way different from that of cancer? The aberration profiles of no two tumors match due to differences in genetic and epigenetic factors[2]. But the timing and location of mutations in a pair of cancer cells belonging even to the same tumor are random and continuous. Thus, it becomes difficult to adopt any particular suppression mechanism to effectively tackle cancerous proliferation.

Acquiring random mutations is an adaptation of the cancer cell to gain multidimensional fitness to strengthen the functional aspect of its genetic niche[3]. Metastasis adds to such fitness. Intra-tumor differences following mutation burden difference among cells increases their ability to hide the reasons behind their heterogeneity. Further, if one oncomutation is figured out, several such mutations develop and make it impossible to trace the exact reason behind specific driver mutations.

Immortality of cancer cells

The canine sarcoma CTVT (Canine Transmissible Venereal Tumour) has now been updated to be carrying a continuously evolving strain since more than 11000 years[4]. Its inter-individual metastasis is an adaptation which makes it survive beyond one affected body to infect another, as if it were a free living species, like bacteria or other living pathogens. This shows again that cancer has evolved and simultaneously led to the evolution of the canine species in fighting it away. Its survival by immune suppression since such a long time by genetic, epigenetic and extra-genetic mechanisms and its viral origins show that cancer alone is immortal while all else is mortal.

Its ability to sustain and replicate using anaerobic glycolysis pathway to metabolism shows that it has the requisite functional machinery from the time of its presence in and as an anaerobic life-form when conditions were anexic or hypoxic. From this perspective, it ranks among the most ancient pre-oxic life on earth. It existed at first as a biomolecule like free floating RNA or DNA fragments (oncogenes), and then became a virus (family of oncoviruses) and then became an anexic organism and then entered its hosts from bacteria onwards up to humans. Such is the ancientness of cancer.

Population explosion and Species extinction

They say, development of cancer in the individual has evolutionary significance, but we have proposed that individuals (and species) have emerged from, evolved through, and ultimately dissolve in the lap of cancer! The Lotka-Voltera type oscillations in prey-predator interactions are rather idealistic dynamical variations in interdependent species populations[5,6,7,8]. Even in these, the fall in species population follows a boom in that population that creates a local and temporary imbalance in the ecosystem. Dinosaurs were very abundant before going extinct. Any population that goes for an over-growth invites such balancing forces of nature that the proliferation is effectively checked, and even at times, entire population is wiped out. There are species where cannibalism or mass suicide is in place precisely for the same purpose. The species don't consciously do it for bringing down population by census or consensus and resource availability calculations, but are driven by their instinctive nature to do so. This is like programmed cell death in case of cells. They are simply programmed that way by nature to avoid cancerous over-growth.

Thus we find that just like bamboo blooms before death, all species, all individuals, all cells may suffer the cancerous boom before the death of that particular line. This succumbing to overgrowth seems to be the common fate of all of them. The booming of cells before death is called tumor and the organism is said to succumb to cancer. Cancer is the natural death process of all life-forms. They struggle and they survive only to finally succumb to cancer in some form or the other.

Therapeutic approaches to cancer

One of the primary therapeutic interventions in cancer is surgical removal of the tumor, but cancer is powerful enough to induce several peri-operative processes *viz.* increased shedding of motile cancer cells into blood, suppression of anti-tumor immunity, upregulation of adhesion factors in new target sites for metastasis, modulation of cells in the target site for fresh tumor formation, utilization of immune cells to trap cancer cells for metastasis, enhancing motility and invasion ability of cancer cells etc.[9]. This is as true of surgery as of radiation therapy, chemotherapy, immunotherapy, stem cell therapy, hormone therapy and other targeted therapies.

Anticancer chemotherapy, for example, acts to enhance ROS-dependent apoptotic pathways for cancer cells. But ROS are like the proverbial "double-edged sword" in the sense that they can in addition lead to disruption of redox homeostasis in normal cells and tissues leading to additional complications of an irreversible nature[10]. ROS have both pro- and anti- tumorigenic potential. Fine tuning of the redox homeostasis depends on the antioxidant defense system which is paralyzed by cancer[11].

Numerous are the side effects of any form of cancer treatment. Further, if cancer of one type is targeted to be treated, it switches to another type or to another site as if it were having an answer inbuilt to any therapeutic intervention.

Prevention of cancer

Cancer being a manifestation of a tremendous primordial urge for unrestrained proliferation can be completely eradicated by a reversal of such an urge through the adoption of the principles of submission to the cosmic ordering principle which envisages life as an ordered movement towards a realization of the fundamental unity underlying all diversity. Living in accordance with the COP that ever endeavors to mould creatures in the direction of unification can only reverse the cancerous propensity of multiplication and diversification. For the human beings this can be effectively implemented by resorting to practices such as concentration and meditation as individuals or in groups which have realization of unity of consciousness as their goal[12]. There has already been ample published evidence of efficacy of such practices in halting and reversing the progress of cancer[13,14,15,16].

It seems that meditation, not medication, may be the final and complete solution to cancer[17]. Success in meditation requires as a prerequisite a balanced approach to life in its daily movements. This balance is the conscious approach towards more and more order in

the system such that ultimately there can be successful meditation. Meditation becomes effortless for one having a well-concentrated serene mind devoid of too many bubbling and crowding thought-forms as a result of too many desires. Thus the very exercise of meditation is a conscious willful enhancement of order in one's living and thinking.

Theories of cancer

The important theories of cancer origin are tabulated and explained below.

Table-I: Theories of cancer origin and their evolution

Sl. No.	Theory	Proposer(s) and time of proposal
1	Humoral origin theory	Hipocrates (300 BC)
2	Lymphatic origin theory	F. Hoffman and G. Stahl
3	Chronic irritation theory	R. Virchow (1858)
4	Trauma theory	H. Ribbert (1899)
5	Somatic Mutation Theory	T. Boveri (1914)
6	Viral origin theory	Huebner and Todaro (1969)
7	Tissue Organisation Field theory	Sonnenschein and Soto(1991)
8	Atavistic Theory	Davies and Lineweaver (2011)
9	Disorder theory	Tripathy and Pradhan (2019)

According to **the Humoral origin theory** the time of probable cancer origin must date back to the emergence of triploblasts which branched into different phyla having distinct so called 'humors' (blood, phlegm, yellow bile, black bile).The timing of triploblasts has been estimated to be around 600 to 700 million years ago[18]. **The lymphatic theory** ascribes malignant tumor to the fermentation and degeneration of accumulated lymph leaked from the lymphatic vessels[19]. The timing of cancer origin according to this theory dates back roughly to the same era as in the humoral theory. **The chronic irritation theory** proposes chronic irritation if tissue as the cause of malignancy. The origin of cancer thus dates back to the emergence of animal's having distinct organized tissue systems[20]. Somewhat related to the chronic irritation theory is **the trauma theory** of Hugo Ribbert which proposes traumatic tissue injury as the cause of malignancy which has however little support till date[21]. The injured tissue can be considered to be the site of chronic irritation and can evolve to a malignant tumor, though the possibility of such development is not very frequent. The series of modern theories of cancer started in the early 20th century when the seeds of **The Somatic Mutation Theory (SMT)** were sown by Boveri who proposed the idea that combination of chromosomal defects can lead to cancer[22]. Bauer gave the specific proposal that mutations can cause cancer[23].

Failures of SMT to account for all types of carcinogenesis led Sonnenschein and Soto to propose **Tissue Organization Field Theory** (TOFT) that sees tumorigenesis as a reaction to the spatial limitations of tissue organization against the default state of proliferation inherent in every cell[24]. This theory dates the origin of cancer to the time of appearance of multicellularity (complex metazoan) around 600 million years ago. According to **the atavistic theory** cancer is a relapse to phylogenetic capabilities of an earlier age corresponding to evolution of simple metazoans with

multicellular features and dates the origin of cancer back to around 0.5 to 1.5 billion years[25]. Huebner and Todaro hypothesized that the viral information responsible for converting normal cells to cancer cells is transmitted and preserved in all the cells of all vertebrates by inheritance. Though the initial proposal was in connection with C-type RNA-viruses in vertebrates, later on with the identification of many DNA-viruses responsible for carcinogenesis, the viral oncogenesis hypothesis has been extended to include all eukaryotes[26]. About 20% of all cancers is of viral origin. Since fossil records show the period of evolution of eukaryotes from prokaryotes to be around 1.5 to 2 billion years ago, the origin of cancer in this theory roughly dates back to this period.

Disorder theory of Cancer: We propose a new theory of origin and progression of cancer in which evolution is the interplay of order and disorder, with cancer being the primary agent of disorder. Cancer as the tendency for unrestrained proliferation has been there at the very roots of creation of the universe. But the COP in trying to restrain it has led to the current state of the universe as discussed in detail in these essays[27,28,29,30]. In an earlier work we have discussed the interplay of order and disorder in general in the dynamical evolution of all physical and biological systems, where it is proposed that it is consciousness that acts as the COP but the agency of disorder (POD) was as such not identified apart from its role as entropy in all systems[31]. Here we identify POD manifest as cancer and entropy, the physical facet of it. The successive actions of order and disorder in the evolution of life and species and how cancer has evolved to its present invincible status is discussed in detail in the previous essays. We name it **the disorder theory of cancer**. It makes cancer a primordial operative principle that is as old as the universe itself and thus the game of finding the date of its first appearance comes to a venerable closure.

Conclusion

The disorder theory views cancer as an agent of cosmic disorder which was at the very origin of the universe itself and has all along acted towards unrestrained proliferation by multiplication and diversification as opposed to the organizing actions of the ordering principle at all levels.

Appearance of cancer is thus inevitable as it is inbuilt into every particle, nay, every point of space, as the tendency for proliferation. But by means of moving towards more and more order in all levels of one's being one can strengthen the ordering principle in oneself and can keep away cancer which is the agent of disorder. Our finite life-span of can be filled with order in all levels of our being by meditating and attuning ourselves to the cosmic order that is the all-pervading consciousness. This is possible because the consciousness in us can only be aware of this cosmic consciousness and can consciously attune itself with it. The human being alone has this endowment of conscious practice of attunement and it will keep away cancer till one ends one's life-span, thereby effectively eradicating it from one's life. Ultimately order only can counter the disorder that cancer is.

Living with Urostomy: Patient's Perspective

Meenal Sharma[1], Sukhpal Kaur[2], Amlesh Seth[3], Prabhjot Singh[4]

[1]Ph.D Scholar at National Consortium by INC and RGUHS, [2]Lecturer, National Institute of Nursing Education, PGIMER, Chandigarh, [3]Head of Department, Department of Urology, AIIMS, New Delhi, [4]Associate Professor, Department of Urology, AIIMS, New Delhi

Abstract

The diagnosis of bladder cancer and necessity of urostomy is profoundly life changing. This qualitative study was conducted in order to assess lived experiences of patients who had received urostomy due to bladder cancer or any other urinary pathology. The sample included 30 patients with urostomy admitted in the Urology ward, AIIMS, New Delhi. Purposive sampling was used and data was collected using semi structured interviews. Narrative data was analysed using Colaizzi's steps of analysis for qualitative data. Ten themes emerged from the analyses which were further categorized into sub themes. The theoretical framework of the themes and subthemes defined the phenomenon of living with urostomy in entirety.

Key words: *Qualitative research, Lived Experience, Bladder cancer, Urostomy, Colaizzi's Steps of Qualitative Analysis*

Introduction

Urostomy is a procedure that reroutes the flow of the urine out of the body.[1] Urostomy surgery may be required for many reasons, the most frequent indication being bladder cancer, which is the second most common urologic malignancy.[2] Of all bladder cancers, 10-20 percent is the muscle invasive type which is classically treated with cystectomy and urostomy.[3]

Creation of a urostomy significantly alters elimination pattern and can have both physical and psychological effects. The most common physical complications with urostomy are infectious, gastrointestinal, wound related and genitourinary. The physiologic complications involve changes of the stoma and peri-stomal skin including dermatitis, pain, bleeding, necrosis, prolapse, stenosis, herniation, infection and retraction of the stoma.[4,5]

Many urostomy patients have emotional, social and sexual problems. Urostomy patients are concerned about the effect of the stoma on their ability to carry out activities of daily living. Ostomy surgery is a life-enhancing procedure that restores a vital bodily function, but it's not easy to accept.[6]

Nurses involved in the care of patients with a stoma should have an understanding of the reasons for stoma creation, and the types of stoma and appliances available. Issues related to diet, sexual relationships and self-image should also be discussed with patients. [7, 8]

There have been significant advances in stoma appliances and an increase in nurses specialising in stoma care. Despite this, a large proportion reportedly up to 75% of patients continue to experience adjustment problems, which suggest that improvements in stoma management are by themselves not enough to enhance functioning.[7] This inspired the examination of problems of urostomy patients in this study.

Objective: To explore the lived experiences of the patients living with urostomy.

Materials and Methods

Research Design and Sampling:

A phenomenological qualitative research design was used. Sample size was limited to 30 when data saturation

Corresponding Author:
Ms Meenal Sharma,
Ph.D Scholar at National Consortium by INC and RGUHS

occurred. Purposive sampling was used to select patients who had undergone radical cystectomy and ileal conduit surgery. Patients after 5 days of the surgery, above 18 years of age and willing to participate in the study were enrolled.

Research Tools

1. ***Demographic Profile Sheet:-***

The demographic profile sheet was used to collect socio-demographic data of patients. Content validity was obtained from the experts.

2. ***Semi-Structured Interview Guide:-***

An interview schedule was developed which listed the open ended questions to explore the experiences of the urostomy patients. It was validated by experts.

Data Collection

The study was conducted from January 2018 to July 2018. The willing participants were explained about the study and informed consent was signed. Anonymity, confidentiality and privacy of patients were maintained. Face to face interview was conducted by the researcher with a fairly open framework. An interview session lasted 10-30 minutes and was audio taped with the consent of the patient. Field notes were maintained. The place for interview was a private room in the urology ward. Active attention was given to the body language, posture, facial expressions and voice intonation of the participants. Short pauses and silences were dealt with patience as they helped the patient to understand their feelings and put them into words. Emotional support was extended when patient got distraught and cried during the interview.

Data Analysis

The demographic data was analysed using descriptive statistics in SPSS. Statistical tests used to describe the data were frequency distribution, mean and standard deviation.

Qualitative analysis was done simultaneously with data collection. Recorded interviews were transcribed verbatim and translated into English by the researcher and rechecked by translator. Colaizzi's steps of qualitative analysis were used for analysis. The data was read and re-read numerous times to identify the significant responses. A total of 623 significant responses were extracted from the interviews. Meanings were formulated for these significant responses. In total 808 meanings were identified and grouped under 10 themes as some of the responses were not exclusive but were interrelated and overlapping. Formulated meanings were coded in a MS Excel sheet to extract common themes which were further categorized into sub- themes. The derived theoretical framework integrated participants description to achieve comprehension of the experience of living with urostomy.

Results

Demographic description of sample

The sample composed of primarily male participants 90% (n=27) with average age of 57±11.61 years. Urinary bladder cancer was the primary disease in 28 patients, with only two female patients having urinary bladder metastasis. Majority of the patients had radical cystectomy and ileal conduit with or without nephroureterectomy, prostactectomy and lymph node dissection. The mean weight of the participants was 62±9.97 kgs and mean height was 173.2±9.6cms. Most of the patients were not employed 53.3% (n=16). A large proportion of the patients 36.6% (n=11) belonged to lower income group. A striking number of patients 60% (n=18) have smoked or chewed tobacco before diagnosis.

Qualitative Analysis

Ten themes emerged from the lived experiences of the urostomy patients which were further divided into sub themes. [Number] in brackets is the number of significant responses for the particular theme and sub theme. *Italicised sentences* are the expressions of the participants. Following themes were identified.

1. **Knowledge regarding urostomy**

Most of the patients confirmed lack of knowledge regarding urostomy [36].

…"*I don't know how to wear or change bag and also how to manage if a leakage occurs.*"Patient 6

Due to lack of knowledge, patients experienced dependence on the health care staff for changing

urostomy bag [14]. Some patients expressed readiness to learn urostomy care [19].

…"*I want to know about the diet, how to change the urostomy bag and what is the frequency of bag changes and also can I lay in prone position*?" Patient 20

2. **Physical problems**

Patients experienced numerous physical problems related to their disease, treatment and urostomy. Weakness [20] and fatigue [25] was present in most of the patients

…"*I feel very much physically weak. I face difficulty in daily activities."* Patient 1

Skin problems around urostomy were fairly common [9]. Most of the patients had pain and oozing at surgical site [15] thus increasing the risk of infection. [4] Urine leakage from the urostomy was a difficulty faced by almost all the patients [23]. Continuous lying down in bed also caused discomfort [5].

... "*Because of constant lying down on the bed, I have developed bed sores on my back."* Patient 13

Patients had difficulty in maintaining hygiene due to surgical incision and urostomy [6]. Surgical creation of illeal conduit requires resection of illeal segment causing digestive problems in the patient postoperatively like abdominal bloating [18], stomach ache [15], nausea, vomiting [1], and loss of appetite [23], constipation [4] and diarrhoea [1].

…"*I was distressed by stomach ache and gas for which they gave medicine and now it's better.* Patient 25

3. **Psychological Problems**

Mental tension [15] and depression [17] were evident followed by feelings of hopelessness [4], helplessness [24] and dependency [12].

…"*It feels as if half of my life has slipped out of my hands.*"Patient 1

…"*Yes, mental tension is there. It is better to die than to suffer from this.*" Patient 3

Most of the patients were middle aged males and sole earner for the family. They were highly stressed due to the failure to meet family role [22].

…"*We are helpless for my son's education. Even if I sell my land, then where will we go? I dreamt of making him a doctor (Pause).*" Patient 23

Patients had fear of urine leakage from urostomy [7] and were anxious [6] and embarrassed because of the urostomy [16].

…"*I feel sometimes, that why has this happened in front of my children. Now, they will have to even tie my pyjama. I feel ashamed because of that.*" Patient 20

Some patients also expressed anger [11].

… "*Everyone has to die one day, but it should not be so early in my case.*" Patient 27

Feelings ranged from disbelief, confusion and ambivalence towards urostomy [14]. Some patients vehemently denied mental stress [12] to avoid stressful disclosure with the researcher, while some were unwilling to communicate on certain questions [3]. Conversely, some patients talked optimistically about urostomy and were hopeful of the future [43]. Positivity was also noted by in terms of readiness to change to a healthy lifestyle [16].

... "*This operation saved my life otherwise I would have died. So, whatever has happened is for good*. Patient 28

…"*Isn't there is something which can be fitted inside the body. It would be better, if it is not visible outside.* Patient 22

4. **Impact on daily activities**

Patients reported difficulty in performing their daily activities [9]. Sleeping was disturbed in some of the patients [5].

…"*Yes, the sleep is stressful, I worry that it may leak and spoil the bed.*" Patient 27

Doubts related to diet were common [16]. Travelling was deeply impacted because of urostomy [21]. Patients were concerned about bag leakage [10] and practical difficulties in driving [8]. Dressing was also a matter of concern for most of the patients like ability to wear undergarments and their regular clothes [23].

... "*If I wear pants below the stoma, it is not very comfortable, so, I try to wear it above the stoma. The pants have to be stitched according to the stoma.*" Patient 27

5. **Social Problems**

Many of the patients restricted their social activities. They were concerned about extra preparations needed for urostomy [26].

…"*If there is a function somewhere, I won't be able to attend as I will have to keep supplies with me*." Patient 23

Most of the patients felt social stigmatization because of the urostomy and recognized the lack of social support system [22].

…"*People will wonder that what disgusting problem I am suffering from. My neck will be hung in shame.*" Patient 11

6. **Family Problems**

Family functioning was greatly disturbed. Most of the patients perceived anxiety and stress in the family members [7] and were aware of the caregiver's burden on their attendants [5].

…"*Everybody has been caring for me from last 1 year. There has been lot of tension in the family*." Patient 10

Most of the patient were male and were experiencing sexual difficulties but they were not comfortable enough to discuss it with the researcher except few [5].

…"*I have very much problems. I can't talk about sex right now. Please ask about it later.*" Patient 23

…"*I am not able to maintain sexual relations with my wife (nonverbally messages not to talk about sexual problems),*" Patient 26

7. **Occupational Problems**

Patients were anxious about their inability to do heavy work [21] and were uncertain of whether occupation can be continued. Financial consequences of incapability to work were a cause of turmoil.

… "*I am sitting idle for about 3 years now. My work is done partly by my children, so I am able to live. What can I do?*" Patient 2

8. **Financial Problems**

Majority of the patients with few exceptions had strained finances [14] and was worried about additional expense of urostomy [23].

…"*The main problem is monetary expenses. The supplies are very costly.*" Patient 26

Few patients were unable to procure supplies for urostomy and struggling for daily needs [5].

…"*Sometimes, the bag bursts. If by chance we don't have money to buy bag that day, then my clothes are drenched in urine whole day.*" Patient 3

9. **Religious and Spiritual Problems**

Some patients quoted the need to change to spiritual lifestyle considering they have got a second chance at life because of urostomy [5]. In contrast, urostomy was considered causing impurity of body because of bodily contact with urine by some [14]. Patients were emotionally stressed because they couldn't offer prayers [2].

…"*In our religion, even if a drop of urine touches the body then prayers are not offered. We have to be totally pure to pray. (Eyes well up with tears)*." Patient 16

10. **Health Care Issues**

The patients from remote areas were stressed because of the inaccessibility of health care near their home [7]. Some patients experienced distress due to delayed care because of limited health care staff and resources [6].

… "*Staff is very less here.*" Patient 23

Most of the patients had faith in capability of health care team [3].

…"*They have done really good for me. Whatever happened with me has been good so far.*" Patient 24

The detailed description of the themes and sub

themes facilitate vision of the overall experience of living with urostomy. Researcher observed that the experiences of different patients were as varied as their personalities, demographics and social circumstances, but were unified by their common struggle of living with urostomy.

Discussion

In the last 30 years, much has been done to improve the quality of life for patients with stoma. In spite of these, however, even today it is a very difficult to live with urostomy. Literature describes the numerous problems of urostomy patients. The present study also confirmed these issues.

The findings of the present study are consistent with other researchers who have discussed physical problems of urostomy patients.[8] In the present study some of the physical problems were problems due to location of urostomy. Skin problems and urine leakage was a major issue. Patients also described lots of digestive problems.

Around one-quarter of stoma patients experience clinically significant psychological symptoms postoperatively.[9] In this study, mental tension and depressive feelings were present in most of the patients. Patients had fear of urine leakage and were embarrassed of the urostomy and declared it as retribution for their bad conduct. Socially, urostomy patients found themselves vulnerable to other's reaction to the urostomy, thus restricting their social activities.[10] In general, family and friends can be an immense source of support which was also narrated by most of the patients in the study.[11] Ostomy surgery may affect the patients' sexual relationship with their intimate partner which was also the case in present study. [12]

Most of the participants belonged to lower economic group with few exceptions. It was difficult for them to bear the burden of disease and urostomy. Another important finding relates to religious issues. As with many religions, it is important to be clean, especially when praying. This was regarded as the worst effect of the urostomy by some patients. Study participants expressed faith in the health care professionals although they were aware of the shortage of the health care staff and resources.

In this qualitative study, researcher was able to establish a trusting relationship with most of the patients. Interview offered the patients an opportunity to express their thoughts, feelings and beliefs without being judged. Patients acknowledged the interview to be therapeutic. The findings of this study cannot be extrapolated to wider populations because qualitative research results cannot be tested for statistical significance.[13] However, the findings are useful for health care providers when creating a supportive environment to improve quality of life of urostomy patients.

Conclusion

Living with a urostomy takes significant adjustment in daily living. A detailed knowledge can facilitate health care personnel to understand the problems of these particular patients and design the health care accordingly. Motivation of the patient to take independent care of their urostomy will lead to better self care efficacy and psychosocial adjustment.

An Epidemiological Study of Prevalence of Skin Diseases among Secondary School Going Children in District Meerut

Abhishek Kumar Burman[1], Rahul Bansal[2], Saurabh Sharma[3], Arvind Krishna[4] Sartaj Ahmad[5]

[1]Post Graduate Student, [2]Head &Professor, [3]AssociateProfessor, Department of Community Medicine, [4]Head &Professor, Department of Skin and Venereal Diseases, Subharti Medical College, Meerut ,U.P. India, [5]Associate Professor, Medical Sociology, Swami Vivekananda Subharti University Meerut

Abstract

Introduction:-Skin disorders are a common cause of morbidity, especially among school children, worldwide. Present study was conducted among secondary school going children in urban and rural field area of district Meerut to find the prevalence of skin diseases and suggest preventive measures based on the study findings.

Material and Methods:-A Cross-Sectional study was conducted among 400 secondary school going children (aged between 13-15 years from class VIII to X^{th}) of district Meerut . Multistage simple Random Sampling Technique was applied and a self-design, semi structured schedule was used.

Result:-In study 212 (53%) were male and 188 (47%) were female children. Overall prevalence of skin diseases was 195(48.75%). Prevalence of skin diseases was more in rural 134(60.6%) than urban 61(34.1%). Skin diseases were more in males 119 (56.13%) than females 76 (40.43%).Skin diseases were more common in Muslims 39(82.98%) than any other religion. Most common skin diseases in study population were pyoderma (28.20%) followed by scabies (22.56%),Tinea-corporis(10.25%),Nutritional disorders (5.13%), Pediculosis-capitis (5.12%),warts (4.62%) , Folliculitis (4.10%), Miliaaria (4.10%),Molluscum-contagiosam (3.08%). Pityriasis-versicolor (2.56%), Acne (2.56%), Tinea-capitis (2.06), Insect bite (2.06), disorder of nails (2.06), Urticaria (1.03%), Tinea-pedis (00.51%).

Conclusion:-Skin diseases were common among students.Pyoderma, scabies and tinea were most common and these can be prevented by maintaining good hygiene.Periodic orientation programmes for students and parents should be done to make them aware of common skin diseases and prevention. Teachers should be trained to inspect hygiene among students and suggest correction measures.

Keywords: *Skin diseases, School going Children, Prevalence, Urban, Rural*

Introduction

Pediatric dermatology is a significant part of dermatology that manages the determination, treatment, and prevention of skin illnesses happening in earliest stages, youth, and immaturity[1]. Prevalence of skin disorders are more among school children from low socioeconomic classes and developing countries like India[2]. School going children are more vulnerable and constitute special risk group in any population deserving Special health care. It is in this age their personality develops. Also they are exposed to various environmental factors which might cause problems and require health, guidance and care.

School setting provides opportunity to be exposed to infectious agents (viruses, bacteria, fungus, insects and animals) in addition; children share personal items. However, when calculating risk factors for skin disease, there are many other ecological and environmental

Subharti Medical College, Meerut,U.P.
Contact no:-8958207039

considerations. Children are often exposed to climatic and social conditions that predispose them to develop skin infections and suffer from minor skin injuries [3].

The incidence of skin diseases among children in various parts of India has ranged from 8.7% to 38.8% in different studies usually school-based surveys[4].The acute and chronic conditions which can occur during schooling anywhere in the world include scabies, dermatitis, impetigo, pediculosis, warts, furuncle, molluscumcontagiosum[5].

We conducted this study in order to find out the prevalence and factors associated with occurrence of skin disease among school going children in district Meerut ,India. and to suggest preventive measures based on the findings of study.

Methodology

The present Cross-Sectional study was conducted among 400 secondary school going children aged between 13-15 years from class VIII to X^{th} standard in Urban and Rural population of district Meerut. Predesigned pretested and semi structured schedule was used. Multistage simple Random Sampling Technique was applied**.** Duration of study was from 1st March 2018 to 28th February 2019.Sample size calculation was done by using formula$(1.96)^2pq/L^2$ .p was kept 50%(based on a previous study) q = 1-p , L= Absolute Allowable error taken as 5 %..4 Schools were selected randomly by chit method from the list of schools provided by Basic Sheksha Adhikari Meerut,U.P. 2 schools each from urban and rural area were taken. 100 students from each school were selected randomly by chit method using roll numbers of students provided by the school. Training of diagnosis of skin diseases clinically and their examination and investigation was provided by the Professor & Head Dermatology, Venerealogy and Leprosy, Subharti Medical College, Meerut .

Inclusion criteria was the children who were studying at the selected Government/private secondary schools and both boys and girls aged between 13-15 years available at the time of data collection .Exclusion criteria included students who were not available during the study, students who were in the age group of below 13 years and above 15 years and students who refused to take part in the study. Informed written consent was obtained from the concern school authorities. Ethical clearance was obtained from institutional ethical committee. Data entry was done in Microsoft Excel and analysis by SPSS version 19.

Result

The overall prevalence of skin diseases was 48.75% (195).Infections were most common among all the types of skin diseases (Table 1).The most common skin disease in study population was pyoderma (28.20%) followed by scabies (22.56%) (Table 2). There was statistically significant association between Gender, Religion, Residence with skin disease (Table 3).

Table no 1-Type of Skin diseases in the study population

Discussion

A total 400 school going children aged 13 to 15 years were studied by using Multistage Random Sampling Technique .Out of total participants 212 (53%) were males and 188 (47%) were females.

Skin diseases were seen in (48.75%) of study populace which is almost similar to Negi K S (2001) et al[6] with 50.69% and Valia R A (1991) et al [7] with 43%. The study by Dogra S and KumarB (2003) [8] and Sharma N K (1986) et al [4] , the prevalence of dermatoses was (38.80%) and (14.30 %) which is less when contrasted with our investigation. This may be a result of country region (rural).

In our study skin diseases were seen in 56.13% of males and 40.43% of female students, and the difference was found to be statistical significant, In the examination directed by RAO S G(1999) et al[9]and another investigation by Anil K Gupta (2018) et al [10] both uncovered that boys (78.74%) are exceptionally delicate for dermatological diseases than young ladies (71.47%), however in the investigation of Talukdar K (2015) et al[11],and Ewaldo V K (2010) et al[12] ,Tulsyan SH (2012) et al[13] and , Basti B D (2016**) et al[14]** revealed that the prevalence of skin ailments was high among female youngsters.

In the study prevalence of skin disease was significantly higher in Muslims (82.98%) followed by Sikhs (60.53), Hindus(46.86%),Chritians (14.29%), TalukdarK (2015) et al[11] also found that the prevalence of skin illnesses was high among Muslim youngsters .

Skin sicknesses were seen in (60.6%) of rural populace pursued by (34.1%) of urban population. Which is comparative to Devinder Mohan Thapa (2002) [15]stated that schools from provincial (rural) regions indicated moderately higher prevalence of skin diseases.. Numerous different researches from different nations additionally bolster (support) this finding. T TAmin (2011) et al [3], Sehgai V N (1972) et al[16],Yaseen U (2013) et al[17] .

The most common skin disease in study population was infectious lesion (55.38%) followed by skin diseases caused by Arthropods (infestation) (29.74%), Disorders of skin appendages (8.72%), nutritional disorders (5.13%), In a study done by Sugat A Jawade (2015) et al[18] in >1 months to 14 years age group similarly

the most common dermatoses found were infectious disorders that were (56.40%) of the study populace.

The study done in Meerut by Sharma Radha , Rathore B S, Arvind Krishna (2016)[19] the most common contaminating infection in their study was Bacterial then Viral and Fungal and seen in (37.4%), (16.7%) and 15 % of the examination population. Among bacterial infection, pyoderma was the most common followed by dermatophytic diseases (Fungal infection). Bacterial disease incorporate pyoderma which included bullous impetiga, impetigo contagiosum, furuncle, and secondary pyoderma. In a study from eastern piece of India in (1994), pyoderma was the most common and widely distributed skin diseases (35.6%), followed by scabies (22.4%), molluscumcontagiosum (4.6%), Miliaria (2.8%) Ghosh S K (1995) et al[20].

Among fungal infection (27.78%) the most common fungal infection in study population was Tineacorporis 20 (10.25%) followed by Pityriasis-versicolor 5 (2.56%), Tinea-capits 4 (2.06%) and Tinea-pedis 1 (00.51%). This finding is practically like studis led by Shameena A.U et al (2017) (21) fungal disease (13.50%) to (26.1%) with more dominance to pityriasisversicolar. In the investigation led by Anil K Gupta (2018) et al[10] dermatophytic contaminations comprised the limit of the Fungal infection including the skin (48.5). Among dermatophytic infection, tinea-corporis comprised the most elevated extent, i.e., (56.12%), followed by tinea-cruris 28% and tinea-capitis 9%.The high prevalence in our study could be expected due to the humid and hot climatic conditions which straight forwardly supports parasitic contaminations and fungal infection.

Among viral infections 15 (13.89%) the most common viral infection in study population was viral warts 9 (4.62%) followed by Molluscumcontagiosum 6 (3.08%). Sharma Radha , Rathore B S, Arvind Krishna (2016)[19] revealed that prominent common viral infections were warts, molluscumcontagiosum, the kids were school going or having positive family history. While investigations of Patel J K (2010) et al[22] molluscumcontagiosum was most common of all viral infections, followed by viral warts .

In the present study, among Skin diseases caused by Arthropods 58 (29.74%) the most common Skin diseases caused by Arthropods, worm & protozoa in study population was was scabies 44 (22.56%) infestation followed by pediculosis capitis10 (5.12%) and followed by insect bite 4 (2.06%). Incidence rate of scabies, found in different reports, ranges from (5.1%) to (22.4%) .[Dogra S et al[8], Balai M et al[23], Bhatia V et al[24],Negi K S et al[6], Ghosh S K et al[20], Rao SG et al[9]].High rate of scabies in our study could be due to poor hygiene, most cases from low socio-economic strata and over crowding. In various studies like, Talukdar K (2015) et al[11] in his examination expressed that Prevalence of scabies was (21.7%) among the understudies pursued by pityriasis(19.6%) . Prevalence of pediculosis was seen as (18.5%) , and tinea disease among the kids was 16% .Dogra S and Kumar B (2003)[8] Conducted a study in Wardha among tribal younger students found that head lice (42.8%) followed by scabies (36.6%) among younger students.

Among the Disorders of skin appendages (8.72%) ,the most common Disorders of skin appendages was miliaria 8 (4.10%) , Acne was found in 5 (2.56%) in study population. While in a study led by Shekhat P (2017) et al[25]Appendageal issue were (13.41%) of all dermatoses. Among all appendageal disorders, the most noteworthy number of cases was of acne with (33.33 %), followed by milliaria with (31.70%).

In present study Abnormal vascular responses (urticaria) was seen 2 (1.03%) among study populace is almost similar to the finding of Karthikeyan K (2004) et al[26].

In our study, among skin disorders nutritional deficiency dermatoses were seen in 10 (5.13%)which is similar with Rao SG (1999) et al[9] study (6.71%). However, in an investigation by Negi KS (2001) et al[6] it was discovered (17.5%).This distinction may exist on the grounds that the examination was done in a rural region while our investigation focus was in a urban zone and rural zone.

Conclusion

In this study, prevalence of skin diseases was found to be very high. Skin diseases were found to be more common in Muslim male students of rural background. Regular health education to both teachers and parents regarding common skin diseases, personal hygiene practices and appropriate nutrition of the children. Periodic health checkup of all children in schools , providing health care facilities and timely treatment by the doctor.

Prevalence of Musculoskeletal Dysfunction in Clinical Physiotherapist

Aishwarya A. Vedpathak[1], Radhika Chintamani[2]

[1]Final year BPTh Student, [2]Assistant Professor, department of Manual Physiotherapy , Krishna College of Physiotherapy, KIMS 'Deemed to be' University, Karad, Maharashtra, India

Absract

Objectives : Objectives of this study was to find out musculoskeletal pain or dysfunction in clinical physiotherapist. On the basis of questionnaire rating the scale pain assessment was done. The ratings was graded by work related musculoskeletal disorders (WMSDs) questionnaire.

Methodology : There were total 150 subjects , out of which 120 subjects were participates of this study. This was a study of musculoskeletal dysfunction in clinical physiotherapist. Here we evaluated scoring of pain by the work related musculoskeletal disorders (WMSDs) quessionnaire

Result : There is various musculoskeletal joint pain present in clinical physiotherapist. Musculoskeletal joint dysfunction more found in males than females. Shoulder joint pain and knee pain is common in clinical physiotherapist due to standing posture.

Conclusion : There is prevalence of musculoskeletal dysfunction in clinical physiotherapist.

Keywords: *Musculoskeletal dysfunction in clinical physiotherapist.*

Introduction

Low back pain is defined as pain in lower back area that can relate to problems with the lumbar spine, the discs between the vertebrae , the ligaments around the spine , the spinal cord and nerves, muscles of the low back , internal organs of the pelvic and abdomen , or the skin covering the lumbar area[1.] Incidence of low back pain in general and working population has been focused on various investigation. There are 62% to 80% of the population will suffer from LBP. The lifetime incidence of LBP vary from 50% to 80% with average incidence of 60%. As reported by anderssson (1998) women and men have similar prevalence and in most of the studies , highest prevalence rate is seen in 40 to 60 year age group.

The incidence of low back pain appears to be age related. Physiotherapist they are also exposed to many of the same occupational risk factor leading to work related musculoskeletal problem especially with regard to the lower back. The purpose of the present study was to determine the incidence of work related LBP and other musculoskeletal problem among physiotherapist and to determine common personal and professional characteristics of physiotherapists reporting work related musculoskeletal problem. We hypothesized that musculoskeletal problem are related to occupational stress in physiotherapists(1) . Low back pain including lost productivity and expense of medical , rehabilitation and surgical intervention and cost of disabling pain and limited daily function.(7)

Cervical joint dysfunction : The presence of painful upper cervical joint dysfunction is diagnostic criterion for cervicogenic headache. Cervicogenic headaches arise from dysfunction in cervical musculoskeletal system. Dysfunction should be located within upper three cervical joint . Detecting the presence of relevant painful upper cervical dysfunction is therefore a vital part of diagnostic decision making to. Identify cervicogenic headache the physical examination method to detect joint dysfunction are active movement examination and manual passive segmental examination. The detection of symptomatic joint dysfunction by manual examination method has been used in a number of studies. This is perform by a manual examination of the upper cervical segment C0-1 , C1-2 , and C2-3(2)

Shoulder pain : Spinal and shoulder dysfunction are common in orthopedic conditionfound in elderly people. As increasing in age there are changes in spine and shoulder are generally cause kyphosis , spinal sagittal imbalance and limited shoulder range of motion[5]. Neck and shoulder painwas significantly higher for workers with shorter working duration , lower limb for pain was significantly higher for worker with longer duration [6] .

Sacroiliac dysfunction: The confusion and lack of awareness of sacroiliac joint .chronic spinal pain is multifactorial disorder with many possible etiology.the structure responsible for pain originating in the spine and affects on low back and lower extremity include sacroiliac joints and nerve root, spinal cord , spinal muscles and ligaments. [3]

Neck pain : Posture control is a complex task that requires vision, vestibular and somatosensory inputs from all over body assess the position and motion of the body there is ability to generate forces to control body position.[4]

Knee pain : In epidemiological studies have associated prolonged standing at work with lower extremity pain or discomfort. Alternate from sitting to standing its varies mobility during standing. [5]

As far as our knowledge very few studies have been conducted on cluster of musculoskeletal dysfunction in clinical physiotherapists. Hence this study is undertaken.

Methodology

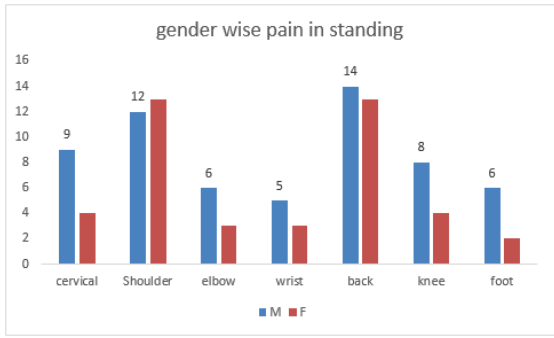
- Type of study- Observational study.
- Place of study - Krishna college of Physiotherapy, Karad.
- Sample size – 150
- Sampling method – convenient sampling.
- Study duration – 6 month

Materials

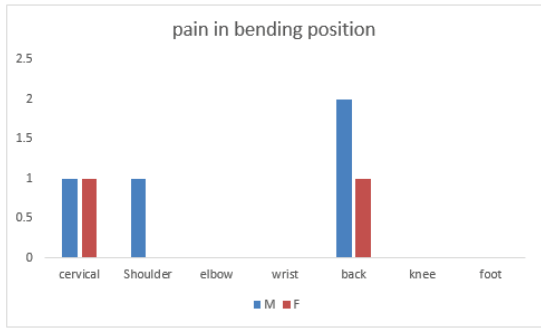
- Question Paper
- pen
- Data collection sheet

Mean± standard deviation	3.447
t value	0.10
p value	<0.442
Interference	Extremely significant

(1) **Pain in standing position**



(2) Pain in bending position



Interpretation :

In this graph shows that physiotherapist are affecting during standing position. There are male and female both are considered in this study. Blue colour shows male and red colour shows female. So for cervical pain 9 male and female 4, shoulder pain male 12 and female 13 , elbow pain male 6 and female 3, wrist pain male 5 and female 3 , back pain male 14 and female 13, knee pain male 8 and female 4 , foot pain male 6 and female 2.

(2) **Pain in bending position**

Interpretation

In this graph shows pain during bending position. In this study

Neurophysiotherapist have pain in bending position. Both male and female physiotherapist participate in this. Cervical pain male 1 and female 1, shoulder pain male 1, and back pain male 2 and female 1.

Pain experience in 5 year

Table no.1 :

5 years	cervical	shoulder	elbow	wrist	back	knee	foot
sum	143	149	124	48	173	39	46
average	5.1	5.32	4.42	1.71	5.96	1.39	1.64

Interpretation :

Pain experience in 5 years in total physiotherapist are as followings . There is total pain in sum and average of all physiotherapist : cervical pain experienced by 143 and its average is 5.1 , shoulder pain by 149 and its average is 5.32 , elbow pain by 124 and its average is 4.42, wrist pain by 48 and its average is 1.71 , back pain by 173 and its average is5.96, knee pain by 39 and its average is 1.39 , foot pain by 46 and its average is 1.64.

Pain experience in 6 years

Table no.2 :

6 years	cervical	shoulder	elbow	wrist	back	knee	foot
sum	21	26	19	11	31	6	4
average	6.2	5.2	3.8	2.2	6.2	1.2	0.8

Interpretation :

Pain experience in 6 years in total physiotherapist are as followings: cervical pain experienced by 21 and its average is 6.2 , shoulder pain by 26 and its average is 5.2 , elbow pain by 19 and its average is 3.8, wrist pain by 11 and its average is 2.2 , back pain by 31 and its average is 6.2, knee pain by 6 and its average is 1.2 , foot pain by 4and its average is 0.8.

Pain experience in 7 years

Table no.3 :

7years	cervical	shoulder	elbow	wrist	back	knee	foot
sum	11	12	6	3	14	7	1
average	5.2	6	3	1.5	7	3.5	0.5

Interpretation :

Pain experience in 7 years in total physiotherapist are as followings: cervical pain experienced by 11 and its average is 5.2 , shoulder pain by 12 and its average is 6 , elbow pain by 6 and its average is 3, wrist pain by 3 and its average is 1.5 , back pain by 14 and its average is 7, knee pain by 7 and its average is 3.5 , foot pain by 1 and its average is 0.5.

Result

The result analyzed for gender,duration of work and duration of constant posture.The prevalence of neck

pain was substantially higher in men (75%) and female (66.67%), which is not in relation with study by B. Cagnie et al[1] which suggests that women had almost twofold risk compared to male. Often holding the neck flexed in a single posture for a prolonged period of time leads to neck pain, though the pain varies with angle of neck flexion. . In 7 year of experiences there is more low back pain and knee pain. There is increasing in age muscles get affected . This study conclude that there is increase in back pain as increase in age position back pain is more due spinal mobility.as increasing in age increase there is more low back pain.in standing and knee pain . The result may be varying because of selection bias due to approaching time limit in the office to the subjects. The result showed $p < 0.05$ which is significant.

Discussion

The current study aimed to find the various musculoskeletal dysfunction in clinical physiotherapist .Physiotherapist are work in most of in standing position .As they increase their year of experience, they may have increase in the pain. Most common problem seen in cervical, shoulder , knee and most common is back pain . continuous standing while treating and assessing affect spinal muscle because of which physiotherapist may develop pain in lower back . In this study we noticed pain increases of year of work increases in clinical physiotherapist. Physiotherapist also have to work in standing , bending and constant sitting position most common position is standing position most of all musculoskeletal and neurological techniques are given in standing position . one of the professional an occupation an dysfunction is musculoskeletal pain. There are mens physiotherapist are affected more than womens physiotherapist as increasing in age they developed knee pain along with back pain. In clinical Neuro-physiotherapist and paediatric physiotherapist they treat patient in bending position. These therapist are treating in low plinth so they may also develop cervical pain and shoulder pain. As this study we noticed pain in increasing as increasing in experience of year in clinical physiotherapist .Physiotherapist have to work in standing , bending and sitting position.

The present study showed that we calculated all over pain by VAS scale . 0 is no pain 5 is minimum pain and 10 is unbearable pain. In this study we calculate all over pain of all physiotherapist and add them and average it . In 5 year experience it seen increase in back pain avg is 5.96,.cervical 4.42, shoulder 5.1. In 6 year back 6.2 in avg and shoulder 5.2. In 7 year shoulder 5.2 ,knee pain is increased in 3.5 back 7 in avg. cervical pain is 5.2 in average. In bending position seen back pain is increased. in men than women. There is increasing in age and increasing in age of experience there is musculoskeletal dysfunction is seen in clinical physiotherapist . female physiotherapist are more affected than male physiotherapist. Common seen conditions are low back pain , knee pain in lower limb . in upper extremity cervical pain and shoulder pain are commonly seen .During mobilization there physiotherapist have to maintain that position then after that session they feel the pain. They given glides to the patients then after that they feel pain in the joint and the mucle.

Conflicts of Interest: There were no conflicts of interest in this study.

Ethical Clearance: Ethical clearance was taken from institutional committee of Krishna institute of medical sciences.

Implications of Physical Therapy to Aid Weight Loss in Individual Suffering from Obesity: A Physical Therapist Perspective

Aksh Chahal[1], Narinder Kaur Multani[2], Harbir Kaur Rao[3], Rajinder Singh Gupta[4]

[1]Professor, MM Institute of Physiotherapy and Rehabilitation, Maharishi Markandeshwar (Deemed to be University) Ambala, Haryana, India, [2]Professor, Department of Physiotherapy, Punjabi University, Patiala, Punjab, India, [3]Professor, Department of General Medicine, [4]Professor, Department of General Medicine, Maharishi Markandeshwar (Deemed to be University) Ambala, Haryana, India

Abstract

Obesity is referred when Body Mass Index of an individual is greater than 30. Making it clearer, individuals with Body Mass Index between 25 to 30 are termed 'overweight' while more than 30 are 'obese'[1]. Till recent years, obesity was considered to be a problematic condition restricted only to developed countries[2]. But, over the course of time with negligence towards dietary habits and lack of physical activity, obesity also started to entrap population of developing countries. India is no exception to it. As per latest statistics, Obesity has emerged as a crucial health problem among Indian population of varied age groups (children, adolescent, middle aged and elderly). Obesity are treated by implementation of therapies via a multi-disciplinary team consisting of Physician, Endocrinologist, Dieticians/Nutritionist, Physical Therapist/Physiotherapist, Psychiatrist/ Psychologist while in severe Obesity, surgery is usually advised.

Introduction

Obesity is referred when Body Mass Index of an individual is greater than 30. Making it clearer, individuals with Body Mass Index between 25 to 30 are termed 'overweight' while more than 30 are 'obese'[1]. Till recent years, obesity was considered to be a problematic condition restricted only to developed countries[2]. But, over the course of time with negligence towards dietary habits and lack of physical activity, obesity also started to entrap population of developing countries. India is no exception to it. As per latest statistics, Obesity has emerged as a crucial health problem among Indian population of varied age groups (children, adolescent, middle aged and elderly). Looking at the demographic stature of India, majority of population resides in rural areas than urban cities. The population staying in rural areas are comparatively fit than urban population due to reduced accessibility towards personal vehicles, lack of public transport facilities, prevalence of malnutrition, reduced availability of junk food, restriction towards surplus purchase and occupations involving more physical activity. According to latest figures, 30 to 65 percent of adults living in urban India are overweight or obese. This can be attributed to reasons of higher income, accessibility to different cuisine, abundance of food venues, easy availability of public transport, occupations involving more of mental dominance rather than physical work and not the least maximization of personal vehicles making commuting easy for individuals of all age groups. As a individual becomes Obese, greater develop the risk to major health problems like Type 2 Diabetes Mellitus and Cardio vascular disease[3], Gallstones, Obstructive sleep apnoea and Dyslipedemia[4]. In addition Depression[5], falls[6], Osteoporosis[7,8], Urinary incontinence[9], Chronic low back pains[10,11,12,13] become a daily issue leaving the patient with low morale,

Professor, MM Institute of Physiotherapy and Rehabilitation, Maharishi Markandeshwar (Deemed to be University) Ambala, Haryana, India
E-mail: drakshchahal@gmail.com

reduced self esteem, lack of interest in daily living and social integration. These issues associated with Obesity are treated by implementation of therapies via a multi-disciplinary team consisting of Physician, Endocrinologist, Dieticians/Nutritionist, Physical Therapist/Physiotherapist, Psychiatrist/Psychologist while in severe obesity, surgery is usually advised.

In the current article, the author concentrates on different therapeutic interventions from a Physical Therapist point of view to treat Obesity and reduce the physical, mental, social and economic burden[14] on the individual. The strategies are as followed:

1. Providence of psychological support.

Individuals' suffering from obesity are usually depressed, low in morale following which they execute less interest in personal, social and professional arena. Repeated jokes and humour being imposed make the condition even more worse. These individuals are counselled at regular intervals to keep them alleviate in terms of mood and positive energy as reducing weight is gradua land steady process taking a course of time for which a continuous motivation is required from professionals. Hence they are taught to be focussed on their path of weight reduction without bothering of external disturbances trying to impend their mode of action or bulling them due to the current bodily status.

2. Incorporation of physical activities on daily basis.

Incorporation of impact physical activities like brisk walking/slow jogging/running is embossed in the activity plan. 30 to 45 minutes of any activity at least 4 times a week should be practised to bring observable deference by 2 to 3 month from the commencement of program. In addition, talking the steps at office, parking vehicle far from the place of concentration are prioritised to bring additional calorie burns. These additional task help to show faster results due to more lose of calorie burn on daily basis.

3. Regularization in life style modification.

This component is greatly focused on as it is one of a primary factor to prevent reoccurrence of Obesity in later stage of life even after a individual lose weight in present ongoing program. Lifestyle modifications like discarding junk food, less consumption of fried products, no food consumption at least 3 hours before sleep, maintaining a protocol of heavy breakfast followed by a moderate lunch subsequently with a fruit as supper and finally a low calorie dinner. This dietary habit should be practised on daily basis to continue being fit throughout life. Any change in quantity of diet intake at inappropriate timing will again predispose the individual towards Obesity.

4. Initiation of self monitoring on daily diet.

Individuals are taught to monitor their diet from morning till they go to bed at night. This can be done by maintaining a register/diary wherein the time and type of food being consumed are documented on daily basis[15]. At the end of each week the individual goes through the weekly dietary consumption to check the compliance with diet plan and realising occurrence of cheat days per week. Individuals should also compare their daily diet with the protocol recommended by the therapist. A slight deviation in diet is considered as normal act because being concentrated on daily basis makes the plan monotonous which escalate the chance of the individual to drop out from the program. But, a large deviation from the expected dietary protocol will reinforce calorie deposition which will add to the already deposited calorie bank in the individual's body. During initial days of weight reduction, cheat days should be avoided and not appreciated. By the time individual completes 2 to 3 months of weight reduction protocol, one cheat day per week can be instituted. This cheat day helps in rejuvenating by consumption of one's desirable food which keeps the individual happy and motivated for continuation of program.

5. Habituation of slow food consumption.

Slow food consumption is another way to accelerate weight loss program. This activity firstly, renders less portion of food inside the body and secondly, greater chewing activity makes the individual feel tired due to which only a smaller portion of food is consumed in a diet. This when followed for all meals bring about significantly reduction in addition of new calories to the body. In addition, when food is chewed to smallest pieces, it is easily digested by the stomach. These individuals are explained about the fact that, longer the food stays in the stomach, greater the chance of obesity.

6. Setting of practical and realistic goals.

While counselling an individual with Obesity, a Physical Therapist puts focus on setting practical and realistic goals to be achieved during the course

of treatment. The individual is explained the fact of continuity as a major goal rather than commencing a weight loss program with enthusiasm and dropping out due to lack of internet after few weeks. A steady go on treatment protocol is the key to success. Amount of weight to be loss per month is calculated depending on individual's current body weight, health condition, psychological mindset, time available for weight loss program. In addition, regular collection of latest information by reading books, articles, newspaper and social media is encouraged.

7. Realization of passive education.

Passive education meaning education/information attained by the individual himself from reading books, articles, newspapers and social media. New concepts and formulations facilitate the progress of ongoing weight loss program[16, 17]. Viewing photographs of people undergone successful weight loss program wherein they compare their pre and post weight loss images motivate individuals to attain success with similar results. Meeting people undergoing same treatment strategies help in sharing views, positive and negative aspects being experienced by individuals help to bring about significant changes. In addition 'Myths and Truths' can be visited and challenged via communication in personal or by making use of social media.

8. Channelization familial/social support.

Active participation from family members plays vital role in success of a weight loss program. Their presence and positive ideology help to motivate and regulate the individual on a regular basis. While counselling the individual's family members should be asked to join for few sessions as they too can appreciate the advantages, disadvantage, positive and negative effects of various aspects as it is wise to think that all of us have different doubts for which there exist personal clarifications. In addition, difference in views between individual and family members can abrupt the smooth implementation of weight loss strategies[18].

9. Prioritising meal replacements.

Replacement of solid meals with liquid food should be incorporated on daily basis to add extra weight loss[19, 20]. Individuals should be made to understand the benefits of liquid diet on solid food. Liquid diet is light and gets easily digested in the stomach which prevents its bloating. In addition, it prevents acidity and percussions of burps. Repeated burps make people embarrassed in social gatherings hence making them vulnerable to jokes embossed on them.

10. Active parental participation in obese children.

Active parental participation play important role in kids and school going children with Obesity. It is usually due to parent's excessive passiveness, affection, overspending on food and excessive consumption of junk food which leads to Obesity in children. As kids and school going children are difficult to comprehend regarding positive and negative impact of Obesity on their health, it becomes the sole responsibility and dependency on the parents to initiate, monitor, control and accelerate the weight loss program from commencement till completion[21]. Grown up children with time, get accustom to the daily dietary and activity schedule but still parents need to put their active participation on a regular basis.

11. Incorporating stretching and strengthening exercises.

Physical therapists recommend regular stretching followed by strengthening exercises[17]. Stretching exercises could be done on the bed, floor and mat, while strengthening exercises are easily performed in a gym. Any regular gym with only basic equipments is also enough, provided the individual is greatly focused and determined to lose weight. Stretching of Pectoralis, Latissmus Dorsi, Rhomboids, Biceps, Triceps, Back Extensors, Rectus Abdominus, External Oblique, Quadriceps, Hamstrings and Gastronemius should be focused without failure. In addition a 'roller' can be prescribed to develop core strength of back and abdominal muscles working in combination with each other. As using a roller is slightly difficult in the initial stages, with regular use an individual can easily expertise.

12. Convincing towards Pet Therapy.

In addition to the about treatment strategies, the author likes to advocate 'Pet Therapy' wherein, if one has a Pet, the human will need to take them for walk and play. When making them perform these activities, it provides additional calorie burn for their humans which speed up the expectancy of results when working on a weight loss program[22]. Pets help human to maintain a discipline schedule of waking up and returning back to home early, preparing food for them. All these activities

help to augment the physical activity altitude, mental attentiveness alongside with fitness[23].

Findings

Management of Obesity is a Multi-disciplinary team work wherein professionals from different domains of healthcare contribute towards weight reduction and hence improving the overall quality of life of an Obese individual.

Conclusion

Physical therapy interventions contribute markedly in weight reduction for obese individuals.

Introduction

Physical therapy is a branch of science which treats patients by means of physical agents to reduce their sufferings from impairments and disabilities. It processes cost efficient mode of treatments which help to reduce the unwarranted burden on patient's personal economy to a vast extent[1]. Hence, it is improvised to improve the overall quality of life. Physical therapy is been in existence since World War II. Over the decades, extensive research led to advancement in assessment and therapeutic intervention to take Physical therapy to its current stature. Physical therapy imparts treatment strategies with varying time period. There can exist a sequential comeback of patient for either days/weeks/ month or years to come depending on the disability. While treating a patient, a therapist mainly works in domains of assessment and rehabilitation of the patient. Both these domains when worked in combination with good communication skills yield presidential results in patient's recovery[2-11]. In this article, the author would like to concentrate on a single parameter which should significantly be given prior most importance while assessing and rehabilitating a patient. These are addressed as "Safety measures". Safety concerns for patient suffering from stroke[12], Alzheimer's diseases[13], Dementia[14,15],Cancer[16,17,18,19], Depression[20], Osteoporosis[21,22,23], Urinary incontinence,[24] Chronic low back pains[25,26,27,28] etc from the moment of stepping in for consultation to return to his personal premises is prioritised by a Physical Therapist as they play a vital role in developing positive mental setup which improves psychological wellbeing leading to early disbursement of disability. For a healthy individual, usually safety is of minimal concern, but for any patient suffering with

drakshchahal@gmail.com

mental or physical impairment and disabilities, it is the highest point of consideration. In Physical therapy this component is tackled in a professional way for the betterment of the patient. With time new strategies have regularly been put into force in improving safety measures. From a Physical therapist point of view these concern towards patient safety in different settings shall be discussed under the following headings:

1. Safety measures in healthcare settings.

2. Safety measures at home.

3. Safety measures during outdoor travel and entertainment.

1. Safety measures at healthcare settings (Clinic, Nursing home, Old Age Homes and Hospital etc):

1. The outpatient department should either be in basement or on the ground floor to keep travel distance to minimalist for the patient.

2. Floor should be of non-slippery nature to prevent predisposing a fall.

3. The entry and exit gateway should possess a ramp for a possible and easy movement of partial and non-ambulatory patients.

4. Handrails should be fixed in walls at the entry, exit and walk areas to provide for accelerating walking with confidence. The same handrails can be used to provide immediate support to maintain balance and prevent fall during rehabilitation.

5. Patient treating areas should be embossed with sufficient light for enabling patient's concentration on therapist commands during treatment sessions.

6. Furniture endings should be blunt or rounded to prevent incidence of physical injuries while assessing or training patient.

7. Overcrowding of furniture should be avoided in order to create ample open area for the patient and therapist to walk around without any hurdles.

8. The walls should be painted with soothing colours, as light colours help the patient to relax and calm during rehabilitation phase of treatment.

9. If possible, a height adjustable couch should be used which can be adjusted according to individual patient's height which prevent sudden or jerky moments while getting in and out of the couch.

10. If a non-adjustable couch is used in a setup, a set of stairs should be placed nearest to the couch used for easy climbing and descending by the patient.

2. Safety measures at home:

1. A patient's personal area should be adjusted near to entrance of the house for easy entry and exit thus, preventing any unwanted physical and mental discomfort to the patient.

2. Matt finished flooring should be encouraged in room to prevent loss of balance during moving in and out of bed for basic activities.

3. Room and pavement area should be well lighted with either white or yellow coloured lights. If possible Red, blue and green colours lights should be avoided.

4. Normally, large door handles and locks should be embossed on for easy opening and locking of doors.

5. The height of the bed should be adjusted according to the patient's height which accelerates easy getting in and moving out of the bed.

6. Toilet facility should be in closest proximity for easy and fast go and back.

7. Almirah, cupboards, side table and any other supportive furniture should be placed in extreme corners of the room to create safe walking area.

8. Rough flooring should be used in toilet and bathrooms to minimise falls.

9. Switch board with switches for light, fan etc should be installed to the nearest point around the bed of the patient for preventing unnecessary travel in the room for the cause.

10. A bell should always be placed near the patient which can be used in case of any emergency to call the family members.

3. Safety measures while outdoor entertainment and travel:

1. Whenever planning an outdoor travel, neither too tight nor loose clothing should be worn. This is due to the fact that tight clothing reduces the overall mobility and loose clothing predisposes the patient to loss of balance and lead to fall.

2. Flat or nearly flat heeled footwear should be used while walking outdoors to overcome any unusual or unseen obstacle which can disrupt then patient's balance.

3. Any required assistive device should always be carried without fail. This is attributed to the fact that if a patient encounters a new walking surface which they have not been accustomed of, might lead to the patient getting unstable and loosing balance. This can predispose him to fall.

4. An adult member should accompany the patient to provide basic or emergency help in the shortest interval of time.

5. While travelling in car, patient should be offered seat closest to door for easy accessibility and exit from vehicle.

6. If possible, patient should be entertained in less crowded areas as firstly, over crowdedness might make the patient uncomfortable psychologically and secondly, a physical push or pull from unwanted external sources might engrave the patient to lose balance and ultimately fall.

7. Whenever travelling, a healthy conversation between patient and accompany should be encouraged to give positive feeling of wellbeing.

8. When travelling via aircraft, seats near the aircraft doors should be preferred to accelerate easy move in and out with minimal energy expenditure and risk.

9. When walking outdoors, patient should be taught to look for obstacles in their way. On noticing of inability to cross the obstacle, accompany should be informed as any miscalculation in crossing over the obstacle might prove to be dangerous for the patient.

10. Certain physiological changes occurring inside the body can be seen as distinguishable facial expressions. These expressions should be taken care of by family members/friends/ peer group when entertaining the patient in outdoor facilities as occasionally patient's don't intend to interrupt the joy of their accompanies.

Findings

While training a patient in any setup, safety from all physical and architectural barriers should be prioritised. Reduction of these barriers to the minimalist boosts patient's confidence and reduces incidence for loss of balance predisposing the patient towards fall. In addition, identification of obstacles in outdoor settings and basic modifications in home can be of great value for patient in early recovery and improving overall quality of life.

Conclusion: Physical therapist should encourage modifications at home and while outdoor engagements by the patient or their family members. These modifications enable the patient to make easy in and out movements without unknown hurdles, hence reducing incidence of loss of balance which is the biggest predisposing factor for falls in any age group.

Bridging the Gap between Patient and Physical Therapist: Emphasis on Good Communication Skills in Assessment and Rehabilitation to Improve the Overall Quality of Life

Aksh Chahal[1], Harbir Kaur Rao[2], Narinder Kaur Multani[3]

[1]Professor, MM Institute of Physiotherapy and Rehabilitation, [2]Professor, Department of General Medicine, Maharishi Markandeshwar (Deemed to be University) Ambala, Haryana, India, [3]Professor, Department of Physiotherapy, Punjabi University, Patiala, Punjab, India

Abstract

A mode of interaction between two individuals is "Communication", while the ability to perform an act with expertise is defined as "Skill". Thus, communication when used with skills in healthcare practise to render positive results towards patient's wellbeing, are categorised as "Good communication skills". These skills form the basis for collecting vast and relevant information from the patient which is later put to tabulation and finally reaching the goal of implementation of evident therapeutic interventions. Good communication skills executed by Physical therapist help in developing effective treatment protocols followed with their timely modifications. The moment a patient steps in to consult a therapist, the first visual contact between the therapist and patient should impart confidence to the patient which ease to develop a positive attitude towards healthy living. In the last few decades, extensive research have been done on aspects of developing, implementation and analysing productive communication skills in different countries. With research focussing on different parameters as basis for good communication skills, the author in the present article would like to brush up with the existing and incorporate new skills to be used for effective communication between patients of any age groups and therapist.

Keywords: *Skills, Communication, Patient, Doctor, Therapist.*

Introduction

A mode of interaction between two individuals is termed "Communication", while the ability to perform an act with expertise is defined as "Skill". Thus, communication when used with skills in healthcare profession to render positive results towards patient's wellbeing is summed as "Good communication skills". These communication skills form the basis for collecting vast information from the patient which are put to tabulation and finally reach the goal of implementation of therapeutic treatment[1], in addition patient adherence along with raised satisfaction level is also elevated. In rehabilitation and health science, good communication skills executed by Physical therapist[2] help in developing effective treatment strategies followed with its execution[3, 4]. As communication between a health care professional and patient influence the after effect of treatment following consultation[5], a therapist should develop and implement imperative communication skills as fundamental components in their assessment protocol and rehabilitation[6].The moment a patient steps in for consultation, the first visual contact should impart positive vibes to the patient towards improvement of his overall health and thus, develop positive attitude towards a healthy life[7]. Simultaneously, a healthy and interactive verbal communication between the two will enhance the already developed confidence to another level of productive expectations which is created through the therapist's clear, audible, bold and encouraging verbal commands[8]. Over the last few decades, vast research

Professor, MM Institute of Physiotherapy and Rehabilitation, Maharishi Markandeshwar (Deemed to be University) Ambala, Haryana, India
E-mail: drakshchahal@gmail.com

have been done on various aspects like developing, implementation and analysing productive skills in communication via research performed in different countries. With these researches focussing on different parameters towards good communication, the author in the present article would like to discuss, less focussed strategies till date and elaborate on efficient and new communication skills in Physical therapy.

Skills for good communication:

1. Well mannerism
2. Clear speech
3. Gentle voice
4. Developing and maintaining positive attitude
5. Concise commands
6. Facial expressiveness
7. Confidence
8. Active listener
9. Maintaining eye contact
10. Encouraging orientation of self-posture and body language
11. Open minded
12. Respect to individual's privacy
13. Communication in patient's layman language
14. Able to create sense of humour

Significance of good communication skills by Physical therapist:

1. Therapist deal with infants and children.

A therapist should be polite in words, soft in handling and use easy understandable commands while treating infants and children[9, 10]. Individuals in this age group firstly, are unaware of health issues he/she are suffering. Secondly, children might develop a negative mind set and low morale due to inefficiency in comparison to peer group. So, a therapist should take great care in dealing with infants and children.

2. Therapist treating adolescent and youths.

Dealing with this age group requires therapist to be patient, soft in speech, active listener and communicative in patient's layman language. Therapist assessment with effective communication should go to the real depth of the problem being faced by the adolescent/youth. In one's life, adolescent stage is a critical stage as ideology and attitude developed during this stage governs thought patterns for rest of life. Adolescents and youth suffering from health issues make experience frustration and irritation due to incompetency with peer group which easily takes them on the path of depression[12]. While handling, patients of this age group a continuous eye contact[7] during conversation and treatment should be maintained to morally boost the patient's confidence. In addition, when handling these patients, extra comfort zone should be created to make them speak from within themselves, thus enabling them to develop positive attitude towards life and reduce the negative impact on psychological and physical health[11].

3. Therapist imparts health in middle aged and elderly population.

For a therapist to deal with this age group is a great challenge. Risk of falls and Osteoporosis[13, 14, 15] are commonly seen and actively treated by various therapeutic interventions. While commencing to treat patients of this age group, therapist must already be inculcated with well mannerism[1], polite in commandment, slow in action and respectful as elderly not only suffer from physical ailments, but they are greatly embarrassed psychologically, personally and face family and social difficulties. A regular eye contact[7] with elderly patients while communicating and treatment helps to develop faith in therapist which enhances cooperation from the patient while delivering in therapeutic interventions. As, in some cases where elderly population suffer from irreversible and progressively disorders like Alzheimer's diseases[16], Dementia[17, 18] and Cancer[19, 20, 21, 22] etc. Along with physical therapy treatment, special concern is paid towards treating urinary incontinence pharmacologically and therapeutically[23] with the aim to develop positive attitude towards health and life and reduce the negative psychological impressions which continuously confront in brain of these patients[11, 24, 25].

4. Therapist deal with conditions which are progressive in nature.

On knowing that one self's is suffering from any disease which is progressive and has no or residual impactful remedial success in nature, it is quite reasonable

for a individual to create clouds of demoralised, negative attitude towards all domains of life (i.e. personal, family, workplace and peer group).So, while dealing with patients of these stature, a therapist should be soft and polite in communication, open minded and more focus put on initiating healthy conversations where the patient express their views, lacking, regrets etc. which impart information to the therapist to bring decline of negative thoughts. Based on the patient's conversation, immediate and future implementation along with upgrading of rehabilitation treatments is focussed[2].

5. Physical therapist work in reducing impact of irreversible disorders.

Certain orthopaedic and neurological disorders are irreversible in nature. These disorders engrave the sufferer's mind to a vast extent. While dealing with such patients, a therapist should make use of effective skills like active listening and open mindedness etc which in return will initiate developing confidence and ultimately, a positive attitude towards life. At times when a patient is depressed or low in mood, a humorous trick or joke is incorporated to reduce impact of negative psychological thoughts. At any moment of time, different aspects of patient wellbeing are being handled by a therapist, so it will be wise to say that a therapist plays multi-dimensional role in improving the overall well-being of the patient.

6. Physical therapist has longer duration of contact with patient (days/weeks/months/years).

Therapist duration of contact with his/her patient might last from a few hours to years, such as in stroke[26]. Over the course of continued treatment, there develops a strong mental and emotional bonding between the two. This bonding is reflected in terms of discussing personal, family and social issues from the patient with the therapist. Patient suffering with short term impairment have different mind-set from patient suffering with long term disability. While treating patient with short term ailments the therapist should poses skills of active listening, direct questions, loud and clear transfer of command. Firstly, these patient should be are addressed towards maintenance of individuality and dignity. Gentle and soft speech to understand their mental turmoil and motivating the patient and reducing stress level by creating a joke/joyful humour as regular treatment should be performed at regular intervals as over the years patient tend to develop lack of mood and no interest in future life[11].Facial expressions via a smile, head nodding and frowning of eyebrows from the therapist during therapy session are helpful in bringing short and long term improvements[27].

7. Therapist continuously motivate patient for active participation in all components of a society.

As the therapist perform its duties by motivating the patient in all stage of treatment (early, middle or late), in addition to the previously discussed, developing mental confidence and creating positive body language are of prior most importance. Communicating with the patient in their language enables them to be more expressive, based on which a therapist will modulate techniques to develop optimistic attitude towards present and future life.

8. Therapist makes efforts in maintaining compliance during therapeutic interventions.

To achieve this goal, a therapist should be innovative to create ideas and techniques of assessment and treating patient. New concepts and therapeutic interventions help in keeping the patient's interest towards treatment intact which help to uphold the compliance from the patient's. Along with regular implementation of new concepts, a enthusiastic conversation with patient's comfortable language keeps the patient actively indulged in therapeutic sessions. To boost patient's confidence, a eye to eye contact[7] throughout the session is made along with focus on sitting and standing posture, are not overlooked as lack of interest and disinterest in life possibly develops a stooped posture which could be easily rectified manually if temporary in nature but, once permanent it leads to structural deformities of the spine which in return cause acute and latter chronic back pains which will have to be treated by different therapeutic exercises. [28, 29, 30, 31, 32]

9. Therapist enumerates prevention and precaution to patients.

It is important role of therapist to enumerate all possible prevention and precautions mandate for a patient safety and security. These components are usually discussed in the concluding phase of treatment session. During the beginning and middle phase of treatment session the patient is usually energetic and concentred towards the session. Secondly, conversation on prevention and precautions might hint the patient about conclusion of ongoing session. This might initiate

low interest in exercises being performed. Finally, while giving instructions, the therapist should be concise, clear and always maintain eye contact as it imparts confidence which ignites a positive feel in elimination of their current condition[7].

10. Therapist play active role in educating patient's family/relative/friends.

The role of therapist is not confined only till treating the patient. It also includes educating the patient's family members and relatives[11, 33] regarding the cause, progression and impact of the ongoing condition on patient's physiological, mental and physical status. In addition, prevention and precautions to be prioritised at home are also explained to the concerned parties. If possible, friends and peer group also should be rolled in for active participation for patient's faster psychological recovery which in return facilitate the physical revival and reduce the brunt of negative impressions from the brain.

Findings

A collective set of good communication skills are required in Physical therapist when working with patient of different age groups, patients with progressive/non progressive and reversible/non reversible conditions. In a nut shell, a Physical therapist should be well mannered, gentle speaking, confidant and active listener who always maintains an eye contact with his patient throughout session, encourage healthy conversation, respect to individuality and privacy.

Conclusion

Array of good communication skills when used by Physical therapist in assessing and rehabilitation, yield multi-dimensional benefits in the form of physical, physiological, and psychological wellbeing, hence improving the overall quality of life of their patient.

A Meta Analysis of Accuracy of Conventional and Digital Impressions of Implants

Anbarasu[1], Raghavendra Jayesh[2]

[1]Post Graduate Student, [2]Professor And Guide, Dept. of Prosthodontics and Crown & Bridge, Sree Balaji Dental College and Hospital, Velachery Main Road, Vgp Rajesh Nagar, Pallikaranai,Chennai,Tamil Nadu

Abstract

Application of computer-aided impression procedures are preferable to conventional impression procedures for Implant supported prosthesis. Data about the accuracy of the digital impression-making technologies in comparison to the conventional ones is scarce. This meta analysis is an attempt to decipher the preferred method of impression making of implant superstructures by analyzing data about these two impression making procedures.

Keywords: *Implants, conventional impressions, digital impressions, Implant accuracy, computer aided impression, intra oral scanner.*

Introduction

To fabricate a prosthetic framework on multiple implants, high-precision procedures are required for most of which is the impression. For almost every step in the procedure, either conventional or computer-aided approaches can be utilized.[1]

Conventional approach

A accurate impressions of tilted abutments is clinically arduous. Elastic recovery of the impression material may not withstand the strain induced during the removal of impression. There is no unanimous scientific agreement regarding which quantity and angulation of implants causes non- compensated impression material distortions, and when they must be splinted. Direct open-tray and indirect closed-tray impression are widely discussed in the literature.[2]

A systematic review reported that more studies confirm a higher impression accuracy (for four or more implants) using an open-tray impression technique than a closed-tray method (H. Lee, So, Hochstedler, &Ercoli, 2008). Polyether and polyvinylsiloxane were recommended as statistically the most accurate materials to make a implant impression (Wee, 2000).[2]

Computer-aided approach

Computer-aided approach in restorative dentistry started late 1980s advances in data acquisition, processing, and manufacturing nowadays, afford much faster and more accurate final outcomes. Intraoral scanners (IOS) available currently.[1]

Materials and Method

The Pubmed library was searched for articles, reviews and meta analysis from year 2013 to 2018 using the following search terms.

Articles that explicitly mention the variables considered for the study were obtained.

INCLUSION CRITERIA

In vitro studies, studies reporting on the accuracy of conventional impression, studies reporting on the accuracy of digital impression, experimental and control groups, Studies providing quantitative results, articles should be in English.

Exclusion Criteria

Studies without experimental and control groups, expert opinions or literature reviews, studies based on charts and questionnaire only, animal studies, studies without author response to inquiry for data clarification.

Data Extraction

Seven articles were short listed and following parameters were retrieved

- Mean linear distortion of conventional and digital impressions.
- Standard deviation (SD) of conventional and digital impressions.
- Confidence interval of conventional and digital impressions.

Meta Analysis

- Mean difference of the mean linear distortion was calculated for conventional impressions and digital impressions and compared using student T test at the confidence interval of 95%
- The data was presented as forest plot to aid incomparison of values

Meta analysis was done using R –3.5.1 statistical software

The descriptive analysis revealed that splinted open tray impression technique has less inaccuracy than the direct non - splinted open tray technique. Of the scanning systems evaluated TRIOS 3 shape is better than the ITERO system followed by LAVA COS, CEREC OMNICAM and 3M True definition.[3] Polyether impression material is superior to polyvinylsiloxane impression material in terms of accuracy. Scan bodies from Nobel Biocare implant system result in better accuracy values compared to Straumann system.[7]

Amin et al(2016) reported that digital implant impressions were more accurate than the conventional direct splinted implant impressions. In vitro study by Papaspyridokos et al (2014) compared the accuracy of digital implant impressions using 3 shape scanner with conventional impression and showed that accuracy of digital impression was comparable to that of the conventional impression.[6]

Several recent studies by Howell et al(2013), Aliabdullah et al(2013) and Lin WS et al (2015) comparing digital vs conventional implant impressions have found a greater error using the digital approach. [5] Lin et al specifically examined the accuracy of models fabricated from conventional and iTero digital impressions and concluded that the digital pathway, with mean errors ranging from 158 to 328 μm, was significantly less accurate.[4]

Sang j lee et al (2015), ElliassonAotorp et al (2012) and Papaspyridakos et al (2016) have found equivalent accuracy between digital and analog impression techniques.[5] Abdel-Azim et al found equivalent error for full complete arch impressions when measuring the marginal fit of final prostheses fabricated using either analog technique or a complete CAD/CAM digital approach.[7] While Lee et al concluded that the accuracy of the digital method was equivalent to the conventional method when examining overall cast accuracy, they did find a statistically significant difference in vertical implant placement between the two approaches.[5] A recent study examining the accuracy of Straumann scan body with the TRIOS scanner found no difference when compared with two conventional impression approaches (papaspyridakos et al). However, the authors compared digitized analog casts to the digital impression–generated STL files and not actual fabricated casts.[6] The average 3D error for the conventional impression technique (56 μm) was found as per the study, to be within the clinically acceptable range and in agreement with previously published studies, which have reported errors ranging from 20 to 89 μm using similar measurement techniques. [5] Conversely, the digital impression technique resulted in an average 3D inter-implant error measurement of 116 μm, which was both in excess of the defined error limit of 60 μm and demonstrated a significantly greater error and variability than the conventional implant impression technique.[6]

Direct digitalization showed higher accuracy compared to the conventional impression making and indirect digitalization (Guth*et al.*, 2013).[7] Due to elastic properties of the impression materials, indirect digitization of the impression was not recommended. (DeLong *et al.*, 2001) the digitization of errors of the impressions was influenced by the shape and the interaction effect with the digitization source. (Quaas*et al.*, 2007; Rudolph *et al.*, 2007; Persson*et al.*, 2009) The digitization source with strong changes of curvature and smooth surface texture showed largest deviations due to high surface angles and light reflection from the digitization source to the object. (Persson*et al.*, 2008; Persson*et al.*, 2009)[3]

Marzieh et al (2018) concluded that digital impression has significantly less angular and linear distortion than

conventional impression. Digital impression of straight implants with internal connection was more accurate than that of the direct technique although the difference was not significant.[3]

The results of the present meta analysis and descriptive analysis show that 1. Statistically there is difference between conventional impressions and digital impressions in terms of accuracy. 2. The error for the digital impression technique was only slightly more than that of conventional impression. This may not be clinically highly significant.[2]

The accuracy values obtained from digital impressions has only a marginal difference from values of conventional impression. The results obtained are similar to the results of Hitoshi et al (2016) who stated that the results obtained in their study suggest that error of the optical impression was greater than that of conventional impression. Trends in digital dentistry are drastic, and a number of newly developed apparatuses may be provided in the near future. Further analyses must be conducted continuously. In the near future, the development of information technology should enable improvement in the accuracy of the optical impression with intraoral scanners.[5]

Scope for Further Studies

Although materials for making impression of the implants may not undergo drastic changes in composition/ techniques, considerable evolutionary enhancements in digital equipment for optical impressions have become an ongoing technical revolution. Hence, the inherent shortcomings of any developing technical system like intraoral scanners and implant systems will be overcome during this development. So, with improved equipments more studies can be done and increased data can be taken up for analysis.[7]

Conclusions

As per the results of the present meta analysis, the following conclusions can be drawn;

1. Accuracy of conventional impressions is marginally better than the accuracy of digitized impressions.

2. Splinted open tray technique resulted in lesser discrepancy than the direct open tray technique and closed tray technique.

3. Polyether yielded better impressions than polyvinylsiloxane.

4. Trios – 3shape was the best scanning system.

5. Nobel Biocare system was better than Straumann system

An Analysis of Preparedness and The Impact of Floods in India

Ansuman Swain[1], Navya Vyas[2]

[1]BDS, MPH (3rd Semester), Prasanna School of Public Health, Manipal Academy of Higher Education, [2]BHMS, MPH, PhD (Pursuing)

Abstract

India is the most flood prone country in the world with instances of at least 15 major occurrences in the last decade. Apart from loss of lives and property, the country suffers huge economic, infrastructural as well as environmental damage on a yearly basis. In addition, several indirect and prolonged effects of floods affect the country as well. This is coupled with facilitating factors such as global warming and unplanned development in flood plains. Understanding the gravity of the situation, the government of India enacted the Disaster Management Act in 2005 subsequently forming the National Disaster Management Authority. This body has developed guidelines for flood mitigation at national, state as well as at regional levels. The country needs to develop effective flood mitigation system in order to reduce the periodic damage endured by the people and the state.

Key-words: *Flood mitigation; NDMA; Impact of floods; flood preparedness;*

Introduction

Human civilizations has been ravaged by natural disasters since time immemorial. They have been mentioned in fact and fiction alike and have shaped our history. The World Health Organization[1] has defined a natural disaster as "an act of nature of such magnitude as to create a catastrophic situation in which day-to-day patterns of life are suddenly disrupted and people are plunged into helplessness and suffering, and, as a result, need food, clothing, shelter, medical and nursing care and other necessities of life, and protection against unfavourable environmental factors and conditions." They account for the deaths of 90000 and affect about 160 million people every year[1]. According to Ritchie & Roser, like almost every other natural calamity, floods have seen an upsurge worldwide accounting for roughly 45% of all natural disasters during the decade of 2005-2014[2,3]. Floods are common around the world with India being the most flood prone country[4]. About one fifths of all global flood deaths occur in India[4]. Further, in the last decade from 1996 to 2005, the average annual flood damage in the country was 4745 crore rupees[5]. There have been at least 15 major flooding events in the last decade in the country and it is on a rising trend[6]. Floods cause great damage not only to lives, properties and infrastructure but also the healthcare system in a country. Moreover, there are risks of waterborne disease outbreaks after a flood, for instance the Cholera outbreak in the 1998 West Bengal floods[7]. Apart from the deleterious impact on health and healthcare, the country's economy, climate, agriculture and animal life takes a toll as well. Therefore, a multi-sectoral effort is required to mitigate and avert floods in India.

The country needs to scale-up efforts towards flood mitigation. This paper analyses the multi dimensional impact of floods on the country with instances from the past and emphasizes on the current flood mitigation and preparedness measures in the country. With a focus on the work of the National Disaster Management Authority (NDMA), it mentions a few global strategies envisaging the probable solutions to deal with the recurrent flood situation in the country.

The impact of floods in the Indian context

Floods have an immediate impact on lives, property, infrastructure and a long term impact like a dearth of safe

Corresponding Author:
Dr. Navya Vyas
[2]BHMS, MPH, PhD (Pursuing

drinking water, vector borne diseases, psychological ailments and an increased risk of epidemics. Likewise, the socioeconomic and environmental effects are profound as well. Damage to infrastructure, agriculture and transport sector directly and indirectly hampers the economy. Further, all these effects consequently affect the health of the affected population in the long run.

Impact on life and health

The health effects of floods are numerous. In a study done by FitzGerald, Clark, & Hou, the immediate impact of floods range from drowning, and injuries, to animal bites, allergies and worsening of existing injuries[8]. There has been a total of 105758 deaths in floods from 1953-2016 in India with highest number of deaths in Uttar Pradesh followed by Andhra Pradesh[9]. Some of the major floods to have affected the country include the Bihar flood of 1987 with 1399 deaths, Assam floods of 1998 affecting 47 lakh people, the Himalayan flash floods of 2012, the Uttarakhand flood of 2013 taking 1000 lives, and the floods in Kerala in 2019[6,10,11]. Apart from loss of lives and injuries, poisoning, impact on mental health, spread of infectious diseases, chemical & electrical contamination, carbon monoxide poisoning, disability and starvation are some of the long-term effects of floods[8]. Further, disruption of health services worsen the health system of the affected place. In addition, the lives and health of animals are adversely affected as well. The loss of infrastructure coupled with health ailments due to floods affect not only the health system but the socio-economy as well.

Socio-economic impact

In the last 65 years the country has suffered a loss of Rs 3,78,247.047 crore due to damage to property, livelihood, infrastructure and health pertaining to floods[9]. For instance, in 2015 India suffered a loss of Rs. 57,291.1 crore due to floods[9]. Further, sectors like agriculture, transport, tourism, livestock and animal husbandry endure irreplaceable damage in terms of economy as well. Damage to public property and houses due to floods in the period between 2013 and 2017 was worth Rs. 72.09 crore[9]. Furthermore, a total of 8,07,17,993 houses were destroyed on account of floods in the past 65 years[9]. What's alarming is that, the economic loss has increased over the years and has the highest figures in the last decade[9]. This increase can be partly attributed to the rapid urbanization and the relative incapability of flood management and drainage systems to cope up[9]. However, the impact of floods are not limited to health and socio-economy only.

Effect on the Environment

As much as natural events like storms, tsunamis and heavy rain exacerbate floods, the environmental aftermath is profound as well. Floods not only derange the ecology but also cause irreparable havoc to livestock and wildlife. For instance, the 1978 floods alone were responsible for the deaths of 2,39,174 cattle[9]. This not only affects sectors like agriculture and animal husbandry, but also has a long lasting economic impact on the people dependent on them. The flooding of forested areas result in innumerable loss of biodiversity, often ecologically valuable species that are difficult to get a count of. In addition, large quantities of water can affect farming habitats, often depriving farmlands of nutrients and accumulation of pollutants[12]. Apart from that, floods cause significant destruction of floodplains, vegetation and forest cover[12]. Thus, preparedness for floods is of substantial importance and requires a multi-sectoral approach to mitigate the deleterious impact of floods in India.

Analysis of preparedness against a disaster in India

The geographical location of India makes it climatically very sensitive, and the increasing usage of land area, climate change and the effect of global warming have made matters worse over the years[9]. A total of 40 million hectares of land (roughly 12% of the country's area by land) in the country is prone to floods[9]. Between 1953 and 2017, floods have occurred almost every year in India and has resulted in an economic loss of Rs. 3,78,247.047 crore and the destruction of 8,07,17,993 houses and property[9]. In addition, the magnitude of damage due to floods over the years have increased drastically as explained by the following figure.

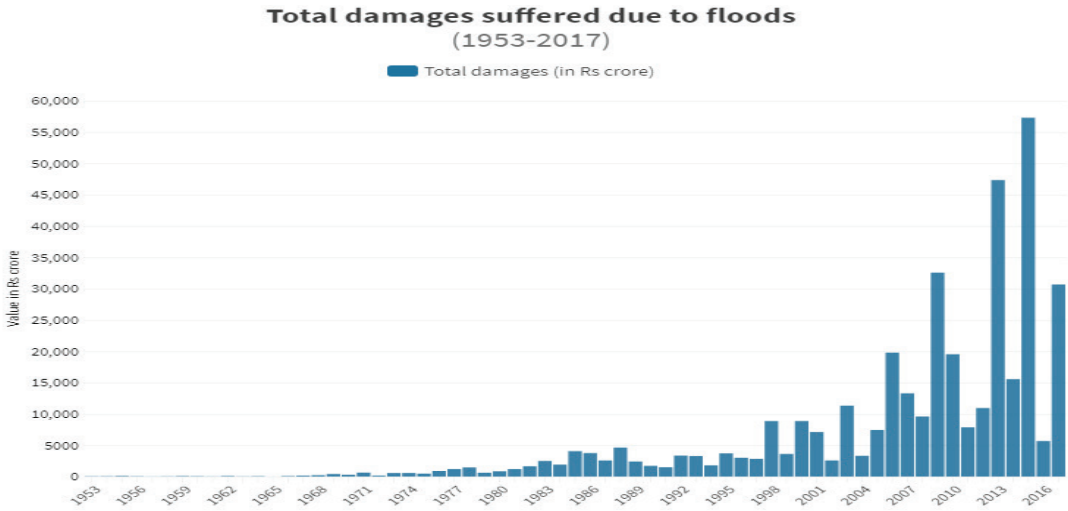

Figure 1. Total Damages suffered due to floods in India[9].

(Source: Available from https://www.indiatoday.in/india/story/loss-due-floods-india-people-killed-crop-houses-damaged-in-65-years-1591205-2019-08-27)

An increasing trend in total damage value caused by floods can be observed in the figure suggestive of firstly an increase in the frequency of the event, secondly, a relationship with population growth and lastly, the inefficiency of mitigation measures. Realising the gravity of the situation, the government of India enacted the Disaster Management Act which led to the onset of the NDMA in 2005[3].

The role of the NDMA in Flood Mitigation

Headed by the honourable Prime minister and State Disaster Management Authorities (SDMA), the NDMA aims to implement a holistic and integrated approach to disaster management in the country[3]. The authority agrees to the fact that increasing population, rapid urbanization, growing developmental and economic activities in the flood plains and global warming can be attributed to the unprecedented rise in the number of floods in the country[5]. Similarly, instances of flooding in urban area have also increased during the last decade largely due to improper urban planning and faulty drainage systems[5]. These statistics reveal that the system needs to upgrade the flood response system to mitigate the impact of periodic floods in the country. India not only lacks cutting edge technologies in flood forecasting and warning but also mitigation measures. In addition, these measures if at all active in some areas, don't cover all the river belts of the country. Furthermore, there is a dearth of awareness about floods and public participation. Despite the focus on planning activities, unplanned development of flood plains continue and pose a threat. Likewise, there is little documentation about the long term impact of floods and the way these were dealt with. Often this has resulted in poor infrastructural response, improper allocation of manpower and a dearth of strategic planning when required. As a result, the country has witnessed massive damage in the past not only in terms of lives and property, but also infrastructure and economy as stated in the previous sections[5]. Therefore, it is imperative to understand the need to address the deep rooted factors in flood mitigation and management.

The way foreword

The NDMA has prepared the executive summary guidelines to minimize damage due to floods[5]. The primary objectives of the guidelines are to improve forecasting and real time monitoring, strengthening emergency response capabilities and multi-sectoral involvement[5]. To effect the plan, the NDMA plans to set up a National Flood Management Institute (NFMI) at a strategic location in the country[5]. Further, a Flood Forecasting and Decision Support System (DSS) are planned to be set up as well[5]. In addition, the activities proposed to minimize flood risk and losses are to be implemented in 3 phases at the central as well as state levels[5]. Apart from that, the NDMA plans to regulate the unplanned developmental activities in the flood plains to say nothing of the strategic construction of dams,

reservoirs and other storages[5]. Additionally, a National Disaster response Force (NDRF) has been made by the government of India for prompt response to disasters[5]. The NDMA has acknowledged the fact that multi-sectoral collaboration is essential in this aspect and has partnered with the Meteorological department, the Central Water Commission, Remote sensing department, weather forecasting department at both the state and national levels[5]. Further, initiatives like the Calamities relief fund, Flood insurance, drainage improvement, catchment area afforestation, anti-erosion works, the National Flood Mitigation project and Medical preparedness strategies are also underway to strengthen the cause[5]. In spite of the above mentioned strategies, certain issues remain unaddressed. For instance, the ecological protection of the flood prone areas, insufficient funding allocations, frequent river erosions, infrastructural lack, biodiversity loss and lack of concrete relief & redemption strategies are some of them.

Although the NDMA has developed strategies to combat damage caused by floods in India, some grey areas still remain which need to be addressed. For instance, the people living close to the flood plains can be educated and trained about planned vegetation and retention ponds that help to retain water during flooding[13]. In addition, they can be edified with easy control measures such as usage of sandbags and inflatable tubes[13]. Certain blockade methods like construction of dikes, dams, diversion canals, bunds and weirs are few options that can be employed at strategic positions to mitigate the devastation caused by the water flow[13]. Some compelling evidences can be seen in the Dutch flood mitigation system, for instance the "Delta program"[14]. The program has resulted in the planning of canals within cities to minimise the risk of urban flooding[14]. Correspondingly, the Netherlands has developed national policies to tackle the issue of flooding and as a part of the Delta program, has developed multi-sectoral collaborative strategies for that matter[14]. Be that as it may, some of these strategies can be implemented in the Indian setting to help the cause. Likewise, some of the UN strategies such as the 'Sendai Framework' for disaster risk reduction can be implemented in the country as well.

The framework was adopted at the 3rd UN conference in Sendai, Japan in 2015[15]. Supported by the United Nations Disaster Risk Reduction (UNDRR), the framework aims to build on strategies to reduce disaster risk and subsequent loss due to the disaster. The framework emphasizes on 7 targets based on the ultimate goal of preventing new and reducing existing disaster risk through multi-dimensional approaches[15]. Additionally, it has 4 priority areas of action which are; understanding the disaster risk, strengthening disaster risk governance to manage disaster risk, investing in disaster risk reduction for resilience and enhancing disaster preparedness for effective response[15]. Further, it is based around several guiding principles that ensure a holistic and multi-sectoral support in the cause[15]. Thus the framework can be employed to device strategies to mitigate the risk of floods in the Indian context.

The government needs to tackle the perennial problem of frequent floods more effectively to reduce damages caused by the same. As explained in the Sendai framework, a multi-sectoral approach incorporating economic, structural, legal, social, health, cultural, educational, environmental, technological, political and institutional measures need to be developed[15]. Moreover, an effective funding mechanism needs to be developed and planned for the cause both at the central as well as the state levels. Likewise, infrastructure development in terms of preparatory measures both at the state as well as national levels can be planned. Similarly, at the level of policymaking, actors and stakeholders need to be aware of the ground realities and incorporate members of the population prone to floods. In other words, progress needs to be made at every level of the country's functioning to mitigate the frequent losses that happen due to floods.

Conclusion

Floods have been ravaging India since long and the loss of lives, property and economy has been enormous. Correspondingly, there has been an increase in both the frequency and magnitude of floods in the last decade. The infrastructural, economic as well as ecological loss is also on a rising trend as well. Additionally, the lurking factors facilitating this upsurge like global warming, urbanisation and unplanned development of flood plains have increased over the years. Natural as well as human factors as stated before can be attributable to the increasing instances of floods. The substantial losses endured in the past also suggest that the country's flood mitigation measures need to be evaluated and sharpened up. Further, the lack of effective management and control strategies in the country has resulted in frequent degradation of economy and environment alike. India not only has a dearth of appropriate technologies but also strategies at the policymaking level to design efficient

intervention measures to tackle the problem. For these reasons and many more, the NDMA has designed the 'Executive summary guidelines', emphasizing on forecasting, real time monitoring, emergency response and multi-sectoral collaboration. In addition, it also plans to tackle the causative elements responsible for floods for instance, river erosion and unplanned development in the flood plains. However, many grey areas remain unaddressed which need to be effectively dealt with. The country can take ideas from the international platform for instance the Netherlands, which has developed effective flood mitigation measures. To put it in another way, the government can take ideas from others and try and incorporate some global strategies such as he Sendai framework for disaster risk reduction, in the local context. A multi-sectoral approach is required to deal with the issue of floods in the country. The NDMA guidelines although promising, face many challenges along the way.

Abstract

Background: The aim of the study was to evaluate and correlate the effect of non surgical periodontal therapy on homocysteine levels in patients with chronic periodontitis.

Methods: Fifty participants were enrolled in the study *(n=50)* in the age range of 20-45 yrs. Each patient was examined using a mouth mirror and UNC-15 graduated periodontal probe. After recording the clinical parameters & indices (CAL, OHI-S, GI), venous blood was drawn from the antecubital vein and transferred to a vial and centrifuged to isolate the plasma, which was then sent for evaluation of plasma homocysteine level. Non-surgical therapy was performed which consisted of scaling and root planing (SRP). After 90 days, the patient was re-evaluated for clinical parameters and the readings were recorded again. Blood samples were sent for analysis of post treatment plasma homocysteine levels.

Results: The plasma Hcy level in periodontitis subjects during pre treatment was 20.7± 3.4 µmol/L which was significantly higher. Post therapy levels reduced to 14.7± 2.2 µmol/L. The OHI's and GI were also significantly reduced after post therapy.

Conclusion: An inflammatory condition like chronic periodontitis is significantly associated with elevated plasma homocysteine levels. However, no significant change was seen in the plasma homocysteine levels between males and females. Periodontal intervention shows statistically significant improvement in plasma homocysteine values.

***Keywords**: Chronic Periodontitis, Root planning, Scaling, Homocysteine, Plasma*

Introduction

Homocysteine (Hcy) is an amino acid and a breakdown product of protein metabolism. Homocysteine present in high concentrations has been linked to increased risk of cardiovascular diseases and strokes.[1,2] A positive correlation exists between the concentration of Hcy and bio-humoral parameters of inflammation, indicating an increase in Hcy levels during inflammatory conditions. [3]

Periodontal disease is an inflammatory condition and is the major cause of tooth loss in adults. Periodontitis is characterized by inflammation of gingiva, destruction of periodontal ligament, and alveolar bone resorption. Chronic periodontitis is also associated with increased circulating levels of CRP and IL-6.[4] Therefore, a similar association could exist between chronic periodontitis and plasma Hcy. Recently, a study showed a highly significant relationship between elevated plasma Hcy and periodontal disease.[5] Furthermore, both chronic periodontitis and raised plasma Hcy levels could act as independent risk factors for cardiovascular disease/ atherosclerosis. This new association could help in part by explaining how a chronic infection like periodontitis could be linked to cardiovascular disease through elevated plasma Hcy levels.

Several studies have shown that levels of various inflammatory biomarkers commonly associated with cardiovascular disease and periodontal disease are reduced following periodontal treatment.[6] With this background the current study was undertaken to assess the levels of plasma Hcy in periodontitis patients and to evaluate the effect of non surgical periodontal therapy on plasma Hcy levels among them.

Materials and Method

A total of 55 subjects suffering from moderate to severe periodontitis were selected for the study from outpatient section of Department of Periodontology, School of Dental Sciences, Karad. All the selected subjects were explained about the objective of the study and the nature and benefits of the clinical investigation and associated procedures. An informed consent was obtained from all participants before enrolling them. Institutional ethical clearance was obtained from Krishna Institute of Medical Sciences, Deemed University, Karad (KIMSDU/IEC/04/2014) before commencing the study. The study was conducted during the period from December 2015- September 2016.

Sample size estimation: The optimum sample size to ensure adequate power for this clinical study was calculated considering standard deviation of 8.27 and a precision of 0.5 i.e. 50% of mean. Based on the above values, it was found that 43 subjects should be studied. As the present study was a follow up study, the final sample size selected was 55 subjects.

Criteria for selection: Screening was conducted among systemically healthy, non- smoker subjects, age 20-45 years, who wilfully consented to attend follow- up visits. Subjects with less than 20 permanent teeth remaining, who had received either antibiotic, anti-inflammatory or vitamin supplementation therapy within 3 months or had undergone any periodontal therapy (surgical or non- surgical) within 6 months of baseline examination were excluded from the study. Systemic diseases and conditions such as cardiovascular disease (CVD), renal disease, rheumatoid arthritis, diabetes mellitus, nutritional deficiencies, pregnancy and lactation have the potential to influence systemic Hcy concentrations and hence, were excluded from the study. A structured proforma was designed to collect patient's personal and demographic data which also included periodontal parameters.

Periodontal parameters: Gingival Index (Loe and Sillness 1963), Oral Hygiene Index (Loe and Sillness) and clinical attachment level were recorded for each patient. Subjects included in the study group (n=50) suffered from moderate to severe chronic periodontitis and were classified based on the AAP classification as, moderate periodontitis = 3 or 4 mm CAL, severe periodontitis ≥ 5mm CAL.[7] Each subject underwent an initial full-mouth periodontal examination. The CAL was measured on six sites (mesio-buccal, midbuccal, disto-buccal, mesio-lingual, mid-lingual and disto-lingual) per tooth using a UNC-15 periodontal probe (UNC-15, Hu-Friedy, Chicago, IL, USA).

Sample collection and storage: Pre treatment venous blood samples about 5 ml were collected from median cubital vein. The collected blood samples were centrifuged immediately to extract plasma. The plasma was pipetted out and immediately transferred to a vial and stored till the time of Homocysteine estimation.

Homocysteine analysis: The collected plasma samples were then used for homocysteine analysis using Autopure® (Accurex Homocysteine kit) in EM 360 auto analyzer. The Siemens Diagnostics enzymatic test for the quantitative Homocysteine determination (HCY) is based on a series of enzymatic reactions, causing a decrease in absorbance value due to NADH oxidation to NAD+. HCY concentration in the sample is directly proportional to the quantity of NADH converted to NAD+ (ΔA_{340nm}).

Periodontal treatment: The subjects in the study received nonsurgical periodontal therapy, which included Scaling and root planing (SRP) along with oral hygiene instructions. The periodontal treatment was performed by the same clinician (A.P).

Recall visits: Each patient was recalled after 90 days for follow up examination. Out of 55 patients, 5 failed to follow up, therefore only 50 patients reported. The follow up visits included examination of periodontal parameters and evaluation of homocysteine levels.

Statistical Analysis

Data analysis was performed using the Statistical Package for the Social Sciences (SPSS)-20 for windows (SPSS Inc., Chicago, IL, USA). The 'Wilcoxon' matched pairs test was used to test the hypothesis and significant difference in the level of Hcy, GI and OHI-s scores between pre-treatment and post-treatment. P-values

<0.05 were considered statistically significant.

Results

The demographic data of the study subjects is illustrated in Table 1. The degree of severity of gingival inflammation was evaluated by Gingival Index at baseline and 90 days after treatment. The baseline Gingival Index was 2.0 ± 0.27 which indicates severe gingival inflammation. Following treatment the Gingival Index value was 1.1 ± 0.22 resulting in decrease of 0.9 ± 0.05 post treatment. There was a significant improvement in the gingival condition following periodontal treatment with a p-value of <0.0001*. Similarly the oral hygiene index improved significantly after treatment with a p-value of <0.0001* **(**Table 2).

The baseline mean plasma Hcy value was 20.7± 3.4 µmol/L while the mean Hcy values after 90 days of follow up were 14.7± 2.2 µmol/L. Thus the treatment resulted in a significant reduction of 6.0±1.2µmol/L with a p-value of <0.01* (Table 3).

Hcy levels when compared based on gender revealed that there was no statistical significant difference found between Hcy levels of both males and females pre operatively and post operatively (Table 4). A correlation analysis was carried to confirm any relationship between Hcy and age which was suggestive of, no correlation between Hcy and age (p>0.05) (Table 5).

Table 1: General characteristics of the study population

Characteristic	**N**
Number of participants	50
Males	28
Females	22
Age in years	
≤ 30 years	06
31-39 years	25
40-45 years	19
Mean ± SD	37.6 ± 5.7

Table 2: Periodontal parameters at baseline and after 90 days of follow-up

Periodontal parameters	**Baseline**	**After 90 days of follow up**	**Mean Difference**	**P-value**
GI	2.0 ± 0.27	1.1 ± 0.22	0.9 ± 0.05	<0.0001*
OHI's	2.6 ± 0.5	1.6 ± 0.9	1.0 ± 0.5	<0.0001*

Table 3: Comparison of Hcy scores at baseline and after 90 days of follow-up

Biochemical Parameter	Mean	Mean Diff.	p-value
Baseline	20.7± 3.4		
After 90 days of follow up	14.7 ± 2.2	6.0± 1.2	<0.0001*

Discussion

Hcy is a sulphur containing amino acid obtained during the metabolism of methionine. Dietary protein, methionine is the only known source of Hcy in the human body.[5] The average daily intake of methionine is about 2 grams. Methionine is liberated from dietary protein in the digestive system after meal ingestion. Blood acts as a transport media for free methionine in the body which is ultimately taken up by the cells. Animal dietary proteins contain twice as much as methionine unlike cereals, fruits and vegetables.[8,9]

Periodontitis affects the systemic health of an individual, and may contribute to CVD, coronary artery disease (CAD), diabetes mellitus, and preterm low-birth-weight infants as suggested by the current era of evidence-based medicine.[10-12] These novel risk factors include chronic infections and infection related biomarkers such as CRP, elevated Hcy levels etc.[13,14] Impaired Hcy metabolism has been implicated in CAD/ atherosclerosis, cerebrovascular disease, and peripheral vascular disease.[15]

Plasma homocysteine levels are increased in patients having cardiovascular disease as mentioned in numerous case-control studies.[16] Additionally various meta-analyses indicate that increased plasma homocysteine levels serves as a independent risk factor for atherosclerosis and vascular disease. A study also showed that, for every 5-µmol/L increase in serum homocysteine concentration, the risk of ischemic heart disease increased 20% to 30%.[17] Analysis of the data showed that after adjusting for known cardiovascular risk factors and regression dilution bias in the prospective studies, a 25% lower homocysteine level is associated with an 11% lower IHD risk and 19% lower stroke risk.[18]

The present study was undertaken to evaluate the effect of non-surgical periodontal therapy on plasma homocysteine levels. The study group chosen had a mean age of 37.6 yrs. Studies done by Chang et al 2002[19], Ferruci et al 2005 [20] have shown that a large percent of old (>65years) and very old persons are affected by a chronic mild pro-inflammatory state mediated through their nutritional deficiency which could be linked to HHcy, thus indicating that the total Hcy increases with age. Chronic periodontitis is also found to be age associated, and its prevalence and severity increases with age.

Framingham heart study cohorts has shown that total homocysteine concentration is higher in men and in post-menopausal women.[21] Robinson et al[22] showed that males had increased levels of homocysteine as compared to females, but in the present study it was found that there was no difference associated in homocysteine levels when compared between males and females.

The baseline plasma Hcy values in the current study were 20.7 ± 2.43 µmol/L, which is categorized as mild hyperhomocysteinemia and are similar to those obtained by Joseph et al in 2011.[5] Thus the mean values of Hcy obtained in the current study group show that chronic periodontitis could be a risk factor for CAD. Endothelial dysfunction is considered to be the first inflammatory change of the vascular endothelium leading to arteriosclerosis. The atherogenic and thrombogenic potentials of Hcy have been implicated in promoting endothelial dysfunction; however the exact mechanisms are not clearly understood.[23] Oxidation of low-density lipids, increased monocyte adhesion to the vessel wall, increased lipid uptake and retention, activation of the inflammatory pathway, stimulatory effects on smooth-muscle proliferation, thrombotic tendency mediated by activation of coagulation factors and platelet dysfunction could mediate the relationship between CAD and Hcy. Subjects with periodontitis have also been reported to have higher levels of endothelial dysfunction.[6]

The link between periodontal bacterial systemic exposure and atherosclerosis is biologically plausible. Periodontal pathogens especially P.gingivalis has been detected within inflamed atheromatous plaques and have molecular pathways to induce macrophage uptake of LDL cholesterol, leading to foam cell generation and atheroma progression.[24]

The results of the present study are in accordance with the study done by Bhardwaj S et al[25], which showed significantly higher levels of Plasma Hcy in chronic periodontitis subjects than healthy subjects. There was a significant reduction in plasma Hcy after periodontal treatment.

Thus, from the above discussion it is evident that the elevated levels of plasma homocysteine in chronic periodontitis patients can act as a marker for systemic inflammation. Moreover in patients with chronic periodontitis, periodontal treatment can be used to augment conventional homocysteine lowering therapies.

Conclusion

In the current study, subjects showed elevated plasma homocysteine levels which were reduced following interventional non-surgical periodontal therapy, this reduction was statistically significant. Periodontal therapy can be used to augment the traditional therapies used to improve the cardiovascular status. To enumerate the limitations of the present study the cofactors involved in homocysteine metabolism namely vitamin B6, B12 and serum folate were not assessed in the current study. Hence, large scale multicenter randomized controlled trials using heterogeneous populations are required to assess the correlation between periodontitis and inflammatory pathways.

Abstract

Background: Health literacy refers to the knowledge and competencies of persons to meet the complex demands of health in modern society**.** Healthcare professionals play an essential role in helping patients to obtain and understand health information. It is important to assess the health literacy of students of health science professions as they can contribute to enhancing the health literacy of the communities in the future. **Objective:** The study aimed to measure the levels of health literacy among students attending different health-related courses in a university situated in the coastal town of southern India using the HLS-EU-Q16 (Health Literacy Survey-European Union). **Methods:** A cross-sectional study using a self-administered health literacy survey in google forms questionnaire was conducted among 812 students enrolled among various health-related courses of which 770 students were taken for final analysis. The index scores were recoded into four health literacy categories as follows (according to thresholds established by the HLS-EU consortium): excellent (>42-50); sufficient (>33-42); problematic (>25-33); and inadequate (0-25). **Key Results:** The overall average health literacy score was 31.3 ± 4.4, which indicates that health literacy among the students was limited. The average health literacy score of the students of the medical college, dental college, and allied health sciences (AHS) was 32.8, 32.4 and 30.7, respectively, indicating sufficient health literacy among the different courses individually. **Conclusion:** The level of health literacy gives important leads to initiate curricula and educational activities, including cross-disciplinary courses.

Introduction

Health literacy (HL) is defined as the necessary capabilities to make well-informed health-related decisions. Health literate means placing one's health and that of one's family and community into context, understanding which factors are influencing it, and knowing how to address them. An individual with a sufficient level of HL can take responsibility for one's health as well as one's family health and community health.[1] The World Health Organization (WHO) defines HL as the personal, cognitive and social skills determining the ability of people to gain access to, understand and use the information to promote and maintain good health.[2] As patient's decision-making is a crucial element of patient-centric health care, insight into patient's HL might help healthcare professionals to organize their care accordingly.[3]

The role of HL in health care professionals makes it an important focus as it helps in understanding the challenges people face when attempting to find and use health care services. The concept of HL was originally used in the United States and Canada; however, it is now being used internationally, not only clinically, but also within the public health context.[4] HL has been an essential

focus in public health research in the past decades as it is necessary for making appropriate decisions in everyday life in a way to promote and maintain good health. Many international studies have revealed that limited health literacy affects large parts of the population in terms of adverse health outcomes and higher healthcare costs.[1]

HL is a relatively new concept in India. The health science students will be the flag bearers of health literacy dissemination in the years to come since, they play an important role in educating individuals, particularly about the remarkable subjects that require information, such as medication management and planning preventive measures. It is a tough task to demarcate general literacy and health literacy in India. The current study aims to assess the health literacy level among health science students by using HLS-EU-Q16 (Health literacy Survey-European Union).

Methodology

Study Design and tool

A cross-sectional study was conducted involving undergraduate students from medical, dental, and allied health science courses at a tertiary level college in southern India. A short form (HLS-EU-Q16), comprising 16 items, was used through a self-administered questionnaire. The tool was chosen since it measures comprehensive health literacy. Further, these 16 items of the questionnaire focus on the three HL domain which includes health care, disease prevention, and health promotion.

Sampling

The sample size of 854 was calculated (CI=95%, d=5%) based on the anticipated prevalence of 50% health literacy among students of health sciences, out of which 812 was achieved. Probability proportional to size (PPS) was adopted to select participants from the various health science courses like medical, dental and AHS. For a valid index score generation, at least 13 items of the 16-item questionnaire must have been answered. Therefore, scores could not be calculated for 42 respondents, and they were excluded from further analysis, resulting in 770 students finally.

Data collection.

The institutional ethical committee clearance was obtained (IEC number 134/2019). Informed consent was obtained from all participants.

Prior permission was obtained from the heads of the institutions, and data was collected during the free hours of the students using a self- administered questionnaire via google forms that were sent to class group mail ids. The surveyors explained the purpose of the study, and the students were assured of anonymity. All questions about HL were required to be answered.

Statistical Analysis

The data were entered, cleaned & coded using 'Excel.' Data analysis was performed using the 'R studio.' The 16 items have four responses (very easy, easy, difficult, and very difficult). The 'don't know' option was included resulting in five responses for each item. All responses were given a numerical score as follows: 0- don't know; 1- very difficult; 2- fairly difficult; 3- fairly easy and 4- very easy. Mean scores were calculated for all items on the scale and then converted to an index score according to the recommendations of the HLS-EU consortium.[5] The index scores were recoded into four health literacy categories as follows; excellent (>42-50), sufficient (>33-42), problematic (>25-33), and inadequate (0-25).

Results

The overall mean HL score was 31.3(SD 4.4). The mean HL score of the medical college was 32.8 (SD 7.9) the dental college was 32.4(SD 8.1), and AHS was 30.7(SD 7.3). Table 1 shows the mean scores of HL among the health science students and indicating that the HL level among the students was limited as they had problematic HL scores.

According to the index score, the percentage of students showing an excellent score was less than those showing a low score across different streams.

The index score among the various streams has been represented in the bar graph, as shown in Figure 1 below, with a significant percentage of students showing scores falling in the problematic and sufficient range.

The index score among dental and AHS students showed an increase from the 1st years to the 3rd years in the excellent scoring category, showing a better performance among students in higher classes. Since only 2nd-year medical students participated in the study, year-wise conclusions could not be drawn among them (See table 2).

Concerning the percentage distributions on the difficulty-easiness scale, 41.2% of the study participants found it very easy to understand the doctor's or pharmacist's instructions on taking medications. 13.5% found it very difficult to find information regarding the management of mental issues. 7% did not know how to identify health warnings due to behavior such as smoking, low physical activity and drinking too much.

Table 1: Institute wise health literacy score

Institute	Mean	Standard Deviation
Overall	31.32	4.40
Medical	32.78	7.9
Dental	32.52	8.1
Allied Health Sciences	30.57	7.3

Table 2: Year-wise Index Score among dental and allied health students

Institute	Inadequate n(%)	Problematic n(%)	Sufficient n(%)	Excellent n(%)
Dental 1	11(25.6%)	14(32.6%)	16(37.2%)	2(4.7%)
Dental 2	11(21.2%)	16(30.8%)	18(34.6%)	7(13.5%)
Dental 3	4 (14.3%)	9(32.1%)	11(39.3%)	4(14.3%)
AHS 1	54(28.7%)	75(39.9%)	56(29.8%)	3(1.6%)
AHS 2	24(24.5%)	37(37.8%)	31(31.6%)	6(6.1%)
AHS 3	34(15.5%)	77(35.0%)	89(40.5%)	20(9.1%)

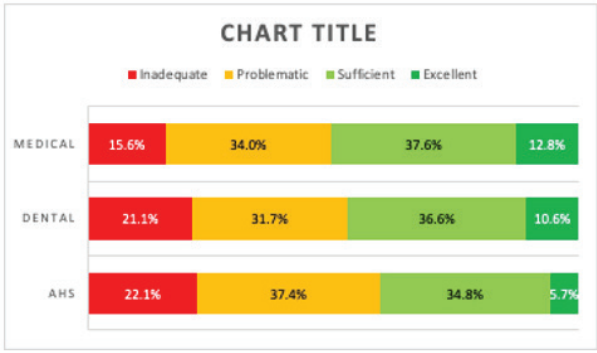

Figure 1: Graphical representation of the index scores

Discussion

The current study indicates that 7.8% of the students have excellent HL, 35.6% have sufficient HL and 35.8% of the students have problematic HL and 20.8% have inadequate HL. These findings are comparable with the findings of the study conducted by Evans AY et al, among students in a university in Ghana, where the students had 12.4% excellent HL, 33% sufficient, 34.2% problematic and 20.4% inadequate HL.[6]

Another study conducted among the general population of Catalan, 84.6% showed sufficient HL, 10.3% inadequate HL, and 5.1% problematic HL. This is higher than the findings of our study. This can be attributed to the 100% literacy rate of Catalan.[7]

In Europe, limited HL was found in 47.6% of a sample among the general population with a mean score of 33.8. The findings of the present study indicate that 56.6% of the students had limited HL with a mean score of 31.32.[8]

In another study among attendees of outpatient clinics at a University hospital in Egypt, it was seen that 34.3% had inadequate HL.[9] The inadequate HL level is less (20.8%) in the current study, which indicates the HL levels are among the health science students.

In a similar study conducted among schoolteachers in Colombo, 61.2% of them belonged to the sufficient HL and only 1% belonged to the inadequate HL.[10] which is in contrast to our study where only 35.6% had sufficient HL. This is due to the usage of the health-promoting school concept among the schools in Colombo where teachers are trained in HL to impart HL to the students.[10] This suggests that HL concept should be ingrained in the curricula of Health sciences institutions which can further contribute to enhancing the HL levels of the

health science students.[11]

The current study shows a significant difference in levels of HL among different health science institutions and across the academic years in each of these institutions. The mean HL scores among the dental and AHS students were significantly higher among senior students compared to the junior students. The medical and dental students had a higher percentage of excellent HL levels when compared to AHS students. This is in coherence with a study conducted among health professional students, where the medical students recorded the highest scores in comparison to the other AHS courses.[12] and also with a study conducted by LOU Peng Yu et al., which stated that because of its disciplinary nature and good executive ability, medical specialty scored significantly higher in health literacy.[13] Most university-based health literacy studies have demonstrated increasing health literacy with an increase in academic level,[14-17] which is consistent with the findings of our study.

Among the various items of HLS EU 16, our study participants found it difficult to access information on managing mental health problems (Item 8). However, they did not find it difficult to decide if they needed a second opinion (Item 5). In the study conducted by Evans AY et al, the students found it difficult to access information for managing mental health problems as well as deciding if they needed a second opinion.[6]

Conclusion

This study is the first of its kind in India to describe comprehensive health literacy among undergraduate university students using an internationally validated instrument. The overall HL was inadequate among the students across various health science courses. The medical students had higher levels of HL among all the health science students. It was also found that the HL levels were higher as they progressed in their academic years. It was found that countries having better general literacy had higher HL levels. This shows that general literacy can influence HL. Incorporation of the HL concept in the curricula across various health science courses will make them more equipped to make better decisions regarding their future community health practices. Mental health is one of the most neglected public health issues in India. More access to mental health information, especially for health science students cannot be overemphasized.

Recommendations

HL component should be included in the curriculum for health science students, especially dental sciences and AHS. Measures have to be taken to enhance general literacy thereby increasing the HL level of the population. Initiatives should be taken by public health sectors to increase the availability of information about mental health and related services, consequently increasing the mental health literacy levels.

Acknowledgment: The authors would like to thank Dr. Prakash Narayanan Vasudevan Potty for his insights with the analytical work for this study. They would also like to thank Dr. Sabu K.M. for providing them with the necessary permission required to conduct the study, from the allied health science institution. The authors would also like to thank Dr. Navya C for her contributions during the data collection process.

Evaluation of Perception on Intra-Oral Scanning and Alginate Impression among Orthodontic Patients in Chennai

Arathi M[1], Arvind Sivakumar[2]

[1]Post graduate Student, [2]Senior Lecturer, Department of Orthodontics, Saveetha Dental College, Saveetha Institute of Medical And Technical Sciences, Chennai, India

Abstract

Background: Most of the treatment modalities in dentistry are based on obtaining study models. The study models are of two types, namely, conventional study models made of gypsum products and digital models

Aim: To evaluate patient's perception on intra-oral scanning and alginate impression in Chennai population.

Methodology: 20 subjects were selected from the Department of Orthodontics, Saveetha Dental College and Hospital, Chennai. Conventional impression was made using alginate and intra-oral scanning was done for the same patient after 5 days. The patients were asked to fill a questionnaire comprising of 12 questions.

Results: Majority of the participants reported that alginate impression had more gag reflex and made the mouth dry. Participants preferred alginate impressions in terms of maximum mouth opening. The overall discomfort was equal for both techniques. Intra-oral scanning consumed more time than alginate impressions. Thus the overall preference rate was equal for both intra-oral scan and alginate impression.

Conclusion: Orthodontic patients in Chennai reported equal preference for intra-oral scan and alginate impression.

Keywords- *Intra-oral scan, alginate impression, conventional impression, patient perception, digital scan*

Introduction

Most of the treatment modalities in dentistry are based on obtaining study models. Study models are the accurate replica of the intraoral structures of the patient that helps in diagnosis and treatment planning even in the absence of the patients. These study models are of two types, namely, conventional study models made of gypsum products and digital models. Conventional study models are obtained by making impressions of the dental arch using various impression materials. The digital models are obtained by either directly or indirectly. Indirect method is by laser or cone-beam computed tomography scanning of plaster models or alginate impressions. Direct method is by scanning the dentition with an intra-oral scanner.[3,5,12-14]

Computer-aided design and manufacturing (CAD-CAM) system, was introduced in the field of orthodontics in the 1990s[1].Even though it was introduced earlier, its use is being gradually increasing only in the recent times for diagnosis, treatment-planning and documentation of treatment results.[13,15-17] The first digital intraoral scanner was introduced by Mormann and Brandestini in the 1980s, and was further developed as a powerful tool for Chairside Economical Restoration of Esthetic Ceramics (CEREC).[2,19,20]

Intra-oral scanning has many advantages over conventional study models from a clinician's perspective. The advantages are that the time required for pouring the cast is minimised, reduced physical storage space, no chances of wear of the models, and no changes

Corresponding author:

with respect to variations in environmental factors [1,4,18,11]. Moreover, scanned images make it easier for the clinicians to communicate the case with their fellow colleagues or technicians.[1,4] Treatment planning and Kesling's set up has become less time consuming with the use of virtual models. Literature reviews report that the measurements made in the intra-oral scanned images and conventional study models are clinically reliable and valid.[2,3]

Even though the clinicians find this new technology advantageous, the advantages from patient's perspective are questionable. Patient's perception on intra-oral scanning can vary among different population, as the attitude or mentality of the people depends on their nature of living and cultural diversity. Therefore, the present study was aimed to evaluate the perception on intra-oral scanning and alginate impression among the orthodontic patients in Chennai.

Material and Methodology

Patient selection

20 subjects (9 males and 11 females) were selected for the study from our department.

Inclusion criteria

- Age group- 15 to 30 years
- Patients with no previous experience on impression making.
- Orthodontic patients before the start of the orthodontic treatment.

Exclusion criteria

- Patients with restricted mouth opening.
- Patient with deep carious lesions.
- Patients with active periodontal disease.
- Patients with temporomandibular disorders.

Study design

Alginate impression making

Maxillary and mandibular tray of appropriate size was selected. Patient was explained about the procedure. Alginate was mixed according to the manufacturer's instructions and the impression was made. Care was taken not to overload the tray with alginate in order to prevent gag reflex. Impressions were made by well experienced clinician, so that good orthodontic diagnostic impressions were made in a single attempt without the need to repeat the impressions.

Intra-oral scanning

Intra-oral scanning was done after 5 days of making alginate impression. Before starting the intra-oral scanning, the procedure was explained to the patient. Intra-oral scanning was done by an experienced clinician using Trios, 3Shape intra-oral scanner. After the completion of the scan, a questionnaire comprising of 12 questions were given to the patient.

Questionnaire

The questionnaire comprised of 12 questions were given as print outs. The questionnaire was designed in such a way that it evaluated both the preference and perception of the patients on impression technique. 6 questions assessed the preference of the patient while 5 questions assessed the perception of gag reflex, pain, discomfort, time consumption etc. The perception and acceptability was assessed by a 5 unit rating scale, i.e., strongly disagree, disagree, neutral, agree and strongly agree. One of the questions was repeated to make sure that the patients fill the questionnaire after carefully reading the questions.

Statistical analysis

Statistical analysis was done using IBM SPSS Statistics Software Version 20.0 for Windows.

Results

Tables 1 and 2 represent the frequency percentage for the questions that assessed patient preference and perception respectively. It was observed that all the questions were answered by all the subjects.

Table 1: Frequency percentage for questions that assessed patient preference

Questions	Alginate impression (%)	Intra-oral scanning (%)
Which impression technique do you feel is comfortable?	55	45
Which impression technique do you feel has minimum gagging reflex?	0	100
Which impression technique has more breathing difficulty?	85	15
Which impression technique do you prefer in terms of maximum mouth opening?	65	35
Which impression technique do you think is more time consuming?	10	90
Which impression technique do you think has more gag reflex?	100	0
Which impression technique do you prefer/suggest in case of a friends' need for impression making?	50	50

Table 2: Frequency percentage for questions that assessed patient perception and acceptability

Questions	Strongly agree (%)	Agree (%)	Neutral (%)	Disagree (%)	Strongly disagree (%)
Intra-oral scanning is more comfortable than alginate impression.	15	30	55	0	0
Intra-oral scanning is a painless procedure compared to alginate impression.	10	30	60	0	0
Alginate impression has a burning sensation compared to intra-oral scanning.	5	10	30	50	5
Alginate impression makes your mouth dry compared to intra-oral scanning.	0	45	30	20	5
Intra-oral scanning is a less time consuming procedure than alginate impression	0	0	40	45	15

Discussion

The present study was targeted towards the young orthodontic patients in Chennai who had no previous experience with any type of impressions in order to prevent skewing of the data with any previous experience. Patients with restricted mouth opening, TMJ disorders, active periodontal disease and deep carious lesions were excluded since these factors can cause pain and discomfort while taking impressions or scanning and skew the result. Intra-oral scanning was done 5 days after taking alginate impression in order to reduce the chair side time for that particular day and continuously opening the mouth wide can lead to pain and discomfort.

The questionnaire comprised of questions to identify both preference and perception of the patients on alginate impression and intraoral scanning. 6 questions assessed the preference and 5 questions assessed perception. One of the questions was repeated to make sure the participants read the questions carefully before answering. It was noted that all the subjects responded correctly to the repeated question. The questions were focused on gag reflex, breathing difficulty, comfort, burning sensation, mouth dryness, and time consumption of both alginate impression and intra-oral scanning.

Results of the present study shows that patients who had more gag reflex while making alginate impressions preferred intra-oral scanning while those who did not have gag reflex while making alginate impressions preferred the conventional alginate impressions. Most of all the patients had the same opinion that intra-oral scanning was a more time consuming procedure than alginate impressions. Majority of the patients experienced dryness of the mouth after making alginate impressions. When maximum mouth opening was considered patients preferred alginate impression. This may be because patient had to open the wide while scanning the most distal aspects of the oral cavity. When the overall comfort and preference was assessed, both alginate impressions and intra-oral scanning were at the same level.

Studies by Burzynski et al[6], Burhadt et al[5], Mangano et al[7],Yuzbasioglu et al[8], Sfondrini et al[9], Vasudavan et al[10] reported that orthodontic patients preferred intra-oral scanning than conventional impression techniques. Burzynski et al[6] and Burhadt et al[5] also reported that the eventhough intra-oral scanning consumed more time than conventional impression techniques, patients preferred digital impressions. All the studies report that most of the patients experienced gag reflex during alginate impression. The overall dsicomfort level was the same for both the techniques. The results of the present study correlated with the results of the previous studies in terms of perception of the patient on alginate impressions and intra-oral scanning. Whereas, when preference was considered, the results of the present study differed from that of the previous studies. The participants of the present study had equal level of preference for both the techniques. Since the sample size of the present study was limited, future studies on the perception of intraoral scan and alginate impressions among orthodontic patients in Chennai, with a large sample size is required.

Conclusion

We found that the orthodontic patients in Chennai had equal preference for intra-oral scanning and alginate impression. As the intra-oral scanning technology continues to advance, the time consumed for the technique will decrease and the tip size will reduce. This might lead to greater acceptance of intra-oral scanning by the patients.

Ethical Clearance: The study was approved by the Institution Review Board, Saveetha Dental College and Hosiptals, Saveetha University, Chennai.

Knowledge, Attitude and Practice of Dentists Towards Provision of Dental Care to Pregnant Women

Aroonika S. Bedre[1], Subash Sharma[2]

[1]Graduate Student, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Poonamallee High Road, Chennai, Assistant Professor, Department of Conservative Dentistry and Endodontics, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University

Abstract

Aim : The objective of this study was to evaluate the knowledge, attitude and practice of dentists towards provision of dental care to pregnant women.

Material and Method: A multiple choice questionnaire was self-administered to dentists in Chennai. The collected data was statistically analysed.

Results: Although majority of the dentists were well informed about the management of pregnant patients, dilemmatic attitudes were seen regarding dental radiographs, local anaesthesia and prenatal fluoride supplementation.

Conclusion: This demonstrates the need to broaden the knowledge of dental surgeons via CDE programs and workshops.

Keywords: *Oral health, pregnancy, dentists, knowledge, drugs, radiographs.*

Introduction

Pregnancy begins when the embryo becomes implanted into the endometrial lining of a woman's uterus. In humans, it lasts for approximately nine months. It is divided into 3 trimesters[1]. The gestation period is characterised by both physiological and emotional changes. The hormonal transformations may bring out oral changes, requiring greater assistance from dentists [2-5]. Common symptoms such as gastro-intestinal reflux, nausea and vomiting result in an acidic oral environment that promotes demineralization of tooth enamel and the growth of dental caries causing pathogens [6-9]. Rising levels of oestrogen and progesterone produce an inflammatory response that predisposes women to gingival manifestations like gingivitis, periodontitis, gingival hyperplasia and pyogenic granuloma [6,8]. In fact, pregnancy gingivitis is recognized as the most common oral manifestation in pregnant women [10-12]. Moreover, the increased susceptibility to infections and reduced ability to repair soft tissue caused by hormonal fluctuations increases the risk of developing periodontitis [13]. Untreated periodontitis results in loss of alveolar bone, supporting structures and ultimately in tooth loss [14]. Oral disease during pregnancy could lead to complications beyond the oral cavity. Periodontal disease, has been linked to preeclampsia (pregnancy hypertension) gestational diabetes, preterm birth, low birth weight and still births [15-24].

Pregnancy is a normal physiological phase in a woman's lifetime and warrants the routine preventive and emergency oral health care provided to other members of the general population [25]. The provision of dental treatment during pregnancy is not only safe, it is also an important aspect of antenatal care and is advised by the American Congress of Obstetricians and Gynecologists and the American Academies of Periodontology and Pediatrics [26-31].

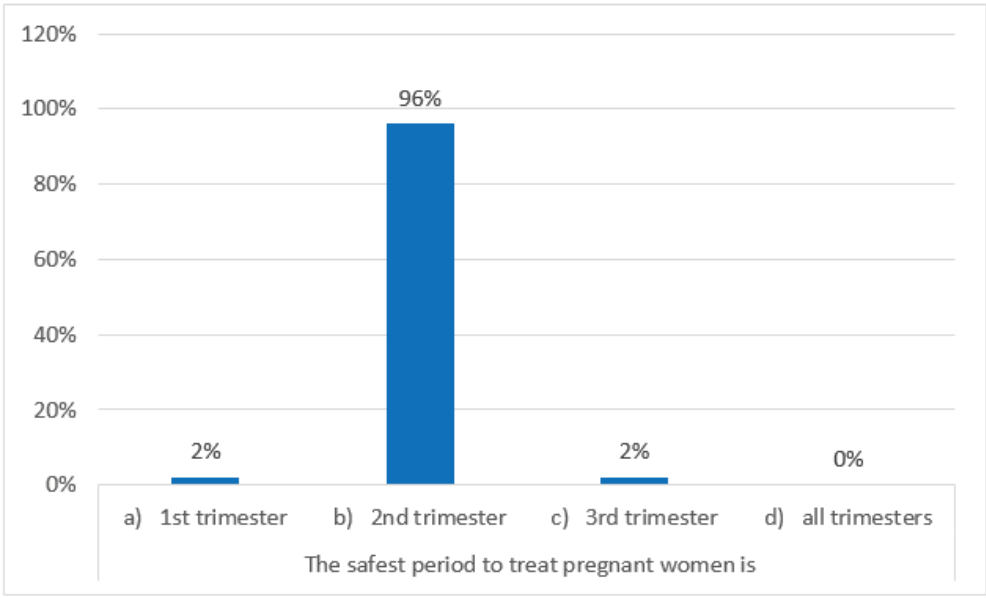
Comprehensive oral examination of pregnant patient is recommended to diagnose disease processes that need immediate treatment to prevent self-medication with unsafe over the counter medications for pain relief [32]. In a study it was found that general dentists with low/moderate knowledge were less likely to provide comprehensive care for the pregnant patient [33]. Efforts to promote oral health of pregnant woman have increased in the recent years due to identified link between maternal transmission of bacterial and early childhood caries [34]. In addition, poor maternal oral health has also been linked to adverse pregnancy outcomes [32, 34, 35]. Nutritional intake of pregnant woman can also be affected due to poor oral health which in turn can impair the supply of nutrients necessary for fetal growth and survival [32].

Most pregnant patients are generally healthy and hence dental treatment need not be denied solely because they are pregnant [32,36]. There is concern among dentists that dental procedures that cause bacteremia may lead to uterine infections, spontaneous abortions or preterm labor. However, there is no evidence that dental procedure induced bacteremias increases the woman's risk of experiencing fetal loss or preterm labor or delivery [37]. Inspite of this, practitioners may hesitate to treat pregnant patients for the fear of injuring either the mother or the unborn child [32,37,38]. This may be due to lack of preparation and the knowledge required, which may aggravate the oral condition of the patient and bring harm to both mother and baby [39, 40]. This reluctance is attributed, to deficiencies in the training of undergraduate dental surgeons [41]. Curricular studies of US and Canadian dental schools suggest changes towards a more interdisciplinary curriculum in collaboration with other professions' health schools, is desirable [42].

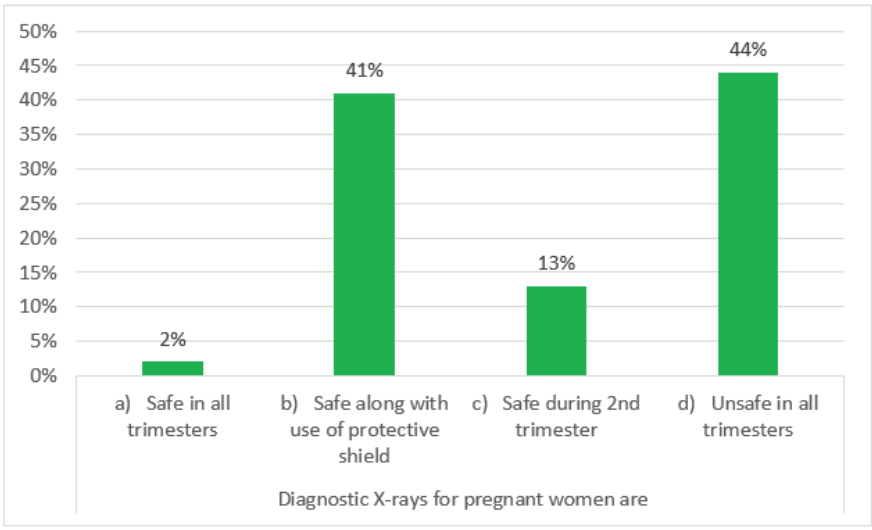
Materials and Method

A cross-sectional survey was conducted among dentists in Chennai in December 2017. The survey instrument was a structured, self-administered multiple choice questionnaire which was developed in consultation with oral medicine specialist to improve its content validity. The study included a random convenience sample comprising of 200 participants. The questionnaire had 20 questions in total, regarding drug administration, infection consequences, oral findings, treatment aspects, and radiation exposure with respect to pregnant patients. Data was collected and statistically analysed using Chi-square test.

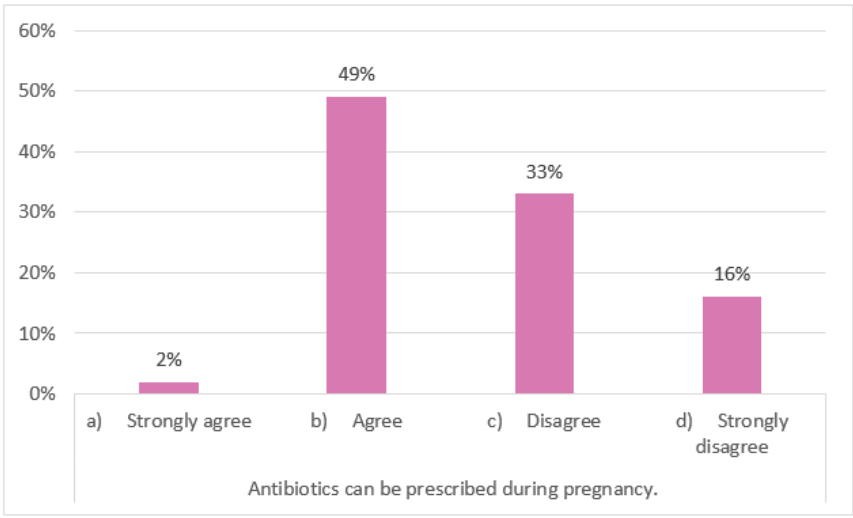
Results



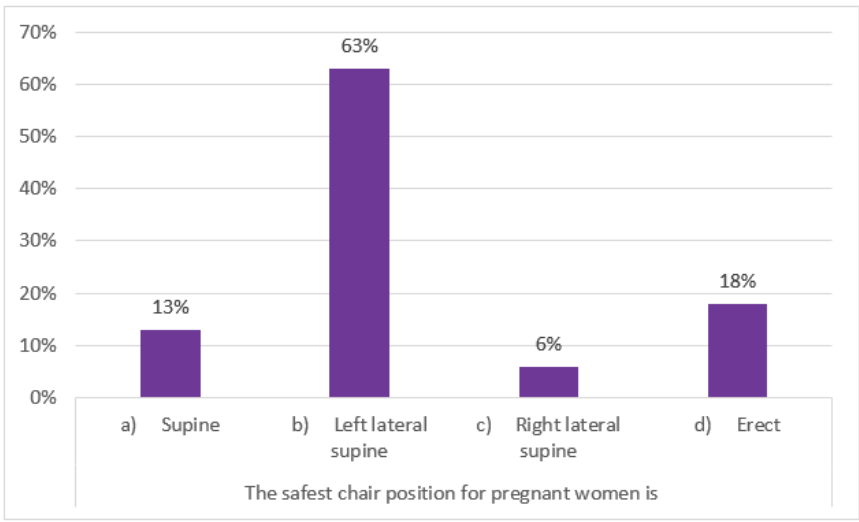
Graph 1: Safest period to treat pregnant women



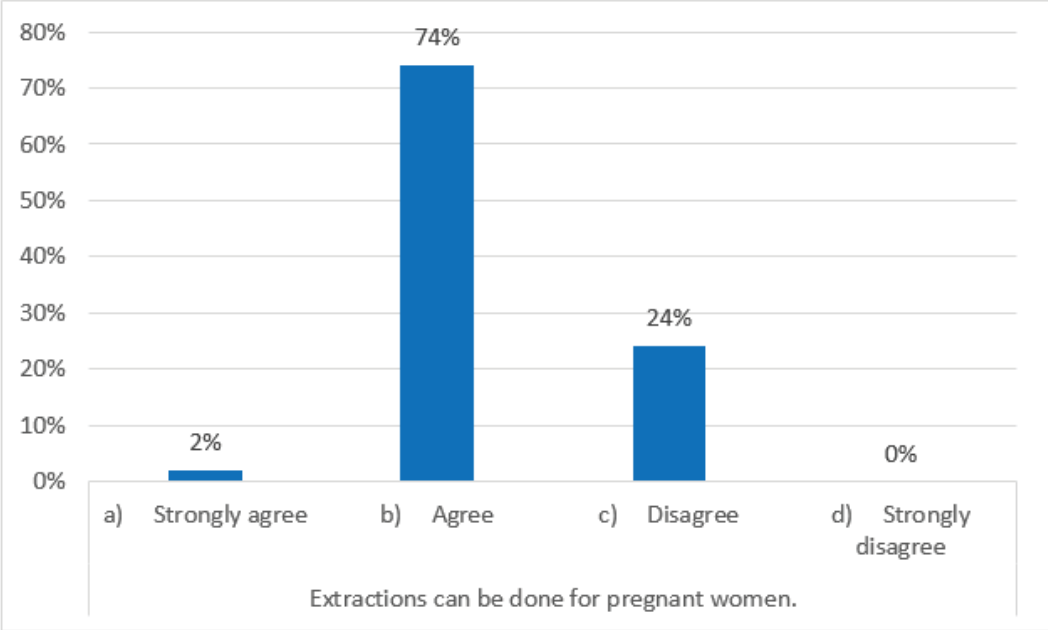
Graph 2: Diagnostic X-rays for pregnant women



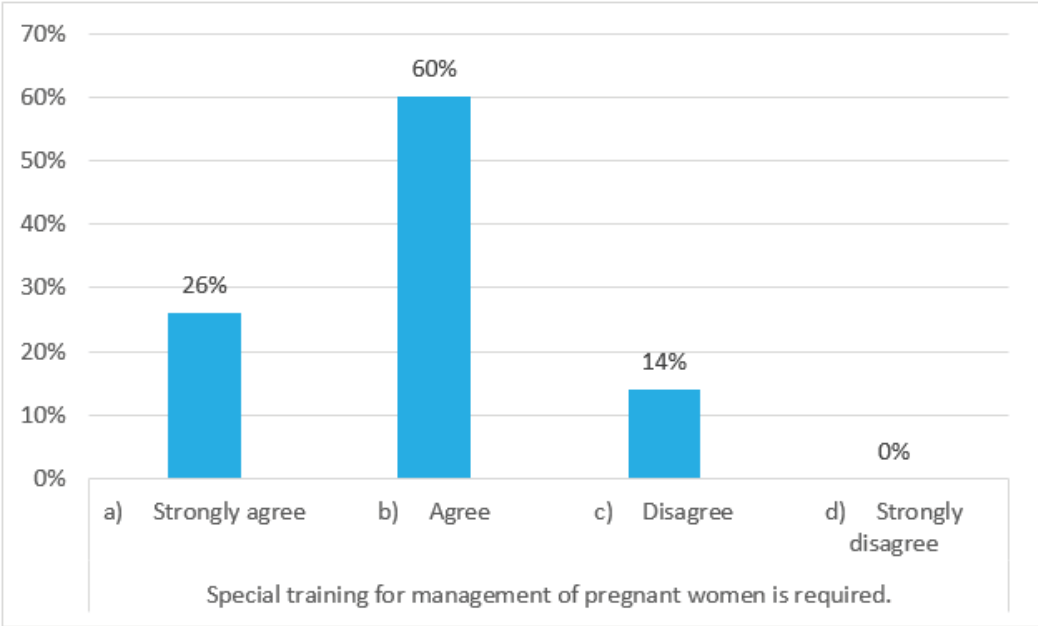
Graph 3: Prescription of antibiotics during pregnancy



Graph 4: Safest chair position for pregnant women



Graph 5: Whether extractions can be done for pregnant women



Graph 6: Whether special training for management of pregnant women is required

Discussion

Most of the study participants (91%) were aware of the fact that the most common oral manifestation in pregnant women is gingival disease. Similar results were obtained in several other studies too [43]. The increase of the level of progesterone in the gingiva increases the synthesis of prostaglandins, being the probable explanation for the intensification of gingival inflammation [44]. Majority of the dentists (96%) knew that the 2nd trimester was the safest period to treat pregnant women (graph 1). During the second trimester organogenesis is completed and hence is the safest period for providing dental care. Though there is no risk to the fetus during the third trimester the pregnant woman may experience discomfort due to the increased size of the

uterus [43]. Dental radiographs can be taken during all the trimesters of pregnancy if standard radiation hygiene practices like use of lead apron and thyroid collar are followed [45]. Estimated fetal exposure from a single dental radiograph is 0.0001 rad. Therefore, it would take 50,000 examinations to reach the cumulative 5-rad dose limit [46]. In our study, 44% of the members considered dental radiography unsafe in all trimesters, 41% of them considered it safe along with use of protective shield, and 13% of them considered it safe during 2nd trimester (graph 2). The results were similar to other studies as well [43,47].

Food and drug administration (FDA) has classified drugs into five categories. Drugs in category a and b are safe for use, whereas those in category c may be used only if the benefits outweigh the risks. Drugs in category d are avoided with some exceptional circumstances, while those in category x are strictly avoided [48]. Most antibiotics permitted by the dentist belongs to category b of FDA classification with exemption of gentamycin and doxycycline both of which fits in to class d. Penicillins and cephalosporins which are beta-lactum ring derived antibiotics are the first choice for orofacial infections [49]. 49% of the participants agreed that antibiotics can be prescribed during pregnancy, while 33% of them disagreed and 16% of them strongly disagreed (graph 3). Regarding the use of antibiotics, 80% of the dentists said they would prescribe amoxicillin for pregnant women, while 11% said cephalosporin. Similar results were seen in several other surveys [43]. Acetaminophen is the most common and safest analgesic used in pregnancy and is categorized in group b by the FDA classification.[50] Most of the participants (74%) were aware of the fact that acetaminophen is the safest analgesic for pregnant women. Anaesthetics such as lidocaine and prilocaine are categorized in class b of the FDA classification. The concentration of epinephrine in a local aesthetic used in dentistry is considered safe provided a check is kept on the proper aspiration technique and the amount injected [51]. In our study, regarding the use of anesthetic, 50% said they would administer lidocaine without adrenaline for pregnant women, while 38% said they would administer lidocaine with adrenaline. Similarly, results from several studies suggest that dentists avoid the use of vasoconstrictors in pregnant women [52]. Regarding inhalation sedation with nitrous oxide, 66% of the participants in our study disagreed with the fact that it is advisable for pregnant women, while 21% agreed with the fact. Nitrous oxide is not listed in the FDA classification as its use during pregnancy is still controversial. It is best to avoid nitrous oxide during first trimester [53]. Regarding inhalation sedation with midazolam oxide, 68% disagreed with the fact that it is advisable for pregnant women, while 18% agreed with the fact. Benzodiazepines are contraindicated during pregnancy, as they could have a teratogenic power [52].

During treatment, the patient should not be placed in the supine position because of the possibility of supine hypotensive syndrome and deep venous thrombosis. If supine hypotension develops, rolling the patient on to her left side affords return of circulation to heart by moving the uterus off the vena cava [43]. 63% of the participants knew that the left lateral supine position is the safest chair position for pregnant women, while 18% of them said erect position was the safest (graph 4). 58% disagreed that prenatal fluoride supplementation (for pregnant women) reduces risk of caries in children, while 34% agreed. Although fluoride is a known substance that prevents tooth decay, fluoride supplements are not necessary for pregnant women because its benefits are proven only in the postnatal stage [43]. It's safe to perform elective procedures i.e. Root canal, extraction, restorations during the 2nd and 3rd trimesters [48]. 74% agreed that extractions can be done for pregnant women, while 24% disagreed (graph 5). 76% of the study participants agreed that root canal treatment can be done for pregnant women and 18% of them strongly agreed. 55% of the dentists disagreed that periapical surgeries can be done for pregnant women, while 36% agreed. 71% of the people agreed that amalgam restorations can be done for pregnant women, while 23% disagreed. 60% agreed and 26% strongly agreed that special training is required for management of pregnant women (graph 6). Similarly, in a study by Praveena Tandradi participants claimed to have "just a little" information and were interested to attend CDE programs [43].

Conclusion

Majority of the dentists in our study were well informed about the dental management of pregnant women. Nevertheless, dilemmatic attitudes were seen in relation to few aspects such as dental radiographs, local anaesthesia administration and prenatal fluoride supplementation. This demonstrates the need to broaden the knowledge of dental surgeons regarding dental care of pregnant women via changes in dental curriculum, CDE programs and workshops.

HIV/AIDS – Related Knowledge and Attitudes Amongst Medical, Dental and Nursing Students of Saveetha University, Chennai

Aroonika S. Bedre[1], Gheena S[2]

[1]Graduate Student, [2]Reader, Dept. of Oral Pathology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai

Abstract

Aim: This study is aimed at assessing the HIV/AIDS - related knowledge and attitudes amongst medical, dental and nursing students of Saveetha University, Chennai. With increasing number of people having HIV/AIDS, students of medicine and health allied science should have sufficient knowledge about the transmission of the disease, and their attitude should meet professional expectations.

Materials and Method: A self-administered questionnaire was devised and a cross sectional study was conducted on 300 students in toto i.e. 100 medical students, 100 dental students and 100 nursing students. Data recorded was subjected to statistical analysis and appropriate conclusions were drawn.

Results: A small number of students in the medical fraternity had inadequate knowledge and misconceptions about HIV and harboured negative attitude towards HIV patients.

Conclusion: The findings from our study suggest that in order to instil a professional, ethical and empathetic approach towards AIDS patients, awareness and training programs are essential.

Keywords*: Knowledge, attitude, HIV/AIDS patients, medical students, dental students, nursing students.*

Introduction

AIDS is a serious medical condition caused by HIV. The patient's immune system becomes too weak to fight off infection, resulting in serious complications that ultimately prove fatal. The first case of HIV was recognized in the U.S. in 1981.[1] In 2009, India was estimated to have the third highest number of HIV infections in the world, with about 2.4 million people currently living with HIV/AIDS. However, according to United Nations 2011 AIDS report, there has been a 50% decline in the number of new HIV infections in the last 10 years in India. [2]

In 1988, the WHO has stated that all dentists should treat HIV patients.[3] Despite these recommendations, ignorance of the risk of HIV transmission during dental procedures has led many dentists to refuse and/ or become reluctant to treat these patients. [4-6] This is particularly significant in developing countries like India where these patients do not receive professional treatment owing to financial barriers. [7]

Students of medicine and health allied sciences play an important role in the delivery of health care to HIV/ AIDS individuals and are therefore of special interest and importance in this respect. With increasing number of people having HIV/AIDS, students of medicine and health allied science should have sufficient knowledge about the transmission of the disease, and their attitude should meet professional expectations. Thus a cross sectional study was conducted to assess HIV/AIDS – related knowledge and attitudes amongst these students.

Materials and Method

The cross sectional study was conducted in Saveetha University, Chennai during April 2015 after receiving approval from the Review Board of Saveetha Dental College. The study included a random convenience sample comprising of 150 participants. ie. 75 from the medical, dental and nursing sectors each. These students were either third year students, fourth year students or interns. Their knowledge about AIDS and attitude towards HIV patients was assessed by a structured, self -administered questionnaire. Knowledge based questions covered various aspects such as causative agent, pathogenecity, transmission, prevention and treatment of AIDS patients. (Table 1) Attitude based questions tested students' empathy, neutrality and indifference towards AIDS patients. Data was collected and analyzed.

Results

- 97.3% of all the students were aware that AIDS stands for Acquired Immuno Deficiency syndrome and 96.5% knew that its causative agent is Human Immuno deficiency Virus.

- 90% of the students knew the difference between AIDS and HIV.

- 57.7% of them agreed that AIDS is less communicable than Hepatitis B.

- 43% of them knew that the virus is icosahedral in shape.

- 88.3% were aware that gp 140 and 41 are the transmembrane glycoproteins present in the envelope of the virus.

- 71% of the members knew that the virus binds to CD4 and chemokine receptors on the host cell.

- 46.7% were aware of the classification of HIV based on CD4+ cell counts i.e. .

- 54.8% of them agreed that there is no phase during which all the viruses are in the form of proviral DNA when the host cells remain uninfected.

- 77.3% of the study population were aware of the fact that HIV infected patients can remain asymptomatic for months or years.

- 97% of the study members agreed that sexual contact, blood transfusion, sharing needles/ syringes and mother to child are the modes of HIV transmission.

- 83.68% of the students knew that mosquito bites, saliva, sweat, tears, social contact (casual kissing, hugging, sharing utensils and clothes), toilet seats, coughing and sneezing are not responsible for HIV transmission.

- 94.5% of the study participants knew that ELISA and Western blot are the preliminary and confirmatory tests for AIDS.

- 79.3% of the people knew that one cannot protect themselves by being vaccinated against AIDS.

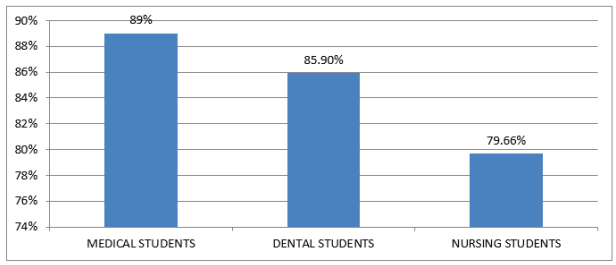
- 88.2% of the students agreed that abstinence, fidelity and condom usage can lower risk of AIDS

- 88.2% were aware that barrier technique includes wearing double gloves, surgical cap, protective eye wear and disposable gowns.

- 34.6% of the people agreed that heat sterilization does not kill HIV.

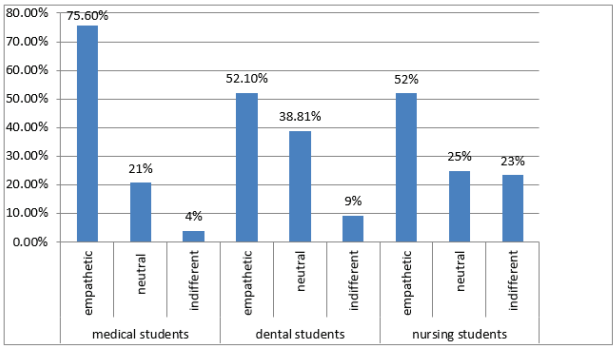
- 77.5% of the study participants knew that reverse transcriptase inhibitors and anti-viral drugs are the most widely available HIV medication.

- 75.8% of the study population were aware that there are specialized clinics for treatment of HIV patients.



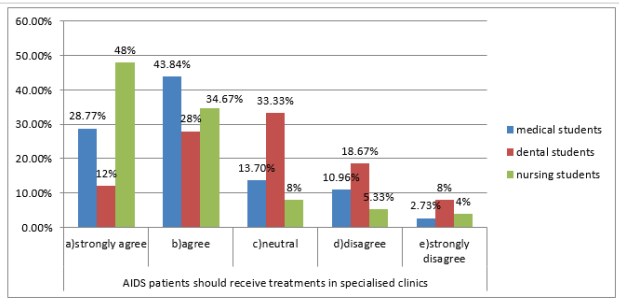
Graph 1: Over all knowledge levels.

- 84.85% of all the students gave the correct response to knowledge based questions. 89%, 85.8% and 79.7% of medical, dental and nursing students respectively gave the correct response to knowledge based questions.



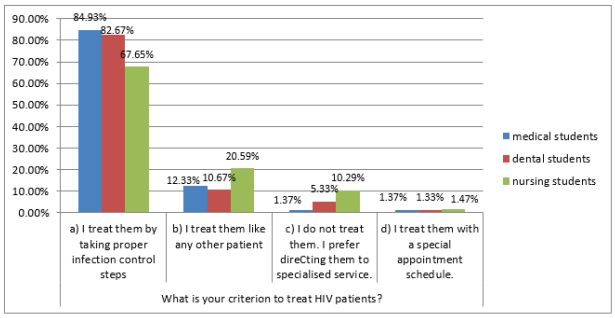
Graph 2: Over all kinds of attitude.

- 59.90 of all students showed empathetic attitudes. 75.6%, 52.10 and 52% of medical, dental and nursing students respectively showed empathy towards HIV patients. 21%, 38.81% and 25% of the same groups showed a neutral attitude. While the rest remained indifferent.



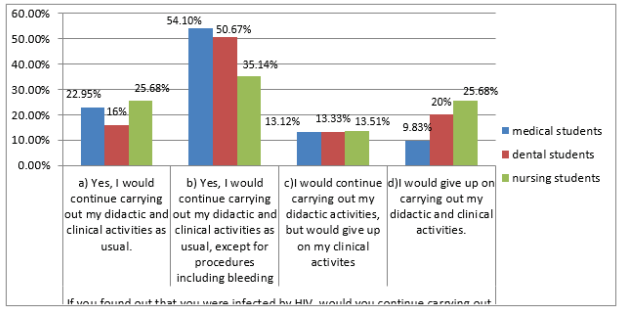
Graph 3: Student's response to whether AIDS patients should receive treatments in specialized clinics.

- And 65% of the study participants felt that these patients require treatment in specialized clinics.



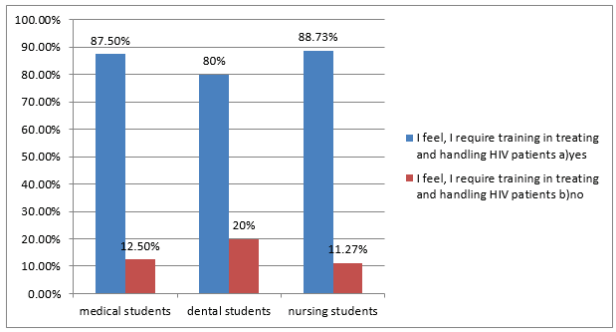
Graph 4: Students' criterion to treat HIV patients.

- 78.4% of the entire group responded that they will treat AIDS patients with proper infection control steps.



Graph 5: Students' response to whether they would carry out their health care duties if they were found to be infected with AIDS.

- 46.6% of the participants altogether claimed that they would continue carrying out their didactic and clinical activities as usual, except for procedures including bleeding, if they contract AIDS themselves.



Graph 6: Students who felt they required/ didn't require training in handling AIDS patients.

- 85.4% of the total students felt that they require training in treating HIV patients.

Discussion

In our study majority of the participants were aware of the full form of AIDS, its causative agent, the difference between AIDS and HIV, the transmembrane glycoproteins on the virus, the host receptors, the latency period, modes that help in HIV transmission. They were also aware of the preliminary and confirmatory tests for AIDS. They agreed that abstinence, fidelity and condom usage can lower risk of contracting AIDS. And were cognizant of the barrier techniques that should be adopted by health professionals and the presence of specialized clinics for treatment of HIV patients. They also knew that reverse transcriptase inhibitors and anti-viral drugs are the most widely available medication and that there is no vaccination. Only a minority of our study participants were aware of the shape of the virus, the classification of AIDS based on CD4 count, and that

heat sterilization cannot kill the virus.

A commendable majority (84.5%) of all the students gave the correct response to knowledge based questions. Medical students seemed to have the most knowledge compared to dental and nursing students (graph 1). Although our results show satisfactory levels of knowledge, considerate number of students had misconceptions regarding the transmission of AIDS. Medical students were also the most empathetic, as with knowledge comes empathy (graph 2). Most of the students across all specialties felt that patients require treatment in specialized clinics (graph 3). They agreed that they would take proper infection control steps to treat them (graph 4). Majority of the people mentioned that if they contracted AIDS themselves, they would continue their professional activities but would give up on procedures involving bleeding (graph 5). Also, a large number of the participants felt the need to undergo training in treating AIDS patients (graph 6).

Various similar studies have been conducted worldwide, and wide differences in results have been obtained. According to studies conducted by Jain et al and Shan et al, in Udaipur and Bhopal respectively, over all knowledge levels were found to be satisfactory.[8,9] Excellent knowledge levels of 78.8% and 82.1% were obtained in studies among Indian and Iranian dental students conducted by Ashish Aggarwal and Sadeghi respectively. [10] According to Hidayathulla et al, overall knowledge and attitudes of dental students in Bangalore was moderately adequate to adequate. [11]

According to Daneil M, lack of knowledge about transmission of HIV was observed among the healthcare professionals in private and government hospitals in India. His study had identified serious knowledge gaps among medical practitioners leading to refusal of treatment to persons living with HIV. [12] According to Abhimanyu et al, from Bhubaneshwar and Anjum et al from Karachi low knowledge and attitude scores were found. [13,14] In a study by V. D. Thenarasu among dental students, interns had more knowledge and awareness compared to final year students. [15]

According to McCartan, there are reports of reluctance by dentists to treat patients, including denial of treatment. [16] A study on medical students conducted by Mohsin et al, has shown certain misconceptions regarding transmission of AIDS. [17] According to Azodo CC willingness to treat AIDS patients among dental students appeared to be related to their knowledge of the disease, and understanding the modes of its transmission.[18]

Although there is considerable research on AIDS, uncertainty towards HIV positive patients and refusal to treat them still persists along with the fear and possibility that an HIV positive professional might be prevented from practising his profession. Our participants have good knowledge about AIDS and also empathise HIV patients. Increased knowledge of issues concerning HIV has led to increased willingness to treat these patients.

Conclusion

A small number of students in the medical fraternity had inadequate knowledge and misconceptions about HIV and harboured negative attitude towards HIV patients. These findings suggest that awareness and training programs are essential in order to instil a professional, ethical and empathetic approach towards AIDS patients.

Stress, Obesity and Quality of Life in Adolescents

Arun Kumar[1], Chitwan Bhasin[2], Udai Prakash Verma[3]

[1]Assistant Professor, [2] M.A. Student, Psychology, [3]Research Scholar, Department of Psychology, Gurukula Kangri Vishwavidyalaya, Haridwar, Uttarakhand, India

Abstract

Stress and obesity has emerged as a major problem in society. According to "The Economic Times" report, India is second largest in the case of obese children in the world[1].The present study is an attempt to investigate the obesity, stress and quality of life in adolescents. For this sample of 60 (thirty each) obese and non-obese adolescents in the age range on 13 to 17 years were included in the study through purposive sampling technique from district Haridwar. WHOQOL-BREF and the Student Stress Scale were used to measure the quality of life and stress of adolescents. Critical analysis of the data revels that significant differences were found in stress and quality of life in obese and non-obese adolescents.

Keywords: *Obesity, Stress, Quality of life, Adolescents*

Introduction

Obesity is a global public health challenge that not only increases the number of chronic disease like diabetes, cardiovascular disease and cancer (Foss and Dyrstad, 2011) but also stress, depression and many more mental health disorder[2]. If a person is 20 percent more than normal body weight then he is called fat. This normal body weight is taken into account with height, age, gender and construction. According to the WHO (2000), criteria, BMI of 25 kg/m or more and less than 30 kg/m indicates overweight, and BMI of 30 kg/m or more obesity[3].

Stress is the body's emotional and physical response to the danger of the risk mainly in the environment. In psychological terms, the body is being ready to "fight or flight". According to Koch and his associates (2008), Stress in the family increases the risk of obesity in children[4]. Further Foss and Dyrstad (2011), in the finding of research describe that stress is a cause of obesity[2]. Eating behavior of people suffering from stress or anxiety is eating behaviors similar to obese (Nishitani and Sakakibara, 2005)[5]. Stress increases the secretion of glucocorticoids, which stimulates food and increases insulin. This gives rise to obesity (Dallman, 2010)[6]. In stress, the person either consumes more food and increases the weight, or eats lesser which result in decrease in weight. Comfort food leads to abdominal obesity. "Comfort foods" help in reducing severe stress, which later causes obesity (Dallman *et al.*, 2005)[7]. High level of stress changes the eating pattern and increases consumption of highly palatable (HP) foods (Sinha and Jastreboff, 2013)[8]. The condition of obese children is worsened due to general health, psychosocial functioning, and specific health disorders (Halfon *et al.*,2013)[9]. Binge eating disorder (BED), body image, self-esteem, mood disorders, and social and family factors help in increasing obesity in different ways (Talen and Mann, 2009)[10].

According to the World Health Organization (WHO), quality of life is defined as ―the individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals. It can be expected that obesity has a bad effect on the quality of life (Lahteenkorva *et al.*, 1995)[11]. In adolescence, poor physical quality of life is associated with obesity (Swallen *et al.*, 2005)[12]. Obesity has a negative effect on the physical and psychosocial aspects of the quality of life (Kushner and Foster, 2000)[13].

Email: arunk@gkv.ac.in

The following factors contribute to increasing obesity - genetic factors, dietary intake, physical activity, environmental and socioeconomic factors, eating disorders, and social influences (Manna and Jain, 2015)[14]. Low social class category women are more likely to have obesity than those of high social class category (Moore *et al.*, 1962)[15]. Obesity affects physical, mental health and health related quality of life directly - indirectly (Dixon, 2010)[16]. Fat children have to face more mental problems (Sawyer *et al.*,2006)[17]. Thus in the present investigation an attempt is made to investigate difference in the level of stress and quality of life in obese and non-obese adolescents.

Objectives

The main objectives are:

1. To study the level of stress in obese and non-obese adolescents.

2. To study the level of quality of life in obese and non-obese adolescents.

3. To find out the difference in the level of stress and quality of life of obese and non-obese adolescents.

Hypothesis

The main hypotheses have been formulated are:

1. There will be significant difference in the level of stress of obese and non-obese adolescents.

2. There will be significant difference in the level of quality of life of obese and non-obese adolescents.

Method

Sample

For this study, samples of 60 (thirty each) obese and non-obese adolescents in the range of 13 to 17 years were undertaken. The participants were selected without any bias through purposive sampling technique from district Haridwar.

Tools

The Student Stress Scale (Bhatia and Pathak, 1999)[18]

WHOQOL-BREF(World Health Organization, 1996)[19]

Procedures

Every participant was seated comfortably and informal consent was taken for participation in the study. All two tests were administered individually and instructions for the test clearly delivered to each participant. Responses to Student Stress Scale and WHOQOL-BREF were noted down. The tests were administered strictly according to their prescribed manual instructions. Participants were assured that their results and the information obtained would be kept confidential and used for research purpose only.

Statistical Techniques and Analysis of Data

The necessary data for each of the test that was used in the study was collected and scrutinized; scores were tabulated for finding out the nature of test scores of all variables. Mean, median, standard division and *t*-test were conducted.

Results and Discussion

The present study has been undertaken to assess the stress and quality of life among obese and non-obese adolescence. The data was collected from district Haridwar (Uttarakhand). The data has been organized and described to yield the statistics namely mean and standard deviation to study the general nature of the data sample for the variables of stress and quality of life.

Table-I: Mean, standard deviation, standard error mean and *t*-value of Stress of obese and non-obese adolescence.

Variable	Group	N	Mean	S.D.	t-value
Academic Stress	Non-obese	30	15.98	3.745	1.092NS
	Obese	30	16.90	2.695	

Cont... **Table-I: Mean, standard deviation, standard error mean and *t*-value of Stress of obese and non-obese adolescence.**

Financial Stress	Non-obese	30	11.77	3.245	2.163*
	Obese	30	13.57	3.202	
Vocational Stress	Non-obese	30	15.03	3.605	0.492NS
	Obese	30	14.63	2.606	
Family Stress	Non-obese	30	13.17	4.136	1.246NS
	Obese	30	14.43	3.730	
Social Stress	Non-obese	30	12.43	3.839	2.242*
	Obese	30	14.73	4.102	
Emotional Stress	Non-obese	30	13.70	3.415	2.149*
	Obese	30	15.67	3.670	
Total Stress	Non-obese	30	81.80	11.86	2.497**
	Obese	30	89.90	13.22	

NS not significant, * significant at level of 0.05, ** significant at level of 0.01

Table-I shows that mean score and standard deviation of stress of obese and non-obese adolescents. This shows no significant difference in the academic stress, vocational stress and family stress of obese and non-obese adolescents but financial stress, social stress, emotional stress and total stress have significant difference of obese and non-obese adolescents. So hypothesis-1 is partially accepted and shows that there is significant difference in level of financial stress, social stress, emotional stress and total stress of obese and non-obese adolescents. Study of Scott *et al.* (2008), supports present study. Obesity significantly associated with mood disorder, major depressive disorder, anxiety disorder, and most strongly with some individual anxiety disorders such as post-traumatic stress disorder[20].

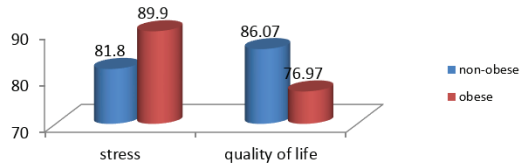
Table-II: Mean, standard deviation, standard error mean and *t*-value of Quality of life of obese and non-obese adolescence.

Variable	**Group**	**N**	**Mean**	**S.D.**	**t-value**
Physical	Non-obese	30	24.87	4.918	1.422NS
	Obese	30	23.03	5.068	
Psychological	Non-obese	30	21.50	3.130	2.338*
	Obese	30	19.07	4.152	
Social	Non-obese	30	10.03	2.198	3.315**
	Obese	30	7.63	2.684	
Environmental	Non-obese	30	29.67	4.294	1.967*
	Obese	30	27.23	5.224	
Total Quality of life	Non-obese	30	86.07	12.225	2.587**
	Obese	30	76.97	14.896	

NS not significant * significant at level of 0.05 ** significant at level of 0.01

Table-II shows that mean score and standard deviation of quality of life of obese and non-obese adolescents. This shows no significant difference in the physical level of obese and non-obese adolescents but psychological, social, environmental and total quality of life has significant difference of obese and non-obese adolescents. So hypothesis-2 is partially accepted and shows that there is significant difference in level of psychological, social, environmental and total quality of life of obese and non-obese adolescents. Study of Kushner and Foster (2000) supports present study. Obesity has a negative effect on the physical and psychosocial aspects of the quality of life[21].

Bar Diagram-I
Bar diagram of the mean score of Stress and Quality of life in obese and non-obese adolescence.



Bar diagram shows that mean score of stress is high in obese adolescents but mean score of quality of life is high in non-obese adolescents which mean that obese adolescents feel more stress than non-obese. Also, the level of quality of life is not good compared to non-obese.

Conclusion

In the present research comparative study on obese and non-obese adolescents on stress and quality of life have been conducted. Results show that there are significant differences have been found in the stress and quality of life of obese and non-obese adolescents. Study of (Halfon *et al.*, 2013) and (Dixon, 2010) supports present study. According to Halfon's study, Obese children have increased odds of worse reported general health, psychosocial functioning, and specific health disorders[9]; According to Dixon, obesity has a clearly measurable impact on physical and mental health, health related quality of life, and generates considerable direct and indirect costs[16]. There is a positive correlation between stress and obesity index in male children (Kim *et al.*, 2001)[21]. Studies have shown that weight increases due to excessive stress in men. Stress induced eating behavior may be a cause of obesity (Torres and Nowson, 2007)[22].

Smartphone Vs DSLR Dental Photography among Orthodontists

Arya S Prasad[1], Arvind Sivakumar[2]

[1]Postgraduate Student, [2]Senior Lecturer, Department of Orthodontics and Dentofacial Orthopaedics, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences,, Saveetha University

Abstract

Introduction: Smartphone photography has come a long way in terms of technological advances in sensor quality, resolution, and lens sophistication, giving much improved image quality over the last few years. Smartphones being relatively compact and lighter than a Digital SLR camera hence the younger generation dentists prefer it over the conventional cameras. We did a survey to assess the perception of quality of images taken using smartphone and DSLR (Digital Single Lens Reflex) intra oral cameras. The aim of this study is to compare the quality of intraoral images taken using mobile phones with DSLR cameras.

Materials and Methods: 20 intra oral images of subjects were taken using DSLR (Canon 700D) and 2 renowned smartphones (iPhone 7 plus and Oppo R7 plus). A questionnaire was prepared and sent through social sources to general dentists and specialists. The questions included in the survey are based on the knowledge, attitude and practice in the usefulness of mobile phones compared to DSLRs for taking intra oral images.

Results: The primary outcome measure of this study was to assess the orthodontist's perception towards the various image characteristics of intra oral photographs taken using digital SLR camera, iPhone 7 plus and Oppo R7 plus.

Conclusion: So, from this study we can conclude that there were no statistically significant results found. In the coming years smartphone cameras can really give a tough challenge to bulky cumbersome DSLRs.

Keywords: *Mobile dental photography, smartphone dental photography, DSLR (Digital Single Lens Reflex), iPhone 7 plus, Oppo R7 plus.*

Introduction

Clinical photography in dentistry is mainly used for documentation, evaluation of craniofacial and dental relationship, assessment of soft tissue profile, smile analysis, medicolegal purposes, evaluation and monitoring of treatment progress etc. [(1) (2) (3)] A Digital Single Lens Reflex, or DSLR is necessary for high-quality images of both extraoral and intraoral structures. [(4)] The DSLR camera with a high-quality lens is considered to be the ideal choice for dental photography, as it is capable of taking portraits as well as close up or macro images of the dentition, by through-the-lens viewing and metering, precise focusing and accurate framing [(5)] A full set of clinical photographs must be taken before any treatment is started as it is an invaluable record detailing the original clinical situation. These should be a mandatory record for each and every patient before we diagnose and design the treatment plan, even if the treatment is only extraction of teeth to intercept the developing malocclusion. Clinical photographs allow us to record the relationship of the teeth and jaws to the

facial structures.[5]

Digital photography can have several influences on dental practice: Photos can educate patients and improve patient acceptance and improve patients' confidence following treatment. The dental treatment is subject to change, can be recorded in detail by means of photography. Intraoral pictures can provide improved documentation and the option of checking particular conditions over longer periods of time.

In today's smartphone generation, mobile dental photography has become one of the fastest and easy ways to record or document cases. Smartphones, as it is very aptly named in the way that it can turn an amateur into a professional photographer. Nowadays many professional photographers are ditching their heavy, sophisticated DSLRs in favour of more compact, lightweight, handy smartphones. [6] [7] It is quite common nowadays to see people clicking pictures using their phones to take photos, leaving their expensive DSLRs at home. [8] A DSLR has a camera body with some fantastic technology but nowadays cell phone photography has raised its standards to a considerable extent to compete with a DSLR setup, and yet is light and easy to operate. The image sensors have come a long way & are capable of capturing pictures of more than 10 MP (megapixel).

Nowadays its quite common to take portrait shots and other face photographs with smartphone camera which produces good quality photographs with adequate recording of the details. Smartphone cameras are viable alternative to heavy DSLR cameras in taking intraoral and extraoral photographs.[9] Hence in this study, we wanted to compare the quality of photographs obtained with smartphones and compare them with gold standard DSLR.

Materials and Method

This cross sectional questionnaire study was conducted by using intraoral pictures of 20 random subjects who reported to our hospital for treatment were taken using Canon 700D (Canon India Pvt. Ltd., Gurgaon, India) and two renowned mobile phones iPhone 7 plus and Oppo R7 plus which has got a good camera. Intraoral photos of each subjects were taken thrice using three cameras and were sorted into three groups: in group 1 – photos were taken using DSLR (Canon 700D), in group 2 – photos were taken using iPhone 7 plus, in group 3 – photos were taken using Oppo R7 plus. All the photos were taken by one author to avoid inter operator bias. The operator had good experience with the usage of all three cameras and had undergone specific training and standardisation for using all the three cameras for taking the intra oral pictures on ten patients before the study was started.

Figure 1: Intraoral images taken using iPhone , DSLR, and Oppo R7

The photos with Canon 700D DSLR were taken with following settings: ISO between 400-600, shutter speed of 30-40, f 20-22 at 30 mm zoom used with ring flash (Meike FC-100). While using iPhone 7 and Oppo R7 the photos were taken using auto mode with flash kept on.

The intraoral images taken in each subject includes the frontal intraoral image in centric occlusion with all the teeth focused from incisor to molars, right side in occlusion and left side in occlusion. The right and left side occlusion was taken with the camera pointing almost perpendicular to the buccal surface of molars &

premolars. Three intra oral images were taken for the twenty subjects using three different cameras to obtain a total of 180 images. This resulted in sixty images per group. All the images taken were cropped in uniformity by using Adobe photoshop software (CS6) to the size of 4 X 6 inches (Figure 1). All the patient images which lacked in clarity, improper lighting and camera positioning & any form of distortion were removed from the study. Finally, the best set of ten photographs out of frontal, right and left occlusion were chosen for the questionnaire survey.

The questionnaires were created using google survey. Each set of the selected photographs, were arranged in individual slides containing 3 photos (same photo taken using the three different cameras) & the examiners were asked to choose the best photograph based on the image quality. These questionnaires were mailed to 80 orthodontists through google survey link.

Results

Out of the 80 google survey links sent to orthodontists, 55 orthodontists responded to the survey. The survey results of the 55 orthodontists was as follows: 38% orthodontists liked photos taken using DSLR photography, 34% liked photos taken using iPhone 7 plus and 28% liked photos taken using Oppo r7 plus (Table 1) (Figure 2).

Table 1: Results of the Survey

S.No.	Intra oral images taken using	Response (n=55)
1	DSLR (Canon 700 D)	38%
2	iPhone 7 plus	34%
3	Oppo R7 plus	28%

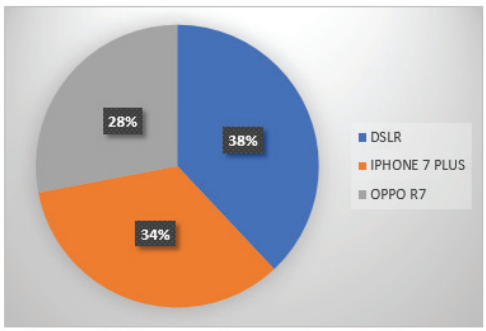

Figure 2: Overall results of survey

Discussion

The purpose of this study was to assess the perception of orthodontists towards intraoral pictures taken using DSLR and two popular phones in the market which have good cameras. In this study we have taken one high end smartphone and a midrange smartphone to assess the quality of images produced with both the phones and compare them with the SLR cameras which are currently the gold standard in intra oral photography. Also, we have evaluated whether the quality of images produced using these smart phone cameras were adequate enough for using it to take pictures in intraoral photography.

The characteristics of the photographs are affected by many factors including different operators, camera settings, room lightings and various other factors. As the image characteristics varies according to the operators, the present study used a single operator. The settings were standardised among all the photographs. The operator had already undergone a phase of standardisation were the settings of the camera were altered to find the best settings for each camera.

In a DSLR camera the inbuilt flash of the DSLR camera is placed away from the lens (on top of the lens) and hence the light from the flash gets obstructed from the presence of the protruding lens and the flash does not light up the area covered up by the lower part of the lens. This is the reason why ring flash is used for intra oral photography to produce light which is unobstructed by the lens and adequately lights up all parts of the images.[10] The characteristic of the light produced by a ring flash is precise and therefore shadow-free illumination of the object without shadowing effect of the lens, whereas in a smartphone camera the lens is not protruding outside and the flash is right next to the lens and hence there is almost zero obstruction of the light from the flash.

Smartphone cameras has really come of age from less than 1 MP to more than 20 MP , from simple CCD (charged couple device) to latest CMOS (Complementary metal–oxide–semiconductor) sensors which are far more accurate and more sensitive.[11]

Smartphones has evolved rapidly in terms of advancement and technology.[12] [13] [14] Smartphones are a part of our day to day life and because of their compactness, ease of carrying around , requires less expertise and versatility of use. They are always present within our arms reach, whereas DSLRs are cumbersome to carry, bulky, technique sensitive and requires a

lot of training. Till now there is no doubt that DSLR cameras is the gold standard in dental photography. [15] A smartphone camera is very simple to use and even an amateur photographer can produce excellent photographs due to the smartness of the phone. Other advantage is its instant access of digital images to the operator, optimal choice of illuminating the object of interest which spares us from costly accessory equipment for like ring flashes; technical data of each photograph are automatically recorded, which makes its adequate reproduction possible; possibility of copying, fast printing, and sending by electronic mail to any part of the world; possibility of fast reviewing and removing of spotted errors as well as the possibility of instant deleting and repeating shooting procedures until till desired results are obtained .

iPhone 7 plus photographs have really given a tough competition to DSLR photographs in intraoral dental photography. Smartphone cameras can be used alternatively for intra oral dental photography. Utilization of mobile dental photography can help in the treatment planning and patient consultation that is organized and more user friendly for both the dentist and easily understandable by the patients.

Conclusion

The application of smart phone photography in dental practice is simple, fast and very useful in documentation of clinical procedures, help in education of patients and for clinical investigations, thus enhancing many benefits to dentists and as well as patients. To overcome the bad reputation of smartphones in producing low quality pictures mobile phone manufacturers try to counteract these shortcomings mainly through clever programming of the camera software parameters, as they cannot overcome such physical limitations. So many smartphone companies have started creating *add on flash lights attachments and Macro lenses* for mobile phones and making it much lighter, easier and quicker to use setup for dental photography. Mobile Photography is certainly here to stay and will advance further in the future and digital dental photography is an exceptional tool for communication and documentation. Many shortcomings will be overcome in coming years. And so mobile phone manufacturers try to counteract these shortcomings mainly through clever programming of the camera software parameters. Smartphone dental photography will advance further in the future.

Critical Overview of Adolescent Suicides in India; A Public Health Concern

Ashwin Mathew[1], Suja M.K[2], V. Priya[3]

[1]PhD Scholar, [2]Associate Professor, [3]Assistant Professor Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Abstract

Suicide is the second most leading cause of death among the 15-29 age group (adolescent). The World Health Organization statistics indicate that 8, 00,000 people suicide annually. The National Crime Records Bureau records indicates that suicidal deaths in 2014 is 15.8% more than 2004, 17% of the suicides worldwide happens in India. Suicides is a contingency that affects the victim's family community and nation at large and has a long lasting effect on the people left behind. The adolescents often don't get help when needed which leads to suicides. Sustainable Development Goals 3 intents to promote healthy lives and promote wellbeing for all.

Aim: To understand; 1) the percentage increase of suicide in India, difference between male and female suicides, 2) identify states with maximum number of suicides, 3)identify states with maximum number of student suicides, 4) Major Causes for suicide among adolescent male, female and transgender and to study 5) Major means adopted for suicides in India, 6) Understand the significance promoting wellness addressing adolescent suicides. . Results: there is significant increase in number of suicides form 2013 to 2016 and it affects the nation's economy. The states with maximum number of adolescent suicides are 1) Maharastra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh and 5) Karnataka. The major Causes for suicides among adolescents male, female and transgender were identified. The most common means adopted for suicide among adolescents have been identified and listed. Conclusion: The adolescent and student suicides in the nation are increasing rapidly causing serious economic burden to the nation. Hence a comprehensive suicide prevention plan must be developed, the policy should individually target the states with highest number of adolescent and student suicides, access to the most prominent means of suicides must be limited. A national suicide prevention help line and community based access points could be created to provide mental health first aid to the vulnerable adolescents and students.

***Key Words**: Adolescent Suicides, Student Suicides, Economic Burden of Suicides, Suicide Prevention Policy, Adolescent Wellness, Adolescent Suicides in India, Suicides in Indian States.*

Introduction

WHO recognizes suicides as a public health priority and plans to increase the awareness regarding suicide and suicide attempts and intents to make suicide prevention as global public health priority. The Sustainable Development Goals (SDGs) 3 is to ensure healthy lives and promote wellbeing for all. (1) The WHO statistics indicate that 8, 00,000 people attempt suicide and many more attempt suicide suicides. Suicide is the second most leading reason cause of death among the age group 15-29 age group (adolescent), 79% of the suicide worldwide happens in lower middle income country and hence India is at greater risk. (2) The National Crime Records Bureau reports indicate that the suicides rate has increased 15.8% from 2004 to 2014(3), this significantly impairs the nation's development the government and parents of the adolescents spend considerable amount of

money in their upbringing.

Suicide mental health problems and depression has high correlation especially in developed nations. Suicide occurs impulsively at crisis situations as the victim is not able to deal with the life stress in situations such as; financial problems, relationship issues and chronic diseases. The most significant factor for suicide is a previous suicide attempt. The crucial aspect in suicide risk reduction is to identify the Causes for suicide and address them and to limit access to the means of suicides. (4)

Research studies indicate that; indicate that suicide victims and inpatients showed similarly high rates of affective disorders. The suicide victims with family history of affective disorders and suicidal tenancies are more vulnerable to suicide. Four significant risk factors identified are 1) Bipolar Disorders, 2) Affective disorders with comorbidity, 3) Lack of previous mental health treatment and 4) availability of fire arms which accounted for 81.9% of cases. (4) Prevention programs including Peer Educators (PEs) have been found useful in helping young people in school especially the adolescents going through heavy psychological burden. The results indicate that that the mindfulness and Support, Appreciate, Listen, Team (SALT) using Peer Educators (PE) have enhanced the PEs broad emotional intelligence and PEs expressed increased ownership of life, taking action and seeking support when needed. Research studies also suggest that future research should be carried out in developing nations to understand the knowledge regarding suicides especially in the adolescent age group (5). WHO further emphasizes that India develop a comprehensive suicide prevention plan and integrate it with the mental health act to contain the growing threat of adolescent suicides. (1)

Method

This study is based on the secondary data available from the official government websites. The adolescent suicides related data from 2013 to 2016 has been used in the study. The basic statistical analysis was done using Microsoft Excel 2013.

The rationale behind this study is to understand 1) National adolescent suicide rate and difference between male and female suicides, 2) States with highest number of suicides, 3) States with highest number of student suicides and rate of student suicides, 4) Major Causes for adolescent suicides 5) Major means adopted by adolescent suicides and 6) Understand the significance promoting wellness addressing adolescent suicides. The researcher would also attempt to identify future research areas and try to lay down a comprehensive suicide policy guidelines keeping in mind the recommendations of WHO and UNICEF and relevant research studies.[16]

Results

1) TOTAL SUICIDES AMONG 15-29 AGE GROUP (ADOLESCENT) IN INDIA; YEARS 2013, 2014 & 2015.(6), (7) (8), (9)

The number of suicide in 2013 is 46,368, in 2014 it has raised to 54,100. The percentage increase of suicides form 2013 to 2014 is a whopping 16.675 % which is a matter of concern when we compare this data with the National Crime Records Bureau report stating that "suicidal deaths of 2014 is 15.4% higher than that of 2004", we can understand the rapid increase in adolescent suicide in India which is a public health concern. The increasing number of suicides is a threat to the nations GDP, it's estimated that death of one adolescent between the 15-29 years cost approximately 70 lakhs. The economic loss in 2014 alone would account to 70 lakhs × 54100 adolescent suicides which equals to 378.7 billion rupee, this significantly affect the nation's economic progress and the public health initiatives.

MALE AND FEMALE SUICIDES AMONG THE ADOLESCENT AGE GROUP IN INDIA; YEARS 2013, 2014 AND 2015. (6), (7) (8), (9)

There is significant difference between male and female suicides. The number of male suicides is significantly higher than that of the female suicides. The difference between male and female suicide in 2013 is 7,064 suicides, in 2014 the difference between male and female suicides is 9,950 suicides, and in 2015 the difference between male and female suicides is 9,435 suicides.

2) SUICIDE RATE AMONGST ADOLECENS IN INDIA 2013-2015(6), (7) (8), (9); STATES WITH HIGHEST NUMBER OF SUICIDES.

The states with highest number of suicides in 2013, 2014& 2015 are 1) Maharashtra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh, 5) Karnataka and 6) Andra Pradesh. Specific strategies must be formed to address suicides in these states as they contribute to the majority of the adolescent suicides in India.

3) TOTAL NUMBER OF STUDENT SUICIDES IN INDIA 2013-2016[10],[11],[12],[13]; STATES WITH HIGHEST NUMBER OF SUICIDES.

The states with maximum number of student suicides in India in the years 2013, 2014, 2015 and 2016 are; 1) Maharashtra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh, 5) Karnataka,6) Chhattisgarh , 7) Andra Pradesh.

The percentage increase in student suicide from 2013 to 2016 is an alarming18.31%. The government and parents spend a lot of time and effort in developing the career and character of a student and hence the rapid increase in student suicides significantly affects our nation's developmental gains.

4) Causes FOR SUICIDE AMONGST ADOLESCENT AGE GROUP IN INDIA 2013 & 2015; MALE, FEMALE & TRANSGENDER.[16][17]

Male

Figure No. 1, Causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Male (Suicide rate in percentage) [14][15]

The most common Causes for suicide among male in 2014 and 2015 are: 1) Other Causes, 2) Other Family Problems, 3) Causes not known, 4) Illnesses, 5) other prolonged illnesses, 6) love affairs, 7) Insanity/ Mental Illnesses, 8) Failure in examination, 9) Marriage related issues , 10) Unemployment, 11) Drug Abuse/ Addiction

Female

The Figure no. 2, Causes for Suicide amongst Adolescent Age Group In India 2013 & 2015; Female Illustrates that:-

The most common Causes for death among adolescent female in India in 2014 and 2015 are; 1) Other Family problems, 2) Other Causes, 3) Marriage related issues, 4) Illnesses, 5) Causes not known , 6) Other Prolonged Illness , 7)Love affairs , 8) Dowry Related Issues , 9) Insanity/ Mental Illness, 10) Examination Failures.

Trasgender

The Figure No. 3, Causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Transgender illustrates that:-

The most common Causes for adolescent transgender suicides in 2014 and 2015 are; 1) Other Causes , 2) Illnesses, 3) Other Prolonged illness, 4) Suspected/ illicit relation, 5) Professional/ Career Problem, 6) Other family problem, 7) Insanity/ Mental illnesses:- , 8) Drug Abuse Addiction , 9) Causes not known.

5) MEANS OF SUICIDE ADOPTED BY ADOLESCENT AGE GROUP IN INDIA; MALE, FEMALE AND TRANSGENDER IN 2013 AND 2015.[14][15]

Male

The Figure No.4, Means of Suicide Adopted By Adolescent Age Group in India 2013 & 2015; Male illustrates that:-

The most common means adopted by adolescent male in 2013 and 2015 in India are; 1) Hanging, 2) Poisoning , 3) consumption of insecticides, 4) fire/self-immobilization, 5) consumption of other poison, 6) other means , 7) drowning, 8) coming under running trains, 9) jumping , 10)overdose of sleeping pills.

Female

The Figure No. 5, Means of Suicide Adopted By Adolescent Age Group in India 2013 & 2015; Female illustrates that :-

The most common means adopted by women in the adolescent age group for suicide in the years 2013 and 2014 are 1) Hanging, 2) Poisoning, 3) consumption of other poison, 4) fire self-immobilization, 5) consumption of other poison, 6) other means 7) drowning, 8) coming under running vehicles/ trains, 9) Jumping and 10) over dose of sleeping pills.

Transgender

The Figure No. 6, Means of Suicide Adopted By Adolescent Age Group in India 2015; Transgender illustrates that :-

The most common Causes for suicide among transgender suicides in India are; 1) by fire/ self-immobilization, 2) by hanging, 3) Jumping and 4) jumping of moving trains/ vehicles.

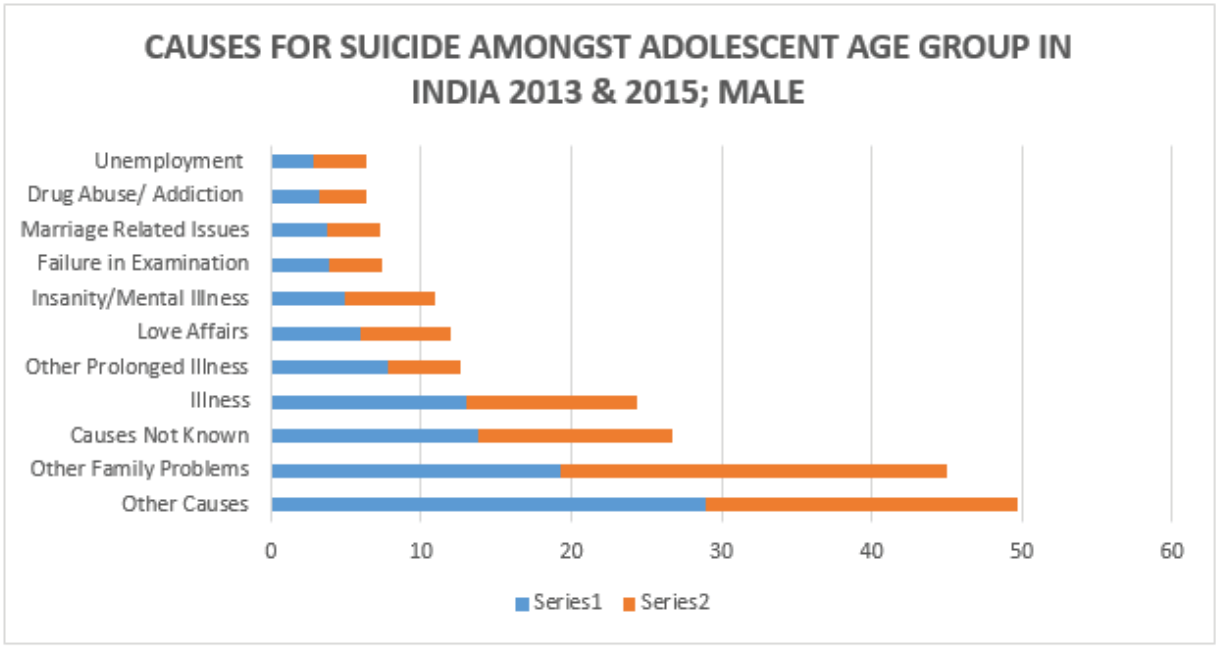

Figure No. 1, Causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Male (Suicide rate in percentage) [16][17]

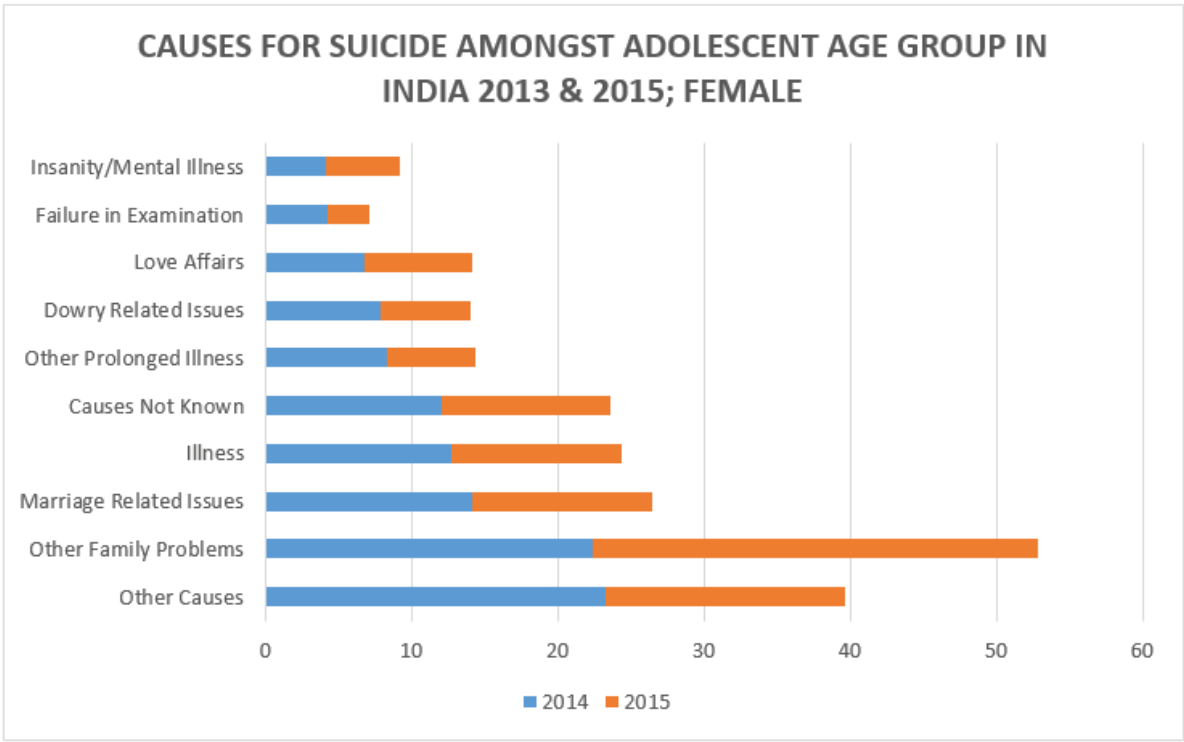

Figure No. 2, causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Female (Suicide rate in percentage) [16] [17]

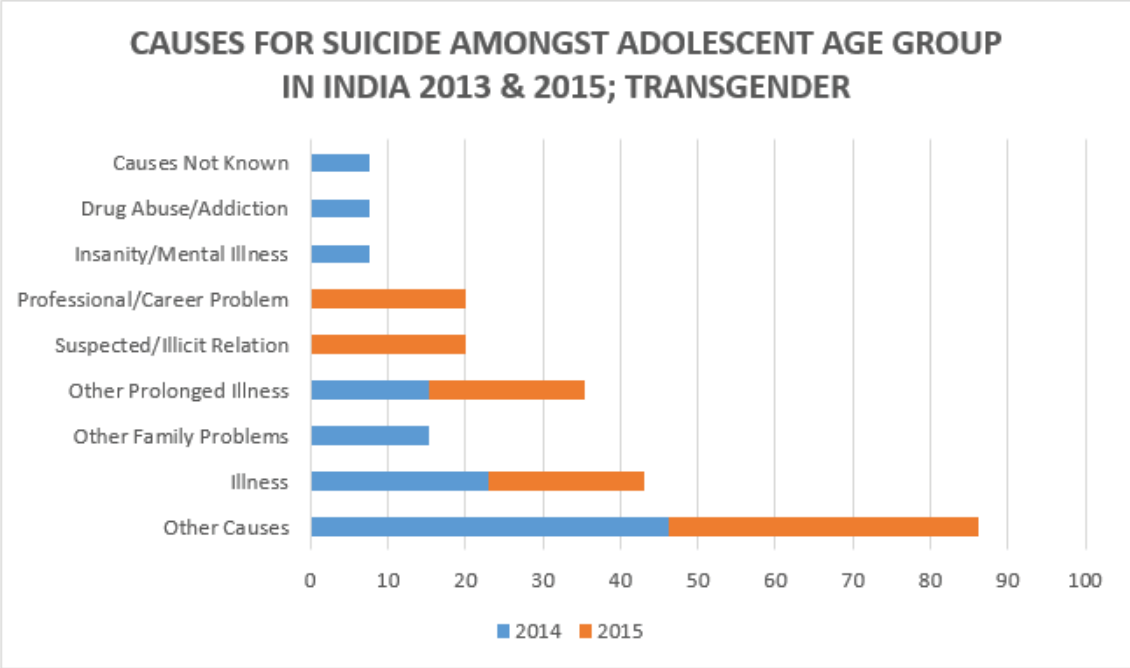

Figure No. 3, Causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Transgender (Suicide rate in percentage) [16][17]

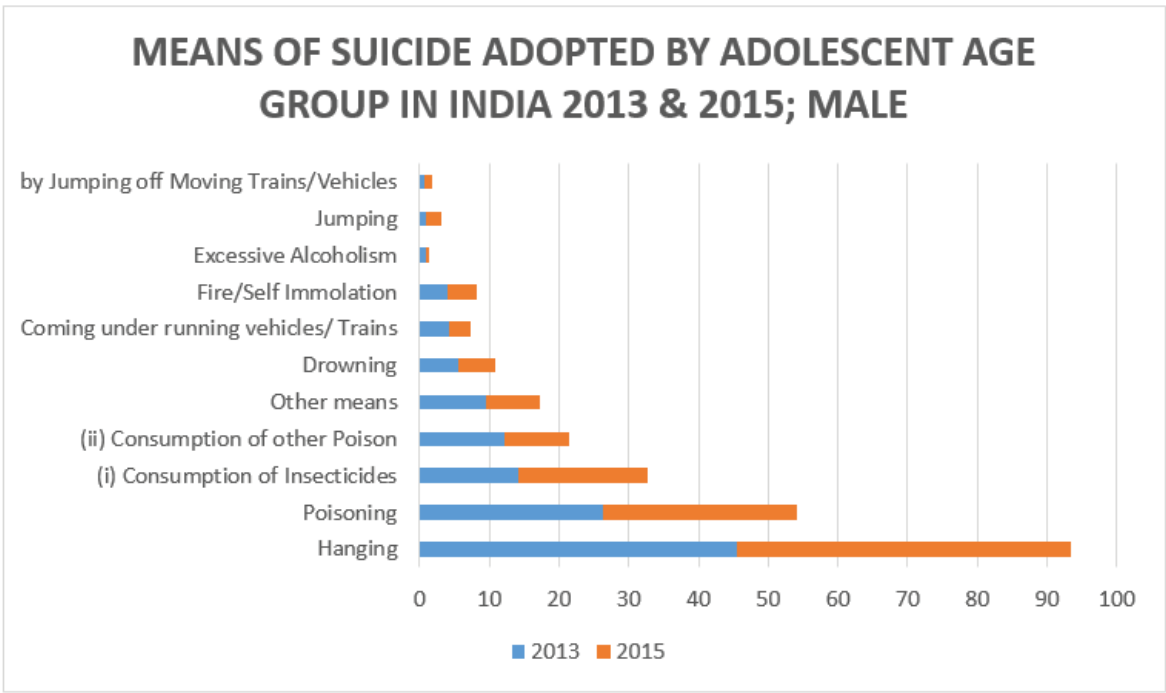

Figure No.4, Means of Suicide Adopted By Adolescent Age Group in India 2013 & 2015; Male (Suicide rate in percentage) [14] [15]

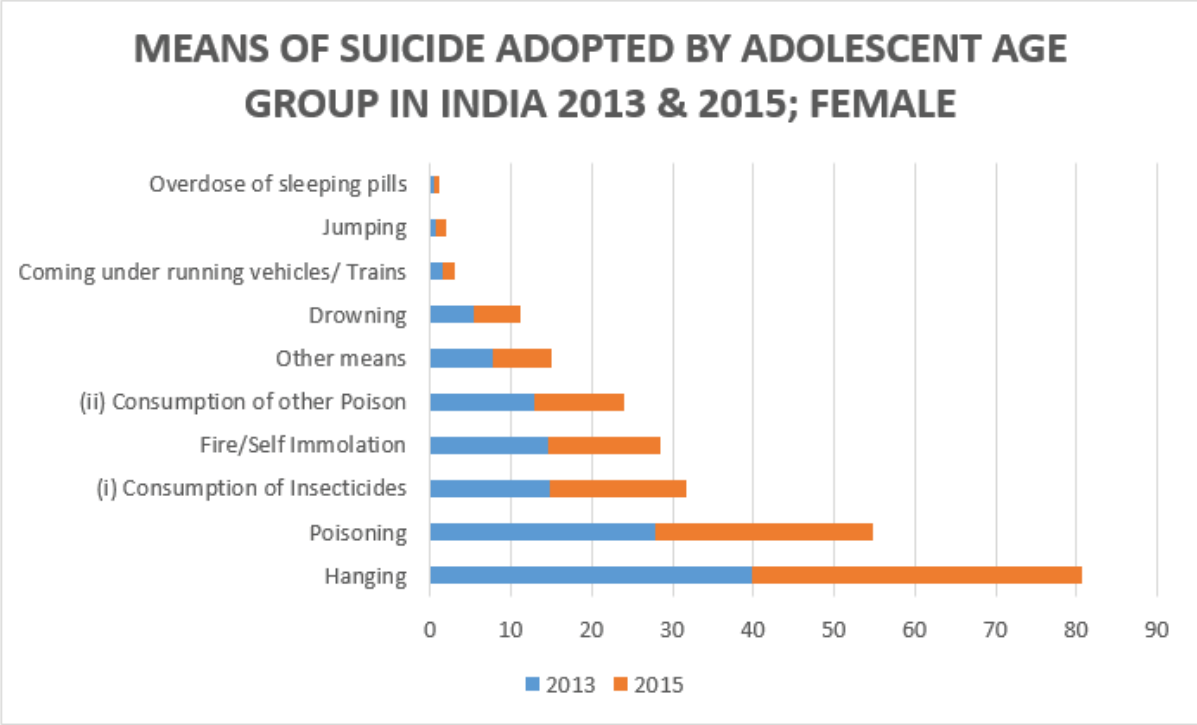

Figure No. 5, Means of Suicide Adopted By Adolescent Age Group in India 2013 & 2015; Female (Suicide rate in percentage) (14)(15)

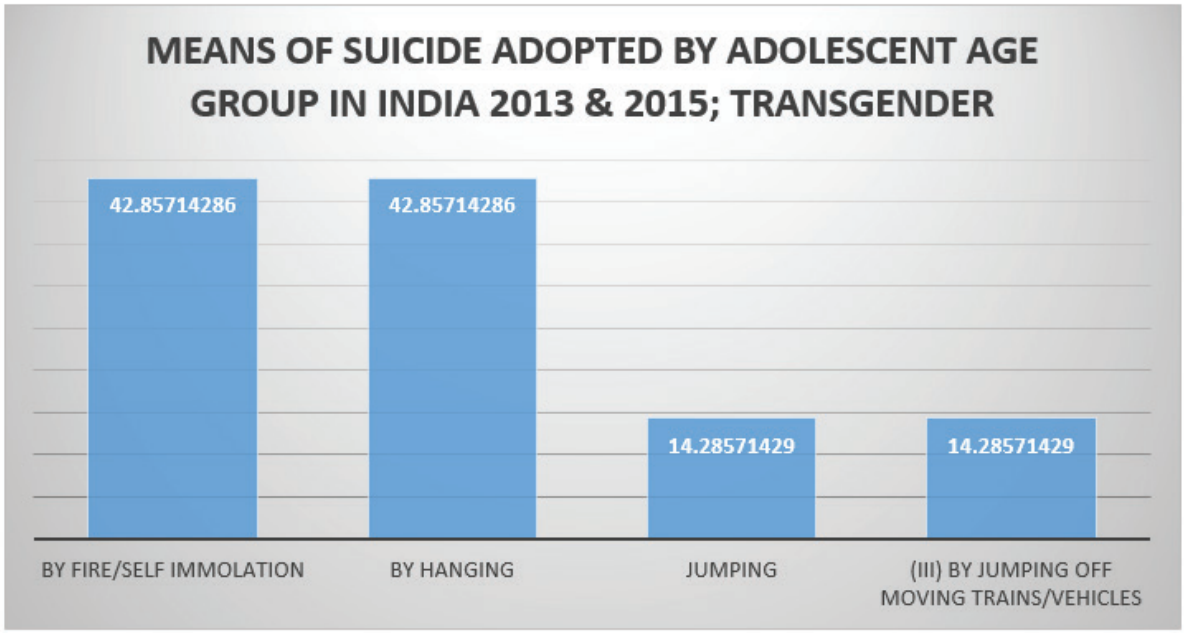

Figure No. 6, Means of Suicide Adopted By Adolescent Age Group in India & 2015; Transgender. (Suicide rate in percentage) (14)

Discussions and Conclusions

The percentage increase in adolescent suicide in India from 2013 to 2014 is 16.67% is higher that the records published by the National Crime Records Bureau 15.4% in increase from 2004 to 2014. The economic loss caused by adolescent suicides in 2014 accounts to 378.7 billion rupees which seriously affects the nation's developmental gains. The priority should be to prevent male suicides which is significantly higher than that of female suicides in India. The government

and NGO's must individually target the states with maximum number of suicides in 2013,2014 and 2015 1) Maharashtra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh , 5) Karnataka and 6) Andra Pradesh.

The percentage increase in student's suicide from 2013 to 2016 is 18.31% is alarming. The states with the maximum number of student suicides should be individually targeted and suicide prevention strategies involving student volunteers and teachers could be introduced in the educational institutions to address student suicides.

The best way to prevent adolescent suicides is to understand the Causes for suicides and to take appropriate measures to address them states the WHO, hence the suicide prevention policy could try and target people who are vulnerable to; other causes, other family problems, causes not known, love affairs, illnesses, other prolonged illnesses, insanity or mental illness, failure in exams, marriage related issues, dowry problems, drug abuse/addiction, unemployment, suspected/ illicit relations and professional and career problems.

Preventing access to the means of suicide helps in reducing the number of suicides as per WHO guidelines and we suicide prevention policy could try and limit access to the most common means of adolescent suicides; Hanging, poisoning, consumption of insecticides, consumption of other poison, other means, drowning, coming under running vehicles/ trains, jumping, jumping of moving vehicles, overdose of sleeping pills, fire/ self-immobilizing'

Further research must be done to understand - 1) high number of male suicides, 2) high number of student suicides, 3) high student and adolescent suicides in certain states, 4) the leading causes of adolescent suicide other family problems and other problems, 5) the actual number of transgender suicides in India.

The government should try and develop a suicide prevention policy considering the recommendations; 1) the states with highest number of adolescent and student suicides should be targeted individually, 2) student volunteers should be trained in educational institutions to give support to the students, 3) the adolescents who are vulnerable to common means of suicide should be assisted, 4) Access to the common means of suicide should be reduced 5) government should try and start a suicide prevention helpline, computer based and mobile based chat support to help adolescents 6) community based access points to give mental health first aid 7) Community mental health volunteers could be trained and employed in the PHC- SHC –CHC respectively. The primary focus should be to reduce the adolescent suicides and to foster their growth for the betterment of the nation.

Awareness of Therapeutic Positions in Women During Pregnancy Related Lumbar and Pelvic Pain

Ashwini Pawar[1], Chandrakant Patil[2]

[1]Final year student, Faculty of Physiotherapy, KIMS "Deemed To Be University" Karad, Maharashtra, India,
[2]Associate Professor, Department Cardiopulmonary Physiotherapy, Faculty of Physiotherapy, KIMS "Deemed To Be University" Karad, Maharashtra, India

Abstract

Objectives- Pregnancy related lumbar and pelvic pain is very common. This pain is mainly because of hormonal and postural changes occur during pregnancy. Lumbar and pelvic pain is the most common cause of discomfort experienced by pregnant women during pregnancy. so, Awareness about therapeutic positions to reduce that pain is very necessary. Some ergonomic positions given to the women which can help to improve posture and decrease discomfort and also relieving pain. It will give more comfort to the patient for day to day activities during pregnancy. Hence, this study aims to aware the pregnant women about therapeutic positions , that decrease the lumbar and pelvic pain and discomfort.

This study was conducted to find out the awareness of therapeutic positions in the pregnant women about lumbar and pelvic pain.

Methodology- The study group consisted of 64 women. . Females with age group of 25 to 35yrs. A prevalence study was conducted among females of all three trimesters of pregnancy. Females were selected on the basis of inclusion and exclusion criteria. They were assessed by performing visual analog rating scale and questionnaire was used to evaluate any physical disability contribute to lumbar and pelvic pain.. The data was collected and analysed accordingly.

Result- Data from sixty four females were obtained and analysed. Most of women were not aware about therapeutic positions ,only few were aware about therapeutic positions who was well educated. So 33% were aware and 67% were not aware about those positions. Following were some preferred therapeutic positions : 87% of women preferred side lying .8% preferred Quarter turn from prone, 3% preferred Sitting leaning forward, 2% preferred Sitting astride a chair.

Conclusion- We found out that there is awareness about therapeutic position and there effects is not seen in all women during pregnancy in Krishna hospital , Karad.

Keywords-*: lumbar and pelvic pain ,Therapeutic positions, Pregnant women*

Introduction

Pregnancy related low back or pelvic pain has been recognized as a medical entity since mentioned in the 4th century BC.[1] The majority of the studies reports that back pain experience in women during a pregnancy that cause substantial impact on their daily lives.[2-5] There are common physical changes associated with pregnancy ;those are ligamentous laxity, weight gain and hyperlordosis.[1] common musculoskeletal complaints of pregnancy women are low back pain and pelvic pain.[1,2]

Lumbar pain commonly presents as same as back pain experienced before pregnancy. Lumbar pain is located over and around lumbar spine with or without

radiation to leg or foot. Its functional limitations are prolonged weight bearing in standing or sitting and repetitive lifting. lumbar pain may resemble episodes of low back pain experienced before pregnancy. Erector spinae muscles may be tender on palpation.[2,7,8]

Pelvic pain approximately four times more prevalently seen than lumbar pain during pregnancy.[9] Pelvic pain located in buttocks and low back ,distal and lateral to the lumbar spine, may radiate to posterolateral thigh, occasionally to knee and rarely to calf. Functional limitation for this pain are turning in bad, climing stairs. running, walking ,lifting and twisting. this pain has been particularly associated with work involving lifting with twisting. it aggravates by jarring activities. Pelvic pain risk increased with work postures involving flexion of the upper part of body.[2,8-9,10-12]The 50-90% of women will experience some type of back pain during their pregnancy. In fact, recent research has shown that the severity of back pain and that pain of pregnancy may impact the entirely of some women's lives.[2-6]

It was found that 75% of women will have posterior posture at the end of pregnancy and suggested that an anterior posture associated with pubic symphysis problems. women gain weight during pregnancy and some postural changes also seen in women to maintain balance because of their center of gravity shifts.[13]

Generally some women use some general position for their comfort and decreasing strain on pelvic. Therapeutic positions helps to manage pain and prevent further complications at any stage of pregnancy, such as 1)Sitting leaning forward position in which patient sits on chair with knees apart, hands and upper body supported on raised table or plinth, back should be straight. 2) sitting astride a chair position in this patient sits astride in a chair in forward leaning position with back straight. 3) Patient in side lying position with pillows kept between two flexed knees. 4) Quarter turn from prone position in this position patient lies slightly prone position with flexed upper hip and knee, the lower arm should keep behind the trunk.[1]So every pregnant women should know these positions to avoid pain and further complications.

Therefore, the aim of study was to create awareness among four different therapeutic positions in pregnant women about lumbar and pelvic pain and which position is more preferred in pregnancy.

Methodology

Total 64 females were selected from Krishna Hospital, Karad, for the study who fulfilled inclusion criteria. The procedure was explained and consent was taken from those willing to participate.

Here, visual analog rating scale and questionnaire was used to evaluate any physical disability contribute to lumbar and pelvic pain performed. so these were performed to rule out the presence or absence of pregnancy related lumbar and pelvic pain. The data were collected and statistical analysis was done.

Result

1) **Distribution of Awarenness About Therapeutic Positions:**

	Frequency	**%**
YES(A)	21	33
NO(B)	43	67

Interpretation- Above table represents awareness about therapeutic positions in subjects. Out of 64 subjects, 22 subjects aware and 43subjects not aware. soo awareness about therapeutic positions is 33% and 67% not aware about that.

2) **Distribution of Preference of Therapeutic Positions:**

	Frequency	**%**
SL(A)	56	87
QTFP(B)	5	8
SLF(C)	2	3
SAC(D)	1	2

Interpretation- Above table represents preference of therapeutic positions in subjects. Out of 64 subjects. Side lying preferred by 56 subjects(87%),Quarter turn from prone preferred by 5 subjects(8%),Sitting leaning forward preferred by 2 subjects(3%),Sitting astride a chair preferred by 1 subject(2%)

3) **DISTRIBUTION OF TRIMISTERWISE:**

	Frequency	%
1st T(A)	0	0
2nd(B)	52	82
3rd(C)	12	18

Interpretation- Above table represents trimesterwise pain in subjects. Out of 64 subjects ,0 subjects (0)% had pain in first trimester,52 subjects (82%) had pain in second trimester and 12 subjects (18%)had pain third trimester.

4) **DISTRIBUTION OF Visual Analog Scale:**

	Frequency	%
0-5cm(A)	8	13
6-10cm(B)	56	87

Interpretation- Above table represents results of visual analog rating scale in subjects. Out of 64 subjects. 8 subjects(13%)had pain in between 0-5cm and 56 subjects (87%)had pain in between 6-10cm.

Discussion

The purpose of the study is to study the awareness of therapeutic positions can be adopted by pregnant women during pregnancy and that impact on the lumbar and pelvic pain.The objective of this study to find awareness of therapeutic positions in the pregnant women about lumbar and pelvic pain.

The study was carried out and result was drawn by using visual analog scale and with the help of questionnaire.

This project was done in six months of duration with sample size 64 and age group of 25-35 years. Then baseline information of age(yrs),weight(kg),and height(cm) along with details regarding the current pregnancy were taken.This participants were selected according to the inclusion and exclusion criteria. This study was conducted in Krishna hospital, karad. Consent form was taken from the subjects and assent form was taken by their caretakers. Visual analog scale and lumbar and pelvic pain questionnaire were performed to rule out the presence or absence of lumbar and pelvic pain.

The procedure was carried according to visual analog rating scale and lumbar and pelvic pain questionnaire. Then the intensity of the pain was seen by using visual analog rating scale in which ,we had asked patient to mark over 10cm line according to their pain intensity, that is at rest and on activity.

And also questionnaire was used to evaluate any physical disability contribute to lumbar and pelvic pain.

According to a article, it is said that there are lumbar and pelvic pain present in females .so some therapeutic helps that pain decrease and make pregnant women comfortable. so following positions are:

1) Side lying: participant in side lying with bilateral hip and knee flexion seperated by a pillow placed between the knees.

2) Quarter turn from prone :participant lies as far into prone as possible with the upper knee and hip flexed and lower leg straight. The lower arm should be behind the trunk in this position

3) Sitting leaning forward: participant sits with knees apart and upper body supported with arms on a raised table or plinth, keeping the back straight.

4) Sitting astride a chair: participant sits astride a chair in a leaning forward position while supporting the upper body on the back of the chair, and keeping the back straight.

Each of this position was explained to the participant and made them aware about effects of that therapeutic positions. And them about these positions

In age group,72%women in between 25-30yrs and 28%women in between 31-35yrs.In BMI ,88%women were normal category ,9% had were overweight ,3% were obese. most of the women in normal category and some in overweight. 53% women had full term normal pregnancy is type of previous pregnancy. 40% had lower segmental cesarean section. 7% women were primigravida. Usually in all cases back pain is commonly seen. 14%women had lumbar and 12% had pelvic girdle ; 74%women had both. Pain is present at lower back as well as lumbar area also. And in all women aching type of pain was seen.

Excessive pain usually seen second trimester. so,82%women had pain in second trimester.18% had in third trimester.67% had Activity limitations in prolonged standing and 33% had in prolonged bending. Most of women were not aware about therapeutic positions ,only few were aware about therapeutic positions who was well educated. So 33% were aware about that and 67% were not aware about those positions.from some preferred therapeutic positions, 87% of women preferred side lying .8% preferred Quarter turn from prone, 3% preferred Sitting leaning forward, 2% preferred Sitting astride a chair.

Conclusion

On the basis of result of study, it was concluded that there is lumbar and pelvic pain present in all pregnant women .But awareness about therapeutic position and there effects is not seen in all within age group of 25 to 35yrs. Pregnant women mostly preferred side lying position, but not aware about therapeutic positions. In pregnancy usually aching pain is seen. Mainly most of the women had low back pain and some had pelvic girdle pain and few had both pain. In most of women started low back pain in 2nd trimester. Side lying position is mostly prefer to relieve your lumbar and pelvic pain

Awareness about therapeutic positions in pregnant women is 33% and 67% women are not aware about those positions.

Conflicts of Interest: There were no conflicts of interest in this study.

Ethical Clearance: Ethical clearance was taken from institutional committee of Krishna institute of medical sciences.

Comparison of An *App* Based Low Density Lipoprotein Cholesterol (LDL-C) Estimation with Direct Assay and Friedewald Formula in Indian Population

B. Pallavi[1], Krishnamurthy U[2]

[1]Senior Registrar, Department of Clinical Biochemistry, Central Laboratory, St. Martha's Hospital, Bangalore,
[2]Associate Professor, Department of Biochemistry, Ramaiah Medical College, Bangalore

Abstract

Introduction: Accurate measurements of Low Density Lipoprotein Cholesterol (LDL-C) are imperative in classifying individuals with risk of cardiovascular Disease (CVD). Guidelines around the world advocate aggressive LDL-C lowering therapies. A novel equation, Martin Hopkins Equation [LDL-C (MH)], has been proposed to be an alternate to provide precise LDL-C estimates to initiate and/or adjust drug dosage.

Method: Lipid profile data of 739 adults were measured by enzymatic colorimetric methods. Calculated LDL-C by Friedewald formula, LDL-C (FF) and LDL-C (MH) was computed from ldlcalculator.com/ smartphone application.

Results: The sensitivity and specificity of LDL-C (MH) was 92.3% and 87.8% respectively. On Receiver Operating Characteristics Curve (ROC) analysis, Area under Curve (AUC) was 0.97 ($p<0.001$). Bland Altman plots revealed a minimal positive bias of 1.2 for LDL-C (MH).

Conclusion: The findings are suggestive of better estimates of LDL-C (MH) when compared to LDL-C (FF). A diagnostic laboratory could report LDL-C for absolutely *FREE* in the future. A new horizon in LDL-C estimation!!!

Keywords: *Low Density Lipoprotein Cholesterol, Cardiovascular Disease, Friedewald Formula, Martin Hopkins Equation, ROC.*

Introduction

Circulating Low Density Lipoprotein Cholesterol (LDL-C) has been considered as the main culprit and key contributor to plaque formation and atherosclerotic cardiovascular disease (ASCVD).[1] LDL-C cut points are considered as primary treatment goals to reduce risk of major cardiovascular events and mortality.[2-3] Thus its accurate estimations is the need of the hour to enable tailoring of therapies [(statins and non-statin based options like ezetemibe, proprotein convertase subtilisin/ kexin type 9(PCSK-9 inhibitors)] to reduce LDL-C levels which leads to improved patient care and outcome.[3]

The gold standard in estimation of LDL-C, β-quantification, is resource expensive and time-consuming. [4] Hence other scalable alternatives were developed. The analysis can be done either by **Direct estimation [LDL-C (Direct)]** which are detergent based assays or calculated using the defacto clinical standard, **Friedewald formula [LDL-C (FF)]** that considers a fixed factor of 5 to provide Very Low Density Lipoprotein Cholesterol (VLDL-C) values. [5]

Here we explore the plausibility of usage of a Novel equation to estimate LDL-C that utilizes an adjustable factor for Triglycerides (TGL)/VLDL-C ratio. With increasing incidence of high TGL states like Diabetes mellitus, Obesity, Insulin resistance, it would affect the variance of TGL/VLDL-C ratio, hence LDL-C

measures could be inaccurate. [6] The recent AHA/ACC 2018 Guidelines have approved the usage of an alternate method of LDL-C estimation [**Martin- Hopkins equation**: LDL-C (MH)]. [2]

In an era of digital/mobile health with an App being developed for the same, ***LDL CALCULATOR,*** clinicians and patients can easily avail LDL-C values at the click of a few buttons from a lipid profile. In this age of precision medicine an attempt has to be made to begin looking beyond LDL-C (FF) and Homogenous assays for accurate LDL-C estimates enabling the correct classification of risk of CVD in all patients.

Objectives:

1) To determine underestimation/overestimation of LDL-C when calculated by using the formulae [LDL-C(FF) and LDL-C(MH)] compared with LDL-C by direct homogenous assay [LDL-C(Direct)], assuming the assay to be accurate.

2) To determine which of the calculated formulae shows maximum correlation with LDL-C (Direct) at various TGL levels.

Materials and Method

A) Data Collection:

A **cross- sectional comparative study** was conducted by the Department of Biochemistry, Ramaiah Medical College, Bengaluru and data was collected during the period May 2015 to July 2015(Power of study is 80%). The lipid profile parameters[Total Cholesterol(TC),High Density Lipoprotein Cholesterol(HDL-C),LDL-C(Direct) and TGL] were measured by enzymatic colorimetric methods on fasting venous samples on a fully automated Cobas® 6000 analyzer (Roche Diagnostics, Basel, Switzerland) at Ramaiah Hospital Laboratory. The data of 753 adults (≥18 years) was collected and those of children and pregnant women were excluded in the context of primary hyperlipoproteinemia and hemodilution respectively.

B) Calculated LDL-C:

a) FRIEDEWALD FORMULA:

LDL-C is almost always measured using LDL-C(FF) and is given as **TC-HDL-C-(TGL/5)**.[5] It begins underestimating LDL-C in patients with TGL levels as low as 150 mg/dl leading to reduced treatment of such patients and under-classification of risk of CVD. [6]

b) MARTIN HOPKINS EQUATION:

It was derived and validated by Martin et al using a large sample of lipid profiles (n=13,50,908),3015 times larger than the original Friedewald database, inclusive of fasting and non- fasting samples. The methods employed for TC was ultracentrifugation and TGL was directly measured. [7]

It features an adjustable factor for TGL/VLDL-C ratio based on the patient's Non- High Density Lipoprotein Cholesterol (Non-HDL-C) and TGL estimates. The approach consists of 6 levels of stratifying Non-HDL-C from <100 mg/dl to >220 mg/dl and TGL into 30 ranges from 7-49 mg/dl to 400-13975 mg/dl in a 180 cell table. [7]

LDL-C (MH) = TC-HDL-C-(TGL/adjustable factor)

= Non-HDL-C-(TGL/adjustable factor)

The factor ranges from 3.1-11.9 and are personalized to the specific lipid panel. It was found to be more accurate in comparison to LDL-C (FF), particularly when classifying LDL-C levels <70 mg/dl in the presence of high TGL levels. [6-9]

It is available as an online calculator on **ldlcalculator.com** or also as a **smartphone application** downloadable on Google Play or Apple play store.

C) STATISTICAL ANALYSIS OF DATA:

Statistical analyses were performed on Microsoft Excel and Medcalc software (version 19.0.5). The distribution of continuous variables were described as means with standard deviations **(mean ± SD)** and compared using **Student t-test.** Correlation between various methods of LDL- C was assessed by **Pearson's correlation**. Agreement between two measurements was tested by calculating systematic errors (Bias), and 95% limits of agreement (LOA) as Bias±2SD by **Bland-Altman plots**. The level of statistical significance was established at $p < 0.05$.

The risk of CVD was decided on the basis of LDL-C cut-points in accordance to NCEP –ATP III Criteria, i.e. <100 mg/dl (no risk of CVD) and ≥100 mg/dl (with risk of CVD). The sensitivity and specificity for LDL-C by the estimated formulae was calculated.

Receiver operating characteristics curve (ROC) and **Area under curve** (AUC) was used to evaluate the ability of the formulae to discriminate diseased cases from normal subjects.

Results

A total of 753 subjects aged between 18-93 years, of which 449(60.7%) were males and 290(39.2%) females were included in the study. Among them 14 patients had TGL> 400 mg/dl, the remaining 739 individuals were considered as the study cohort in final analysis.

The analysis at a cut- off point of LDL-C 100 mg/dl, showed sensitivity and specificity of LDL-C (MH) as 92.3% and 87.8% respectively. Odds ratio (OR) was found to be 87.22. On ROC analysis (Figure 3) the AUC was 0.97($p<0.001$). Also the sensitivity and specificity of LDL-C (MH) relative to LDL-C (FF) was 90.2% and 99.7% respectively and AUC was 0.99 ($p<0.001$). The overall mean LDL-C (Direct), LDL-C (FF) and LDL-C (MH) were 108.8±40.8, 103.5±37.5, 107.7±36.7 mg/dl respectively. On an overall basis, a minimal difference of 1.1±4.1 mg/dl was noted between LDL-C (Direct) and LDL-C (MH) values.

Gender wise comparison with and without risk of CVD of all measures of LDL-C:

There exists a significant difference ($p <0.001$) in the LDL-C estimated by both the formulae in both genders with and without risk of CVD as shown in Table 1. Also when LDL-C (Direct) was <100 mg/dl, in both genders overestimation by LDL-C (MH) was noted.

Effect of TGL on measurements of LDL-C (FF) and LDL-C (MH):

The consequences of serum TGL concentrations on the divergence of LDL-C (FF) and LDL-C (MH) values from LDL-C (Direct) was assessed. In Table 2, the study cohort was stratified into four groups on the basis of TGL levels and a measure of comparison of means of LDL-C calculated by the formulae against LDL-C (Direct) was attempted. At high TGL levels (Group III and Group IV) overestimation of LDL-C (MH) is observed though statistical significance could not be proved (Group III: $p= 0.59$, Group IV: $p= 0.42$) while underestimation was noted in LDL-C (FF) in all the groups. A strong correlation was also noted for LDL-C (MH).

Concordance in Guideline classification:

The concordance of values between LDL-C (Direct) and estimated LDL-C was analysed using NCEP-ATP III criteria. The study population was again assorted into 5 categories with respect to LDL-C (Direct) values. In Table 3, LDL-C (MH) showed a superior concordance with LDL-C (Direct) when compared with LDL-C (FF) across all the categories, also reaching statistical significance. With increasing values of LDL-C (Direct), the ability of LDL-C (FF) to correctly identify the patient population reduces but the same was not observed when LDL-C (MH) was used.

Correlation and Bland Altman plot between LDL-C (Direct) and calculated LDL-C:

Linear regression analysis between LDL-C (Direct) and estimated LDL-C revealed a strong, positive and similar correlation. The correlation coefficients were 0.87 ($p=1$) for LDL-C (MH) and 0.87 ($p <0.05$) for LDL-C (FF). (Figure 1) To find an agreement between LDL-C (Direct) and estimated LDL-C, the Bland Altman plots were used. (Figure 2) It shows a minimal positive bias of 1.2 for LDL-C (MH) and 5.3 for LDL-C (FF).

Discussion

Why is it time to look beyond the classic Friedwald formula that has been historically tolerated for five decades? The answer is Statins and PCSK-9 inhibitor therapies for hypercholesterolemia which are extremely effective at lowering LDL-C and its values are required by clinicians. As these drugs have undesirable side effects, inappropriate use is not encouraged, and thus the need for an extremely accurate LDL-C estimate is acute. Direct LDL-C offers relatively better accuracy but are costlier than a ***"FREE"*** calculation.

In 2013 a team led by Dr. Martin S Seth at John Hopkins University developed the equation which basically customizes the denominator through the 180-cell approach. Its beauty lies in the fact that using the information from a standard Lipid profile an accurate and FREE measure of LDL-C is obtainable. Besides, it obviates the need for a fasting sample thus attaining more patient compliance. [6]

This study was undertaken to assess the validity of LDL-C (MH) and LDL-C (FF) in comparison to LDL-C (Direct) assay. To the best of the author's understanding the equation has not been studied in the Indian population. This study demonstrated a superior performance of LDL-C (MH) at low LDL-C (<100 mg/dl). LDL-C (MH) tends to overestimate the LDL-C significantly ($p<0.001$) when compared to LDL-C (Direct) and LDL-C (FF). Thus it was capable of identifying individuals with high risk of CVD.

With an increase in TGL concentrations, the difference between LDL-C (Direct) and LDL-C (FF) increased but LDL-C (MH) values were independent of TGL levels. This outcome was comparable to studies by Choi *et al* [10], Decordova *et al*[11] and Martins J *et al.* [12] A strong, positive correlation ($r=0.87$) was noted for LDL-C (MH). The Bland Altman plot displayed a minimal positive bias of 1.2 for LDL-C (MH), similar to the study by Saiedullah *et al.* [13] but LDL-C (FF) showed a larger positive bias of 5.3. This can be indicative of a possibility of usage of LDL-C (MH) to obtain accurate measures in place of LDL-C (Direct) and LDL-C (FF). LDL-C (MH) showed a higher concordance with LDL-C (Direct) when compared to LDL-C (FF) across all the categories when stratified on basis of LDL-C cut points in accordance to NCEP- ATP III criteria, which was statistically significant ($p <0.001$). LDL-C (MH) showed a greater overall concordance of 62.5% in comparison to 60.9% by LDL-C (FF) which is in agreement to studies by Martin S *et al* [6] and by Lee J *et al.* [14] The sensitivity, specificity and ROC analysis as described in Results section emphasizes the strong association of LDL-C (MH) to correctly identify all individuals who are at higher risk of CVD at a cut point of LDL-C ≥100 mg/dl in comparison to both LDL-C (Direct) and LDL-C

(FF).

In our country with a burdening population of high TGL states and an increased risk of CVD, it would be thoughtful for us to move away from Friedewald formula and adopt the novel equation to prevent misclassification of risk of CVD. With diagnostic laboratories most often running on shoe string budgets LDL-C (MH) offers a cost effective and accurate solution. To routinely report LDL-C (MH), will require a re-programming of the Laboratory Information Systems (LIS) which will initially prove to be costly and daunting, but with time it will mitigate the need for Direct LDL-C assays. There could be a day in the future when a laboratory could report LDL-C for absolutely free, without costing any money to the patient for the same!

Limitations of this Study:

1) It requires verification on a large sample size of Indian population as it was originally derived and validated on the American population.

2) Difference in methodology of cholesterol estimations (Ultracentrifugation versus direct homogenous assay).

Conclusion

The novel approach can thus provide precise LDL-C levels without associated costs and inaccuracies inherent to other established methods of LDL-C measurement.

Association of *Viharaja* and *Manasika Hetus* (Behavioural and Mental Factors) with A*mlapitta (*Hyperacidity) amongst Police Professionals in Pune

Babar Smeeta Shivaji[1], Joshi Mrudula Vinayak[2,] Joshi Vinayak Nilkanth[3]

*[1]Ayurveda Samhita and Siddhanta), M.A.(Sanskrit). Ayurveda Practitioner, Pune, Maharashtra, [2] Professor and HOD, P. G. Department of Ayurveda Samhita and Siddhanta, [3]Professor and HOD, Rognidan and Vikruti Vidnyan, Dr. D.Y. Patil Vidyapeeth, Dr. D.Y. Patil College of Ayurveda and Research centre, Pimpri, Pune, Maharashtra***,** *India*

Abstract

Background-Changing life style in conjunction to unhealthy dietary pattern, mental stress and strain is leading to *Ajeerna* (indigestion), and further *Amlapita* (hyperacidity). **Aim-**To evaluate the association of *Viharaja* and *Manasika Hetus* (behavioural and mental factors) with A*mlapitta (*Hyperacidity) amongst police professionals in Pune.

Settings and Design- This cross sectional study was conducted among Police professionals in Pune region. **Methods and Material: S**tudy included 100 identified patients of *AMLAPITA*; both males and females from the age group of 25-50years. A self administered, structured, pilot tested 9 item questionnaire was used to collect data. **Statistical Analysis:** Descriptive data was analyzed using number and percentages. **Results:** Maximum patients with *Pitta-Vataja Prakruti were* n=47, *Kapha-Pittaja Prakruti* were n = 41 and *Kapha-VatajaPrakruti were* n= 12. 71 (100%) *Amlapitta* Police Professionals did daily ***Ratri-jagarana*** who had night shift and 29 (100%) reported day shifts out of which 21(72.41%) Police Professionals did daily *Ratri-jagarana* yet they had day shift duty. Mental stress was more in Night shift personnel n=52 (73.24%) than stress observed in Day shift participants n=17(58.62%).

Conclusion: Present study help us to estimate association of *Amlapitta* with changed life style pattern. These etiological factors like *Viharaj and Manasika hetus* namely *Ratrijagarana,Vegavidharana,* Mental stress cannot be eradicated totally due to current career progression scenario. But definitely alternative therapies like yoga, meditation and diet plans can be suggested and practiced as and when necessary.

Key Words –*Amlapitta, Etiological factors, Police Professionals, Hyperacidity, Stress, Behavioural causes, mental causes*

Introduction

Amlapitta(Hyperacidity) is a very common disease of this era.30% of the general population is suffering from gastro-oesophageal reflux and gastritis resulting in heartburn.It is very troublesome disease and can give rise to many serious problems if not treated in time. Signs and symptoms of *Amlapiita* are very similar to gastritis [1]. *Amla* means sour and *Pitta* is the functional digestive component of the body. Thus *Amlapitta* (Hyperacidity) is a disease; in which sour blenching is the major symptom. *Avipak*(Indigestion), *Klama*(Exhaustion including normal 8 hr. duty) , *Utklesha* (Nausea) ,*Katu/ Tikta / Amla udgar* (pungent/ bitter/ sour Blenching) , *Hrut / kantha daha*(Heart / Throat burning) , *Aruchi* (Tastelessness), *Chchardi*(vomiting) ,*Shirashoola*(Head ache) are the important signs and symptoms of the

disease[2,3].

It has been indicated that *Amlapitta* occurs in the persons having unhealthy food habits[1, 4]. The diet today is governed by social and professional background, has led people to consume unhealthy food and subsequently indigestion. Indigestion caused produces *Annavisha* (toxins) which get mixed up with *Pitta Dosha* and lodges in *Amashaya*(Stomach) and then it produces *Amlapitta* disease[5].

Police officer's job is one such public service profession wherein noxious conjunction due to disturbed life pattern is seen.Policeman has to be on duty for longstanding hours either in a day or night shift, leading to disturbed body clock. *Ratrijagarana* (Night awakening)[6,7,8,9], *Atapa sevana* (exposure to bright Sunlight), *Vega vidharana* (suppression of natural urges like hunger, thirst stool, urine, etc.)[7] is very common in their day to day life. *Ajeernashana*(repeated eating)[1,10,11,12], *Amla / katu / Vidahi/ ViruddhaAhar*[12,13,14]*sevan*(sour, pungent, spicy food & food having opposite qualities)are mentioned as dietary causes of the disease.This disturbed life pattern also causes, addiction of Paan, tobacco chewing, Gutka, alcohol which in addition contributes to Gastro-Intestinal disorders like *Amlapitta*. Moreover, work pressure causes high stress level especially mental stress, which again contributes to vitiate the *Pitta dosha* leading to *Amlapitta* disease.Therefore it becomes necessary to avoid *Hetus* (etiological factors) to minimize diseases like *Amlapitta* in police professionals.

This study will help us to evaluate the association of *Viharaja* and *Manasika Hetus* (behavioural and mental factors) with A*mlapitta (*Hyperacidity) amongst police professionals in Pune.

This data will help to fetch remedy for different preventive and curative modified dietary and life style changes on the basis of dominant etiological factors.

Materials and Method

This cross sectional study was conducted among 100 pre- diagnosed police professionals from Pune region suffering from *Amlapitta*, who were working on various posts, of both sex and aged between 25 to 50 years, willing to participate in the study were selected. Individuals suffering from *Avipak*, *Klama ,Utklesha ,Katu/ Tikta / Amla udgar ,Hrut / kantha daha ,Aruchi ,Chchardi , Shirashoola* (Head ache) as main symptoms were included; while those who suffered from Hypertension, Cardiac diseases, Diabetes mellitus, Congenital and Immunological disorders were excluded from the study. Approval was obtained from the scientific committee and Institutional Ethics committee (No: AY/PG/130/2014/15/IEC). Every participant signed an informed consent form before starting the study. A structured questionnaire with 9 major questions was administered. All the Police Professionals were asked to complete the questionnaire. Information regarding *Hetus*, *Lakshanas* of *Amlapitta*, Daily schedule and duty shifts and other occupational causes related to stress in Police profession was recorded.The collected data was entered in Microsoft Excel 2007. Descriptive analysis in the form of number and percentages were calculated.

Results

This cross sectional study was completed among 100 police professionals. Important findings regarding demographic variables like Age, *Prakruti* (Physical constitution), *Viharaja hetus namely Ratrijagarana, Vega vidharana* and Mental stress are listed. It was found that according to age, maximum number of patients were n= 39 from the group of 45 -50 years i.e. belonging to higher grade and minimum patients i.e. n= 24 from age group 35-45 years (Table 1).

Prakruti -Observations related to Physical constitution denoted maximum patients with *Pitta-Vataja Prakruti* n=47, *Kapha-Pittaja Prakruti* in n = 41 and *Kapha-VatajaPrakruti* n= 12(Table 2).

71 (100%) *Amlapitta* Police Professionals did daily ***Ratri-jagarana*** who had night shift and 29 (100%) reported day shifts out of which 21(72.41%) Police Professionals did daily *Ratri-jagarana* yet they had day shift duty.

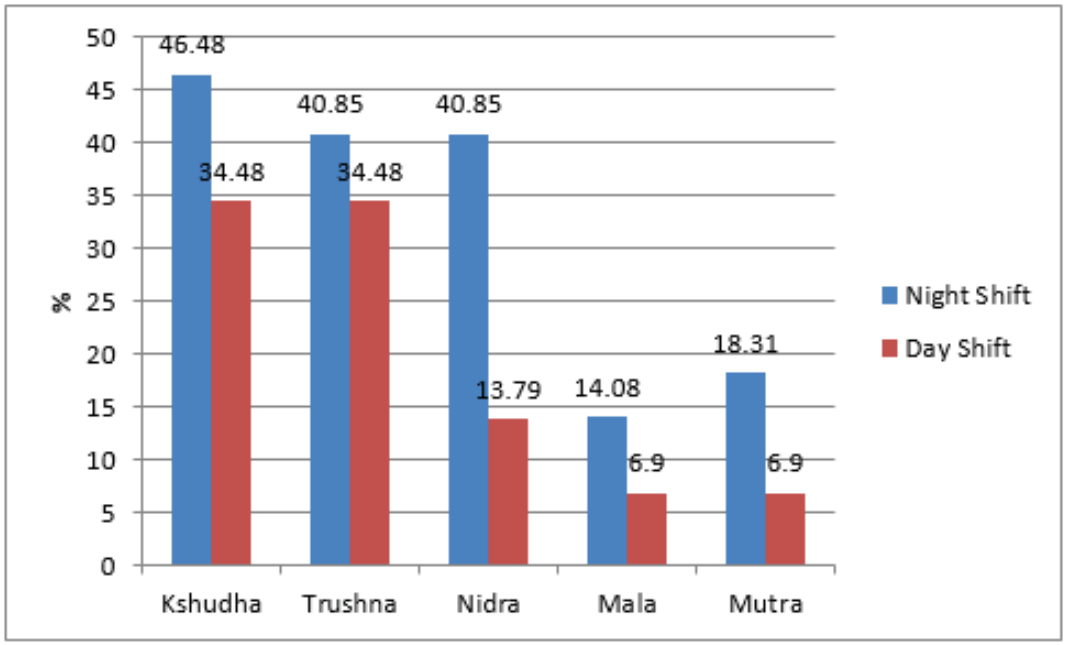

Fig1: Distribution of police professional based on the daily Vega Vidharana

Figure 1.***Vegavidharana*** ***(***suppression of natural urges***)*** It was noted in Night shift Participants *-Kshudha (hunger), Trushna(thirst), Nidra(sleep) and Mala(stool),Mutra (urine)Vegavidharana* was prominently noticed in 46.48%, 40.85%, 40.85%, 14.08% and 18.31% respectively.

It is more in comparison with Day Shift duty Police Professionals where the percentage noted was 34.48%, 34.48%, 13.79%, 6.90%, and 6.90% respectively.

TABLE 1 - Distribution of 100 patients of *Amlapitta* according to Age

Age Range in years	Number	
25 – 35		37
35 – 45		24
45 – 50		39
Total		100

MENTAL STRESS	Number (%)
Night duty(n =71)	52(73.24)
Day duty(n =29)	17(58.62)

Table 3.***Manasikhetu-***Mental stress was more in Night shift personnel n=52 (73.24%) than stress observed in Day shift participants i.e. n=17(58.62%)

Discussion

Present survey study executed on 100 Police Professionals, pre-diagnosed with *Amlapitta*; acknowledges prevalence of disease *Amlapitta* in Police Professionals; along with important role of *Viharaja and Manasika Hetus* in disease creation. Age of Police professionals plays vital role in disease progression mainly due to continuous change in life style for longer duration. Working in shift duty is trigger factor for uneven sleep pattern, unpunctual and unhealthy food habits.

Present study reveals that Police Professionals with Night Shift were found to be more exposed to *Hetus* of *Amlapitta* and were suffering from classical symptoms of *Amlapitta* as compared to Day shift Police Professionals. According to this study *Hetu* – **Age** between 45-50 years in participants indicates the middle age group which is *Pitta* dominant phase of life. Further, the increasing load of responsibilities is also a characteristic of this age group which can be an etiological factor. ***Sharirprakruti(***Physical constitution***)*** adds on to susceptibility to disorders. *Pitta Vataj prakruti* dominates with n=47. These type of constitutions in persons make them physically weak and more sensitive to external factors.

Working in Night shift exposes them to *hetus* like *Ratrijagarana, Vegavidharana of Kshudha, Trushna, Nidra, Mala and Mutra vega.* These *hetus* are *Viharaj hetus* and cause *Annavaha and Rasavaha srotas dushti*(disturbed digestion and assimilation). This leads to *ajeerna*(indigestion), *agnimandya(weak capacity of digestion)* and finally results in *Amlapitta*.

In *Manasika hetus*[15]; *Krodha* (Anger) causes *Pitta prakopa(increase in Pitta), Chinta* (Stress)causes *rasa dhatu dushti, Bhaya(Fear)* causes *Trasa (*pain) and *Shoka(*Grief *)* causes *vataprakopa(Increase in Vata)*[16]. *Vata pitta anubandha* is there in *Manasika hetus* which causes indigestion[15] which again leads to Agnimandya and creates Vidhaha(burning), Shuktata(sour blenching) and Amlapitta symptoms appear.

Apart from above hetus if person takes Pitta prakopak (spicy ,pungent food items) Ahara, Vihara, Adhyashana(excessive eating), Viruddha-ahara(opposite property in food) ,Pishtanna (Bakery products), katu-lavan Rasa sevana (food with pungent and salty taste), it leads to vidagdhata (incomplete digestion) of Ahar(food) and then leads to Amlapitta.

Conclusion

Present study help us to estimate association of *Amlapitta* with changed life style pattern. These etiological factors like *Viharaj and Manasika hetus* namely *Ratrijagarana,Vegavidharana,* Mental stress cannot be eradicated totally due to current career progression scenario. But definitely alternative therapies like yoga, meditation, diet plans etc. can be suggested and practiced as and when necessary. This may help in lowering the rate of incidence, symptomatic relief and act as preventive measure in young Police professionals.

Clinical Correlation, Isolation, Speciation, and Antibiotic Susceptibility Pattern of Tribe Proteeae from Various Clinical Samples

Bavitha C[1], Udayalaxmi J[*2], Elizabeth G[1], Pooja Rao[2]

[1]MSc Microbiology student, [2]Associate Professor, Microbiology department, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Organisms belonging to Tribe Proteeae are usually present as commensals in the environment but can cause urinary tract and wound infections. There is a need for regular studies on sensitivity pattern of various bacteria causing infections to decide a suitable empirical therapy and there are not many studies on Tribe Proteeae.

Aim: To clinically correlate, isolate, speciate and determine the antibiotic susceptibility pattern of Tribe Proteeae from various clinical samples.

Materials and Method: All samples were cultured on standard culture media as per routine protocol. Isolates were identified by standard biochemical reactions. Antibiotic sensitivity was done by Kirby Bauer's disk diffusion method as per CLSI guidelines. ESBL production was detected by double disk diffusion method using ceftazidime (30µg) disk and ceftazidime/clavulanic acid (30/10µg) disk. Clinical data was collected from the record section of the hospital.

Results: Sixty samples yielded bacteria belonging to Tribe Proteeae. Most of the patients belonged to male gender 46 (76.7%) and >50 years 38 (63.3%) of age. *P mirabilis* was the predominant isolate 42 (70%). Maximum rate of isolation of *Proteus spp* was from diabetic foot ulcer 21 (35%). The predisposing conditions were diabetes mellitus, tracheostomy cases and only one case of carcinoma tongue. Most of our isolates were sensitive to various drugs tested. There were only three (5%) ESBL producers. Most of the isolates of *P.mirabilis* were sensitive to antibiotics than *P vulgaris* isolates.

Conclusion: Maximum rate of isolation of tribe Proteeae was from diabetic foot ulcer cases. *P.mirabilis* was the predominant isolate and was more sensitive to the antibiotics tested than *P.vulgaris.*

Key words: *Beta lactamases, Diabetic foot, Proteus mirabilis, Proteus vulgaris*

Introduction

The three genera, Proteus, Providencia and Morganella belong to Tribe Proteeae These bacteria are usually found in water, sewage and soil as they are the normal flora of the intestine. [(1)] They cause a variety of community-acquired and nosocomial diseases, which include bacteremia, wound infections and urinary tract infection. [(1-4)]

Among genus Providencia, *P. rettgeri* is most frequently isolated from urine of the catheterized patients in hospitals and nursing homes.[(4)] The genus Morganella causes opportunistic infections in humans. [(1,4,5)]

The antibiotic resistance due to the inadequate and inappropriate use of antibiotics is a public health

problem, hence the need for regular studies on sensitivity pattern of various bacteria causing infections to decide a suitable empirical therapy.[6] The present study aims to clinically correlate, isolate, speciate and determine antibiotic susceptibility pattern of Tribe Proteeae from various clinical samples.

Materials and Method

It was a prospective time bound study conducted from October 1st 2017 to March 31st 2018 in Microbiology department of a tertiary care hospital in South India. All samples received at microbiology laboratory which were positive for Tribe Proteeae and the gram's stain picture indicates active infection from October 1st 2017 to 31st March 2018 were included in the study. Samples which did not yield Tribe Proteeae, which were received on dates other than the period of study and which yielded scanty mixed growth were excluded. Clinical data was taken from the records section of the hospital. Gram staining was done on all samples. All samples were cultured on Mac Conkey's agar, Chocolate agar and Blood agar. Semi quantitative standard loop method were used for urine samples and they were cultured on CLED, Mac Conkey agar and on blood agar.[7] Isolates were identified by standard biochemical reactions.[7]

Antibiotic sensitivity was done by Kirby Bauer's disk diffusion method according to CLSI guidelines.[8] ESBL production was detected by double disk diffusion method wherein Ceftazidime (30µg) disk and Ceftazidime/clavulanic acid (30/10µg) disk was used. If the difference between the two zones is > 5 mm the test was considered as positive. [8]

Statistical Analysis

Statistical analysis was performed by using SPSS version 16.0. Also between two variables statistically significant correlation will be done using Chi Square test. P value <0.05 was considered as significant.

Results

Sixty samples yielded bacteria belonging to Tribe Proteeae. Of these there were 46 (76.7%) male and 14 (23.3%) female; 38 (63.3%) were >50 years of age, 15 (25%) were 30-50 years of age and 7 (11.7%) belonged to <30 years of age. Of the 60 samples, there were 21 (35%) cases of diabetic foot ulcer, 18 (30%) cases of wound infection, 8 (13.3%) cases of endotracheal tube tip, 5 (8.3%) cases of urinary tract infection, 4 (6.6%) cases of skin and mucous membrane infection, 2 (3.3%) cases of sepsis were blood culture became positive, one (1.6%) case of endopthalmitis and one case (1.6%) of cholangitis where bile was received (Figure 1). Of the different skin and mucous membrane infection we had one case of carcinoma tongue with an ulcer over the tongue, 2 cases of perineal and perianal abscess, discharging sinus over axilla, one case of eczema and cellulitis. Diabetic foot ulcer patients were treated with magnamycin (cefaparazone sodium) and clindamycin. Tracheostomy cases were put on cefaperazone sulbactum, Cholangitis was treated with meropenem, eczema, cellulitis with augmentin (amoxyclav) and clindamycin, discharging sinus over the axilla was treated with linozelid and chloramphenicol, perianal abscess was treated with amoxiclav, metronidazole, clindamycin. Almost all patients had underlying co morbidities like diabetes mellitus or carcinoma.

Of the different isolates, there were 42 (70%) *Proteus mirabilis*, 15 (25%) *P.vulgaris,* 1(1.7%), *P.penneri*, 2 (3.3%) *Providencia* spp. Most of the isolates were sensitive to all the drugs tested. There were only three isolates which were ESBL producers (one isolate was *P. mirabilis* from urine sample, one isolate of *P. vulgaris* from diabetic foot ulcer and the third isolate was *P. penneri* from diabetic foot ulcer). Comparatively *P.vulgaris* showed more resistance to drugs then *P. mirabilis* (Table 1). *P. penneri* and *Providencia* spp showed resistance to most of the drugs studied but the number of isolates were very less to conclusively say so. We did not find any statistically relevant correlation between different clinical conditions and the antibiotic resistance.

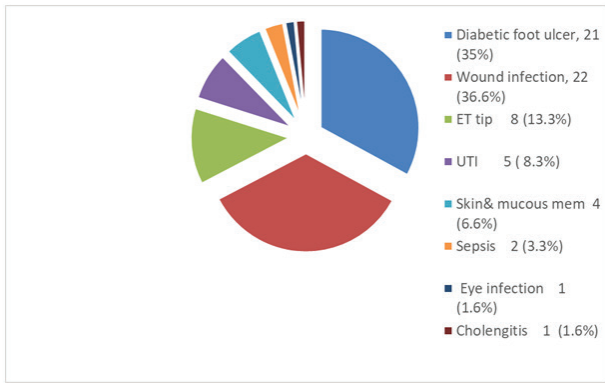

Figure 1: Clinical Correlation

Discussion

In a study conducted in Rajasthan, India, of 1876 clinical samples 5.4% (101/1876)

yielded *Proteus* species. Maximum isolation was from pus 80.2% (81/101) followed by urine 8.9% (9/101) and also maximum proteus species was isolated from inpatients than out patients and 91% (92/101) were ESBL producers. *P. mirabilis* was the predominant isolate. [2]

In a study conducted in Chandigarh, India, 60 consecutive non-repeated strains of *P. mirabilis* were evaluated for production of ESBLs, AmpC b-lactamases, and carbapenemases. Of these, 36 (60%) isolates were found to be ESBL producers, and 7 (12%) were positive for production of AmpC b-lactamases.[3]

In a study conducted in Ghana, Africa, of the 200 Proteus species obtained from patients suspected of bacterial infection, wound isolates were the highest (64.5 %) followed by ear swab. *P. mirabilis* was the commonest species (61.5 %), followed by *P. vulgaris* (30.5 %), and *P. penneri* (8 %). There was no significant difference between the out-patient and in-patient cases, just as there were no preferences for gender or age of the patients. All the species were resistant to chloramphenicol, ampicillin and co-trimoxazole. About 72.9 % of the isolates produced β -lactamase and 88.5 % were resistant to more than 2 antibiotics. *P. penneri* was the most resistant among the recovered species.[9]

In a study conducted in Mumbai, India, three Proteus species were recovered from 56 (1.12%). of the 4995 clinical samples collected, 38 of these samples (67.85 %) were taken from male patients and 18 (32.14 %) from females. Wound samples contributed the highest percentage of Proteus (67.85%) followed by urine. ESBL production was highest in *Proteus penneri* 58.33% followed by *Proteus vulgaris* 33.33% and *Proteus mirabilis* 8.33%..[10]

In a study conducted in Tamil Nadu, India, out of 3972 clinical samples 121 (3.04%) Proteus strains were isolated. *Proteus mirabilis* was more commonly isolated than *Proteus vulgaris*. Pus (44.6%) and urine (50.4%) were predominant samples. There were more numbers of male (63.6%) patients than female (36.4%). Isolates of Proteus spp were highly sensitive to imipenem, piperacillin-tazobactum, ofloxacin.and highly resistant to ampicillin, amoxycillin-clavulanic acid and 24.8% were ESBL producers. [11] In the present study also most of the patients were male and *P.mirabilis* was the predominant isolate but ESBL production was only 5% (3/60).

In another study, 100 isolates of Tribe Proteeae were collected over a period of 6 months from clinical specimens obtained from patients suspected of bacterial infection. Wound infections were the highest (52%) followed by urine (47%). *Proteus mirabilis* was the predominant species (61.5 %), followed by *Proteus vulgaris* (30.5%). More than 80% were resistant to ampicillin and cefazolin, 34% to quinolones, 32% to aminoglycosides and 48% to Co-trimaxazole. About 49 % of the isolates produced ESBL and 16 % were multidrug resistant. *Providencia stuartii* was the most resistant among the recovered species. Maximum sensitivity was noted with carbapenems and maximum resistance with ampicillin and first and second generation cephalosporins. [12]

In a study conducted at Republic of Cameroon, of the 1136 culture positive clinical specimens, 164 (14.4%) isolates were identified as members of Proteeae of which 110 (67.1%) were from urine, 37 (22.6%) from wounds and burns, 10 (6.1%) from blood and 7 (4.3%) from CSF. Speciation of the Proteeae isolates showed that 111 (67.7%) were *Proteus mirabilis*, 21(12.8%) *Proteus vulgaris*, 11 (6.7%) *Providencia alcalifaciens*, 6 (3.6%) *Providencia stuartii*, 4 (2.4%) *Morganella morganii* and 5 (3.0%) *Proteus penneri* and *Providencia rettgeri*. Most Proteeae isolates were susceptible to imipenem, ceftazidime, chloramphenicol, gentamycin, nalidixic acid, ofloxacin and amikacin.[13]

In the present study as in studies conducted in past, most of the Tribe Proteeae were isolated from diabetic foot ulcers, but we did not find much antibiotic resistance. But as in the past studies, *P.vulgaris* was more resistant to antibiotics than *P.mirabilis*.

Conclusions

Most of the patients belonged to male gender and >50 years of age. As in previous studies, *P mirabilis* was the predominant isolate. Maximum rate of isolation of *Proteus spp* was from diabetic foot ulcer. The predisposing conditions were diabetes mellitus, tracheostomy cases and only one case of carcinoma tongue. Most of our isolates were sensitive to various drugs tested. There were only three ESBL producers. *P.mirabilis* was more sensitive to antibiotics than *P vulgaris*.

Effect of Garbhini Ahara-Vihara (Diet & Lifestyle in Pregnancy) On Garbhastha Sishu (Fetus) and Offspring

Bharadwaj Pooja[1], Kumar Pradeep[2], Srivastava Niraj[3], Saxena Varsha[4]

[1]Director General Ayush (Retd.), Government of Uttarakhand, Dehradun, [2]Professor, Department of Shalya Tantra, Faculty of Ayurveda, Institute of Medical Sciences Banaras Hindu University, Varanasi (U.P)., [3]Associate Professor, Department of Kaumarbhritya/ Balroga, Government Ayurvedic PG College & Hospital, Varanasi (Sampurnanand Sanskrit University), [4]Assistant Professor, Department of Shalya Tantra, Main campus Uttarakhand Ayurved University (UAU), Harrawala, Dehradun (Uttarakhand)

Abstract

Ayurveda not only focus on preventive and promotional health but also has strong footing in the field of healthy progeny. *Garbhini Paricharya* refers to antenatal care or prenatal which recommends *Ahara* (specific dietary regimen) and *Vihara* (activity for physical, mental and emotional well being). In *Ayurveda*, *Garbhini paricharya* is divided in three categories such as *Masanumasik Pathya ahara* and *Vihara* (monthly dietary regimen and lifestyle), *Garbhasthapak karma* (diet and activities for maintenance of pregnancy and better progeny) and avoidance of *Garbhopaghatakar Bhavas* (diet and activities which are harmful to fetus). We always say "you are what you eat" it may also be true that "you are what your mother ate". Modern medical science also believes that fetal growth is dependent on appropriate diet and life style of pregnant mother. Organogenesis is that period when important organ of fetus are developing. It is 6-10 wks of intrauterine life. During this period fetus is most at risk from birth defects caused by external factors. Many diseases and fetal development disorders are consider as being related to prenatal exposure to endocrine disrupting chemicals (EDC). The physical, mental, social, and spiritual well-being during pregnancy and practice of a wholesome regimen, play a prime role in achieving a healthy progeny.

In the present review article prime focus is given on effect of diet and life style of pregnant woman on fetus described in *Ayurveda* and modern medical science.

Keywords: - *Garbhini, fetus, Ahara-Vihara, Pranayama, endocrine disrupting chemicals (EDC).*

Introduction

Ayurveda not only focus on preventive and promotional health, but also has strong footings in the field of healthy progeny. Pregnancy is a beautiful period in women's life. *Ayurveda* believe on "pregnancy by choice not by chance" and life of women is not complete until and unless she gets pregnant and gives birth. In *Ayurveda*, Regular supervision of a woman during pregnancy is called *Garbhini paricharya* (antenatal care). The term *Garbhini Paricharya* is a compound of two separate words i.e. *Garbhini* & *Paricharya*. According to *Amarkosha*, *Garbhini* means a woman in which *Garbha* is present [1] and '*Paricharya*' means caring in every aspect. *Garbhini Paricharya* includes all aspects of care of pregnant women like *Ahara* (dietary regimen), *Vihara* (activities), *Pathya* (wholesome diet) *Apathya* (unwholesome diet), *Yoga* and Meditation etc.

Ayurveda has beautifully explained a quotation regarding the care of pregnant women that the *Garbhini* should be treated just like a pot filled with oil as the slightest oscillation of such pot can cause spilling of oil similarly slightest stimulation in *Garbhini* can cause *Garbhapata* (abortion) or *Garbha vikriti* (anomalies in fetus). [2] In Modern medical science, antenatal care (ANC) is systemic supervision of pregnant lady including the examination &advice from beginning of conception to delivery. Modern medicine describes antenatal Care by describing antenatal Diet i.e. extra calorie diet, diet to Prevent Anemia, Personal Hygiene, Rest and Sleep, Exercise, Light Work, drugs prohibited and Coitus, etc.[3]

In *Ayurveda, Garbhini Paricharya* (Antenatal care) advised for a pregnant woman can be summarized under following three categories such as *Masanumasik Pathya ahara* and *Vihara* (Monthly dietary and lifestyle regimen) *Garbhasthapak karma* (diet and lifestyle for maintenance of pregnancy and better progeny) and *Garbhopaghatakar Bhavas* (diet and lifestyle which are harmful to fetus) and.

Masanumasik Pathya Ahara (Monthly dietary regimen) during pregnancy:–

Ayurveda advised that *Garbhini* (pregnant lady) should take sweet, liquid, nutritive diet with good quantity of milk, freshly cooked rice, meat or meat-soup, butter extracted from milk, milk cooked with *Madhura* group of drugs and other congenial diet. Fetus derives its nutrition from mother, what so-ever she takes the rasa derived is divided in three parts i.e. for the nourishment of the mother, for nourishment of fetus and for development of breasts / formation of breast milk [4]. The requirement of mother nutrition varies according to development of fetus and changes month wise.

Effect of excessive use of Rasa in pregnancy on fetus:-

The diet has to be balanced, excess use of any particular rasa or *Dosha* aggravating causes various congenital abnormalities or influences gene expression at a later life producing various diseases. [5] If pregnant women take *Vata* aggravation diet then fetus may suffer from *Kubja* (dwarf), *Kuni* (Arm without hand or finger), *Pangu* (motionless limb), *Muka* (Dumb) and *Minmin* (Nasal voice) [6]. If any body part of pregnant women is affected by the *Vatadi dosha*, then the same part of the fetus will also be get affected by *Vatadidosha* [7]. If pregnant women take *Kapha Vardhak Ahara* then fetus may suffer from- *Kustha* (Skin diseases), *Kilasa,* Congenital teeth at birth, *Switra* (Lucoderma) and *Janmajata Pandu roga* (Congenital anemia) [8].

Effect of Diet and environment in Pregnancy:-

EDC are natural or synthetic chemical molecules able to modify an organism's operation of the hormonal system [9]. Many diseases and disorders of children are associated with prenatal exposure of endocrine disrupting chemicals (EDC), including low birth weight (LBW) baby [10], premature delivery [11], autism [12], allergic disorders [13], pubescent development disorders [14] and even Cancers are also a possible consequence [15].

(1) Effect of Alcohol Consumption on fetus:-

Consumption of alcohol during pregnancy may result in abortion, fetal mortality and prematurity [16]. Alcohol consumption during first five weeks pregnancy may harm embryos and fetus; such damage is referred to as fetal alcohol spectrum disorders (FASD) [17]. Fetal alcohol syndrome (FAS) has a typical pattern of facial alterations, pre- and/or postnatal growth restriction associated with evidence of structural and functional changes in CNS changes due to intrauterine alcohol exposure [18].

(2) Effect of Smoking on fetus:-

Exposure to tobacco smoke is considered most harmful and it is associated with high rates of long and short term morbidity and mortality for mother and child [19]. Maternal smoking during pregnancy has also been linked with increase BMI in children (due to reduced height and increased amount of body fat [20] and risk for obesity in childhood and adult life [21].

(3) Effect of Physical and mental stress on fetus:-

Physical and mental stress such as grief, shock, anger, excessive exercise etc. influences on secretion of vasopressor hormones which lead to IUGR, Preterm and more chances of LBW babies associated, gestational diabetes and congenital defects. It can also affect development of brain and might lead to behavioral disorder in childhood period [22].

(4) Effect of excessive coffee intake on fetus: -

Caffeine is rich source of foods such as coffee, tea, soft drinks, chocolates and its excessive intake increase chance of birth defect on fetus [23]. Caffeine intake is negatively associated with low birth and placental weight, greater number of stillbirths, increased expression of apoptotic markers and altered placental and bone formation [24].

Effect of Mode of life on fetus:-

A. **Abode**:- The abode of pregnant woman should be regularly fumigated and be free from mosquito etc.[25]

B. **Bath: –** Pregnant women should take daily bath with water boiled with specific drugs capable of suppressing *Vata* [26]

C. **Daily routine**: – *Garbhini* (pregnant women) should get up in the morning, worship the rising sun, fumes, homage and pray in loud voice or move in fresh air with deep breathing [27].

D. **Behavior**: - *Garbhini* (pregnant women) should be made to live in harmonious, happy atmosphere; behavior of everyone should be congenial and affectionate.

Mode of life which is harmful to fetus:-

Ayurveda believe that *Garbhini* (pregnant women) should not move in dirty, foul smelling places; avoid wine and other intoxicants, smoking and excessive exercise etc. [28]. Due to *Ati-vyayama* (physical activities or exercise in excess), *Ati-langhan* (excessive fasting), *Ati-vyavaya* (excessive sexual indulgence), *Ati-karshana* (Excessive emaciation because of affliction of disease) etc. affect the different organs or body parts in a pregnant women by vitiating the relative *Dosha* and that *Dosha* will also affect the same body parts or organs of fetus [29]

Effect of non fulfillment of Dauhrida:

Ayurveda describes that in 4th month of pregnancy mother consider as *Dauhrida* (one sense organ of mother and another of fetus). If pregnant mother is not having fulfilled desires during this period it can cause – distorted eyes or no eyes, Hump back, crooked arm and legs, mental retardation, dwarf, abnormality in sense organ, congenital abnormality and even death of fetus [30].

Drugs beneficial for maintenance of pregnancy (Garbhasthapaka dravyas):-

Ayurveda describes many *Garbhasthapaka aushadh* is in *Prajasthapana mahakashaya* such as Aindri (*Bacopa monnieri*), Brahmi (*Centella asiatica*), Satavirya (*Asparagus racemosus*),Sahrshravirya (*Cynodon dactylon*), Amogha(*Stereospermum suaveolens*), Avyatha (*Tinospora cardifolia*), Shiva (*Terminalia chebula*), Arista (*Picrorhiza kurroa*) Vatyapushpi or Bala (*Sida cardifolia*) and Vishwasenkanta (*Callicarpa macrophylla*) [31].These drugs can be use orally by preparations of milk or ghee and cold decoction of these drugs for bath. *Acharya Kasyapa* has advised that amulet of Trivrit (*Operculina tharpethum*) should be tied in the waist of pregnant woman [32]. In present era many therapy such as music therapy, happiness in pregnancy, yoga, meditation etc. help to maintenance of pregnancy and better progeny.

How to live a Happy and Healthy life style during pregnancy:-

1. Music therapy in pregnancy:-

The infants of mothers exposed to music during pregnancy have significantly influences neonatal behavior. Many studies showed that 30 minutes music therapy per day for two weeks significantly reduced their stress, anxiety, and depression, when compared with participants who did not take music therapy [33].

2. Happiness in pregnancy:-

Children of depressed mothers may experience a delay in cognitive development, such as language delays and even lower IQ. Many studies indicate that the happiness during the pregnancy, the lower the chances of the baby facing mental and physical health challenges [34].

3. Yogasana in pregnancy:-

Yogasana in pregnancy reduces muscle cramps during third trimester, increases the flexibility of spine, tones up the lower body, improves digestion, relives constipation, improves blood circulation, and relives stress. Common *Yogasana* in pregnancy is *Vrikshasan* (Tree pose), *Vajrasan* (Thunderbolt pose), *Matsyakridasan* (Flapping fish pose) and *Marjariasan* (Cat stretch pose) etc.

4. Effect of Pranayam (Breathing exercise) in pregnancy:-

In Sanskrit, the *Pranayama* word is prepared by -'*Prana*' and '*Ayama*'. Here *Prana* means energy and *ayama* means the distribution of energy. *Pranayam* provides rich oxygenation to the blood and promotes a calmer mind and body. *Anulom* and *Vilom* is main *pranayam* which is practiced during pregnancy in each trimester. It provides more oxygen to the pregnant women and more oxygen is transferred to the fetus. *Swastikasana* and *Vajrasana* are the best *Yogasana* for practiced the breathing techniques. *Yogasana* and *Pranayama* is very effective in high risk cases of pregnancy also such as hypertension, asthama, Gestational Diabetes Mellitus, cardiac diseases diabetes and thyroid disorders. [35]

Discussion and Conclusion

Garbhini Paricharya aims at excellence in the formation of the fetus, its development without anomalies,

a secure full term normal delivery and maintenance of the health of the fetus. In this regard they divide whole *Garbhini paricharya* in three categories such as *Masanumasik Pathya ahara* and *Vihara* (Monthly dietary and activities regimen), *Garbhasthapak karma* (diet and activities for maintenance of pregnancy and better progeny) and *Garbhopaghatakar bhavas* (diet and activities which are harmful to fetus). *Acharyas* considers milk is an ideal product as a diet for pregnant women because it is a rich source of calcium, lactose and fat [36]. Milk help in relieving constipation which is common problem during pregnancy. In second trimester pregnant women mostly suffer from edema of feet and other complications of water retention. In 6th month Gokshura (*Tribulus terrestris*) is advised which act as good diuretic and prevent retention of water. In *Ayurveda* many *Garbhopaghatakar bhavas* (diet and activities which are harmful to fetus) described such is *Ati-vyayama* (physical activities or exercise in excess), *Ati-langhan* (excessive fasting), *Vegavidharana* (suppression of natural urges) and not fulfillment *Dauhrida* desires etc. But if *Garbhini* practicing *pranayama* then during labour minimum release of adrenaline and proper release of oxytocin which make labour easier and smoothen. There is urgent need to include this plan in RCH (Reproductive and Child Health) programme for maternal and fetal wellbeing. So that national goal may be achieved in more effective manner.

Age determination using Nolla's Method- A Radiographic Study

Bharathi.S[1], Meenakshi.K[2]

[1]Undergraduate Student, [2]Senior Lecturer, MDS Oral Medicine And Radiology, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Background: Tooth development shows less variability in relation to chronological age. Tooth development is widely used to assess maturity and predict age. So, dental tissues can be used as a better aid for estimating age. Radiography plays an important role in humane age determination. There are five common methods to determine age using radiographs: Gleiser and Hunt (1955); Demijiran et al (1973); Gustafson and Koch (1974); Harris and Nortje (1984); Kullman et al (1992). Nolla's method (1960) was one of the various method used in age determination using radiographs. The aim is to estimate the age using Nolla's method of forensic age estimation.

Materials and Method: The present study was conducted on 20 selected individuals(10 males and 10 females) between age 9-17. Dental age assessment was done using OPG. The radiograph were compared with the Nolla's chart (fig-1) and dental age was assessed using age norms for upper and lower teeth including third molars proposed by Nolla. The chronological age and dental age obtained using Nolla's method was later subjected to statistical analysis.

Results: There is no significant difference between chronological age and estimated age with Nolla's method both in males and females i;e is 'p' value is not significant in both males and females (.161 in females and .757 in males).

Conclusion: Nolla's method of age determination was accurate in both males and females.No statistical significance was found between chronological age and estimated age for males and females. Hence Nolla's method can also be used in forensic dentistry.

Keywords: *Nolla's method , dental age, chronological age.*

Introduction

Growing individuals not only differ in the timing of the maturational events, but also in the sequence of maturational events. The developmental status of an individual can be assessed from various parameters such as height, weight, chronological age, secondary sexual characteristics, skeletal age, and dental age [(1)]. Age is one of the essential factors, which play an important role in every aspect of life. The assessment of age is useful in planning treatment of orthodontic and pedodontic patients, and in forensic medicine and forensic odontology and also provides valuable information when the birth date is not available, as in case of illegal immigrants. Its use is increasing in both civil and criminal matters and is also helping in the identification of age at death of a dead individual in mass disasters and natural calamities. In children, age determination from the teeth is relatively simple and accurate; it is based on the stage of development and eruption of teeth [(2)]. The branch of radiology comes handy which provides baseline data for age estimation [(3)]. The aim of an ideal age estimation technique is to arrive at an age as close to the chronological age as possible. Various age estimation methods have been tested and reported in the literature [(4)]. Visual, radiographic, chemical and histological methods are various methods of estimating age [(3)].

Visual method: It is based on of the sequence of eruption of the teeth and the changes that are caused due to function such as attrition, changes in colour are indicators of ageing.

Radiographic method: Radiographs of the dentition can be used to determine the stage of dental development of the teeth. This method is the most commonly used method as it aids in age determination over a long span of time.

Histological method: Histological methods require the preparation of the tissues for detailed microscopic examination which can determine more accurately the stage of development of the dentition. This technique is more appropriate for post-mortem situations.

Chemical analysis: The chemical analysis of dental hard tissues determines alterations in ion levels with age. These techniques are not of great value to the forensic odonatologist and future developments may provide adjunctive means of collecting evidence of value in the dental framework.

Radiograph plays an important role in human age determination. Demirjian and Nolla's method was widely used age estimation methods using radiographs since it utilizes maturation of teeth for age assessment. Demirjian et al classified teeth development into 8 stages which includes only 7 mandibular teeth and concluded a method for age estimation [1]. This method is most widely accepted [5,6]. Later, Acharya included the 3rd molar as well and arrived at a formula for Indian population [7]. Nolla classified the teeth development into 10 stages and arrived at a method [8]. Tooth development shows less variability than other developmental features and also low variability in relation to chronological age [9]. Dental tissues are resistant to mechanical, chemical and thermal changes and is suitable for estimation of age because it is continuous, progressive process that can be followed radiographically from the crypt stage to the closure of root apex. Dental age estimation is based upon the rate of development and calcification of tooth buds and the progressive sequence of their eruption in the oral cavity. Also tooth development is uniform and is less influenced by external factors such as malnutrition, diseases and mental stress and less affected by endocrine status [10]. As radiographs provide a two-dimensional view of the dental tissues it is very much helpful in estimating age. With this background the aim of our present study was done with an objective to assess age by using Nolla's method and to estimate the efficacy of Nolla's method.

Materials and Method

The present study was conducted on randomly selected 20 individuals. Among them, 10 were males (50%) & 10 were females (50%). The age ranged from 9-17 years. Age assessment was done using radiographs (OPG). A brief history of each individual including name, age, sex, date of birth, name of the school and address were recorded. Age and date of birth was reverified using valid identity proofs. Chronological age was calculated from date of birth to date of radiograph being taken. Chronological age= Date of radiograph taken-Date of birth. Dental age or estimated age was calculated from the radiographs taken using Nolla's normalized table for boys and girls. The results were then subjected to statistical analysis.

Criteria for sample collection:

- None of the subjects selected had undergone orthodontic treatment
- All the subjects selected were moderately built and were of growing age with no history of deformities, bone diseases, and major illness in the past
- None of the subjects showed any facial asymmetry.
- No history of trauma or surgery was reported in the dentofacial region
- The subjects with muscular dystrophy, congenital abnormalities affecting growth and development, or traumatic injuries of hand wrist and jaws were excluded.
- The presence of all the eight left or right maxillary and mandibular teeth (erupted or not) was considered.

Nolla's method:

It was devised by C M Nolla [11] in 1960. Nolla evaluated the mineralization of permanent dentition in 10 stages. Each tooth is assigned a reading and a total of the maxillary and mandibular teeth are made. The total is compared with the pre-determined values in the norms table to determine the age. This method is one of the most acuurate and reliable method as girls and boys are dealt separately.

The radiograph was compared with the Nolla's developmental stages (fig-1) and dental age was assessed using age norms for upper and lower teeth for females (table-1) and males (table-1) including third molars proposed by Nolla.

Fig-1

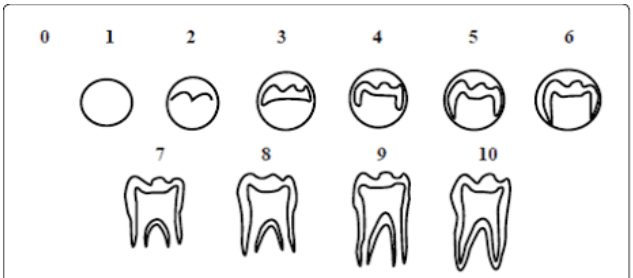

Figure 1: showing Nolla stages of development of third molar. Stage 0 - absence of crypt, Stage 1 – presence of crypt, Stage 2 – Initial calcification, Stage 3 – 1/3rd crown completed, Stage 4 – 2/3rd crown completed, Stage 5 – crown almost completed, Stage 6 – crown completed, Stage 7 – 1/3rd crown completed, Stage 8 – 2/3rd crown completed, Stage 9 – root completed, apex open, Stage 10 – apical foramen closed.

Nolla's developmental stages:

Stage 10: Apical end of root completed

Stage 9: Root almost complete; open apex

Stage 8: Two-third of root completed

Stage 7: One-third of root completed

Stage 6: Crown completed

Stage 5: Crown almost completed

Stage 4: Two-third of crown completed

Stage 3: One-third of crown completed

Stage 2: Initial calcification

Stage 1: Presence of crypt

Stage 0: Absence of crown.

Table 1- Norms for males and females including third molars.

	Age in years	Sum of stages of 8 mandibular teeth	Sum of stages of 8 maxillary teeth.	Sum of stages of 16 maxillary and mandibular teeth.
Males	7	54.2	49.5	103.7
	8	59.5	57	116.5
	9	66.7	62	112.7
	10	67.5	66.6	134.1
	11	70.0	68.3	138.3
	12	72.6	73.2	145.7
	13	74.7	75.4	150.1
	14	75.9	76.5	152.4
	15	76.7	77.1	153.8
	16	77.5	78	155.5
	17	78.0	78.7	156.7
Females	7	49.5	45.5	95
	8	55.1	51.8	106.9
	9	59.7	57.3	117
	10	63.5	61.8	125.3
	11	66.7	65.6	132.3
	12	69.8	69.3	139.1
	13	72.3	72.2	144.5
	14	74.3	74.4	148.7
	15	75.9	75.9	151.8
	16	77.3	77.7	155
	17	77.6	78	155.6

The estimated age was obtained using Nolla's method and was compared with chronological age and was subjected to statistical analysis.

Results

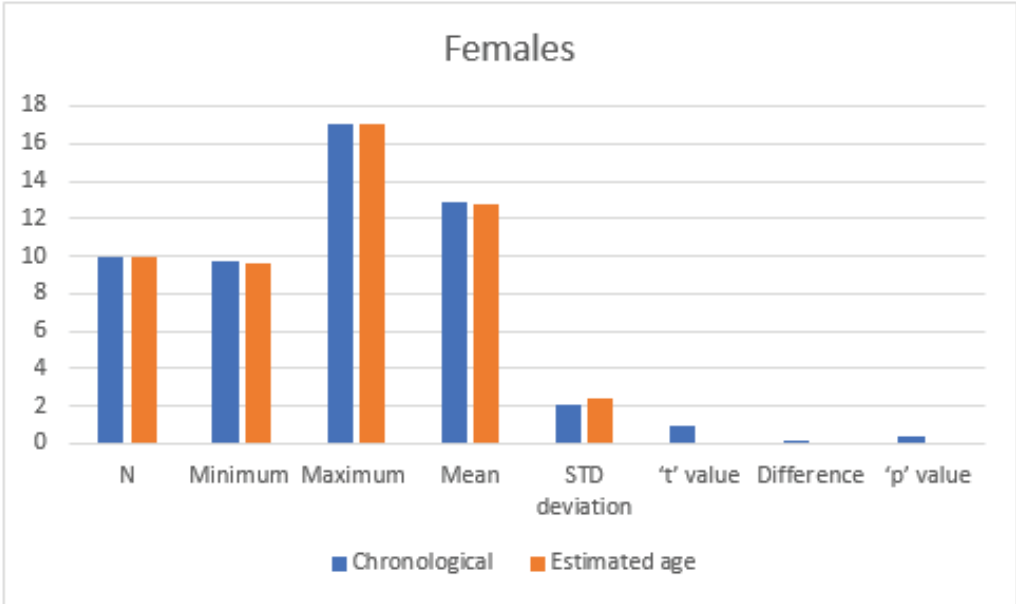
This study comprised of 20 patients between the age group of 9-17 years and the method used to determine the age was Nolla's method. Chronological age and estimated was calculated for females and males. Paired 't' test was done (graph-1,2)(table 2,3). Distribution of patients with their gender, chronological age with minimum and maximum and the estimated age using Nolla's method with minimum and maximum was calculated. Mean and standard deviation was also calculated for females and males (table-2,3). There is no significant difference between chronological age and estimated age with Nolla's method both in males and females i;e is 'p' value is not significant in both males and females (.376 in females and .468 in males)

Table-2- Females (Paired 't' test)

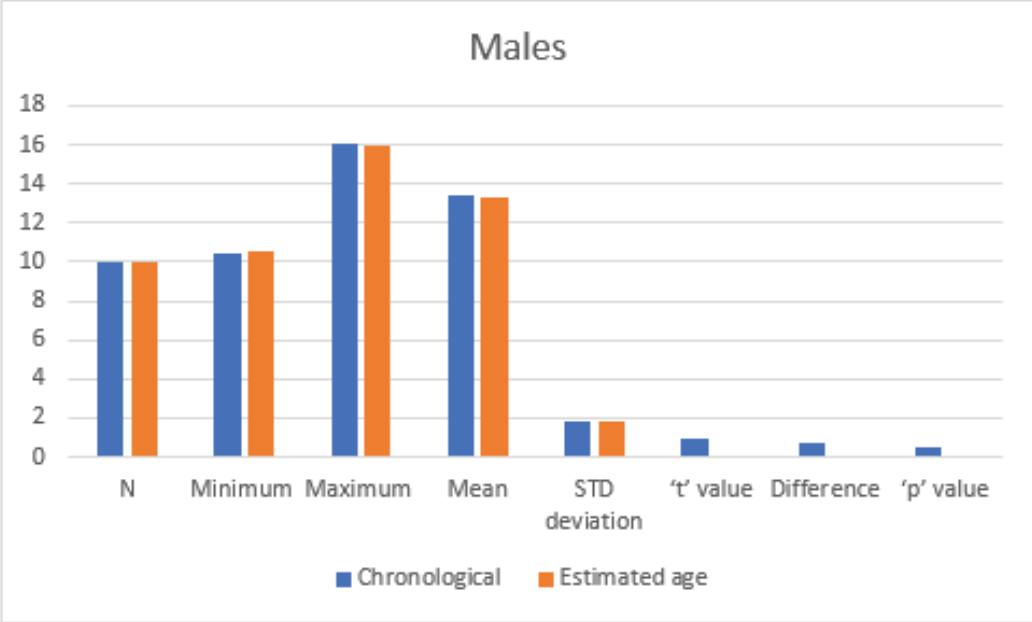
	N	Minimum	Maximum	Mean	Std. Deviation	't' vale	Difference	'p' value
Chronological age	10	9.70	17.00	12.8920	2.12701	.930	.161	.376 Not Significant
Estimated age	10	9.60	17.00	12.7310	2.40482			

Table - 3 – Males (Paired 't' test)

	N	Minimum	Maximum	Mean	Std. Deviation	't' vale	Difference	'p' value
Chronological age	10	10.40	16.10	13.3700	1.84695	.930	.757	.468 Not Significant
Estimated age	10	10.50	16.00	13.2910	1.84226			



Graph-1



Graph-2

Discussion

Our study comprises 20 individuals which includes 10 females and 10 males of age 9-17 years. Out of 10 female individuals, five females showed dental age underestimation by 5 months and 2 months and three female individuals showed dental age underestimation by 1 month. Two females showed exact correlation with estimated age

Out of 10 male individuals, three male individuals showed dental age underestimation by 3 months and 2 months. Four male individuals showed dental age overestimation by 5 months, 3 months, 2 months and 1 month. Three male individuals showed exact correlation with estimated age. Difference of less than 6 months was considered as normal [12].

Distribution of patients with their gender, chronological age with minimum age of 9.70 for females and 10.40 for males and maximum of 17.10 for females and 16.10 for males and the estimated age using Nolla's method with minimum age of 9.60 for females and 10.50 for males and maximum of 17 for females and 16 for males is shown in table 2 and table 3 and graph 1 and graph 2.

There is no significant difference between chronological age and estimated age with Nolla's method both in males and females. 't' value was 0.930 for both males and females. 'p' value was .161 in females and .757 in males (table-2,3) and (graph-1,2).

It also shows mean and standard deviation in two methods. Mean chronological age was 12.8920 and standard deviation of 2.12701 was seen in females and mean of 13.3700 and standard deviation of 1.84695 was seen in males. The mean of estimated age by Nolla's method was 12.7310 and standard deviation of 2.40482 was seen in females and mean of 13.2910 and standard deviation of 1.84226 was seen in males. Average chronological age and average estimated age by Nolla's method shows statistically non-significant difference and good correlation was found. (table-2,3).

The dental system is an integral part of the human body; its growth and development can be studied in parallel with other physiological maturity indicators such as bone age, menarche, and height [13].

Nolla's method was introduced by Nolla in 1960. In this method the staging is done based on calcification of individual tooth which is from stage 0 to 10. It has additional staging of mineralization which proves it to be more accurate and reliable and thus making it the most commonly used method around the world [14].

Miloglu et al conducted a study on Turkish males using the Nolla's method and inferred that the mean difference in the dental and chronological age

ranged from -0.5 to 0.0 years proving the accuracy of Nolla's method above any other method of dental age estimation, similar statistics were obtained by Caro et al (2001) [15, 16]. And the study by Green found that dental age showed the highest degree of correlation with chronological age [17]. Lauterstein supported this study by his study finding that chronological age bore a positive correlation to the number of erupted teeth [18]. Nolla's method was also used on Maltese school children in 2005 and no significant difference was found between dental age and chronological age [19]. Another study was conducted on Brazilian population in 2007 to evaluate the applicability of the methods proposed by Nolla and Nicodemo and colleagues for assessing dental age and its correlation to chronological age and concluded that the mean difference between true and estimated age for males and females was underestimated and the use of correction factors were recommended [20].

In 2011 Nolla's method was applied to investigate whether or not this method is appropriate for Turkish children for the determination of the dental age. The study suggested that the method is suitable for Turkish boys, but it is less suitable for Turkish girls [21]. In another study conducted in 2012 Validity of Demirjian and Nolla methods for dental age estimation for North Eastern Turkish children were compared and Nolla's method was found to be a more accurate method for estimating dental age in North Eastern Turkish population [22].

The present study agrees with the previously mentioned analysis by various researchers and proves that Nolla's method of estimating dental age by analysing 10 stages of teeth development is better as compared to other methods and easy to perform.

Conclusion

Nolla's method can be considered as a good method of dental age assessment. No statistical significance was found between chronological age and age estimated using Nolla's method for males and females. It could be stated that assessment of maturation is of utmost importance in certain orthodontic protocols such as for myofunctional therapy and the importance of age estimation includes an assessment of minor/major status in individuals without legal documents, Nolla's method, the widely used method shall be a reliable method. And also, dental radiographs have been used in forensic applications mainly for age estimation [23]. Besides the technique is cost efficient as compared to other methods of age estimation and is readily available across all dental clinics.

Assessment of Mass Drug Administration activities for Lymphatic Filariasis Elimination in Vizianagaram District of Andhra Pradesh

Bikash Chandra Nayak[1], Aurobindo Samantaray[2], Y. Bharani Krishna[3]

[1]Assistant Professor, [2]Associate Professor, [3]Professor & Head, Department of Community Medicine, Maharajahs Institute of Medical Sciences, Nellimarla, Vizianagaram

Abstract

Background: Lymphatic Filariasis commonly known as elephantiasis is a painful and profoundly disfiguring disease that has a major social and economic impact. Mass Drug Administration (MDA) programme for the elimination Lymphatic Filariasis (LF) has been implemented globally since 1997 and the MDA campaign launched in India during 2004 to interrupt the transmission of Lymphatic Filariasis

Methods: The present study is a cross-sectional descriptive study conducted from 13th to16th June, 2019 in Vizianagaram district of Andhra Pradesh. The three rural and one urban area of Vizianagaram district were selected using multistage cluster sampling technique Clusters of 30 houses from one village of each PHC and one ward of urban area with a total of 120 households were selected for the study.

Results: A total of 120 households covering 456 population were surveyed out of which 47.1% were male and rest 52.9 % were females. Overall drug distribution coverage is 94% and effective coverage rate is 88%.

Conclusions: There is a pressing need to promote operational research on possible transmission from nearby districts and confirmatory mapping of uncertain areas. Further qualitative comprehensive studies with more diverse participants are needed to ascertain the causal relationship.

Keywords: *Mass drug administration, Lymphatic Filariasis, Drug coverage, Effective coverage rate*

Introduction

Lymphatic Filariasis commonly known as elephantiasis is a painful and profoundly disfiguring disease that has a major social and economic impact[(1)] Currently 886 million people in 52 countries worldwide remain threatened by lymphatic Filariasis and require preventive chemotherapy to stop the spread of this parasitic infection[(2)]. Two-thirds of the endemic population resides in South-East Asia and one-third lives in India[(3)]. LF is prevalent in 256 districts in 21 states and union territories (UTs) and, as on 2017 around 630 million population live in the endemic districts[(4)].

The Global Program to Eliminate Lymphatic Filariasis (GPELF) was launched by the World Health Organization (WHO) in 2000 with the goal of eliminating LF as a public health problem by the year 2020[(5)]. The Government of India (GOI) in 2004 began a nationwide mass drug administration (MDA) campaign in all the known LF endemic districts with an annual single dose of diethylcarbamazine citrate (DEC) with the aim of eliminating it as a public health problem by the year 2015. The current strategy of MDA is to administer annual single supervised dose of anti-filarial drugs by door to door visit along with drug administration at booths and groups preferably on a single day with two-day mopping up operations. MDA is to be repeated annually for a period of 5 years or more aiming at minimum 85% drug compliance for interruption of transmission[(6)]. National Health Policy 2017 envisages achievement and maintenance of elimination of LF in endemic pockets of India by 2017[(7)].

Post MDA assessment is routinely conducted to find out the performance of the implementing units in terms of Coverage and compliance of MDA activities and also to evaluate the reported coverage. This schedule process assist in finding out hindrance if any and to suggest suitable remedial measures. As per the program guideline, this sample survey study was conducted in Vizianagaram district, which is one of the 10 enlisted endemic districts of Andhra Pradesh. Post MDA independent assessment has been conducted in Vizianagaram district after the last round MDA activities conducted between 8th to10th February 2019.

The present study was conducted with the following objectives.

1. To find out the coverage, compliance, and effective coverage rates.

2. To evaluate the reported outcome along with processes followed all through the mass drug administration activities.

3. To determine the constraints in MDA activities and suggest suitable corrective measures.

Materials & Method

Study design and period of study:

The present study is a cross-sectional descriptive study conducted from 13th to16th June, 2019 in Vizianagaram district of Andhra Pradesh.

Study Area:

The present evaluation study was conducted in Vizianagaram district of Andhra Pradesh. In line with the proposition by National task force for evaluation of post MDA activities, the present assessment was conducted in four areas (clusters) – three rural and one urban[8].

Eligible population:

Study population includes all eligible individuals residing permanently in the MDA campaign area. Aligned with the program recommendation, DEC and Albendazole tablets were distributed to the eligible beneficiaries (excluding children under 2 years, pregnant women & seriously ill persons) and special consideration given for on-spot consumption of tablets (9)

Sampling technique:

The three rural and one urban area of Vizianagaram district were selected amongst the 50 endemic PHC and 5 endemic urban areas by using multistage cluster sampling technique. In first stage of stratification, One PHC was selected randomly from each cluster (High, Moderate and Low Coverage based on coverage report). From each of the earmarked PHCs, one sub-centre and thereafter one village from each of the selected sub-centres were finalized for the study purpose. One urban area was randomly selected with lowest reported coverage considering the similar technique. So the areas finalized for the evaluation study were three villages (i.e. Nelivada of Bondapalli PHC, Ramavaram of Gantyada PHC and Kella of Gurla PHC) and Bit-1 ward of Vizianagaram Urban area. Clusters of 30 houses from one village of each PHC and one ward of urban area with a total of 120 households were selected for the study.

Tools and techniques:

Following the program recommendations, the data were collected in a pre-designed pretested semi structured proforma during interviewing the study participants. In-depth interview of health care service providers conducted as part of qualitative assessment and the response were captured in an open ended questionnaire form.

Data analysis & Statistical Methods:

Data Collected during the sample evaluation survey entered in MS Excel and analysed using SPSS version 21. All the analysed results are shown in the form of percentages and projected as tables.

Results

Post MDA assessment conducted in four clusters including three rural and one urban area. Table-1 shows distribution of populations surveyed in listed four clusters. A total of 120 households covering 456 populations were surveyed in Vizianagaram district. Overall 47.1% of studied populations were male and rest 52.9 % were females. Out of the total 456 study populations, only 08 were below <2 years so DEC tablets were distributed to 448 (98.2%) eligible individuals. Out of 448 eligible study participants, majority (79.7%) were aged ≥ 15 years while 12.5 % were in the age group of 2 – 14 years. The age and sex wise distribution of study population in both urban and rural areas were almost similar. Similarly, in both the rural & urban majority of the population were in the age group 15 years or above.

Gender and age wise composition of all 120 interviewed respondents were illustrated in Table-2. Overall, Male and female respondents correspond to 40 % and 60% respectively. Likewise collectively in both settings, majority (77.5%) of the respondents belong to the age group 30–59 years and only 5.8% respondents were above 60 years of age.

The area wise drug distribution coverage, Drug compliance rate and effective coverage rate is described in Table-3. Overall drug coverage was 94% in all the four clusters. Drug coverage in rural area (95%) is marginally better than the urban area (92%). Out of the three rural clusters, maximum coverage was attained in PHC, Gurla area (96%) which corresponds to the reported coverage data shared by the district authority. On the whole drug compliance rate was 93%, as 394 persons consumed the drugs out of 422 drug receivers. Drug compliance rate in both the urban (94%) and rural (93%) is found to be approximately comparable. Effective coverage rate in rural clusters is somewhat better (88%) than the urban cluster (86%).

As illustrated in Table-4, knowledge shared to 92% of interviewed persons by the drug administrator on mode of transmission and various MDA activities. Additionally, Drug Administrator persuaded everyone to swallow the tablets in presence of him/her.

The role of various service providers in creating awareness in the community is elucidated in Table-5. Respondents of all 120 (100%) households were aware of MDA prior to the scheduled activities. Though almost all type of frontline health workers supported in generating awareness in the community, but the role of ASHA is significantly appreciable in rural areas (100%). On the other hand, AWW had taken noticeably effort in sharing knowledge among urban populations.

Various forms of IEC material used and their impact in creating community awareness are well revealed in Table-6. Overall in both urban and rural clusters, posters (58%) were responded as the most effective form of IEC material followed by Banners (32%), handbills (7%) and news papers (3%).Though there was a provision for mike announcement and street play as other forms of community awareness activities, but no one responded regarding the same.

Table-1: Age and Sex-wise distribution of study population

Age group	**Rural**			**Urban**			**Total**		
	Male	**Female**	**Total**	**Male**	**Female**	**Total**	**Male**	**Female**	**Total**
< 2 years	00	05	05 (1.4%)	02	01	03 (2.7%)	02	06	08 (1.8%)
2 – 4 years	03	10	13 (3.8%)	02	02	04 (3.54%)	05	12	17 (3.7%)
5 – 14 years	16	11	27 (7.9%)	06	07	13 (11.5%)	22	18	40 (8.8%)
> 15 years	145	153	298 (86.9%)	41	52	93 (82.3%)	186	205	391 (85.7%)
Total	164 (47.8%)	179 (52.2%)	343 (100%)	51 (45.1%)	62 (54.9%)	113 (100%)	215 (47.1%)	241 (52.9%)	456 (100%)

Table-2: Gender and Age wise distribution of respondents

Age group	Rural			Urban			Total		
	Male	Female	Total	Male	Female	Total	Male	Female	Total
15 – 29 years	03	09	12 (13.3%)	03	05	08 (26.7%)	06	14	20 (16.7%)
30 – 59 years	29	42	71 (78.9%)	09	13	22 (73.3%)	38	55	93 (77.5%)
> 60 years	04	03	07 (7.8%)	00	00	00 (0%)	04	03	07 (5.8%)
Total	36 (40.0%)	54 (60.0%)	90 (100%)	12 (40.0%)	18 (60.0%)	30 (100%)	48 (40.0%)	72 (60.0%)	120 (100%)

Table-3: Area wise distribution of Drug (DEC +Albendazole) Coverage, Compliance and effective coverage rate

Area	Eligible study population (X)	Drug Received (Y)	Drug Coverage (Y/X)	Drug Consumed (Z)	Drug Compliance (Z/Y)	Effective Coverage rate (Z/X)
PHC Bondapalli	107	100	93 %	92	92%	86%
PHC Gantyada	122	116	95 %	107	92%	88 %
PHC Gurla	109	105	96 %	100	95%	92 %
Total Rural	338	321	95%	299	93%	88%
Urban Vizianagaram	110	101	92 %	95	94%	86 %
Grand Total	448	422	94 %	394	93%	88 %

Table-4: Performance indicator of Drug administrator during MDA activity

Approach of Drug Administrator	Rural (N=90)	Urban (N=30)	Total Number of interviewed person (N=120)
DA explained regarding ELF and mode of transmission	84	26	110 (92%)
DA persuaded to swallow the drug concurrently	Yes	Yes	Yes

Table-5: Role of service provider in awareness generation prior to MDA activities

Informed about MDA	Rural Total (N=90)	Urban Vizianagaram (N=30)
Number of Respondents informed about MDA previous to drug distribution	90	30
Source of information (Multiple response)	ASHA-90 AWW – 66 ANM – 51	ASHA- 05 AWW – 30 ANM – 7

Table-6: Most effective form of IEC material assisted in generating community awareness

Area	Posters	Banners	Handbills	News paper	Mike announcement	Drama/Street play
Rural(N=90)	54 (60%)	30(34%)	3 (3%)	3(3%)	Nil	Nil
Urban (N=30)	16 (53%)	8(27%)	5(17%)	1(3%)	Nil	Nil
Grand Total(N=120)	70 (58 %)	38(32%)	8(7%)	4(3%)	Nil	Nil

Discussion

In the present study, multistage sampling technique adopted to select 3 rural clusters and one urban area. Similar techniques used in a study Dr Ashok Rupraoji Jadhao et al in Nagpur district of Maharastra[10] and Paul A et al in in Purbabarddhaman District, West Bengal[11]

Sex wise distribution of our study was found to be 47.1 % for males and 52.9 % for females. The result is being in congruence with the study finding by Patel et al conducted in Gulbarga district of Karnatak in 2010 (Male and female composition was 46.9% and 53.1%). [12]

With regard to the age group of respondents, in our study 94.2 % of the respondents were in the age group 15–59 years. Whereas in a study conducted by Patel et al though majority of the respondents were in this age

group (62.7% in Bagalkot district and 63.9% in Gulbarga districts, respectively) but it was significantly lower than our study. [12]

A high MDA coverage (>85%) with sustainable efforts for 5 years, is required to achieve the interruption of transmission and thereby elimination of LF in India [13]. The overall estimated drug distribution coverage is 94% and effective coverage was 88%, which is more than the expected targets and it is fairly better in rural clusters (88%) than the urban cluster (86%). The result is being in resemblance with the study conducted by Singh et al in Tikamgard district of Madhya pradesh in 2013 with overall coverage rate of 94.6% and an effective coverage rate of 85.2% [14]. This achievements might be due to increased awareness through community participation coupled with highly supervised program implementation.

Undoubtedly in our study it was found that, all the respondents aware about the MDA programme prior to the scheduled date by the Front Line Workers coupled with messages communicated through various forms of IEC materials. The role of ASHA is significantly appreciable in rural areas (100%). Our finding is higher than the study result conducted by a Jadhao AR et al in Nagpur district of Maharashtra (86.4% obtained the information from various field level health workers) [10] and similarly another study conducted by Paul A et al shows, FLW were the most frequent (80.82%) source of knowledge sharing about MDA.[11]

With regard to various forms of IEC material used, Posters and banners were found to be the effective forms of IEC material assisted in creating community awareness both in rural and urban Vizianagaram. This finding is comparable with the study conducted by Rajkumar et al, where 79.3% of respondents were aware of MDA trough banners / posters in the Medak district of Telengana state.[15]

Conclusion and Recommendation

In spite of good drug coverage and compliance observed in recent past consecutive years, Vizianagaram district failed to meet the transmission interruption criteria even after prolonged MDA. This necessitates promoting operational research on possible transmission from nearby districts and confirmatory mapping of uncertain areas.

Creating an enabling environment, through coordinated community awareness programs involving different stakeholders and local media with announcements by loudspeakers may be undertaken.

Programme implementation can be improved by ensuring supervised 'on-the-spot' drug consumption. This may be achieved by engaging trained external monitors during the MDA round through third party institutional partnership.

The present evaluation study is only cross-sectional in nature having resource constraints, so further qualitative comprehensive studies with more diverse participants are needed to ascertain the causal relationship.

Acknowledgement: Authors would like to acknowledge Govt of Andhra Pradesh under NVBDCP for their funding and support. We also truthfully acknowledge the cooperation provided by health authorities at all levels.

Funding: As part of the independent third party evaluation survey, fund was received from the Director of Public Health and Family Welfare, Government of Andhra Pradesh

Ethical Approval: Not required

Conflict of Interest: None

Maternal Education and its Relation with Fertility and Mortality: A Case Study among the Deoris of Assam, with Special Reference to Lakhimpur District

Biren Saikia

Asst. Prof. (Guest) Dept. of Humanities and Social Science, North-Eastern Regional Institute of Science & Technology (NERIST) Nirjuli, Arunachal Pradesh

Abstract

Education is considered to be one of the most important variables affecting fertility behaviour and is believed to be the single most important variable accounting for a large reduction in fertility. It is not only played a historic role in demographic transition but still remains a significant variable affecting fertility behaviour in present times. Therefore, this paper has attempted to study the possible relationship of maternal education with fertility and mortality among the Deori communities and also attempted has been made to study the wife's attitudes towards additional children in relation with different demographic and socio-economic variables for the same communities.

Key wards: - *Education, Fertility, Mortality etc.*

Introduction

Education is considered to be one of the most important variables affecting fertility. It is not only played a historic role in demographic transition but still remains a significant variable affecting fertility behaviour in recent times. The couples with higher educational attainment level are likely to have less desire for additional children. Apart from that, it leads to improved knowledge of and favourable attitude towards birth controlled and make better communication between husband and wife. Educated women are more likely to marry at a late age, postpone childbearing, use family planning methods and seek prenatal care when pregnant. Educated persons are aware of the problems that may result from a big family. P.k.B. Nayar[1] found that women education is the most responsible factor causing fertility decline in recent times in Kerela. Before dwelling at length the education and its relations with fertility and mortality among the Deori communities the present authors considered necessary to give a short description of the origin of the Deoris, their present divisions and the settings.

The Deoris are one of the important social groups of Assam. Ethnically they belong to Indio-Mongolioid race and linguistically to the Tibeto-Burman family Bharali[2]**.** The Deoris are a Scheduled Tribe Plain found mostly in Lakhimpur, Dhemaji, Sonitpur, Jorhat, Sibsagar, Dibrugarh, Tinsukia districts of Assam and some are also found in Lohit and Changlang districts of Arunachal Pradesh. The Deoris are one of the four divisions of Chutiya Bordoloi *etal*.,[3]**.** They were the priest group of the great Chutiya community. These four divisions are-(1) Dibangiya (2) Tenga Paniya (3) Borgoyan and (4) Patrogoyan. According to the 2001 census, the total population of the Deoris are 2, 45,000 in Assam and the Lakhimpur District contributes 53,3,56 numbers of the population. There is a total of 133 numbers of revenue villages in Assam and 43 numbers of villages under Lakhimpur District.

A Deoris woman is of yellow-brown complexion, moderate height, long black hair, straight, medium broad face. She wears colourful traditional artificially woven clothes shows as to how the Deoris women weave traditional fine clothes. Like the other communities, marriage is an indispensable part of the Deoris Society which can be regarded as a social institution. The girls generally marry between the ages of 18 to 24. The tribe endogamous systems, as well as clan exogamy, are strictly adhered to in respect of marriage. Once a girl marries she belongs to her husband's family. The children take their father's clan name. Divorce generally

does not occur in the Deori community.

The present paper studies the possible relationship of maternal education with fertility and mortality among the Deori communities and also focuses the wife's attitudes towards additional children in relation with different demographic and socio-economic variables for the same communities.

Objectives of the Study

The present study has been pursued keeping in view the following objectives-

(a) To study the possible relationship of maternal education with fertility and mortality among the Deori communities and

(b) To study the wife's attitudes towards additional children in relation with different demographic and socio-economic variables for the same communities.

Review of Literature

There is enough literature about the effect of education on fertility. According to **Caldwell and McDonald**[4] education of mother is a tool which helps them in breaking some of the traditional norms and makes them relatively more independent in taking decisions within the family situation. **Palloin**[5] has shown that literacy has a much greater influence on child mortality than on infant mortality. In the case of India, several surveys reveal that the education of women is an important factor for determining the fertility rate. A **Mysore population study**[6] reported that the average number of children born to women in Bangalore city who were illiterate or educated up to middle standard was higher than that of women who were educated up to higher school or more. The **National Sample Survey** [7] reports 1960-61 and 1961-62 rounds, showed a decrease in the average number of children born alive with an increase in women's education. It is well established that the decline of fertility in Kerala is due to the high literacy level of women there. **Borah**[8] found that infant and child mortality as a very significant determinant of fertility among the Adis of Arunachal Pradesh.

Data and Methodology

Relevant data for the study have been collected from both primary and secondary sources of information. The secondary data has been collected from Deori Autonomous Council, Narayanpur, different report of the National Sample Survey, articles in different journals, unpublished research works, newspapers and various websites etc. For the collection of primary data, we have restricted to the Narayanpur revenue circle of Lakhimpur District of Assam where the large numbers of Deoris are found. Out of the 27 Deori villages we have selected five villages for the collection of primary data. The villages are, viz Bordeuri, Kinapather, Kachikata, Pichala and Deotola. About 15% of the total Deori households of each of the five sample villages have been randomly selected for our investigation which works out to a total of 600 households for our detailed study.

The finding out the determinants of fertility differentials the technique of multiple regression and in analyzing the attitude of the couples towards additional children the technique of Binomial Logit Model have been applied. The technique of multiple regression analysis has been applied to examine the influence of various direct and indirect determinants of fertility differentials of the Deori couples under the present study. In the applied model live birth (LB) has been taken as the dependent variable, which depends on the following proximate and distant variables, viz.,

Proximate Variables:

Wife's Age at marriage (AM), Breast feeding (BF), Contraceptive use (CU), (using dummy variable, 1 for using and 0 for not using contraceptives), Abortion (AB)

Distant Variables:

Wife's and Husband Education (E) (Using dummy variables, scored 1 either of the couple is having education of M.E. level and beyond and 0 if otherwise), Per Capita Monthly Income (I), Wife Monthly Income (WMI), Wife's Nature of Occupation (WNO) (using dummy variables, 1 for wives who are cultivators and 0 for otherwise), Husband Nature of Occupation (HNO), (using dummy variables, 1 for husband's who are cultivators and 0 for otherwise),Wife's Labour Force Participation (WLFP), (using dummy variables, 1 for working women, and 0 for non-working women), Infant and Child Mortality Experience (ICM), Miscarriage and still Birth Experience (MSB), Effective Married Life Lived (EMLL), Type of Family (TF),(using dummy variables, 1 for nuclear and 0 for joint families), Family Members (FM)

Results and Discussion

To examine the effects of the above mentioned 15th variables on live birth (LB), the following multiple regression function has been framed-

$$LB_r = \beta_0 + \beta_1 AEM_r + \beta_2 BF_r + \beta_3 CU_r + \beta_4 AB_r + \beta_5 E_r + \beta_6 I_r + \beta_7 WMI_r + \beta_8 WNO_r + \beta_9 HNO_r + \beta_{10} WLFP_r + \beta_{11} ICM_r + \beta_{12} MSB_r + \beta_{13} EMLL_r + \beta_{14} TF_r + \beta_{15} FM_r + \epsilon_r$$

The results summarizing the effects of all the fifteen variables on live births have been presented in the following table-1

Table-1: Determinants of Fertility among the Deoris: Multiple Regression Results

Regressor	Unstandardized Coefficient	Standardized Coefficient	't'-Ratio	Tolerance	VIF
Constant	.980	-	-	-	-
AEM	-0.07314	-0.061	-2.478*	0.792	1.262

Note: *=Significant at 1 % level, **= Significant at 5 % level.

R^2=0.721, $\overline{R}^2$=0.713, D.W=1.785, F=88.568*

The estimated result shows that for the Deoris, wife's age at marriage (AEM), breastfeeding (BF), per capita monthly income (I), infant and child mortality experience (ICM), miscarriage and stillbirth experience (MSB), effective married life lived (EMLL), type of family (TF), and number of family members (FM) are found to be significant variables explaining the variations in live birth (LB). The intercept value of 0.980 indicates that if the values of all the 16 regressions were fixed at

zero, the live birth will be less than one, (i.e., 0.980)

For examining the relative importance of the independent variables, it is revealed that the partial regression coefficient (β1) of the female age at effective marriage (AEM) is -0.07314, indicating that with the influence of all other explanatory variables held constant, as AEM increases say by one year, on an average, live birth goes down by 0.07314 units.

It is also found that controlling all others, longer duration of breastfeeding practice increase, on an average, live birth by a negligible amount of 0.018 units.

The regression coefficient for infant and child mortality experiences reveals that there is a highly significant positive relationship between live birth and infant and child (up to 5 years of age) mortality experiences of the couples. The partial regression coefficient of ICM being 0.996 indicates that an increase in infant and child mortality experience of the couples by saying one unit, controlling the influences of the other variables included in the model, increases live birth on an average, by almost one unit.

The regression co-efficient of the miscarriage and still birth experience (MSB) of the couple's shows that it has a depressing effect on live births. Holding all the others variables constant, an increase in miscarriage and still birth experience of the couples, say by one unit, reduces on an average, live birth by 0.160.

The partial regression co-efficient of EMLL being 0.08929, indicates that an increase in the length of effective married life lived, say by one year, increases live birth, on an average by 0.08929 units.

The regression co-efficient of TF indicates that fertility increases by 0.629 units if the type of family is nuclear. Moreover, Number of members in the family (FM) has also been found to have a significant positive influence on live birth. Having an additional member in the family, controlling the effects of all other factors, increases live birth, on an average, by 0.339.

The comparison of the standardized beta coefficients indicate that amongst all the determinants included in the model, infant and child mortality experience is the most important determinant of fertility. A standard increase in infant and child mortality experience leads, on an average, to a 0.558 standard deviation increase in live births. The effective married life lived by the couples has been found to be the third most significant factor influencing fertility among the Deori couples of the surveyed areas.

The data for the survey areas shows that the fertility level declines considerably with an increase in the educational level of women among the Deoris. The enhancement of educational amenities directly works as a contraceptive. The higher educational attainment couples are likely to have less desire for additional children. Educated persons are aware of the problems that may result from big family. Moreover they have the knowledge of family planning and practice contraceptives. Table-2 gives the information about education and wife's attitude towards additional children among the survey areas-

Table-2: Education and Wife's Attitude Towards Additional Children

Education	Percentage					
	Husband			Wife		
	Favourable	Unfavorable	Total	Favourable	Unfavorable	Total
Illiterate	118 (62.11)	72 (37.89)	190(100)	223(59.15)	154(40.85)	377(100.0)
Literate	231(63.28)	134(36.72)	365(100.0)	98(55.05)	80(44.95)	178(100)
Upto primary level	41(63.07)	24(36.93)	65(100)	18(69.23)	8(30.77)	26(100.0)
Upto M.E. Level	64(64.0)	36(36.0)	100(100.0)	26(47.28)	29(52.72)	55(100.0)
Upto High School level	65(58.55)	46(41.45)	111(100.0)	29(45.31)	35(54.69)	64(100.0)
Beyond High School level	61(68.53)	28(31.47)	89(100.0)	25(75.75)	8(24.25)	33(100.0)
Total	349(62.88)	206(37.12)	555(100.0)	321(57.84)	234(42.16)	555(100.0)

Source:-From field survey.

From the Table-2 it is found that, so far as the education is concerned, the study revealed that the percentage of wives having favourable attitude to additional child is higher for the illiterate females (59.15%) than the literate females (i.e.55.05%). On the other hand, in case of the husbands it has been noticed that the literate husbands have more preference for additional child (63.28%) as compared to the illiterate husbands (i.e.62.11%) It is also reveals that among the literate Deori wives and husbands the desire for additional child is more for those who have attained education beyond high school level.

Factor Affecting Attitude to Additional Children:

To quantify the factors determining the wife's attitudes towards additional children in relation with different socio-economic and demographic variables have been examined by applying the Binomial Logit Model.

In the applied model, wife's attitude towards additional children (ATAC) is the dummy dependent variable (using 1 for favourable and 0 for unfavorable attitude towards additional children) and the independent variables are- (1) Live Birth (LB), (2) Infant and Child Mortality Experience (ICM), (3) Per-Capita Monthly Income (I), (4) Wife's Monthly Income (WMI), (5) Number of Family Members (FM), (6) Type of Family (TF), (using dummy variables, 1 for nuclear families and 0 for joint families), (7) Wife's Age at Effective Marriage (AEM), (8) Miscarriage and Still Birth Experiences (MSB), (9) Wife's Labour force participation (WLFP), (using dummy variables, 1 for working women and 0 for non-working women), (10) Wife's Nature of Occupation (WNO), (using dummy variables, 1 for wives who are cultivators and 0 for otherwise) (11) Husband's Nature of Occupation (HNO), (using dummy variables, 1 for husbands who are cultivators and 0 for otherwise) (12) Education (E), (using dummy variables, scored 1 if either of the couples is having education of M.E. level and beyond and 0 if otherwise),(13) Effective Married Life lived (EMLL), (15) Knowledge of Family planning (KFP) (using dummy variables, 1 for wives having knowledge of family planning and 0 for otherwise)The model is –

$$ATAC = I_n\left(\frac{D}{1-D}\right) = \beta_0 + \beta_1 LB_i + \beta_2 ICM_i + \beta_3 I_i + \beta_4 WMI_i + \beta_5 FM_i + \beta_6 TF_i + \beta_7 AEM_i + \beta_8 MSB_i + \beta_9 WLFP_i + \beta_{10} WNO_i$$

$$+ \beta_{11} HNO_i + \beta_{12} E_i + \beta_{13} KFP_i + \beta_{14} EMLL_i + \beta_{15} KFP_i + U_i.$$

Where, D_i is a dummy variable, If the expected value of D_i continues to be P_i the probability is that the i^{th} person will make the choice described by D_i =1(i.e, having favourable attitude towards additional children) the results of the estimated Logit Model are reported in the table-3

Table-3: Determinants of Attitude Towards Additional Children, Binomial Logit Regression Results-Dependent Variable: Attitude Towards Additional Children (ATAC)

Regressor	Coefficient (β)	Std. Error	wald	Antilog (β*)
Constant	6.821	1.399	23.761*	917.107
LB	-0.802	.104	59.473*	.449
ICM	0.615	.127	23.368*	1.850
I	0.000	0.000	1.537	1.000
WMI	0.000	0.000	2.626	1.000
FM	-0.042	.062	.458	.959
TF	0.106	.320	.110	1.112
AEM	-0.138	.061	5.095**	.871
MSB	0.097	.150	.420	1.102
WLFP	0.697	.453	2.363	2.007

E	0.201	.290	.478	1.222
EMLL	-0.091	0.021	19.498*	0.913
KFP	-0.830	0.279	8.848*	0.436

Note: *=Significant at 1 % level, **= Significant at 5 % level.

N=555, R^2_p =0.79, Cox & Snell R^2=0.379, Nagelkere R^2=0.509

Hosmer and Lemeshow Goodness of fit test statistic =15.613

From the estimated regression coefficients it is found that there is a highly significant negative relationship between live birth (LB) experience and wife's attitude towards additional children. If the number of live birth experience increases by one unit, holding other variable constant, the log of odds of wife's favourable attitude to additional children is reduced by .802 units.

It is revealed that there is a highly significant positive influence of infant and child mortality experience on the wife's favourable attitude towards additional children. The ICM coefficient of 0.615 indicates that with other variables held constant, as the infant and child mortality experience increases by one unit, on an average, the log of odds of the wife's favourable attitude towards additional children increases by 0.615 units.

The antilog of ICM coefficient (i.e.1.85) suggest that, controlling for the other variables, an increase in wife's infant and child mortality experience increases by one unit, increases the chance of having favourable attitude towards additional children by 1.85 percent.

Wife's age at effective marriage has been found to have a significant negative effect on the favourable attitude towards additional children. The AEM coefficient being -0.138, suggests that with other variables constant, if wife's age at effective marriage increases by one year, on an average the estimated logit decreases by about 0.14 units.

The antilog of the AEM coefficient (0.871) indicates that one year increase in wife's age at effective marriage, other things remaining constant, reduces the favourable attitude towards additional children by 0.871 units.

It is observed from the table that husband nature of occupation has a highly significant influence on the wife's favourable attitude towards additional children. The HNO coefficient (1.44) indicates that, other things remaining constant, with a cultivator's wife increases the log of odds of having favourable attitude towards additional children by 1.44 units. The antilog (4.22) of the coefficient HNO also suggests that, other things remaining constant, the odds of wife's having favourable attitude towards additional children is four times more if the husbands are cultivators than when husbands are having different nature of occupations.

Similarly, the knowledge of family planning has been found to have a highly significant negative influence on the wife's favourable attitude towards additional children. The coefficient of KFP (-0830) indicates the negative impact of having knowledge of family planning on the log of odds of wife's having favourable attitude towards additional children.

Thus, the other regressors included in the model have no statistically significant effect on the attitude towards additional children. The R^2_p (i.e. 0.79) indicates that, the model correctly 'predicts' that in respect of about four fifths of the wives, the attitude towards additional children is dependent on the 15 independent variables included in the model.

Conclusion

As it has been observed from the survey that higher educated women are not only favourable predisposed towards family planning but also use modern and effective contraceptives and start practicing contraception soon after marriage or the first birth. For the findings of our survey it is also revealed that the wives having favourable attitude to additional child is higher for the illiterate females (59.15%) than the literate females (55.05%) but in case of the husbands it has been revealed that the literate husbands have more preference for additional child (63.28%) as compared to the illiterate husbands (i.e.62.11%) among the Deoris.

A Study to Assess the Effectiveness of Critical Care Education on Knowledge of Students in Care of Patients with Mechanical Ventilator among Nursing Students in Srm College of Nursing, Kattankulathur, Tamil Nadu, India

C. Kanniammal[1], T. Suseelal[1], A. Akila Devi[2], K.Ambiga[2], A. Sheeba Jebakani[2]

Dr. C. Kanniammal[1] Dean, Dr. T. Suseelal[1] Associate professor, Mrs. A. Akila Devi[2] professor, Mrs. K.Ambiga[2] Associate professor, Mrs. A. Sheeba Jebakani[2] Associate professor, Medical surgical department, SRM College of Nursing, SRM Institute of Science and Technology, Kattankulathur, Chengalpattu District, Tamil Nadu, India

Abstract

Critical care education among nursing students is an emerging topic globally.Nurses lead a vital role in all hospital setting. Critical care nursing skills must be taught to the student nurses to provide optimum care during emergency situation.The present study assessed the impact of critical care education among students in SRM College of Nursing. A quantitative study with one group pre and posttest design was used.Totally hundred students between age group 18-20yrs participated in the study. After explaining and getting their consent by convenient sampling technique pretest was taken with 18 self structured objective type questions.Education on critical care was given by experts on current trends, technologies, evidenced based practice, pharmacological management, and role play, quality nursing care during ventilator support and legal responsibilities in critical care for 6 hrs. After the education post assessment was done with same questionnaire. Analysis was done with descriptive, MCNemar's test, and student paired t test. The post knowledge of students with care of patient in mechanical ventilator was significant with $p < 0.05$. This study high lights the need for educating the staff in critical care in the hospital setting.

Key words: *Critical care, Nursing students, Quality nursing care, Mechanical ventilator, Education*

Introduction

Critical care Nursing is one of the challenging area for nurses.In 18th century Florence Nightingale developed evidenced based care in Nursing.During 18th and 19th century general nursing staffs were trained to provide care to the patients in emergency situation.As technology advanced there was many changes evolved in nursing field.In 1923 Critical care facility first evolved. During 19th century it boostup and 20th century it was implemented with excellence in critical care.It enhances quality care as most important aspects in CCU. Undergraduate students need skills to care critically ill patients[1].

Current scenario is mainly focused to develop nurse practitioners to work in critical care unit. Nurses provide efficient care when the patients are brought in critical condition.

Nurses has to report to the doctor about any abnormal results,regarding their patients,so that it can be solved immediately[2]. Now a day the life expectancy of the people is more and there is increasing number of acutely ill patients are being admitted in hospital[3].

Delayingthe care may lead to severe complications and death.Students has to develop right attitude and Knowledge when they are posted in intensive care unit[4]. A nurse has a primary role in the health care of patients. Quality aspect of care should be strengthened with

excellence of research study. Nurses are always near to the patients. They can understand abnormal rhythms, changes in vital signs and immediately report to doctors[5].

Evidenced based practice(EBP) is important to avoid the outdated practice.EBP it includes clinical expertise,patient value and preference. If the nurses in ICU are Knowledgeable they will not do harm to the patients[6]. Evidenced based practice in critical care reflect to improve quality patient care. It bridge the gap between theory and practice.[7]Critical care nurses are expected to provide standard nursing practices that requires expert guidance[8].Critical care nurses must be skilful, punctual, dedicated and they should cultivate attitude to care patients sincerely[9].Nurses must be intelligent to handle critical situation and should be emotionally prepared to work even the patients are very sick and at times of death and departure[10].The present study intended to evaluate the Knowledge of students and to educate them regarding the care of patient in mechanical ventilator.

Materials and Method

It was a descriptive study based on Knowledge assessment of critical care among nursing students in SRM College of Nursing, Kattankulathur. Formal approval was obtained from SRM Institute ethical committee. One group pre and post test design is used in this study. After explaining and getting the written consent from the participants with convenient sampling technique the data was collected from 100 samples on 22nd July 2019.After pilot study reliability of the tool was assessed by using Test retest method. The knowledge score reliability correlation co efficient value is 0.83. Pre test was taken by using standardized objective type interview questionnaire (18) in number on care of patient during ventilator. Continuing Nursing Education was given for 6 hours by various experts on current trend, evidenced based practice, and role of nursing team, pharmacotherapy, and quality care on patient during mechanical ventilator and legal aspects of critical care. A role play – mime programme on dealing with emergency situation was demonstrated by 10 students. Post test was taken with the same questionnaire .Each correct answer was given a score of (1) and the wrong answer was given a score of (0).The collected data was spread in Excell sheet SPSS Version 16.0 and analyzed. Confidentiality and anonymity was maintained throughout the study.

Results

The demographic table revealed among 100 participants majority of them were between the age group of 19-20 years (40%), between 18-19 and 20-21 years were (30%). Regarding education majority of them were BSC nursing fourth year (30%), second year (30%), third year ((26%), Diploma nursing second year (14%). Regarding their residential background urban and rural region were (50%). In relation to religion Hindus were (80%) and Christians were (20%).

9	Which of the following is selected when the patient is not able to continue any spontaneous breath during ventilator?	46	46.00	54	54.00
10	How often chest physio should be given when the patient is in ventilator?	47	47.00	53	53.00
11	Which of the ventilator parameter is adjusted in order to reduce paCo2 ?	42	42.00	58	58.00
12	What are the key indicators to evaluate the adequacy of oxygenation in ventilated patient?	60	60.00	40	40.00
13	When the intubation is required for a short period, which of the following is recommended?	62	62.00	38	38.00
14	The dosage of Inj. Morphine is	62	62.00	38	38.00
15	Which is the most common sedative used when the patient is on ventilator?	61	61.00	39	39.00
16	What is the action of dopamine?	60	60.00	40	40.00
17	Which of the following is an indication for weaning?	64	64.00	36	36.00
18	Ventilator associated pneumonia can be prevented	59	59.00	41	41.00

The above table shows each question wise post-test percentage of knowledge .They are having maximum knowledge in How often do you change the humidifiers (88.0%) and minimum knowledge score in Which of the ventilator parameter is adjusted in order to reduce $paCo_2$ (42.0%).

Table 3: Comparison of pre and post knowledge mean score of students in critical care education programme

N=100

	No. of students	Mean score	SD	Mean Difference	Student paired t-test
Pretest	100	7.06	2.31	4.18	t=10.29 P=0.001***
Posttest	100	11.24	3.43		

Significant at p<0.05 level

The above table shows in the pretest the students are having 7.06 knowledge score and after intervention they were having 11.24 knowledge score, so the difference is 4.18 knowledge score, this difference is large and it is statistically significant. It was calculated using student paired t-test.

Table 4:Comparison of pre and post Knowledge score among students in critical care education programme

N=100

Level of knowledge	Pretest		Posttest		Extended McNemar's test
	n	%	N	%	
Inadequate knowledge	85	85.00	20	20.0	$\chi 2$=65.89 P=0.001***
Moderate knowledge	15	15.00	54	54.0	
Adequate knowledge	0	0.0	26	26.0	
Total	100	100	100	100	

Significant at p<0.05 level

The above table reveals before Critical care education, 85.0% of the students are having inadequate level of knowledge score, 15.0% of them having moderate level of knowledge score and none of them are having adequate level of knowledge score.

After Critical care education, 20 %of the students are having inadequate level of knowledge score , 54.0% of them having moderate level of knowledge score and 26.0% of them are having adequate level of knowledge score.

Level of knowledge gain of between pretest and posttest was calculated using Extended McNemar's chisquare test is significant with p<0.05.

The association with demographic variables revealed elder students and urban area students are having more knowledge score than others. Statistical significance was confirmed using chi square test (P<0.05) all the other variables are not significant P>0.05. So there's no association between the post level Knowledge score and the demographic variables.

Discussion

This continuing nursing education programme dealt on various aspects of critical care nursing to improve

students Knowledge and skills to work in critical care unit. Most of the students are willing to work in ICU after their graduation. Critical care area is a place where serious patients are admitted at time they are in a stage of fight or flight. At this junction the expertise Nursing assessment and care is needed without any delay. The nurses must understand their responsibility and they work deligently in saving the life of patients. Many adult patients were admitted in critical care unit and most of them died within 6 hrs after all expert treatment loosing the patient's life is a horrible situation for the family and it reduces the economical status of our country. ICU nurse must be vigilant in observing the signs and symptoms, nursing care in critical situation and documentation. After the death of patients all documents are saved for legal concern. Nurses must keep it in mind and they should provide optimum care to their patients to save their lives. The present study post test revealed out of 100 students 28% of them having adequate Knowledge 54% of them having moderately adequate Knowledge and 20% having inadequate knowledge with x^2=65.84,P<0.01. Also the mean score is difference 4.18 (P<0.01). This study result was consistent with the study done by Jaber. A etal., (2016) revealed positive students experience after critical care course. This study can be done in hospital among staff nurses working in critical care unit.

Conclusion: The present study concluded that the student's knowledge is improved after the critical care education programme.

Conflict of Interest: The authors have no conflict of interest.

Funding/Support: None declared.

Food Habits and Physical Activity among Adolescent Medical Students of a Medical College in Tumkur, Karnataka, India

Chandana Krishna[1], Sagar MK[2], Krishna Iyengar[3], Viswanatha PG[4]

[1]Assistant Professor of Community Medicine, Sri Siddhartha Medical College, Agalkote, Tumkur, [2]Intern, Sri Siddhartha Medical College, Agalkote, Tumkur, [3]Professor and Head, Dept of Community Medicine, Sri Siddhartha Medical College, Agalkote, Tumkur, [4]Assistant Professor of Community Medicine, Subbaiah Institute of Medical Sciences and Research centre, Shimoga

Abstract

Background: Adolescence is a transitional stage of physical, physiological and psychological development from puberty to legal adulthood. Worldwide more than 1.2 billion are adolescents i.e. one in every six persons is an adolescent. About 21% of Indian population is adolescents. The health status of an adolescent determines the health status in his/her adulthood. Healthy dietary habits & physical activity among medical students are even more important as they are future physicians.

Objectives: 1. To assess the dietary habits of the study subjects. 2. To assess the physical activity of the study subjects

Methodology: A cross-sectional study was conducted among the adolescent medical students (<19yrs) during January-April 2019. Data on dietary habits & physical activity was collected using pretested semi-structured questionnaire & PAQ-A scale (Physical activity questionnaire- Adolescents).

Results: Among the study subjects, 73.5% were male, 25.8% consumed all three meals in a day, 90.3% and 58.1% skipped their breakfast & dinner respectively, <30% consumed healthy foods like fruits & vegetables, milk etc. Almost everyone consumed junk food at least once a week. 51.5% felt that they had unhealthy food habits. 29.4% spent their free time doing very little/no physical activity. 50% never engaged in sports activity. Walking was the most common physical activity (45.5%).

Conclusion: There was an alarming prevalence of unhealthy dietary practices, & poor physical activity that should be targeted and modified. Strategies need to be adopted to improve young youths' nutritional status and to establish a healthy lifestyle.

Key words: *Food habits, physical activity, adolescent, medical students*

Introduction

Adolescents are the young people aged between 10 to 19 y. It is a transitional stage of physical, physiological and psychological development from puberty to legal adulthood. Worldwide more than 1.2 billion are adolescents: this indicates that roughly one in every six persons is an adolescent.[1] About 21% of Indian population is adolescents (about 243 million).[2]

They are the future of the nation, forming a major demographic and economic force. The health status of an adolescent determines the health status in his/her adulthood. Many serious diseases in adulthood have their roots in adolescence.[3]

Physical activity is every movement produced by skeletal muscles that results in energy expenditure[4]

E-mail address: vgowda300@gmail.com

and is also one of the most important steps in health improvement. Sedentary behavior is not simply a lack of physical activity but is a cluster of individual behaviors where sitting or lying is the dominant mode of posture and energy expenditure is very low.[5] It is well-known that physical activity decreases the prevalence of many chronic diseases, such as cardiovascular, autoimmune and malignant diseases as well as diabetes mellitus.

Beside physical activity, adequate dietary habits are equally important in the prevention of many diseases and health improvement. Therefore, one of the most important problems of modern life is obesity that arises from inadequate physical activity and bad dietary habits.[6] A shift from high school to college is one of the most vulnerable periods in the life of young adult person who is faced with many different challenges. During this period an individual deals with huge pressure and expectations which therefore inevitably lead to changes in the lifestyle. A great number of students leave their parents' homes, resulting in alteration of dietary habits and life conditions. Healthy life habits are exchanged with an unhealthy lifestyle usually at the beginning of college. This unhealthy lifestyle mostly refers to increased consumption of fast food and decreased consumption of fruits and vegetables. Snacking and breakfast skipping are frequent in young youth.

Healthy dietary habits among medical students are even more important as they are future physicians. Amongst this college population, it is assumed that the medical students have a great knowledge about healthy lifestyle and dietary habits. However there is no evidence to indicate that this knowledge translates into practices in terms of maintaining good health.

Hence this study was taken up to assess the dietary habits and physical activity among adolescent medical students of a Medical college.

Objectives:

a. To assess the dietary habits of the study subjects

b. To assess the physical activity of the study subjects

c. To assess the association between the dietary pattern and physical activity of study subjects

Materials and Methods

A cross-sectional study was conducted between January – August 2019 at a medical college in Tumkur. Medical students in the adolescent age group (10-19years) studying in the college.

Inclusion criteria: Medical students in adolescent age group (10-19years) who consent for the study

Exclusion criteria: Absent at the time of data collection even after 3 visits

Methodology

After taking permission from head of the Institution & IEC, the first and second year students who fulfil the inclusion & exclusion criteria were approached and the purpose of the study was explained. Data was collected using pre-tested semi structured questionnaire regarding the dietary pattern in the last 7days in collected and data on physical activity was collected using PAQ-A (Physical activity Questionnaire-Adolescents). Data was entered in MS-excel and analysed using SPSS version 20. Data like socio-demographic data was analysed using descriptive statistics. Association was assessed using chi square and Fischer's exact test. Quantitative data was analysed using T-test to compare between 2 groups.

Results

A total of 131 study subjects responded to the questionnaire and hence were included in the study.

i. Socio-demographic profile of study subjects:

Among the study subjects, 53 (40.5%) were females and 78 (59.5) were males. Age of the study subjects was 18.84±0.39years. Height, weight and BMI was 62.5±15.9Kg, 163.8±14.57cm and 23.5±5.9 respectively. 76 (58.0%) had normal BMI, 15 (11.5%) were thin and 9 (6.9%) were severely thin. 15 (11.5%) were overweight and 16 (12.2%) were obese. There was a statistically significant difference in weight and height between male and female study subjects. (Table 1)

ii. Dietary pattern of the study subjects:

Only 59 (45.0%) of study subjects consumed all three major meals of the day. Skipping of breakfast and dinner was seen in 22 (16.8%) and 3 (2.3%) respectively. Adequate fruits and vegetables were consumed by 55 (41.9%) and 61 (46.6%) respectively. Unhealthy foods like soft drinks, salted snacks and fried food & chats were consumed by 40 (30.5%), 40 (30.5%) and 39

(29.8%) respectively. Only 32 (24.4%) felt that they had healthy food habits. There was a statistically significant difference in consumption of 3 major meals, skipping of breakfast, consumption of fruits, vegetables, soft drinks, salted snacks and perception regarding dietary habits between male and female subjects. (Table 2)

iii. Physical activity among the study subjects:

Among the study subjects, 91 (69.5%) were inactive, 32 (24.4%) were minimally active and only 8 (6.1%) were very active. There was a statistically significant association between physical activity and sex of the study subjects. (Table 3)

iv. Association between dietary pattern and physical activity:

Consumption of all three meals, not skipping of breakfast or dinner, adequate consumption of fruits and vegetables was relatively higher in very active study subjects compared to minimally active and inactive study subjects. There was a statistically significant association between perception about diet and physical activity. (Table 4)

Table 1: Socio-demographic profile of the study subjects

Discussion

Among the study subjects, 53 (40.5%) were females and 78 (59.5) were males. Age of the study subjects was 18.84±0.39years. In a study in Surat by Piyushkumar[11] et al., 56% (164) were girls and 44% (129) were boys with the mean age of 18.65 ± 1.45years. In another study by Goran Janković[10] et al., the age of study subjects was 19.97 ± 0.56years

In the present study,76 (58.0%) had normal BMI, 15 (11.5%) were thin and 9 (6.9%) were severely thin, 15 (11.5%) were overweight and 16 (12.2%) were obese. In a study by Piyushkumar[11] et al., 115(43%) had normal BMI, 89(33%) were underweight and 65(24%) were pre-obese and obese. In another study by Goran Janković[10] et al., 369 (75.80%) had normal BMI, 31 (6.40%) were underweight, 81 (16.60%) were overweight and 6 (1.20%) were obese.

In the present study, only 59 (45.0%) of study subjects consumed all three major meals of the day. Skipping of breakfast and dinner was seen in 22 (16.8%) and 3 (2.3%) respectively there was a statistically significant difference in consumption of 3 major meals, skipping of breakfast, consumption of fruits, vegetables, soft drinks, salted snacks and perception regarding dietary habits between male and female subjects. In another study by Mohanty BB[7] et al., there was a statistically significant difference in number of meals & snacks, meat, fruits & vegetables, dairy food and juice. In another study by Manijeh Alavi1[12] et al., (48.4) skipped breakfast while only few (8.3 percent) skipped lunch

In the present study, 91 (69.5%) were inactive, 32 (24.4%) were minimally active and only 8 (6.1%) were very active. There was a statistically significant association between physical activity and sex of the study subjects. In another study by Goran Janković[10] et al., 305 (62.20%) were moderately active, 110 (22.40%) were very active and 75 (15.30%) were inactive. But there was no statistically significant association between physical activity and sex of the study subjects. In another

study by Hamdan[13] et al., about 50% of the students performed physical activities and exercise sometimes, whereas very few performed physical activities and exercise on regular basis.

In the present study, Consumption of all three meals, not skipping of breakfast or dinner, adequate consumption of fruits and vegetables was relatively higher in very active study subjects compared to minimally active and inactive study subjects. There was a statistically significant association between perception about diet and physical activity. In another study by Goran Janković[10] et al., there was a statistically significant association between physical activity and consumption of meat & meat product, white flour products and commercial drinks.

Conclusion

- There was an alarming prevalence of unhealthy dietary practices, & poor physical activity that should be targeted and modified.
- Strategies need to be adopted to improve young youths' nutritional status and to establish a healthy lifestyle

Anaemia and Its Determinants among Adolescent Medical Students of a Health University in Tumkur, Karnataka, India

Chandana Krishna[1], Venkatesh P[2], Krishna Iyengar[3], Rajesh S[1]

[1]Assistant Professor, [2]Associate Professo, [3]Professor and Head, Department of Community Medicine, Sri Siddhartha Medical College, Agalkote, Tumkur

Abstract

Introduction: Adolescence is the period of most rapid growth second to childhood. The physical and physiological changes that occur in adolescents place a great demand on their nutritional requirements and make them more vulnerable to anemia. Anemia in adolescence causes reduced physical and mental capacity and diminished concentration in work and also possess to major threat to future safe mother hood in girls. Medical students, even though from a good socio-economic background, are vulnerable to anaemia because of poor diet and increased physiological demand.

Methodology: This cross-sectional study was undertaken among adolescent medical students of a health university in Tumkur, India.

Results: In this study, anaemia was seen in 11 (11.22%) of the study subjects. There was a statistically significant association between anaemia and sex, type of diet, consumption fruits, and presence of pallor.

Conclusion: In the present study, anaemia was seen in 11 (11.22%) of the study subjects. Socio economic factors have a significant role in occurrence of anaemia which later manifests itself as poor performance.

Keywords: *Anganwadi, nutritional assessment, undernutrition, socio demographic factors*

Introduction

Adolescence is a period of transition from childhood to adulthood. It is characterised by rapid physical, biological and hormonal changes resulting in psycho-social, behavioural and sexual maturity in an individual. Anaemia, a manifestation of under-nutrition and poor dietary intake of iron is a public health problem, not only among pregnant women, infants and young children but also among adolescents. Anaemia in India primarily occurs due to iron deficiency and is the most widespread nutritional deficiency disorders in the country today. The prevalence of anaemia in girls (Hb<12g%) and in boys (Hb< 13g%) is high as per the reports of NFHS-3 and the National Nutrition Monitoring Bureau Survey. According to NFHS 3 data, over 55 percent of both adolescent boys and girls are anaemic.[1]

Anaemia is a condition in which the number of red blood cells (RBCs), and consequently their oxygen-carrying capacity, is insufficient to meet the body's physiological needs. Anemia is characterised by reduction in number of red blood cells or haemoglobin concentration. AWHO expert group proposed that anemia or deficiency should be consider to exist when the haemoglobin is below 13g/dl and 12g/dl in males and females respectively.[2, 3]

Adolescence is the period of most rapid growth second to childhood. The physical and physiological changes that occur in adolescents place a great demand on their nutritional requirements and make them more vulnerable to anemia. Anemia in adolescence causes reduced physical and mental capacity and diminished concentration in work and also possess to major threat to future safe mother hood in girls. [4,5]

Medical students, even though from a good socio-economic background, are vulnerable to anaemia because of poor diet and increased physiological demand. There is a need to study the magnitude of anaemia in medical students.

Hence this study was undertaken to study health status and burden of anaemia among adolescent medical students.

Objectives of the Study

i. To find out the burden of anaemia among the study subjects

ii. To assess the various determinants of anaemia among the study subjects

Method

This cross-sectional study was conducted during January 2018 to December 2018 at a Health university in Tumkur, Karnataka, India. First & second year medical students of Sri Siddhartha Medical College aged ≤19yrs during the study period.

Inclusion criteria

1. First & second year medical students with aged ≤19yrs studying at Sri Siddhartha medical college, Tumkur, who consent for the study.

Exclusion criteria

1. Students who are chronically absent.
2. Any known case of haemoglobinopathy

Methodology

- After taking clearance from Institutional Ethical Committee, the study subjects fulfilling the inclusion criteria were recruited and the methodology explained.
- After taking written consent for the study, the proforma was administered to collect data on socio-demographic profile, medical history and clinical examination was done.
- All the study subjects were screened for anaemia by using CBC analyser.
- According to WHO criteria (Hb<13 gm/dl in males and Hb<12 gm/dl in females), the study subjects are classified as anaemic or normal.
- Data was entered in MS excel and data was analysed using EPI INFO version 7.2.2.6.
- Socio-demographic data was analysed using percentages and descriptive statistics. Association between various variables and anaemia was analysed using chi-square test. Quantitative data was compared between anaemic and non-anaemic subjects using student T test.

Results

a. Socio-demographic profile:

Age of the study subjects was 18.51±0.80years. Among the 98 study subjects, 56 (57.14%) were females and 42 (42.86%) were males. Weight, height and BMI of study subjects were 66.19±14.06Kg, 165.1±10.03cm and 24.23±4.38 respectively (Table 1).

b. Prevalence of anaemia:

The study subjects were classified based on WHO criteria i.e., Hb<12g/dl among females and Hb<13g/dl among males. Anaemia was seen in 11 (11.22%) of the study subjects. Mean haemoglobin was 14.22±2.03g/dl.

c. Symptoms and signs of anaemia among the study subject:

Hair fall (30.61%) was the commonest symptom among study subjects followed by lack of concentration (13.27%). Pallor was seen in 15.31% of study subjects (Table 2)

d. Association between various socio-demographic variables and anaemia

Anaemia was common in females compared to males, more in urban subjects compared to rural subjects, more among vegetarians compared to non-vegetarians. Anaemia was more among subjects who consumed less fruits and vegetables. There was a statistically significant association between anaemia and sex, type of diet, consumption fruits, and presence of pallor. There was a significant difference in haemoglobin and haematocrit between anaemic and non-anaemic subjects (Table 3).

Table 1: Socio-demographic profile of the study subjects

Characteristics		**N=98**
Sex	Female	56 (57.14)
	Male	42 (42.86)

Platelet		307.54±124.9	283.98±63.93	0.31	

Discussion

In the present study, age of the study subjects was 18.51±0.80years. In similar study by Subramaniyan K[6] et al., age was 19.41±2.78yrs.

In the present study, 56 (57.14%) were females and 42 (42.86%) were males. In study by Subramaniyan K[6] et al., 79.1% were females.

In the present study, anaemia was seen in 11 (11.22%) of the study subjects. All the subjects had mild anaemia. Similar studies done in different parts of India by Abilash Sasidharannair Chandrakumari[7] et al., P.M. Siva[8] et al., Subramaniyan K[6] et al., Bhuvaneshwari Kannan[9] et al., Anil Kumar[10] et al., anaemia was seen in 48.63%, 21%, 43%, 8%, 43% and 39.1% respectively.

In the present study, there was a statistically significant association between anaemia and sex, type of diet, consumption fruits, and presence of pallor, haemoglobin and haematocrit. In another study by Bhuvaneshwari Kannan[9] et al., there was an association between anaemia and symptoms of anemia and BMI. In another study by Saratha A[11] et al., there was an association between anaemia and consumption of green leafy vegetables, history of passing worms. In a study by Subramaniyan K[6] et al., there was an association between anaemia and sex of subjects, bleeding disorder, haemoglobin, WBC, RBC, platelet, haematocrit. In a study by P.M. Siva[8] et al., there was an association between anaemia and haematocrit, jiggery intake, hand washing after toileting & after food intake. In a study by Sanjeev M Chaudhary[12] et al., there was an association between anaemia and socio-economic status, mother's and father's education, mean weight and height. In a study by Premalatha T[13] et al., there was an association between anaemia and type of family, palptation, intake of non-vegetarian food & fruits, weight, mother's literacy.

Conclusion

In the present study, anaemia was seen in 11 (11.22%) of the study subjects. There was a statistically significant association between anaemia and sex, type of diet, consumption fruits, and presence of pallor. Socio economic factors have a significant role in occurrence of anaemia which later manifests itself as poor performance. Inculcating healthy food habits will prevent occurrence of anaemia.

A Study to Find Out Relationship Between Q-Angle, Tibial Torsion and Leg-Heel Alignment amongst Osteoarthritis Knee Patients – A Cross Sectional Observational Study

Chandani Raiyani[1], Guddi Vaghasiya[1], Ashish Kakkad[2]

[1]Internee SPB Physiotherapy College, Surat, [2]Associate Professor, SPB Physiotherapy College, Surat

Abstract

Background: Osteoarthritis (OA) is the most frequent cause of disability in the India, with the medial compartment of the knee being most commonly affected. Osteoarthritis of knee joint is common musculoskeletal problem now days in Indian population. It is most disabling in day to day activities of life.

Purpose: Due to Osteoarthritis of knee joint, multiple changes occur in structure in and around knee joint. Due to these structural changes, biomechanics of knee joint is altered, which in turn leads to secondary changes in muscles, ligaments and other soft tissues also. So, energy cost of walking increases.

Objective: Objective of this study is to correlate Q angle, tibial torsion and leg heel alignment in OA knee patients.

Setting: Different physiotherapy centres of Surat city

Method: Co relational study was done in Surat city. Selection of OA knee patients was done as per selection criteria. Subjects were explained about the study. Informed consent forms were signed by the patient and/or relatives. Subjects selected by purposive sampling were assessed.

Participants: Total 63 male and female OA knee patients

Outcome measure: Q angle, Tibial torsion & Leg heel alignment

Results: Data were entered in Microsoft Excel for Microsoft Windows. Descriptive analysis and corelational test was applied by SPSS version 20 for Microsoft Windows. Moderate positive correlation was found between Q angle & Tibial torsion, between Tibial Torsion & Leg heel alignment, between Leg heel alignment & Q angle.

Conclusion: These findings may suggest that Q angle, Tibial torsion & Leg heel alignment are moderate positively correlated in OA knee joint. So any change in any of above three values may alter values of other remaining values.

Keywords: *Osteoarthrits, OA patients, Q angle, Tibial torsion & Leg heel alignment*

Introduction

Osteoarthritis (OA) is the most frequent cause of disability in the India, with the medial compartment of the knee being most commonly affected. OA is a condition with a multifaceted etiology that affects both load-bearing and non–weight-bearing joints. The risk of developing OA substantially increases with each decade after the age of 40 years. Among reported upper and lower extremity sites, the most common region for OA to manifest is the medial compartment of the knee.[1]

Osteoarthritis (OA) is defined as an idiopathic slowly progressive degenerative joint disease affecting the arthrodial joints mainly in elderly people.[2] It is a chronic localized joint disease and a leading cause of musculoskeletal pain and disability. Osteoarthritic process involves the whole joint including cartilage,

bone, ligament, muscle with changes such as joint space narrowing, bony osteophytes and sclerosis.[3]

Overall prevalence of knee OA was found to be 28.7% in India with age more than 40 years.[4] Andhra Pradesh reported as highly prevalent (68%) and Rajasthan as minimal prevalent (8.42%) state in India for Knee OA. Generally, in all studies from different regions females were reported to be more affected by OA knee than males.[5]

Osteoarthritis occurs when the cartilage that cushions the ends of bones in your joints gradually deteriorates. Cartilage is a firm, slippery tissue that permits nearly frictionless joint motion. In osteoarthritis, the slick surface of the cartilage becomes rough. Eventually, if the cartilage wears down completely, it may be left with bone rubbing on bone. The most common causes of knee OA is age (40 years and older) and gender (more in female). Osteoarthritis predominantly involves the weight-bearing joints, including the knees, hips, cervical and lumbosacral spine, and feet. Other commonly affected joints include the distal interphalangeal, proximal interphalangeal, and carpometacarpal joints.[6,7,8]

As OA progresses, however, the level of proteoglycans eventually drops very low, causing the cartilage to soften and lose elasticity and thereby further compromising joint surface integrity. Over time, the loss of cartilage results in loss of joint space. In major weight-bearing joints of persons with osteoarthritis, a greater loss of joint space occurs at those areas experiencing the highest loads.[8]

Individuals with knee OA experience pain, stiffness, and decreased range of motion of the joints. These symptoms significantly limit an individual's ability to rise from a chair, stand comfortably, walk, or climb stairs. Ultimately, these limitations lead to a loss of functional independence.[9] Risk factors are multifactorial and include older age, female gender, obesity (particularly in knee OA), previous joint injury, genetics and muscle weakness, repetitive use of joints, bone density, joint laxity. All play roles in the development of joint OA determination of risk factors particularly in the weight-bearing joints and their modification may reduce the risk of OA and prevent subsequent pain and disability.[3,10]

On examination, there is swelling due to synovial thickening and/or effusion, muscle wasting and prominence of the articular margins due to osteophytes. Movement are painful and restricted. Crepitus is felt on joint movement in late stage of the disease, loose bodies develop in the joint, which may cause recurrent joint effusion, pain, swelling and locking of the joint.[11]

At the knee, alignment (i.e., the hip knee-ankle angle) is a key determinant of load distribution. The load-bearing axis is represented by a line drawn from mid femoral head to mid ankle. In a Varus knee, this line passes medial to the knee and a moment arm is created, which increases force across the medial compartment. In a valgus knee, the load-bearing axis passes lateral to the knee, and the resulting moment arm increases force across the lateral compartment. These mechanical effects of alignment on load distribution make it biologically plausible that both varus and valgus alignment contribute to OA progression. The position and function of the foot and ankle affect the stresses transmitted to the knee. Foot problems are frequent because the interface between body and ground is subjected to high stresses and load. In weight bearing foot, subtalar motion and tibial rotations are interdependent.[12,13]

Q angle or patellofemoral angle is the angle between the quadriceps muscles and the patellar tendon, it is an important indicator of biomechanical function in the lower extremity.[12]

Tibial torsion is the measurement of angle of lateral rotation of the tibia.[12] It is an important morphological feature of human tibia and is defined as any twisting of the tibia on its longitudinal axis which produces a change in alignment of the planes of motion of the proximal and distal articulations.[14]

Leg-heel alignment is measuring angle between calcaneus and tibia.[12] It plays an important role in knee OA from a biomechanical perspective owing to rotational coupling between the rear foot and tibia.[15]

Osteoarthritis of knee joint is common musculoskeletal problem now days in Indian population. It is most disabling in day to day activities of life. Due to this, multiple changes occur in structure in and around knee joint. Due to these structural changes, biomechanics of knee joint is altered, which in turn leads to secondary changes in muscles, ligaments and other soft tissues also; So, energy cost of walking is more. Very few studies are done to correlate different measurements like Q angle, tibial torsion and leg heel alignment. So, the purpose of this study is to correlate Q angle, tibial torsion and leg heel in OA knee patients.

Materials and Methodology

- **Study design:** Co relational study
- **Source of data:** Different physiotherapy clinics in Surat city
- **Sampling technique:** Purposive
- **Study population:** OA knee patients

Age - ≥40 years

- **Sample size:** 63 OA knee patients

(40 unilateral involvement, 23 bilateral involvements)

- **Search duration :** 6 months

Patients were selected based on following inclusion and exclusion criteria:

- **Inclusion criteria[16]:**

1) Knee osteoarthritis diagnosed by orthopedic surgeon.

2) Subjective complain of knee pain with knee flexion and extension.

3) Morning stiffness ≤ 60 min.

4) Both sexes (male and female).

5) Unilateral or Bilateral knee involvement.

6) Age ≥ 40 years.

- **Exclusion criteria[16]:**

1) Previous knee arthroplasty, history of congenital/adolescent knee disease.

2) Clinical signs of hip and ankle joint disease.

3) Pregnancy

4) Knee fracture

5) Rheumatic disease.

- **Method:**

A B C

Q angle was measured with patient in standing position by placing lower limb at right angle to the line joining to ASIS (Anterior Superior Iliac Spine). A line was drawn from ASIS to base of patella. Second line was drawn from tibial tuberosity to base of patella. The angle formed by crossing these two lines was measured. (Figure A)

For measuring tibial torsion, patient was in prone position with affected knee in 90 degree flexed. A line was drawn between lateral and medial malleoli on the sole of foot. Second line was drawn between lateral and medial femoral condyle on the sole of foot. The angle formed by crossing these two lines was measured. (Figure B)

For measuring leg-heel alignment, patient was in standing position. A mark was placed over the midline of the calcaneus at the insertion of the Achilles tendon. Second mark was placed approximately 1 cm distal to the first mark and as close to the midline of calcaneus as possible. A calcaneal line was drawn to join the two marks. Then tibial line was drawn to make two marks on the lower third of leg in the midline. The angle formed

by crossing these two lines was measured. (Figure C)

Data Analysis & Result

The present study was done to study to find out relation among Q angle, Tibial torsion and Leg heel alignment in OA knee patients. The study comprised of total 63 subjects (19 males & 44 females). Data were entered in Microsoft Excel for Microsoft Windows. Mean ± Standard Deviation values for Q angle, tibial torsion and leg heel alignment found were $27.78^{o} \pm 4.64^{o}$, $13.5^{o} \pm 4.06^{o}$ and $12.86^{o} \pm 3.55^{o}$ respectively. 40 patients had unilateral osteoarthritis and 23 patients had bilateral osteoarthritis of knee.

Pearson co-relation test was applied by SPSS version 20 for Microsoft Windows among above measurements and results were found as below:

Table 1: Correlation Test between Q angle and Tibial torsion

Pearson Correlation	**.150**
Sig. (2-tailed)	.191
N	78

Table 2: Correlation Test between Tibial torsion and Leg heel alignment

Pearson Correlation	.048
Sig. (2-tailed)	.675
N	78

Table 3: Correlation Test between Q angle and Leg heel alignment

Pearson Correlation	.211
Sig. (2-tailed)	.064
N	78

Discussion

Purpose of the present study was to find out the relation among Q angle, Tibial torsion and Leg heel alignment in OA knee patients. In study, moderate positive correlation was found between Q angle and Tibial torsion; Tibial torsion and Leg heel alignment; Q angle and Leg heel alignment of the patients with knee joint OA, which suggest that as Q angle value increase, Tibial torsion value increase as well as Leg heel alignment value also increase and vice versa.

A study by Anand Heggannavar, et.al. (2016) previously done indicate that the Q angle increases with increased tibial external rotation. There is increased load of weight bearing joint, and also changes in compensatory gait patterns like slow walking and increased toe-out angle.[12] A study Anh D N, Michelle B C, et.al. (2009) previously done indicate that increased tibiofemoral angle, which represents the valgus angle formed by the anatomical axes of the femur and tibia, would move the patella medially relative to the anterior superior iliac spine and the tibial tuberosity laterally thus increasing the Q angle. When femoral anteversion is excessive, it may lead to more medial rotation of femur leading to displacement of patella medially. Femoral anteversion may be related to in toeing gait which is compensated with external rotation of tibia on femur causing tibial tuberosity to displace more laterally.[17]

A study by Anand Heggannavar, et.al. (2016) previously done indicate that the torsion is transmitted to hind foot and ankle joint. Increased anterior pelvic tilt and navicular drop result in rotational changes in the femur and tibia displacing the patella medially and the tibial tuberosity laterally. Increased medial joint loading, is evidenced by a greater knee-joint adduction moment, has also been frequently noted in individuals with OA.[12]

A study by Nüesch C, Barg A, et.al. (2013) previously done indicate that the asymmetric alignment of the ankle joint leads to changes in the intra-articular pressure distribution and the contact area. A varus alignment of the hind foot leads a shift of the pressure in anteromedial direction and a reduction of the contact area. For a valgus alignment a pressure shift in posterolateral direction and a reduced contact area. However, in the specimens with an intact fibula and ankle joint, opposite changes were seen: varus lead to posterolateral pressure shifts and increased contact areas, while valgus lead to anteromedial pressure shifts and decreased contact areas.[18]

Holister et. Al. (2011) suggested that in the externally rotated knee the coupled rotation of the femur and tibia in the screw home mechanism may be reversed. With the knee externally rotated, the bony attachments for the

extensor musculature are shifted.[19] G.C. Michael et. Al. (2016) found that with greater externally rotated legs, there was significant increase in calcaneal eversion.[12] Development of degenerative changes after ACL injury was associated with varus deformity knees in the cohort evaluation by McDaniel Jr. And Dameron Jr. (2015)[20] Hiroshi Ohi et. Al. (2017) suggested that the existence of a connection between altered frontal knee alignment and foot posture, which would be helpful to understand the pathogenesis of altered foot posture observed in patients with knee OA.[15]

It is observed in present study that measurement of Q angle, Tibial torsion and Leg heel alignment may be affected by difficulty to palpate bony prominence because of fat.

Limitations:

- Sample size was small
- Only knee joint arthritic patients were included in this study
- Limited age of patients were included in this study
- Females included were more than males in this study

Future recommendations:

- Study can be done with large sample size.
- Biomechanical markers other than Q angle, Tibial torsion and Leg heel alignment can be added.
- Study can be done including other arthritic joints like, hip and ankle.

Conclusion

From this study, it is concluded that Q angle, Tibial torsion & Leg heel alignment are moderate positively correlated in OA knee joint. So any change in any of above three values may alter values of other remaining values.

Ethical Clearance: Permission was taken from college and physiotherapy centres from where data collection was done. Ethical issues were cleared.

Improved Audit-based malevolent Node Detection and Energy Efficiency for Healthcare Applications

Deepa[1], M. Manju[1], Sathyaraj[1]

[1]Assistant Professor, RMK College of Engineering and Technology, Chennai, India

Abstract

Recently Wireless Body Area Sensor Networks (WBANs) are going more democratic and have revealed great possible in real time supervising of the human body. WBANs have involved a wide range of supervising applications for example sports activity, healthcare, and psychotherapy systems. However, WBANs contains more challenging issues should be resolved such as Quality of Service (QoS), energy efficiency and security and privacy issues are the most significant concerns. Because these systems manage life-critical data, they must be secure. To overcome the above issues, Improved Audit-based Malevolent Node Detection for Healthcare Applications is proposed. Audit-based malevolent Detection (AMD) is proposed for discovering and separating malevolent nodes in WBANs. The AMD system incorporates reputation management, trustworthy route discovery, and recognition of malevolent nodes based on behavioral audits. It integrates three critical functions: reputation management, route discovery, and identification of malevolent nodes via behavioral audits. An AMD can build paths consisting of highly entrusted nodes, subject to a desired path length constraint. In addition, the node fitness function is utilized for improving the energy efficiency in WBAN. The simulation result shows that AMD_EE successfully avoids malevolent nodes, even when a large portion of the network drops to forward packets and enhance the lifetime.

Keywords: *Malevolent node detection, trustable routing, Reputation System, Energy Efficiency, Wireless Body Area Network.*

Introduction

As wireless devices and sensors are growingly distributed on people, researchers have begun to focus on WBANs. The WBAN application areas are widely increasing day by day. Applications of WBAN contain sport activity, hobby, healthcare, and personal help, in which sensors gather data from people, physiological and their surrounds. WBAN system architecture has been shown in Figure 1. It contains sensors, actuators and control units. Wireless channels are used to communicate from sensor to user via internet.

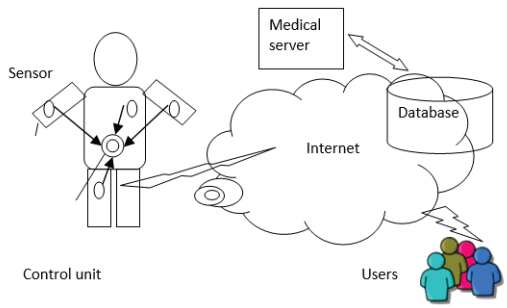

Fig. 1: WBAN System Architecture

The common benefits of WBAN health supervising systems for example unobtrusive, cost effective, and unobtrusive, they provide patients with continuous supervising of physiological signals that is useful particularly for the old peoples. WBAN enables patients to be supervised incessantly, and assisted rapidly by portable health teams while physiological signals illustrate that is required. Uninterrupted supervising of patients speeds up the patient retrieval progression, and minimizes death rate particularly in diabetic patients and cardiovascular.

Deficiency of security in WBANs may hamper the wide public acceptance of this technology, and more significantly can cause life-critical results and even death of patients. However, allowing for severe and scalable security system to prevent malevolent communications with WBANs is complex. Open wireless medium, makes the patient's information prostrate to being modified, eavesdropped, loss and injected. In addition, channel characteristics in WBANs such as very low Signal-to-Noise-Ratio situation and restriction of sensors in terms

of energy shortage, limited memory capacity, lacking computational and communication capability to create the opportunity of security attacks in WBANs. Hence, in WBANs, improving system performance and malevolent node detection is an important factor. Thus in this paper, Improved Audit-based malevolent Node Detection and Energy Efficiency is proposed.

The rest of this work is structured as follows. Section 2 presents a related work. In section 3 explains Improved Audit-based malevolent Node Detection and Energy Efficiency for Healthcare Applications. Section 4 discusses the simulation results and analysis. The final section is a conclusion.

Related Work

The WBAN is broadly predictable that a high stage privacy and system security meet a fundamental task in defending information while being utilized by the healthcare and during storage to make sure that patient's account are maintained secure from intruder's [1].The conventional security scheme that required inexhaustible resources, thus they cannot useful to the enormously resource restrained sensors. In addition, the WBAN security necessities like authentication, confidentiality, availability, data freshness, integrity, and non-repudiations. These are important security issues in healthcare applications in WBAN [2].Securing while Sampling in WBAN [3], rejects the requirement for a part encryption algorithm and the pre key distributed function thus it reduces the usage of sensor memory and other resources. This scheme provides a physical layer security. Also it isolates the eavesdropper present in the network.

Clique-Based WBAN Scheduling algorithm [4] is used to avoid interference. This scheduling method to schedule the sensors for working in a time slots manner. In this scheme, each node works by sleep or awake schedule during its own time slots thus extend the lifespan. Anonymous Authentication scheme [5] is used for reducing the computation burden of the client. This scheme provides the security against impersonation attack in WBAN.A Hybrid Key Management System (HKMS) [6] that introduced lightweight and scalable key management scheme for making resource-efficient WBAN. In this scheme, the one-way hash function builds a Merkle Tree for authentication purpose. This scheme addresses the compromised node also it reduces the network overhead. However, this scheme cannot handle the energy efficiency and QoS improvement in WBAN.

A secure cloud-based mobile healthcare system [7] is used to secure the among sensor communication by multi-biometric key design in WBANs. The e-medical reports are securely stored in the hospital society cloud and isolation of the patients' information is maintained. This scheme offers security resolution for omnipresent mobile healthcare applications.ECC with signature Hash Function scheme [8] is introduced for improving sensor authentication in WBAN. In this scheme, the hash-chain based key signature technique to secure information passing from sensor to user in WBAN. Also, Elliptical Curve Cryptography (ECC) algorithm is used to verifies the authenticate sensor. It extensively formulated to reduce the eavesdropping attack and get the patient information from the legitimate sensor. Secure Sensor Association and Key Management [9] is used to associate the sensor groups and offer a data integrity and confidentiality in WBAN. This scheme provides the data integrity by ECC algorithm. The authentication procedure and group key generation are very simple and efficient.

Revocable and Scalable Certificate less Remote Authentication Protocol [10] featured with client anonymity, key escrow resistance, non-repudiation, and revocability for WBANs. In this scheme, the certificate less encryption and a signature with proficient annulment against short-term key exposure, that considers independent interest. Also, a certificate less anonymous remote authentication with annulment is constructed by integrating the encryption scheme and signature scheme. This scheme is particularly suitable for the large-scale WBANs. However, this scheme creates complexity. Secure and efficient data communication protocol [11] is used to protect the information transmissions among sensors and the users by applying Ciphertext-Policy Attribute Based Encryption method. In this scheme, the sensor signature and patient information's are stored by the ciphertext format at user, thus assuring data security. However, this scheme increases the computational cost.

Improved Audit-based malevolent Node Detection and Energy Efficiency for Healthcare Applications

This AMD-EE provides a complete malevolent node isolation system for rejecting malevolent in WBAN. In this scheme, the AMD contains three phases such as a reputation module, a route discovery module,

and an audit module. Then isolate the malevolent nodes finally, the source transmit the data through the energy efficiency path without malevolent node in WBAN.

Reputation Phase:

In reputation module, the malevolent node is detected by direct trust and indirect trust. Here, every node direct trust is measured by reputation value. The node reputation value is calculated by the equation (1) given below.

$$RV_i^{\mathrm{j}}(\mathrm{t}) = \begin{cases} \beta * RV_i^{\mathrm{j}}(\mathrm{t}-1) \\ \min\{RV_i^{\mathrm{j}}(\mathrm{t}-1) + \beta, 1.0\} \end{cases} \quad (1)$$

Here, the trust factor β is present between $0 < \beta < 1$, t represent the time, i represents the source node and j represent the behavior checking node. If the node has a reputation value is above threshold value that node is a good behavior node. A node with a reputation value is below threshold factor in many time that node is chances for acting malevolent node.

The indirect trust information is used while the direct trust information becomes stale, otherwise is not accessible owing to the deficiency of prior communication among two nodes. The indirect trust is computed based on reputation value is given below.

$$RV_i^{\mathrm{j}}(\mathrm{t}) = \frac{\sum_{k \in \tau_i} RV_k{}^{j}(\mathrm{t})}{|\tau_i(\mathrm{t})|} \quad (2)$$

The direct trust information is failed when the source i collect the opinion of node j from k neighbor nodes. Assume τ_i represents the neighbor nodes report the information about node j to source node i.

Route Detection Phase:

In route detection phase, the source finds out reliable routes from a source to a destination. The trustworthiness of a path based on the reputation value from source to destination is given below.

$$RV_{S \to D} = \sqrt[m+1]{\prod_{i=1}^{m} (\mathrm{RV_s}^{\mathrm{i}} * \mathrm{RV_D}^{\mathrm{i}} * \prod_{j=1, j \neq i}^{m} RV_i^j)} \quad (3)$$

Here, calculate the path reputation value by multiplying individual intermediate node reputation value. Suppose malevolent node present, the path reputation value is cannot increase superior than its own reputation. Then the isolates the accused node and verified it is a malevolent node or not in audit phase.

Audit Phase:

In this phase, the accused node is confirmed by malevolent or authenticated by using the Renyi-Ulam Games. This game engages two players such as a questioner and a responder. Here, the questioner is a source or destination and the responder is a routing nodes. The questions stated by the questioner represent to the audits executed by the source to nodes in the path from source to destination. While replying to an audit, nodes state the set of packets sends to the next hop.

The source aggregates more audits to make cut or membership questions. The responder dishonesty when a malevolent node lies with regard to the packets forward to the next hop. Such as, node dishonesty by either taking to forward all packets established when in actuality it falls them, or not forward the data packets. Then, the source confirms that node is a malevolent node and then send notification message to the network.

Finally, the source transmits the data through the energy efficiency path. The energy efficiency path is selected based on the highest residual energy, minimum distance and minimum hop count. Thus, avoids the frequently utilization of energy in the network.

Simulation Analysis

The simulation analysis is done using the Network Simulator (NS-2). The existing scheme HKMS and the proposed AMD-EE scheme are analysed and compared with the simulation results. The network traffic in the simulation prototype is handled using traffic model Constant Bit Rate (CBR).The parameters used for the simulation of the proposed scheme are tabulated below. The performance of the proposed scheme is evaluated by the metrics packet delivery rate, delay, packet loss rate and throughput.

Packet Delivery Rate (PDR)

PDR is defined as the rate of packets delivered to the destination node. PDR is calculated by the Equation 4.

$$PDR = \sum_{0}^{n} \frac{PacketsDelv}{Time} \quad (4)$$

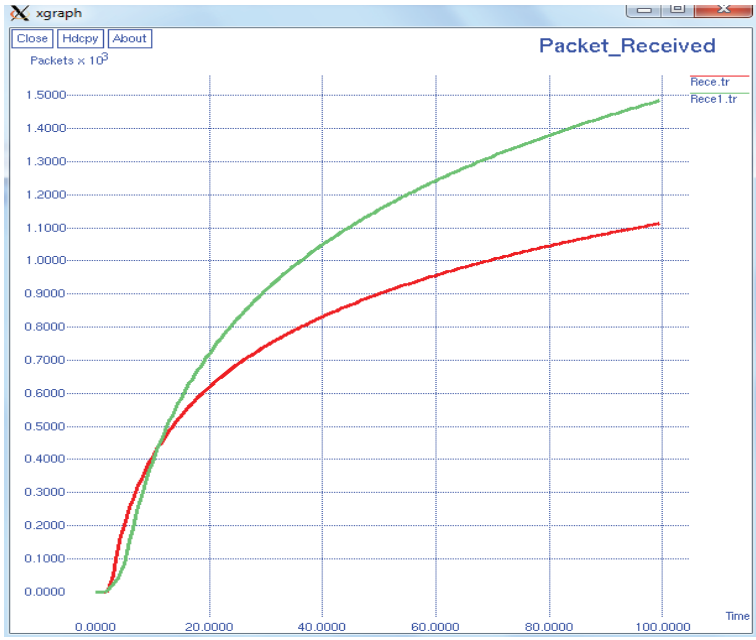

Fig.2 Packet Delivery Rate

Where n = number of nodes, green color line represents the AMD-EE mechanism and red color line represents the HKMS mechanism. The packet delivery rate of the proposed mechanism AMD-EE is higher than the packet delivery HKMS mechanism that is demonstrated in Figure 2. The more prominent estimation of packet delivery rate implies the better execution of the protocol.

Packet Loss Rate (PLR)

PLR is defined as the number of packets lost per unit time. PLR is measured by the Equation 5.

$$PLR = \sum_{0}^{n} \frac{PacketsLost}{Time} \qquad (5)$$

The packet loss rate of the proposed mechanism AMD-EE is lower than the HKMS mechanism that is explained in Figure 3. Lower the packet loss proportion demonstrates that higher execution of the network.

Fig. 3 Packet Loss Rate

Average Delay

Average Delay is defined as the time difference between the received and sent packets to the total number of nodes. It is measured by the Equation 6.

$$\text{Average Delay} = \frac{\sum_0^n \text{Pkt Recvd Time} - \text{Pkt Sent Time}}{n} \quad (6)$$

The delay value is low for the proposed scheme AMD-EE than the existing method HKMS is revealed in Figure 4. The base estimation of delay implies that higher estimation of the throughput of the system.

Fig. 4: Average Delay

Throughput

Throughput is defined as the average packets delivered to the destination successfully. The average throughput is estimated using Equation 7.

$$Throughput = \frac{\sum_0^n Pkts\ Received\ (n) * Pkt\ Size * 8}{1000} \quad (7)$$

The proposed scheme AMD-EE has higher average throughput when compared to the existing scheme HKMS is shown in Figure 5. It can be observed from the graph explains that the number of packets received successfully for every 1000 packets for AMD-EE is greater compared to that of the HKMS mechanism.

Fig.5: Throughput

Conclusion

In this scheme, we have proposed Improved Audit-based malevolent Node Detection and Energy Efficiency for Healthcare Applications. Audit-based Misbehavior Detection technique for identifying and isolating malevolent nodes that drops to forward packets in WBANs. The AMD_EE system integrates reputation management, trustworthy and Energy Efficiency route discovery, and identification of misbehaving nodes based on behavioral audits. The simulation result shows that AMD successfully avoids malevolent nodes, even when a large portion of the network drops to forward packets. Also it detects the selective dropping attacks over end-to-end traffic streams in WBAN. The simulation results indicates that our scheme to improve both the energy efficiency and network performance in the WBAN.

Medication Adherence of Hypertensive Patients: Impact of Clinical Pharmacist Intervention in Treatment of Hypertension in a Tertiary Care Hospital

D Sharma[1], DK Mehta[2], R Das[3], K Bhatti[4], K Mehta[5], RM Chidurala[6], A Petekar[7]

[1]Research Scholar, Pharm D, [2]Professor, [3]Associate Professor, M.M.College of Pharmacy, Maharishi Markandeshwar (Deemed to be) University, Mullana, Ambala, HR, [4]Hospitalist, Department of Medicine, Medstar southern Maryland hospital, 7503, Surratts Rd, Clinton, Maryland, 20735, USA,[5]Professor, Chitkara Business School, Chitkara University, Chandigarh, India, [6]Associate Chief Hospitalist, Department of Medicine, Hospitalist Medicine Physicians of Ohio, Mount Carmel East Hospital, 6001 E.broadstreet, Columbus, Ohio, USA., [7]Assistant Professor, M.M.College of Pharmacy, Maharishi Markandeshwar (Deemed to be) University, Mullana, Ambala, HR.

Abstract

Hypertension is well recognized as an important health risk factor. Adherence to medication is critically important for controlling blood pressure and reducing associated risk of cardiovascular complications in patients with hypertension. Patient counseling is instructing the patient about various aspects of prescribed medicines like; how to take, how long to take, what to avoid, precautions, common side effects, storage & any other relevant information about the illness. In order to achieve pharmaceutical care, pharmacists provide individualized care to patients. Hypertensive patients can benefit from interventions that focus on improving knowledge and adherence to drug treatment. Therefore, this study aims to assess the impact of an educational intervention provided to hypertensive patients from rural and urban areas in a tertiary care hospital by clinical pharmacists with the objective of improving their knowledge on hypertension and their adherence to the medication prescribed.

Key words: *Hypertension, Patient counseling, Clinical pharmacist, Medication adherence, Intervention, Morisky Medication Adherence Scale*

Introduction

Hypertension is well recognized as an important risk factor for cerebrovascular accidents (CVA), congestive heart failure (CHF) coronary artery disease (CAD), end-stage renal failure (ESRF) and sudden death.[1-7] It is a major health problem throughout the world because of its high prevalence and its association with increased risk of cardiovascular disease (1). According to the 7th report of joint national committee, in age ≥60 years' patients who don't have diabetes or chronic kidney disease, the goal blood pressure level is <150/90 mmHg and in age <60 years' patients' blood pressure goal is <140/90 mmHg, though risk appears to increase even above 120/80 mm Hg.[8]

Hypertension is a common chronic disease amenable to control by appropriate medication or adopting relevant lifestyle modifications. However, a lack of knowledge about the severity of the disease and the importance of adhering to the prescribed treatment, long term drug regimens, complex regimens that require numerous medications with varying dosing schedules, cost and a lack of motivation to make some lifestyle changes in terms of diet and physical exercise may constitute barriers to compliance behavior. Various studies conducted worldwide have documented non-adherence

to recommended medication therapy.[9-18] In patients with hypertension, adherence to medication is critically important for controlling blood pressure and reducing associated risk of cardiovascular complications.[19-25] Poor medication adherence, patients' beliefs about hypertension and its treatment, low health literacy and lack of social support are major patient-related barriers to achieving the desired control of blood pressure.[26]

In India patients receive medication as part of their treatment and due to heavy patient load; many prescribers have little time to explain the proper use of medication to their patient. Patient Counseling is instructing the patient about various aspects of prescribed medicines like; how to take, how long to take, what to avoid, precautions, common side effects, storage & any other relevant information about the illness. *The concept of patient counseling in its modern form originated in India in the mid 1990s. Since then, considerable growth and development occurred in the country in the area.* In order to achieve pharmaceutical care, pharmacists provide individualized care to patients. [27]

It has been reported that hypertensive patients can benefit from interventions that focus on improving knowledge and adherence to drug treatment.[28] Therefore, this study aims to assess the impact of an educational intervention provided to hypertensive patients from rural and urban areas by clinical pharmacists with the objective of improving their knowledge on hypertension and their adherence to the medication prescribed.

Method

A prospective, observational study was conducted in the outpatient department of Medicine at Maharishi Markandeshwar Institute of Medical Science and Research (MMIMSR), Mullana, Ambala, Haryana, India. The study duration was one year and was conducted from December 2018 to May 2019. The sampling method was convenient and sample size (n=300) included hypertensive patients surveyed during the study period.

Study participants

The study population consisted of 300 diagnosed hypertensive patients (147 men 153 women). The patients were recruited from medicine outpatient department after being diagnosed as hypertensive by the physicians as per JNC 7 guidelines. All the patients were screened for eligibility of inclusion and exclusion criteria designed for this study. The patients were informed and clarified about the purpose of study in the language understood by the patient, prior to enrollment. All patients provided written informed consent to participate in the study after full explanation of the study. Patient's demographic details were noted in case record form.

Hypertension control status

According to the 7th report of joint national committee in age ≥60 years' patients who don't have diabetes or Chronic Kidney Disease the goal blood pressure level is <150/90 mmHg and in age <60 years' patients' blood pressure goal is <140/90 mmHg, though risk appears to increase even above 120/80 mm Hg.[8]

Ethical Considerations

This study was designed to study the effect of counselling and pharmacist intervention on medication adherence of hypertensive patients. The clinical protocol was approved by institutional ethics committee (project No: IEC-1323) on 19/12/18 and was performed in accordance with the declaration of Helsinki and the code of Good Clinical Practice.

Qualification criteria

- **Inclusion Criteria:**

1. Patient newly and previously diagnosed hypertensive

2. Age >18 years

3. Patient initiated on therapy by the treating physician as per the routine clinical practices.

4. Patient able and willing to give written informed consent.

5. All the patients will be investigated under following: Fasting Lipid Profile, Random Blood Sugar, Fundus Examination, Liver Function Test, and Kidney Function Test & X-ray Chest

- **Exclusion Criteria:**

1. Patient with pre-existing renal failure, liver failure and cardiac disease.

2. Pregnant and lactating mothers.

3. Patients with the history of peptic ulcers,

pulmonary tuberculosis, uraemia, vitamin deficiency, and patients on steroid therapy were excluded.

Research tools

Blood pressure was measured with the help of Sphygmomanometer (Atico Sphygmomanometer) along with the stethoscope. Morisky Medication Adherence Scales MMAS-8 questionnaire was used to evaluate the impact of patient counselling provide by the pharmacists to the patients.[29]

Baseline analysis and randomization

At baseline, current knowledge on hypertension, and medication adherence was measured for all patients in addition to socio-demographic data. Blood pressure readings were taken from medical records. As baseline data were obtained and analyzed, patients attending the medicine and cardiology units for routine follow-up were randomly allocated either to a control group [(CG) usual care, where no pharmaceutical care was provided] or to an intervention group [(IG) pharmaceutical care, consisting of follow-up by the trained clinical pharmacist during a month period]. Participants were allocated to groups following simple randomization procedures using a computer generated list. The pharmaceutical care provided to the IG by a clinical pharmacist took approximately 15 min during the first visit, and the follow-up visits took approximately 10 min. The intervention was conducted with each patient once per week (or in accordance with their appointment schedule). At each visit, the hospital pharmacist conducted a thorough interview with the patient, identified problems leading to poor medication adherence and provided patient education. The CG had no clinical pharmacist involvement, and control patients received the traditional service provided by the hospitals (receiving prescription orders, counseling about medication use and information about follow-up visits).

Assessment of medication adherence

The patient adherence was assessed by using standard questionnaires, i.e. Morisky medication adherence scale (MMAS-8). [29] MMAS-8 is an 8-item questionnaire with 7 yes/no questions while the last question was a 5-point Likert scale. Based on the scoring system of MMAS, adherence was rated as follows: high adherence (=0 score), medium adherence (=1 to 2 score) and low adherence (=3-4 score). The patient's blood pressure values were noted at baseline and each time patient came for the follow-ups. Patients who had a low or a moderate rate of adherence were considered as non-adherent. Mean adherence scores at baseline and for each group (IG and CG) were calculated and presented for the final analysis.

Statistical analysis

Data recorded was entered in Microsoft excel version 2016. The Statistical Package for Social Sciences (SPSS Inc., Chicago, IL, USA) was used for data analysis.

Results

A total of 357 patients attended the cardiac unit of MMIMSR hospital, Mullana, India during the recruitment period (from December 2018 to May 2019), and all were assessed for eligibility. Of these, 57 were excluded (42 did not meet the criteria and 15 refused to participate), and the remaining 300 patients (153 women and 147 men) with hypertension, aged from 18 to 66 years [mean (SD) = 46.0 ± 7.1] were included for the study. Patient were randomized into two groups, control group (150 CG) and intervention group (150 IG). Baseline assessment, demographic study and current medication adherence rate study was carried out for the whole cohort of 300 patients. The IG and CG were comparable with respect to age, gender, education, locality and duration of disease. At baseline, knowledge on hypertension and medication adherence was reported as low in both the IG and CG. Table 1 describes the baseline analysis of the entire cohort (n=300), IG (n=150) and CG (n=150). Evaluation of adherence using the Scales MMAS-8 questionnaire and the MMAS-8 scale data of the study is shown in Table 2. Table 3 highlights the post-intervention analysis of Medication adherence between intervention and control group upon completion of the study. A statistically significant difference was observed, when knowledge, adherence, and blood pressure were compared between IG and CG after completion of the intervention. Medication adherence improved in the IG, as the post-intervention analysis revealed. The CG was more or less the same in terms of medication adherence, and little difference was observed compared with the baseline analysis. Lower systolic and diastolic blood pressures were observed among the IG.

Table 1: Baseline characteristics of study population

Characteristics	Entire cohort n = 300 Frequency (%)	Intervention group n = 150 Frequency (%)	Control group n = 150 Frequency (%)	P value
Age, mean (SD) = 46.0 ± 7.1				0.812
18-42	96(32%)	45(30%)	51(34%)

DBP mean (SD) mmHg	82.04 (5.39)		90.64 (5.86)	

Discussion

Uncontrolled hypertension is one of a leading cause of heart disease and stroke. Controlling hypertension can prevent cardiovascular disease. Controlling hypertension is very challenging. Effectively managing hypertension includes both lifestyle changes and long term medication use.[13] Patient counseling and interventions generate opportunities for patients to understand their conditions better and clarify misapprehensions they have of their disease and its treatment.[30] Therefore, it can be hypothesized that imparting education to patients through a well designed intervention can result in better awareness of disease, and increased medication adherence and therefore better treatment outcomes. Other than reminding patients to take medication properly, regularly on time, we provided adequate knowledge regarding the weight loss and regular exercise, sodium and calorie restriction, restriction of saturated fats and increased intake of dietary fibers, total restriction of alcohol intake, leave the habit of smoking, caution while using cold remedies containing sympathomimetic, self-monitoring of blood pressure etc.

The day 1 and day 30 BP measurements are depicted in Table 1 and 3 respectively. The results of the blood pressure (both SBP and DBP values) show a very good improvement from the base line to the first follow-up. A better result was found in patients who received clinical pharmacist counselling sessions. This strongly indicated that there is a positive impact of clinical pharmacist counselling on hypertensive patients.

In our study medication adherence were found to be high in urban population compared to rural patients. Adherence to the medication were found more in male as compare to the females. As per answer given by the patient's major reasons for non-adherence are forgetfulness, cost of medication, lack of access to medication, travelling, fear of getting used to medicine. The assessment of medication adherence scores by MMAS-8 clearly showed that high adherence was found to be more in the intervention group and low adherence were found to be high in the control group. The intervention group patients were provided with counselling and frequent telephone reminding makes them too strongly adapts to think about disease management. As many of the patients were illiterate it was difficult for them to remember the name of the drug, but on repeated counseling they remembered it with the help of the strips, color, and covers of the medicines which made them adhere to their medication properly. This study strongly suggested that there is a need of continuous education to the patients to improve their medication adherence towards disease management.

Conclusion

The study showed that clinical pharmacist interventions had positive impact in improving the medication adherence and treatment satisfaction of the hypertensive patients and the intervention program was well accepted by the study population. The one-month patient follow-up had shown enhancement in their adherence and also treatment satisfaction. It was quite proved that participants with low treatment satisfaction are more likely to have lower adherence to antihypertensive medications. The results of our study suggested that the treatment satisfaction is consistent indicators of adherence to antihypertensive medications in hypertensive patients. Patients should be educated about the benefits of self-management of diseases, and the common perception that drugs are inherently unsafe has to be eliminated. Additional research is also recommended in order to identify appropriate and targeted interventions in an effort to improve treatment satisfaction in patients with hypertension.

This study also highlights that there is a need of patient counseling services for patients especially rural population in chronic disease maintenance. This study shows that pharmacist-initiated educational interventions increase patients' knowledge about their condition in a way that positively modifies their beliefs about medicines. Such changes are expected to result in increased adherence levels. Therefore, healthcare professionals in India should develop strategies that enlist the patient as a participant in the management of his/her health through the help of patient education and counselling. Although increase in adherence levels is apparent from our study, an important aspect to be considered is the long-term impact of the educational programme on the status of medication adherence. Therefore, it is recommended that continuous medical education (CME) should be applied even after the intervention, so that patients can retain maximum knowledge and obtain benefit from it.

Abstract

Breast milk is considered the gold standard in pediatric nutrition. It contains a wide range of nutrients and other bioactive factors that support enteric and immunologic development of neonates. Some of these constituents have neurobiological properties that play vital role in early brain development and facilitate cognitive development. Understanding the role of these functional nutrients in modulating developmental processes in the brain is emerging area of research. These developmental events depend not only on availability of nutrients, but it also depends on a variety of growth factors and proteins. These components are transported from the mother to the fetus via the placenta prenatally and postnatally through milk. Many studies have highlighted a positive association between breastfeeding on structural brain development, such as increased white matter development and increased cortical thickness. Reports also suggest beneficial effects of breastfeeding on brain and cognitive development from infancy to in adolescence. This review discusses various components in breast milk components which can influence neurodevelopment in children.

Key words: *Brain development, Breastfeeding, Breast milk, Cognition*

Introduction

Early life nutrition is important for the growth and development of the infant. The World Health Organization and United Nations Children's Fund jointly developed the global strategy for exclusive breastfeeding during the first six months of life. [1] Many studies provide evidence of short and long-term benefits of breastfeeding during the critical periods of development. Breastfeeding is also shown to influence the long-term health of children.[2] Accumulating evidence suggests that breastfeeding reduces the risk of non communicable and neurodevelopmental disorders in childhood and adulthood.[3]

Breast milk provides optimal nutrition for the first six months of life. It is the only source of nutrients and bioactive components like growth factors, cytokines and hormones during infancy.[4] These components support brain, enteric and immunologic development of neonates.[5] The article describes the possible role of various nutrients and bioactive components in breast milk which influence neurodevelopment of the children.

Breastfeeding and Neurodevelopment in Children

The relationship between breastfeeding and neurodevelopmental outcome was first discussed in 1929 when Hoefer and Hardy examined the mental and physical outcomes of children at 7 to 13 yrs of age. They concluded that children who had been breastfed for 4 to 9 months outperformed in motor and language development.[6] Horwood and Fergusson also observed a positive relationship between breastfeeding and a variety of beneficial educational outcomes.[7] It has been reported that children who were breastfed for more than 6 months had higher test scores at 10 yrs of age as compared to non-breastfed children.[8] In a group of Asian and Greek toddlers, increased exposure to breastfeeding is reported to be associated with higher scores of cognitive and language development.[9,10] In school aged children (8-11 yrs) who were breast fed, a positive association was found between learning skills as compared to the never-breastfed children.[11]

The duration of breastfeeding is also shown to be associated with cognition. Longer duration of breastfeeding, particularly full breastfeeding is reported to have beneficial effects on child neuropsychological outcomes [12] and with higher verbal and nonverbal IQ at 7 yrs of age.[13] Increasing duration of breastfeeding showed gradual increase in cognitive developmental score from infancy through the preschool age. [14]

Breastfeeding in the first 2 months of life is shown to be associated with structural markers of brain development in infants. Breastfed children exhibited increased white matter development, upto 4 yrs of age.[15] A recent report reveals improved myelination in breastfed children compared to children who were exclusively formula-fed.[16]

The findings of the above studies indicating beneficial effects of breastfeeding on neurodevelopmental outcome could be possibly attributed to breast milk nutrients and bioactive components and is depicted in Fig 1. Human milk is suggested to improve cognition by providing vital components like fatty acids, amino acids, choline, lactose, iron, copper, vitamin A, creatine, and neurotrophic factors to the infant. The role of each of these components is discussed below.

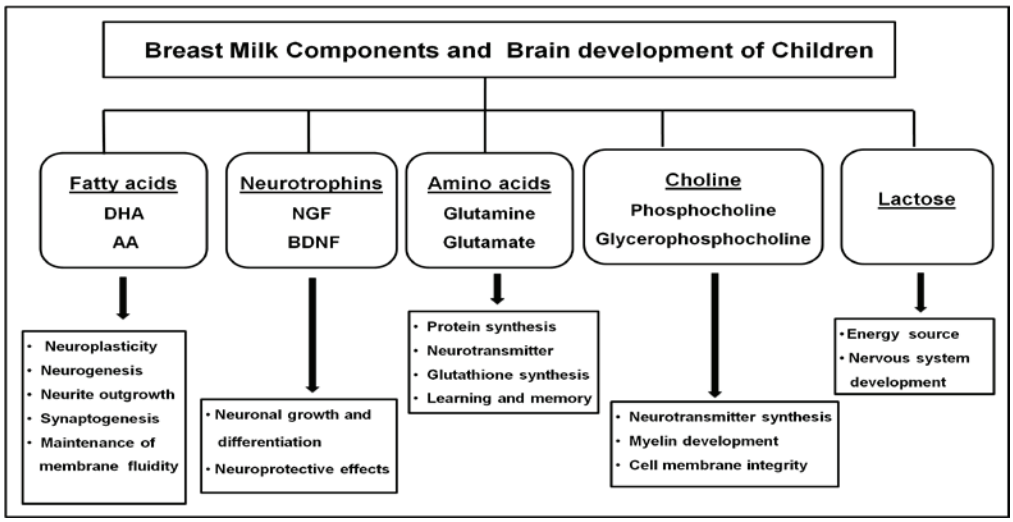

Figure 1: Breast Milk Components and Brain Development of Children

DHA - Docosahexaenoic Acid; AA - Arachidonic Acid; NGF - Nerve Growth Factor;

BDNF - Brain-Derived Neurotrophic Factor

Components of Breast Milk and Cognition in Children

Fatty Acids

Human milk contains 3-5 % of total fat. It is the main source of energy for the newborn. Essential fatty acids are the integral part of cell membranes and play a main role in mental and visual development. Two fatty acids are essential for humans: alpha-linolenic acid and linoleic acid. They are found in breast milk and serve as precursors for long chain polyunsaturated fatty acids (LCPUFA) like docosahexaenoic acid (DHA) and arachidonic acid respectively. These fatty acids are involved in many neurobiological processes like learning and memory. Many studies have shown that PUFA levels in the colostrum are associated with IQ in children up to 6 yrs of age.[17, 18] High content of DHA, in breast milk is reported to be associated with better school performance at 12 yrs of age. [19]

Amino Acids (AA)

AA in breast milk support growth of the infant during the first months of life. Glutamate, glutamine and taurine are the most abundant free AA in human milk. A number of AA like taurine, glutamate, glutamine and glycine, are recognized as precursors of neurotransmitters that play a key role in long-term potentiation, synaptic plasticity and are important for cognitive functions like learning and memory. In a randomized controlled trial, taurine supplementation showed more mature auditory-evoked responses in healthy infants as compared to infants who

did not receive taurine supplementation.[20] In follow up studies, enteral glutamine supplementation showed no effect on cognitive, and behavioural outcomes at 2 and 7.5 yrs of age.[21, 22] Limited studies have attempted to explore the relation between AA and neurodevelopment or cognition.

Choline

Milk contains a high concentration of choline, phosphocholine and glycerophosphocholine.[23] Choline is important for the synthesis of membrane phospholipids, specifically phosphatidylcholine. Choline can also be found in sphingomyelin, another membrane phospholipid formed from phosphatidylcholine. Choline is a precursor of acetylcholine, which is a neurotransmitter and is required for lifelong memory function. Choline supplementation during pregnancy is reported to improve memory in infants at 6 to 12 mo.[24] Recently, Caudill et al, reported that maternal choline supplementation during the third trimester of pregnancy improves infant information processing speed at 13 mo of age.[25]

Lactose

Lactose, a major component of human milk and it provides energy for the growth of the infants. Human milk contains higher quantity of lactose compared with milk of other species in order to meet high energy demands of the human brain.[26] It is relatively low in colostrum, and increases over time. The body breaks it down into two simpler sugars, glucose and galactose. Galactose is a valuable nutrient for brain tissue development. Taib et al. reported that the children who consumed lactose–isomaltulose-containing milk showed better cognitive performance at 5–6 yrs, [27] suggest carbohydrate composition has effects on some aspects of cognitive performance such as attention and memory. However, there is limited literature on role of breast milk lactose and cognitive performance in children.

Iron

The iron content of the breast milk is vital for the optimal survival of the newborn baby. Iron levels in the milk decreases with increase in lactation age. Iron is essential for myelination, and it has been demonstrated that iron-deficiency can cause altered myelination in infants.[28] It is also reported that in infants with iron-deficiency anemia is associated with poor mental developmental outcomes than children without iron deficiency.[29] Iron metabolism is interrelated to DHA and may be associated with suboptimal functional outcomes in infants.[30] Iron deficiency affects Δ-6-desaturase activity i.e., the synthesis of essential fatty acids and has a major impact on neurodevelopment.[31] Iron supplementation in LBW infants was reported to improve neurocognitive and motor development 5.3 yrs of age. [32]

Zinc

In first six months of life, breast milk is a sole source of zinc. Its concentration is high in colostrum than mature milk. Zinc is essential for the development of the central nervous system, particularly for formation and migration of neurons along with the formation of neuronal synapses. Both animal and human studies suggest that zinc deficiency can lead to delays in cognitive development.[33, 34] A study on zinc supplementation to children have shown no effect on motor development and cognitive functioning .[35]

Copper (Cu)

Cu is an element necessary for synthesising haemoglobin, forming myelin sheaths in the nervous system. The content of Cu in breast milk depends on the stage of lactation i.e. the highest content found in colostrum.[36] Most of the studies have found no effect of dietary intake on milk Cu levels.[37, 38] Bumoko et al reported lower serum levels of Cu with neuromotor impairments in children with konzo, a motor neuron disease.[39]

Vitamin A

Vitamin A is crucial for the normal growth and development of the infant. During the first 6 months of life, vitamin A is transferred through breast milk which is 60 times higher than the transfer occurring through the placenta.[40] Vitamin A is three times higher in colostrum than mature milk.. In animal study, vitamin A deficiency has been shown to be associated with neurodevelopmental delays [41] and learning and spatial memory deficits.[42] Low level of vitamin A in premature infants at birth can last through the entire infancy.[43] In contrast, preconceptional to postpartum maternal vitamin A supplementation is reported to impart no benefits on cognition at ages 10-13 yrs of age.[44]

Neurotrophins

Neurotrophins play a crucial role in the development

of the central nervous system and in the postnatal development of the enteric nervous system. [45] There are a variety of neurotrophic factors that have been identified. Among these, NGF (nerve growth factor), BDNF (brain-derived neurotrophic factor) and glial cell-line-derived neurotrophic factor are found in the breast milk.[46] NGF and BDNF control neuronal apoptosis during brain development and play an important role in neuronal differentiation, survival and growth of neurons and also modulate synaptic plasticity. BDNF is involved in different aspects of learning and memory processing, such as memory persistence and storage. NGF is also critical for enhancing memory formation and facilitating hippocampal long-term potentiation. These reports show the potential of breast milk components to enhance cognitive development. However, the role of breast milk neurotrophins in improving cognition in children is unclear.

Concluding Remarks

Breast milk is the primary source of nutrition to the newborn which contains a wide range of nutrients and other bioactive factors which play a vital role in the development of central nervous system. These components work in concert with each other and influence brain development. The current review provides some evidence on the beneficial roles of breast milk components on cognitive performance in children. It supports the existing policies to promote breastfeeding for 6 months to improve infant growth. Understanding of the molecular and cellular mechanisms through which breast milk nutrients and bioactive components influence neurodevelopmental pathways of the infant is an important step towards preventing adverse neurodevelopment in infants.

To Assess the Incidence and Factors Predisposing to Surgical Site Infection (SSI) in Patients Who Have Undergone Caesarean Section in Tertiary Care Hospital of Udupi District, Karnataka- A Retrospective Study

Debalina Ghosh[1], Judith A Noronha[2], Laveena A Barboza[3]

[1]PG Tutor in Teerthanker Mahaveer College of Nursing, Teerthanker Mahaveer University, Moradabad, Uttar Pradesh, India, [2]Professor and Head, Department of Obstetrics and Gynaecological Nursing, [3]Lecturer, Department of Fundamental Nursing, Manipal College of Nursing, Manipal University, Manipal, Udupi, Karnataka, India

Abstract

Caesarean Section (CS) is a life-saving surgical procedure when certain complications arise during pregnancy and labour. Currently, 18.6% of all births occur by cesarean section globally. **Aim:** To determine the incidence of surgical site infections in patients who have undergone Caesarean Section through record analysis and to identify the factors predisposing to surgical site infections (SSI) with Caesarean Section (CS). **Design:** Retrospective cross-sectional survey design was used for this study. The **s**tudy was conducted at tertiary care hospital of Udupi district, Karnataka from January 2017 to March 2017. Consecutive 305 post-operative case records of Caesarean Section were enrolled in the study. The sample is selected purposively as per their availability in record room. **Methods:** It was a retrospective study screening the records of pregnant women who underwent cesarean section in selected tertiary care hospital from 1st January 2015 to 31st December 2015 and came for followup or readmission with surgical site infection at the incision site or not got discharged due to surgical site infection for a period of 6 weeks. **Results:** A total of 305 record are viewed, about 35.8% (n=107) were performed in elective and 64.92% (n=198) undertaken on emergency list. A total of 20 post-operative cases diagnosed with Surgical Site Infection were studied during the specified period. Of these n=17 (85%) had superficial infection and n=2 (10%) deep SSI and n=1 (5%) had organ space SSI. Odds ratio calculation and *p*-value calculation shows that booking status and wound closing material are responsible to develop SSI.

Keyword- *Retrospective review, Incidence, Predisposing factor, SSI, CS.*

Introduction

[1]The word Caesarean Section is imitative from the Latin verb, 'caedere' meaning (supine stem cesium), 'to cut'. A Byzantine-Greek historical encyclopaedia says Caesarean Section name came from infamous Roman Ruler Gaius Julius Caesar. Currently, 18.6% of all births occur by caesarean section globally. America and Caribbean region has the highest caesarean section rates of 40.5%. In Asia, present rates of caesarean section are 19.2%. Between 1990 and 2014 the rate has increased 12.4% (from 6.7% to 19.1%).

[5]Surgical site infection is defined as an infection that occurs at the incision/operative site (including drains) within 30 days after the surgical operation if no implant is left in place/within 1 year if an implant is left in place. According to the CDC's National Nosocomial Infection Surveillance system, 38% of all nosocomial infections in surgical patients are surgical site infections. The rate

Dr. Judith A Noronha
Corresponding author:
Professor and Head, Department of Obstetrics and Gynaecological Nursing, Manipal College of Nursing, Manipal University, Manipal, Udupi, Karnataka, India. Pin- 576104. 0820 2923123. Judith.n@manipal.edu / juval12@gmail.com

of surgical site infection after Caesarean Section range from 3%- 5%.

[7]The incidence reported of surgical site infection following the caesarean section varies widely. Postpartum wound infection varies from approximately 2%- 10%. Surgical site infection arose more recurrently in women with poor nutrition, extremes of maternal weight (underweight or obese), little prenatal care, prolonged labor or rupture of membranes, long duration of surgery, general anaesthesia, multiple procedures, and young maternal age.

Background of the study:

[3]A retrospective cross-sectional study was done to assess the incidence of surgical site infection and identify risk factors, common bacterial pathogens and antibiotic sensitivity in Nizwa Hospital, Oman. A total number of 7923 caesarean section women's, 211 (2.66%) had developed surgical site infection. The study results suggest that the wound infection is highly associated with women with diabetes (P=0.001), premature rupture of membrane (P<0.001), mildly or moderately or severely anaemic (P=0.035). The overall study concluded that to reduce the number surgical site infection and prevent the risk factors it is necessary to maintain aseptic surgeries, implement infection prevention practices and give antibiotic prophylaxis to reduce morbidity in women undergoing caesarean section.

[4]Farret, Dalle, Monteiro, Wurdig Riche, & Antonello (2015) conducted a retrospective case-control observational study that was conducted in Femina hospital in Porto Alegre, Brazil to determine the risk factors and impact of antibiotic prophylaxis for surgical site infection on caesarean section. A total number of 8180 caesarean section records were reviewed and 118 (1.44%) were diagnosed as having surgical site infection. Among them 56 (70.9%) had a superficial skin infection, ten (12.6%) had a deep incisional and 14 (17.7%) had an organ/space surgical site infection.

[6]A prospective study was conducted as a part of the Scottish Surveillance Healthcare-Associated Infection Programme in a city hospital of Glasgow. The data was collected in two phases, during the inpatients stay and in the community setting until 30th postnatal day from 715 women. Among all 715 cases of caesarean section, 80 (11.2%) cases developed surgical site infection. Development of surgical site infection occurred within the hospital stay for 22 (27%) patients, 57 (71%) developed after discharge and one (2%) diagnosed after re-admission. The majority, 90% of the surgical site infection were superficial. The study concluded that an intensive surveillance program with engaged clinicians and infection control personnel was effective to reduce healthcare-associated infection.

[2]A prospective cross-sectional study was carried out by the Department of Gynaecology and Obstetrics, at Butare University Teaching Hospital. surgical site infection was identified during hospital stay or 30 days of the post-caesarean section following readmission. Data were collected by questionnaire and telephone interview. In this study among 323 mothers, 4.9% developed surgical site infections. Most of the surgical site infection was categorized as superficial skin infection 75%, deep 12.5% and organ space surgical site infection 12.5%. The study concluded that close monitoring of prolonged labor and routine visit on the 4th postnatal day can be a measure to control surgical site infection.

Even though the literature review was done on surgical site infection on caesarean section for assessing predisposing factors from 2007 to 2017 the investigator couldn't find any published article from the Karnataka state. The current study was planned to assess the incidence and factors predisposing to develop surgical site infection in the caesarean section to get the status of surgical site infection and adopt preventive measures.

The study wants to determine the incidence of surgical site infections in patients who have undergone caesarean section through record analysis and also to identify the factors predisposing to surgical site infections and antibiotics used in those patients with caesarean section.

Method

The retrospective cross-sectional survey design was found appropriate to meet the required objective of the present study. Formal administrative permission was obtained from the Institutional Research Committee and Institutional Ethical Committee. Permission was taken from the respective Head of the Department. Data were collected from January 6th, 2017 to 4th February 2017. All the hospital number was collected along with IP number from medical record department and 20 files per day were checked both IP and OP simultaneously. The purpose of the study was to find out the incidence of SSI and find out factors predisposing to SSI of those pregnant women underwent Caesarean Section in this particular

time period and data was collected in retrospectively from medical records and it was considered necessary to gather information directly from records of cesarean mothers.

Screening the records of pregnant women who underwent cesarean section in selected tertiary care hospital of Udupi district, Karnataka and pregnant women who underwent Caesarean Section from 1st January 2015 to 31st December 2015 and came for followup or readmission with surgical site infection at the incision site or not got discharged due to surgical site infection for a period of 6 weeks post-delivery through caesarean section.Data collection tools were personally obtained by the investigator from each record. The following data collection tools were developed by the investigator-demographic proforma, semi-structured tool to assess factors predisposing to surgical site infection among pregnant women who underwent caesarean section, semi-structured tool to assess the factors predisposing to surgical site infection among cesarean section women, structured antibiotic assessment tool. The time taken to complete the tools was approximately 20 minutes.

Through this study, we want to find out Obstetrical factor and Surgical factor related to development of SSI and antibiotic used to treat SSI in post-CS. For identifying each record demographic proforma was used. The semi-structured tool was used to assess factors predisposing to surgical site infection among pregnant women who underwent cesarean section and for assessing antibiotic used in post-Caesarean Section mother, the antibiotic assessment tool was formulated.

The data obtained from records were analyzed using "SPSS" 16 version. Here, data related to demographics, factor assessing to surgical site infection, cesarean section assessment tool, and the tool to assess antibiotic use practices were transferred directly to "SPSS" version 16. Missing data are coded as 999. Descriptive and inferential statistics were used to analyze the data. Frequency and percentage were used to calculate prevalence, univariate and multiple logistic regression wares used for analysis of data related to factors predisposing to surgical site infection among cesarean section. Total 305 mothers' data were included in this study.

Findings

The analysis of the study findings is categorized into the following sections:

Section 1: Incidence of occurrence of surgical site infection

Section 2: Description of sample characteristics

Section 3: Factors predisposing to the development of surgical site infection- Obstetric factors and Surgical factor

Section 4: Description of antibiotic usage among women after caesarean section

Section 1: Incidence of occurrence of surgical site infection.

This section describes the incidence of the occurrence of surgical site infection among 305 pregnant women who underwent caesarean section. The occurrence of surgical site infection was based on presence of one or more symptoms (tenderness, redness, discharge, pain, coping any other).

Section 2: Description of sample characteristics.

This section describes the characteristics of 305 pregnant women who underwent caesarean section. The sample characteristics include age, height, weight, BMI, parity, previous history of surgical site infection, previous abdominal surgery and premorbid disease condition. Frequency and percentage distribution were calculated for describing the sample characteristics of women who developed surgical site infection and who did not develop surgical site infection.

Mother who didn't develop SSI among them, majority 180 (63.2%) of the pregnant women who underwent Caesarean Section belonged to the age group of 25-32 years, 202 (77.7%) had height more than 150cm, 174 (66.9%) had weight between 50-70kg, 121 (47.5%) had BMI of 25.1-30.1, 167 (58.6%) were multigravida, 162 (56.8%) had Caesarean Section and other abdominal surgeries in the past, 196 (68.8%) had no previous premorbid disease condition.

Mother who develop SSI, among them majority 15 (75%) of the women belonged to age between of 25-32 years, nine (56.2%) of women's height was more than 150cm, eight (50%) had weight in between 50-70kg, seven (43.8%) had BMI of 20-25, 13 (65%) were multigravida, nine (45%) had no history of previous surgeries, ten (50%) had no previous premorbid disease condition.

Section 3: Factors predisposing to the development of surgical site infection.

Obstetrics and Surgical factors that are responsible for developing an infection. The univariate analysis and odds ratio of each factors are describing in Table 1.

Among women who had taken antenatal care from a tertiary care hospital odd depicts 3.572 {1.29-9.970 (95% CI) and p-value of 0.52} less chance of developing surgical site infection because of a routine investigation, antenatal high-risk assessment, proper timing of conducting delivery.

Suturing the wound with Ethilon and Vicryl will reduce the chance of developing surgical site infection 1.421 times i.e. OR 1.421 {1.084-24.159 (95% CI) and p-value 0.486}.

Conclusion

Based on the findings and interpretation of the present study, the following conclusion was drawn:

- The incidence of surgical site infection among women who underwent caesarean section was only 6.9%.

- The present study shows booking status, wound closing material have a significant associative risk factor in developing women's surgical site infection in who underwent caesarean section. However, to some extent patient above 25 years of age had more risk for developing surgical site infection.

Comparison of the Action of Various Pulpotomy Agents on Pulpal Histology – A Monograph

Deepti Anna John[1], Jaiganesh Ramamurthy[2]

[1]Undergraduate Student, [2]Reader, Department of Periodontics, Saveetha Dental College, Saveetha University, Saveetha Institute of Medical and Technical Sciences, Chennai, Tamil Nadu, India.

Abstract

Pulpotomy is the removal of the diseased or affected part of the pulp with the aim of maintaining the vitality of the tooth by a placement of a medicament. Throughout the years, various therapeutic agents have been used to ensure the vitality of the pulp such a Formocresol, ferric sulphate, calcium hydroxide and zinc oxide eugenol. But also, different alternatives such as electro surgery, laser, collagens, glutaraldehyde and Freeze-dried bone have been used to maintain pulpal vitality. Out of all the agents studied on, freeze dried bone was concluded to be superior as most teeth treated with it, had vital pulps and increased dentin bridge growth. Hence, the aim of this review to study the action of the various pulpotomy agents on the pulpal histology and understand which pulpotomy agent gives the best result.

Key words: *Pulpotomy, freeze dried bone, formocresol, ferric sulphate, histology*

Introduction

The dental pulp is the soft connective tissue which is the vital part of the tooth. It forms a part of the dentin- pulp complex. Histologically, the pulp is composed of four distinct zone: (1) odontoblastic zone (2) cell free zone of Weil (3) cell rich zone (4) pulp core. The main cells that the pulp is composed of are the odontoblasts, fibroblasts, undifferentiated ectomesenchymal cells, macrophages and other immunocompetent cells. The odontoblastic zone is formed by odontoblasts that line the periphery of the pulp with processes extending into the dentin. The cell free zone of Weil is found beneath the odontoblasts is prominent in the coronal pulp. The cell rich zone has a high density of cells composed of mainly the fibroblasts along with undifferentiated ectomesenchymal cells, dental pulp stem cells and inflammatory cells. The pulp core is made up of blood vessels and nerves which is responsible for the sensibility and sensitivity of the pulp[1]

Pulp has a potential to self-regenerate, when exposed due to absence of the overlying dentin with the help of various vital pulp therapy options which can allow the pulp to form new dentin "dentin bridge"[2]. In the cases where certain parts of the pulp have been affected by infection, partial removal of pulp tissue is indicated, this process is called Pulpotomy. This procedure is based on three lines: Devitalization which is focused on the mummification of the entire tissue which obliterates the infection and internal resorption, second is Preservation which is to maintain the vitality of majority pulp with minimum insult and no formation of reparative dentin, the last is Regeneration which aims to maintain vitality of pulp along with formation of the dentin bridge[3].

The various pulpal agents used in pulpotomy are Formocresol, glutaraldehyde, Zinc oxide eugenol, glutaraldehyde, ferric sulphate, calcium hydroxide, Mineral trioxide aggregate, freeze dried bone that shows bone morphogenic protein (BMP 2,3,4,5,6 and 7), collagen and newer materials such as lyophilized freeze-dried platelet, enamel matrix derivative, propolis, sodium hypochlorite and bioactive glass[4].

Action of Formocresol on Pulpal Histology:

Formocresol was one of the most common pulpotomy agents used in the earlier days. The function of formocresol was based on the Devitalization principle of the pulp through mummification, but recently questions have been raised regarding carcinogenicity, mutagenicity and immune sensitization.

When the pulp tissue is exposed to formocresol, a layer of dense homogenous eosinophilic tissue was seen indicating a thick but poorly calcified dentin bridge formation, along with a large inflammatory infiltrate consisting of neutrophils, lymphocytes and macrophages[5].

Action of Ferric Sulphate on Pulpal Histology:

Ferric sulphate has been commonly used as a coagulative and haemostatic agent in the retraction cord used for crown impressions. The mechanism is based on the agglutination of the blood proteins when it meets ferric and sulphate ions.

It is used as a pulpotomy agent based on Preservation, as it is said to control haemorrhage hence reducing the chances of inflammation and internal resorption. Also, the clot formed could also act like a barrier to irritative agents.

Based on a study conducted on 15 baboons which compared Ferric sulphate with Formocresol and it was found that necrosis was seen but recognizable pulp was seen in least 2/3rd the length of the root, inflammatory infiltrate was seen in recognizable pulp along with slight secondary dentin bridge formation and there was a decrease in internal resorption[6].

Action of Freeze-Dried Bone on Pulpal Histology:

Allografts are bone grafts that are taken from one individual to another for transplantation. Bone allografts have been widely used in dentistry especially in the field of craniofacial surgery. Bone allografts are of three types: (1) Fresh bone (2) Freeze dried bone (FDB) (3) Demineralized freeze-dried bone (DFDB).

Freeze dried bone was initially used in the orthopaedic therapy as it provides an osteoconductive scaffold for bone growth and shows resorption when implanted in mesenchymal tissues. It also shows Bone morphogenic proteins (BMPS) which stimulate osteoinduction. Studies also claim that FDB may act as a inducer of a calcific barrier over a wound site. These allogenic grafts show advantages such as availability, predictable results and elimination of donor site surgery. But certain disadvantages such as host incompatibility, contaminated specimens still raise certain questions about freeze dried bone[7].

A study was conducted on two cynomolgus monkeys with their teeth restored with Freeze dried bone, Calcium hydroxide and Zinc oxide eugenol, out of the 32 teeth, 4 were extracted since they failed to show the requirements and 28 teeth were histologically analysed.

From the studied it was obtained that the teeth treated with FDB had vital pulps after 6 weeks, dentin bridges were formed in 87.5% compared to others and inflammatory cells were absent in all those teeth, lack of periapical, furcal and necrotic involvement was seen. The initial hypothesis was that FDB would act like Calcium hydroxide but the results show its superiority over Ca (OH)[8].

Conclusion

Formocresol and Ferric sulphate based on the studies, show similar results but with Ferric sulphate more favourable due to its non-toxicity compared to Formocresol. But Freeze-dried bone proves to be an appropriate alternative as a biological agent for pulp therapy. It is being employed extensively in periodontal osseous defects, as it proven to show both clinical and histological benefits to bone and cementum. FDB has also shown to be superior to Calcium hydroxide but furthermore clinical studies on pulpotomies are required to get a better understanding of the material.

Child Feeding Practices and Stunting: A Case-Control Study in Jember Regency of Indonesia

Devi Arine Kusumawardani[1], Nurul Ulya Luthfiyana[1]

[1]Lecturer in Department of Public Health, University of Jember, 42th Kalimantan Street, East Krajan, Sumbersari, Jember City, East Java

Abstract

Stunting becomes the main nutritional problem which is a consequence of long-term, cumulative inadequacies of health and nutrition. Child feeding practices by good parents can prevent stunting in children from an early age. Child feeding practices include early breastfeeding initiation, exclusive breastfeeding, complementary feeding practice, and frequency of feeding. The purpose of this study is to analyze the effects of child feeding practices on stunting in children aged 12-36 months in Jember Regency. The sample was selected using a simple random sampling technique, totaling 220 mothers. The data were analyzed using chi-square statistic tests and multiple logistic regression tests. The results of the test discovered that most of the respondents were low educated mothers and low-income families. The significant determinants associated with stunting were exclusive breastfeeding (OR = 3.30; 95%CI 1.85-5.90), complementary feeding practices (OR = 1.86; 95%CI 1.04-3.33), and frequency of feeding (OR = 1.95; 95%CI 1.84-3.51). Exclusive breastfeeding is the major determinant for stunting in toddlers and therefore should be a priority program to improve the nutritional status of children in early ages of life.

Keywords: *stunting; exclusive breastfeeding; complementary feeding practice; frequency of feeding*

Introduction

Globally World Health Statistic 2014 of the World Health Organization (WHO) reported that in 2012 more than 162 million of the world's children, particularly in developing countries, were categorized as stunting[1]. Stunting or low height-for-age is a reduced growth rate in human development or a slowing down of skeletal growth and height. It reflects a process of failure to reach linear growth potential. It is a largely irreversible outcome of inadequate nutrition and repeated bouts of infection during the first 1000 days of a child's life[2].

Stunting has short-term and long-term effects on individuals and societies. In the case of short-term effects, when a child is malnourished during the first 1000 days of life, it results in a weaker immune system and a higher risk of severe infectious diseases, including diarrhea and pneumonia[3], which often end with mortality, morbidity, and disability. In the case of long-term effects, stunting has long-term effects on individuals and societies, including diminished cognitive and physical development, reduced productive capacity and poor health, and an increased risk of degenerative diseases such as diabetes[4]. Also, they are more likely to suffer from chronic diseases, such as high blood pressure, heart disease, and obesity. These health impacts have devastating consequences for social and economic outcomes. Poorly nourished children are more likely to complete fewer years of school and have lower productivity as adults, including 10 percent lower earnings over their lifetime[5].

In Indonesia the problem of stunting is stagnant but it is significantly a critical problem. As reported by Riskesdas (2013), stunting prevalence reached 37.2% in composing of 18% of very stunting and 19.2% of moderate stunting, 35.6% in 2010, and 36.80% 2007. In some provinces, the prevalence of stunting exceeds national prevalence. These figures made serious in stunting prevalence; consequently, it requires much

more attention and intervention[6].

Child feeding practices are a critical determinant to support the child's growth and development according to the stage of age. Inappropriate child feeding practices specifically indirect early breastfeeding initiation in one hour after birth, non-exclusive breastfeeding, and inappropriate complementary food can be increased risk of stunting in children. However, inadequate child feeding practices in terms of variety, frequency, and quality can depress the child immunity system. Furthermore, lack of immunity system leads to an increase in disease and the probability that a child will grow inadequately and child can be stunted[7].

Jember Regency still occupies the second position of districts with the highest stunting prevalence in East Java (39.3%)[8]. Therefore, Jember Regency has become one of the stunting priority districts in East Java. Arjasa and Kencong sub-districts of Jember Regency are the highest prevalence stunting areas (39.30% and 38.78%)[8]. The objective of this study is to analyze the effects of child feeding practices on stunting in children aged 12-36 months in Jember Regency, Indonesia.

Material and Method

The design of the study was a case-control study that determined if an exposure is associated with an outcome by compared the cases and the controls. The study was conducted in Arjasa and Kencong sub-districts of Jember Regency in March till April 2018. A simple random sampling was used to select a sample of 220 mothers with children aged 12-36 months (110 stunting children as a case group and 110 non-stunting children as a control group).

Data of child feeding practices were obtained from structured interviews with questionnaires and observations. All of the questionnaires were calculated by the validity and reliability test. Furthermore, to examine the effect of child feeding practices on stunting, the data were submitted to the bivariate analysis with chi-square and multivariate analysis with multiple logistic regression with 95% confidence interval and significance level p <0.05.

Findings

Table 1 shows that most of the stunting children were male (60.0%) while most of the non-stunting children were female (50.9%). Maternal age in stunting and non-stunting children were mostly between 26-35 years (48.6%). Most mothers of children (63.2%) had low education (elementary schools and junior high schools). Furthermore, most of the fathers were unskilled workers (40.9%).

Table 2. Summary of bivariate analyses the investigated variables for stunting

Variables	Stunting status				Total n (%)	OR	p	OR (95% CI)
	Yes		No					
	n	%	n	%				
Early breastfeeding initiation								
No	33	15.0	39	17.7	72 (32.7)	0.78	0.389	0.44 – 1.37
Yes	77	35.0	71	32.2	148 (67.3)			
Exclusive breastfeeding								
No	75	34.1	40	18.2	115 (52.3)	3.75	<0.001	2.14 – 6.55
Yes	35	15.9	70	31.8	105 (47.7)			
Complementary feeding practice								
Poor	72	32.7	49	22.3	121 (55.0)	2.36	0.002	1.37 – 4.06
Good	38	17.3	61	27.7	99 (45.0)			
Frequency of feeding								
< 3 times/day	51	23.2	34	15.5	85 (38.6)	1.93	0.019	1.11 – 3.35
≥ 3 times/day	59	26.8	76	34.5	135 (61.4)			

Table 2 shows that the number of children who had early breastfeeding initiation was higher than children who did not get early breastfeeding initiation. Most of the stunting children did not get exclusive breastfeeding from the mothers. The majority of complementary feeding practices in children whose stunting are poor. However, the frequency of feeding in stunting and normal group was largely more than equal to three times a day.

The result of statistical analysis with the Chi-square tests showed that three independent variables significantly affect the incidence of stunting in children. It shows the results of Chi-Square test between exclusive breastfeeding and the risk of stunting was significant (p=<0.001), complementary feeding practice was significantly affected stunting (p=0.002), and frequency of feeding, have significantly related to the risk of stunting in children (p=0.019). While the early breastfeeding initiation not significantly affected stunting in children (p=0.389).

Table 3. Summary of the results of multiple logistic regression

Independent Variable	OR	CI (95%)		p
		Lower	Upper	
Get exclusive breastfeeding	3.30	1.85	5.90	<0.001
Poor complementary feeding	1.86	1.04	3.33	0.037
Frequency of feeding < 3 times/day	1.95	1.84	3.51	0.026

Table 3 shows the results of multiple logistic regression on the risk factors of stunting in children. Factors that increased the risk of stunting in children under five did not get exclusive breastfeeding, poor complementary feeding, and frequency of feeding < 3 times/day. Children who were not given exclusive breastfeeding had a higher risk for experiencing stunting 3.30 times compared with children who given exclusive breastfeeding (OR = 3.30; 95% CI = 1.85 to 5.90; p = <0.001). Children with poor complementary feeding had 1.86 times higher risk of developing stunting compared with those with good complementary feeding (OR = 1.86; 95% CI = 1.04 to 3.33; p = 0.037). The results also indicated that children who had feeding < 3 times/day were at risk of stunting 1.95 times greater than children who had feeding ≥ 3 times/day (OR = 1.95; 95% CI = 1.84 to 3.51; p = 0.026). Based on the test, the results indicated that exclusive breastfeeding was the dominant factor in the risk of stunting in children.

Discussion

The respondents of this study were dominated by low educated mothers and low-income family. Mother's education and household condition have important influences on children's health status irrespective of the stage of development. Education is the key to further improvement in child nutrition, which can influence the child feeding practice of the mother. Low educated mothers commonly have less ability and less opportunity to maintain better child feeding practice in their children. Furthermore, low-income family has to lack access to information and health facilities, so they tend to perform poor child feeding practice than middle and high-income family[9,10].

The result of the present study has shown that exclusive breastfeeding, complementary feeding practice, and frequency of feeding had a significant effect on stunting. Nevertheless, early breastfeeding initiation did not have a significant effect on stunting. Early breastfeeding initiation can allow the children to get colostrum as the protection factor for the children's health in the future. The result of this study was inconsistent with other studies showing that there is a negative correlation between early breastfeeding initiation and stunting[11]. Other studies showing that early breastfeeding initiation can prevent stunting specifically in one thousand early days of life[12,13].

Exclusive breastfeeding affects stunting in children. Exclusive breastfeeding has many benefits such as the best nutritious food for the baby until six months old, antimicrobial agents and hygiene. The longer duration of the breastfeeding showing that can protect children from many serious health problems and degenerative disease that cause of death in the future such as gastrointestinal infection and respiratory tract infection[14]. Another study shows that the duration of breastfeeding has a negative correlation with stunting. The children who had exclusive breastfeeding for six months until twelve months have less risk of stunting than the children that had breastfeed less than six months. These differences

can be caused by culture, social-economic dynamic, and the mother's education[15,16].

Complementary feeding practice is a complex behavior that includes timing of complementary feeding, variety of complementary food, food preparation methods, quantity and quality of food, responsive feeding, safe food preparation, and food storage. The result of this study showing that complementary feeding practice has a significant effect on stunting. Poor complementary feeding practice can cause an inadequate intake of macronutrient and micronutrient. Inadequate intake of food in the early days of life of children can impair growth so that children have a higher risk to be stunting[17].

The frequency of feeding also affects stunting in children. Most respondents performed three or more feeding for their children in one day. The result of this study is consistent with other studies showing that children who feed less than three times a day have a higher risk to be stunted than children who feed three times a day or more. Children who feed less than three times a day associated with a higher risk of inadequate intake of nutrition[18]. Furthermore, the children are not susceptible to certain malnutrition which in turn can aggravate health conditions and a higher risk of infectious diseases[7,19].

Conclusion

Exclusive breastfeeding, complementary feeding practice, and frequency of feeding affect stunting in children. Based on these conclusions, it is suggested to Community Health Center to improve mother's capability specifically in child feeding practice to prevent stunting with comprehensive counseling. Further research is needed on other factors that affect stunting in children specifically the identification of intake of nutrient consumption in other micronutrients.

Validation of Association Between Breastfeeding Duration, Facial profile, Occlusion of Children in Chennai Population:-A Cross Sectional Study

Devika Warrier. E[1], Deepa Gurunathan[2], Ganesh Jeevanandan[2]

[1]BDS Graduate Student, [2]Department of Pedodontics, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical sciences, Chennai

Abstract

Introduction: Malocclusion is not a disease and is considered as a developmental disorder of the craniofacial complex.It may cause functional and esthetic disturbances in affected individuals.Environmental factors like dietary habits,nonnutritive sucking habits, bottlefeeding, and reduced duration of breastfeeding have often been implicated with various developmental disorders[1]. The .increased breastfeeding duration in preventing the development of malocclusion,and establishing a correct occlusal relationship by stimulating the facial muscles during suckling have a great importance.

Aim: The aim of this study is to assess the relationships among breastfeeding duration,nonnutritive sucking habits,convex facial profile,nonspaced dentition,and distoclusion in the deciduous dentition.

Materials and methods: A sample of 250 children aged 4 to 6 years from south Indian population was clinically examined. Information about breastfeeding duration and nonnutritive sucking habits was obtained from the parents and data was compiled.

Results: From this study it was found that a statistically significant association was observed between breastfeeding duration and nonnutritive sucking habits. Nonnutritive sucking habits had a statistically significant association with distoclusion and convex facial profile. But the occurrence of convex facial profile and distoclusion was not associated with breastfeeding duration.

Conclusion: Thus this study hypothesize that nonnutritive sucking habits may act as a dominant variable in the relationship between breastfeeding duration and occurrence of convex facial profile and distoclusion in deciduous dentition.

Keywords: *Breastfeeding duration, Facial profile, Non nutritive sucking,Occlusion.*

Introduction

In addition to the well-recognized nutritional, immunological and psychological benefits, breastfeeding promotes adequate development of the oral myofunctional structures.Moreover, the association between decreased breastfeeding duration and increased prevalence of non-nutritive sucking habits has already been demonstrated.Several authors have alsoreported the close relationship between the non-nutritive sucking habits and the development of malocclusions[2].

Although shorter breastfeeding practices play an indirect role in the etiology of malocclusions, the extent to which breastfeeding duration periods and the development of malocclusions in primary dentition are associated still remains a matter of concern. Warren and Bishara in the year 2002 compared of mean dental arch measurements and occlusal traits of non-breastfed children and those who were breastfed over three

periods: shorter than 6 months, from 6 to 12 months, and longer than 12 months[3].

The World Health Organization (WHO) recommends exclusive breastfeeding for the first six months of life to achieve optimal growth, development and health[4]. These recommendations are supported by a systematic review which states the benefits of breastfeeding for six months for minimizing the risk of gastrointestinal infection and growth deficits in young children. Despite the medical benefits of breastfeeding, no systematic review has evaluated the long-term benefits of breastfeeding for oral health, especially related to malocclusion in the primary dentition[5].

When analyzing malocclusion in the primary dentition the interaction between genetic and environmental factors has to be considered. The most frequently reported environmental factors are changes in feeding habits. Furthermore, it is known that early sucking activity might influence the growth of the craniofacial complex.It is important to keep in mind that malocclusions have negative effects on oral health-related quality of life, predominantly in the dimensions of social and emotional wellbeing[6].

Breastfeeding is reported to be a nutritive sucking habit that protects against malocclusion in the primary dentition.Nevertheless, a consensus on this subject has not been established in the literature. Some authors report that prolonged breastfeeding decreases the risk of malocclusion others have not found such an association[7]. Moreover, there is no consensus on the length of time newborn children should be breastfed to protect against malocclusion, as some studies report that six months are sufficient and others report the need for longer periods (6 to 12 months).

Non-nutritive sucking is a common behaviour among young children in various populations.Its prevalence is quite variable and depends on several factors, including gender, age, feeding method and socioeconomic status[8]. There is an agreement among a number of authors that non-nutritive sucking habits can be a consequence of industrialisation and modernisation, with more women working and a shorter breastfeeding period, which favours the adoption of digital and pacifier sucking[9,10].

Controversial findings may be related to a positive history of persistent non-nutritive sucking habits while breastfeeding. The present study evaluated the association between different breastfeeding patterns and prevalence of non nutritive sucking habits,convex facial profile and distoclusion.

Materials and Method

A sample of 150 children in the age group 2-6 years in South Indian population was clinically examined. Information about breast feeding duration, Dental Occlusion, sucking habits was obtained.The information such as name, age, sex were also noted. The collected data was compiled to calculate the percentage and graphs were drawn for the individual data.

Information about mother's health during pregnancy and type of delivery was also gathered and only full-term and normally born children were included in the study. The inclusion criteria formulated for the study was as under:

-Age 2 to 6 years

-A student studying at one of the two chosen schools for the study

-Normal number, size, and shape of teeth present

-Absence of root stumps and teeth with poor prognosis

-Unerupted or partially erupted permanent first molars not in occlusion

The exclusion criteria formulated was as under:

-Presence of any local or systemic disease in the child which may affect bone metabolism

-Any anomaly in the number, shape, or size of the teeth

-Presence of rampant caries and teeth with poor prognosis

-Fully erupted permanent first molars

-Parental refusal to fill the written questionnaire.

Based on the above-mentioned criteria, 150 children (50 males and 100!females) were finally selected for the study. The children were divided into two groups: Group 1 (children exclusively breastfed $\geq$ 6 months (n = 55)) and group 2 (children exclusively breastfed $\leq$ 6 months (n = 95)). A retrospective investigation was made for the length of time that children were exclusively breastfed in the study. Information on nonnutritive sucking

habits was also included.Data were accumulated from the questionnaires as well as findings of the clinical examination and recorded in excel sheets. A chi-square test ($p < 0.05$) was performed to verify associations between (1) breastfeeding duration and prevalence of nonnutritive sucking habits, (2) breastfeeding duration and convex facial profile, (3) breastfeeding duration and distoclusion of deciduous second molars, (4) breastfeeding duration and nonspaced dentition, and (5) nonnutritive sucking habits and all the above mentioned parameters..

Results

The prevalence of distoclusion, convex facial profile, and nonnutritive sucking habits was 37.3,8 and 72% respectively. The frequency of breastfeeding for < 6 months duration was 55(36.6%), and the frequency of breastfeeding > 6 months duration was 95(63.3%) (Table-1).On statistical analysis it was found that there was no significant association was observed between breastfeeding duration and convex facial profile and there was a small significance association between breastfeeding duration and distoclusion.A higher incidence of malocclusion was observed with reduced breastfeeding duration. However, the association between breastfeeding duration and nonnutritive sucking habits was statistically significant.

Table:-1 Frequency of breastfeeding duration

Breastfeeding duration	Number	Percentage
Below 6 months	55	36.6%
Above 6 months	95	63.30%

Table :-2 Type of occlusion

OCCLUSION	Number	Percentage
Distoclusion	56	37.3%

Graph:-2 Association between breast feeding nutrition and occlusion,facial profile and sucking habits.

Discussion

Breastfeeding positively affects physiological as well as the psychological development of children. Mother's milk provides all required nutrition which could promote proper immunological protection and therefore prevent chronic diseases and respiratory infections[11]. It is also associated with growth and development of the maxillomandibular complex by the act of sucking which induces perioral muscle activity[12,13].

On the other hand, nonnutritive sucking habits could cause occlusal abnormalities especially if it is prolonged for longer duration[14]. Some authors showed that the prevalence of non nutritive sucking habits is influenced by many factors such as sex, birth order, feeding method, and socioeconomic status[15]. The results of the present study could not identify such relationship but it was found that the reduced duration of breastfeeding was related to the non nutritivesucking habits below the year of four.Though information regarding breastfeeding relating to Non nutritive sucking habits is somewhat contradictory,the Results of this study indicated that the prevalence of non nutritivesucking habits were lower in children who were breastfed longer which might suggest this assumption that breastfeeding time has a preventive effect on non nutritivesucking habit development. An explanation is that the less time of breastfeeding induces more time of bottle feeding which in turn increases the chance of other external object sucking. In other words, bottle feeding gives children this opportunity to be addicted in sucking other external objects[16].

In the current study the dental examination was also performed and the association between non nutritive sucking habits and malocclusion prevalence was documented. Numerous studies identified significant association between sucking habits and anterior open bite, class II occlusion, increased overjet, and posterior crossbite [17].

In this study a significant association between breastfeedingduration and nonnutritive sucking habits and also between nonnutritive sucking habits and convex facial profile and distoclusion were observed. In a study conducted by Bishara et al a higher incidence of malocclusion associated with breastfeeding duration of less than 6 months was observerd[18]. This was similar to our study in which 29 children had distoclusion with a duration of breastfeeding less than 6 months and 27 children had distoclusion with a duration of breastfeeding more than 6 months. Comparing the facial profile it was observed that 97 of children had nonconvex facial profile with a breastfeeding duration more than 6 months.Out of 72 children with non nutritive sucking habits 43 patients were with a breastfeeding duration of less than 6 months and 29 were with a breastfeeding duration of more than 6 months.

There is no doubt that breastfeeding has benefits for general health; nevertheless, the relationship of breastfeeding on oral health is still inconclusive[19]. Although the growth and development of the facial bones is strongly associated with genetic factors [20], it is also believed that environmental factors such as breastfeeding and oral parafunctional habits also affect facial growth[21]. Our findings also point to a hypothesis that nonnutritive sucking habits may act as a dominant factor in the relationship between breastfeeding duration and convex facial profile and distoclusion of the dentition.

Conclusion

From this study it was observed the occurrence of convex facial profile and distoclusion was not associated with breastfeeding duration but with non nutritive sucking habits.However,there was a significant association between reduced breastfeeding duration and nonnutritive sucking habits.Nonnutritive sucking habits may be hypothesized as a dominant variable in the relationship between breastfeeding duration and convex facial profile and distoclusion of the dentition.

Quality of life in Women with Adverse Pregnancy Outcome in Karad

Dimpal Anil Bajaj[1], G.Varadharajulu[2]

[1]Final year BPTh Student, [2]Professor and Dean, Department of Neurosciences, Krishna College of Physiotherapy, KIMS "Deemed to be University" Karad, Maharashtra, India

Abstract

Pregnancy is a period from conception to birth. During this period several physical and emotional changes occurs in women. Women should be physically and more over mentally prepared to have a baby in her womb. Miscarriage is spontaneous loss of the fetus before 20 weeks of gestation. The rate of miscarriage increases with a maternal age of less than 18years or an age of 35 years or more, an increasing number of previous miscarriage, and increasing parity. In rural population women are forced to marry at an early age.

Objective: To study the quality of life on SF-36 questionnaire of women having adverse pregnancy outcomes.

Materials and Methodology: The study was conducted in krishna institute of medical sciences 'deemed to be' university Karad. Subjects were selected according to inclusion and exclusion criteria. The subjects underwent test using quality of life questionnaire- SF36**.**

Conclusion: The present study provided evidence to support the decline in quality of life of women with adverse pregnancy outcome.

Key words: *adverse pregnancy, miscarriage, quality of life, SF-36*

Introduction

Women is a creative force of the universe in almost all its expression. Life begins in her womb and it is in her guiding hands and tender care that it finds expression. Being a mother is one of the most blessed and the challenging job in the world. Giving birth to a new life and making it walk through the new world holding its hands showing a good trial makes a mother victorious in her life.[1]

Pregnancy is a period from conception to birth. During this period several physical and emotional changes occurs in women. Women should be physically and more over mentally prepared to have a baby in her womb. Even before women gives birth, pregnancy thinkers with the very structure of the brain.[2]

In today's generation modern women are enjoying more freedoms than ever before in almost all the field. Today women's don't like to sacrifice anymore. They don't want to work at anything that takes more time. It takes time to invest in people and they want it easy. Fast-food, fast internet, fast coffee, and fast checkout lines. Anything outside of this crumbles their universe. Women today behave very much more like man. They drink alcohol and do drugs. In this modern era women's attitude against pregnancy and being a mother is changing. With the changing attitude of pregnant women and life style there is increase in number of adverse pregnancy outcomes such as miscarriage, fetal death, still births etc. [2,3]

Miscarriage is spontaneous loss of the fetus before 20 weeks of gestation. The rate of miscarriage increases with a maternal age of less than 18years or an age of 35 years or more, an increasing number of previous miscarriage, and increasing parity. In rural population women are forced to marry at an early age. With such marriages the pressure of getting pregnant as soon as possible is also high. Endocrine disorders,

immunological disorders, infection, maternal medical illness, uterine fibroids, alcohol consumption, smoking, drugs are some of the common causes of miscarriage[5]

Quality of life is a general well-being of individuals and societies, outlining negative and positive features of life. Quality of life is an overarching term for the quality of various domains in life. It is subjective, multidimensional concept that defines a standard level of emotional, physical, material and social well-being.

The loss of fetus leads to stressful or traumatic events which can have a lifelong effect. Traumatic experiences involve a various series of physiological and psychological reactions such as depression, anxiety, frustration, sleep disorders, grief, excess fatigue, irritability, pain and lack of concentration. Denial and repression of such feelings can lead to adverse health effects and disorders such as posttraumatic stress. Many studies have shown high rates of symptoms of depression, anxiety and fatigue following perinatal loss.[6]

It is important to understand the effect of this type of loss on the quality of life of women in order to develop intervention to reduce physical and mental stress of mother.

Materials and Method

The subjects in Krishna institute of medical sciences deemed to be university campus were screened and those fulfilling the inclusion and exclusion criteria were involved. 55 subjects were selected for the study. Participants were informed about the study and consent was taken. The subjects underwent test using quality of life questionnaire SF-36.

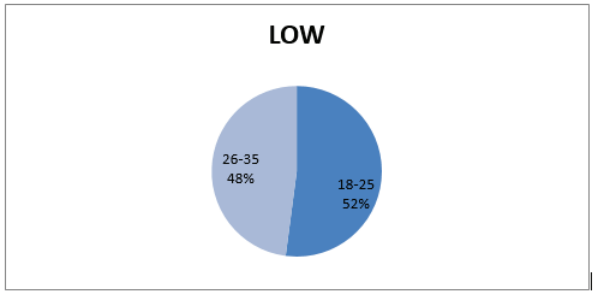
Statistical Analysis

Statistical analysis was done by using the statistics software INSTAT so as to verify the results derived. Arithmetic mean and standard deviation was calculated for the outcome measure MS Excel was used for drawing graph.

Results

Table 1: Age distribution.

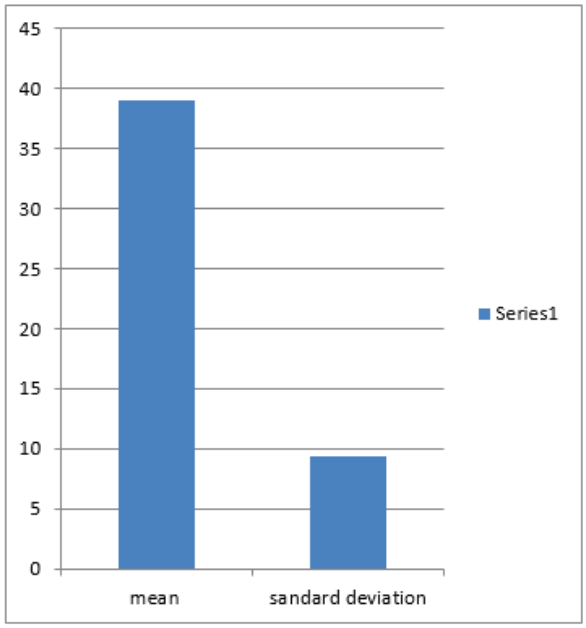
Age	Low QOL	HIGH QOL
18-25	25	4
26-35	23	2



Graph 1: Age Distribution

2. Outcome Measures.

Outcome Measure	Mean	Standard Deviation
Quality of Life Sf36	39.019	9.311



Graph 2: Mean And Standard Deviation of Total Scoring of Sf-36.

Discussion

Child birth is one of the most heavenly things in this universe. Women is a creative force of the universe in almost all its expression. Life begins in her womb and it is in her guiding hands and tender care that its finds expression. Being a mother is one of the most blessed and the challenging job in the world. Giving a birth to new life and making it walk through the new world holding its hands showing a good trial makes a mother

victorious in her life.

Pregnancy is the period from conception to child birth. During this stage many emotional and physical changes occur in the women. In this modern era women's attitude against pregnancy and being a mother is changing. With the changing attitude of pregnant mother and life style there is increase in number of adverse pregnancy outcomes such as miscarriage, fetal death, still births etc.

Miscarriage is spontaneous loss of the fetus before 20 weeks of gestation. Endocrine disorders, immunological disorders, infection, maternal medical illness, uterine fibroids, alcohol consumption, smoking, drugs are some of the common causes of miscarriage.

The loss of fetus can lead to traumatic or stressful events which have a lifelong effect. It involves various series of physiological and psychological reactions such as depression, anxiety, frustration, sleep disorders, grief, excess fatigue, irritability, pain and lack of concentration.

The objective of this study was to see the quality of life of women with adverse pregnancy outcome in rural population using SF-36 questionnaire.

This study was conducted in KIMS, where subjects were selected as per the criteria and underwent a study where they had to answer the questions of SF-36 questionnaire. Subjects were informed about the study and prior consent was taken.

The results of this study showed that there was significant decline in the quality of life of the women with adverse pregnancy outcome.

Women's with age group18-25 has 52% of quality of life and age group 26-35 showed48%of quality of life.

Conclusion

The present study provided evidence to support the decline in quality of life of women with adverse pregnancy outcome.

Funding

Funding was provided by Krishna institute of medical sciences deem to be university.

Conflict of Interest: There was no conflict of interest.

Ethical Clearence: Ethical clearance was obtained from the protocol committee and institutional ethical committee of Krishna institute of medical sciences deemed to be university.

Abstract

Introduction: Migration is a process of social change due to which a person moves from one cultural setting to another to settle for a longer period or permanently. The collapse of rural livelihood forces the workers to migrate. As migrants do several types of jobs, there are high chances of morbidities. **Methods:** A cross-sectional study was done on 392 people selected using simple random sampling in Lingapayyakadu using pre-tested and semi-structured questionnaire. SPSS software was used for data analysis. **Results:** 68.7% were males and rest females. 80.9% had some form of acute morbidity in previous 3 months whereas 16% were suffering from chronic morbidities. Age ($p = 0.046$), working hours per day ($p = 0.017$) and occupation ($p = 0.047$) had significant association with acute morbidity while age, ($p < 0.01$) sex ($p = 0.046$) and education level ($p < 0.01$) had significant association with chronic morbidity. **Conclusion:** Major acute morbidity was musculo-skeletal disorders and age, working hours and occupation had significant association while hypertension was the major chronic morbidity with age, sex and education level having significant association with chronic morbidity.

Key words: *Migration, Musculo-skeletal disorders, Acute morbidity, Chronic morbidity, Risk factors*

Introduction

The word 'Migration' is derived from the Latin word 'Migrate', which means to change one's residence[1]. Migration is a process of social change due to which a person moves from one cultural setting to another to settle for a longer period or permanently[2]. The collapse of rural livelihood in many parts of India forces the workers to migrate from their native places in search of employment. The urbanization level has increased from 27.81% in 2001 to 31.16% in 2011 in India as per census with main reasons being population explosion and poverty induced rural to urban migration[3]. In India, according to 2011 census there is an average of 14 million internal migration every year[4]. Migrants often live in a social context where new social, political and language realities result in great demands on their coping skills and adaptability[5,6]. The relationship between disease, travel and migration have historical roots that continue to influence modern medical activities[7]. Migration is a very stressful process with various factors like job insecurity, poverty, social and geographical isolation, time pressures, poor living conditions, separation from family, lack of recreational activities etc. Knowledge about the health status of migrants is often limited due to lack of data. This is because migrants are often excluded from surveys. As migrants do several types of jobs, there are high chances that they are exposed to different types of physical, chemical and biological agents making them vulnerable to health problems. Migrants from disease-endemic area often settle in urban slums in unprotected houses which is highly vector receptive thus introducing

Corresponding Author:
Dr G. Shiny Chrism Queen Nesan,
Assistant Professor, Saveetha Medical College and Hospital, Chennai, Tamil Nadu, India
Email: shinynesan75@gmail.com

new and drug resistant strains[8]. Unique health problems of migrant workers are i) Spread of communicable diseases ii) Reproductive and Child Health iii) Child labour iv) Adaptation, adjustment and psychological disorders v) Occupational diseases etc[9]. Migration phenomenon will continue to increase anyways in coming years. Addressing their issues mainly relating to health is a matter that affects both the nation and the migrants. While available studies have primarily focused on TB and AIDS, or reproductive health of female migrants, limited research is done on over-all morbidity pattern. In this quest a cross-sectional study was planned to study the baseline socio-demographics, morbidity pattern and its associated factors.

Objectives

1. To assess the morbidity pattern of the migrant workers.

2. To determine the associated factors for the morbidity pattern.

Method

A cross-sectional study was conducted in Lingapayyakadu, that comes under the coverage area of Community Health Centre, Mulki, which was a health provision area of the Department of Community Medicine, K. S. Hegde Medical Academy, Mangalore from May 2017 to May 2018. Sample size was calculated based on previous study where the prevalence was 43% using $4pq/d^2$ formula which comes to 392[10]. Migrants working for more than 3 months and those who were above 18 years were included and among them those who were not willing to participate were excluded. The house list (sampling frame) of migrant workers was taken from the Mulki Town Panchayath. The households of the migrant workers were selected using lottery method of simple random sampling and all the migrant workers in the house who satisfied eligibility criteria and were present physically during the visit were considered. Pre-tested and semi-structured questionnaire containing socio-demographic factors, acute morbidity pattern in last 3 months and chronic morbidity pattern was used to collect the data by interview method. Morbidity pattern was assessed based on self-reported symptoms and hospital/laboratory records if available with the study participants during data collection. Informed consent was taken from participants and Institutional Ethics Committee clearance was taken from the institution. Data was entered into excel sheet and analysed using SPSS software version 16. Proportions and percentages were used for descriptive statistics. Chi-square test was used for inferential statistics. P-value less than 0.05 was considered significant.

Results

Socio-demographic factors:

Table 1 shows the socio-demographic factors depicting the distribution of study participants based on age, sex, education, occupation and working hours per day.

Acute morbidity:

Major acute morbidity among study participants (393) was musculoskeletal disorders (41.5%). Other acute morbidities include skin related problems (29.5%) , Gastrointestinal problems (19.3%), Respiratory problems (12.2%) and Fever of any origin (10.2%).

Over all 318 (80.9%) had some form of acute morbidity at least once in the past 3 months. **(Figure 1)**

Chronic morbidity:

37(9.4%) of the 393 study participants had Hypertension, 27(6.9%) were suffering from Diabetes Mellitus and 7(1.8%) were suffering from chronic heart disease other than hypertension. There was no reporting of any other chronic diseases like thyroid disorder, cancer etc. Overall, 63(16%) participants have some form of chronic morbidity. **(Figure 2)**

Associated factors:

Acute morbidity had significant association with age($p=0.046$), working hours per day ($p=0.017$) and occupation ($p=0.047$). It did not have any significant association with gender though acute morbidity was high among females **(Table 2).**

Table 3 depicts that chronic morbidity had significant association with age ($p<0.01$), gender ($p=0.046$) and education (<0.01). Chronic morbidity did not have any significant association with working hours per day, but it was high among participants whose working hours per day was less than 8 hours and participants who did not have debt.

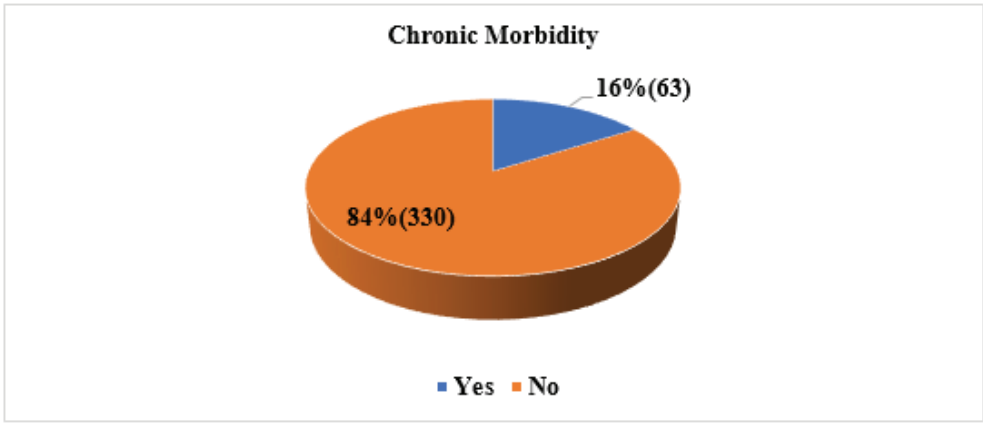

Figure 2: Proportion of chronic morbidity among study participants (N=393)

Discussion

According to this study among 393 migrants 68.7% were males indicating that the share of male migrants is more which is similar to a study done by Mitra A et al[13]. In the present study, majority of the study participants literacy status was primary (32.3%) and secondary (41%) which is similar to a study done by Trupti Bodhare et al[14]. In the present study, 11.7% of the study participants worked for less than 8 hours per day whereas majority of them (88.3%) worked for more than 8 hours per day with 41% working for 8-10 hours per day, 38.7% working for 10-12 hours per day and 8.6% working for more than 12 hours per day. This is similar to a study done by Guddi Tiwary et al[15]. In the present study, 56.2% were un-skilled workers, 42.5% were semi-skilled worker and only 1.3% were skilled worker. This is dissimilar to the studies done by Pratik K. Jasani et al[16] where 76% were un-skilled and 24% were skilled workers and Balakrishna B. Adsul et al[17] where 79.4% were un-skilled workers and 20.6% were skilled. This might be because of the difference in the categorization of the occupation of the study participants (Semi-skilled category was not used in both the above-mentioned studies). In the present study 41.5% had musculo-skeletal problems This is similar to studies done by Mohopatra R[18] where 40% of the migrant workers had musculo-skeletal problems and Dr K. G. Kiran et al[10] where 43.3% had musculo-skeletal problems. In this study 19.3% of the study participants had Gastro-intestinal problems. This finding is similar to a study done by Sandeep H et al[19] where 23.6% have gastro-intestinal problems. Skin conditions have contributed 29.5% which is similar to studies done by Pratik K Jasani et al[16] (25.6%) and Dr K. G. Kiran et al[10] (22.6%). 10.2% of the study participants in the present study had fever of any origin in the past 3 months. This is similar to a study done by Hiteshree C Patel et al[20] where 12.9% of the study participants had fever. Overall 80.9% of the study participants had some form of acute morbidity in the past 3 months. This is similar to studies done by Sithara R. S. et al[21] where 79.1% of the study participants had some form of acute morbidity in past 3 months and Surabhi KS et al[22] where 87% of the study participants had acute morbidity. The prevalence of hypertension among the study participants was 9.4%. In the studies done by Utsav Raj et al[23] and Balakrishna B. Adsul et al[17] the prevalence of hypertension was 4.4% and 3.4% respectively. The prevalence of hypertension was high in the present study. This could be because of a greater number of younger study participants in the former studies and there are various studies which show significant relationship between age and hypertension[24]. In the present study, 6.9% were diabetics and 1.8% had heart diseases (other than hypertension). In a study done by Safraj Shahul Hameed et al[25] 15.1% of male study participants were diabetics and 10.1% of female study participants were diabetics whereas 7.1% males and 4.4% females had cardiac conditions. In the present study acute morbidity was more among study participants aged more than 50 years (93.9). This could be because as the age progresses the capacity to work decreases. The study participants who worked for more than 10 hours per day had more acute morbidity as it involves lot of strenuous work and exposure to dust and harm physical and chemical agents. Unskilled workers were the majority population to have acute morbidity (82.8%) as they have to work in difficult conditions and for longer periods. Chronic morbidity was highest among study participants aged above 50 years (57.6%). There are well known studies which show that the chronic morbidities increase as age progresses. In the present study males (18.5%) had more chronic morbidity than compared to females (10.6%).

Conclusion

This study concludes that majority of the study participants had acute morbidity (80.9%). Musculo-skeletal problem was the most common compliant followed by dermatological problems, gastrointestinal problems and respiratory problems. Small proportion of participants had chronic morbidity like hypertension (9.4%), diabetes mellitus (6.9%) and cardiovascular problems except hypertension (1.8%).

Prevalence of Heel Pain in Farmers

Gayatri Sunil Landge[1], Pragati Salunkhe[2]

[1]Final Year Student, Faculty of Physiotherapy, KIMS Deemed To Be University Karad, Maharashtra, India,
[2]Assistant Professor of Department of Neuroscience , Krishna College of Physiotherapy, Karad, Maharashtra, India

Abstract

Objectives: The objective of this study was to find out prevalence of heel pain in farmers.

Method: Study was conducted with 100 subjects in and around Karad. Subjects were selected as per inclusion and exclusion criteria and consent was taken. Both males(56) and females(44) subjects were included for study. Then they were assessed with help of foot pain questionnaire, study was done according to results obtained the conclusion was given.

Result: After analyzing the data, it was found that there is a prevalence of heel pain in farmers. 24% of subjects are having heel pain & 76% of subjects do not have heel pain. It is found that prevalence of heel pain is more in females than males and pain distribution is more in age group of 41 to 51.

Conclusion: The prevalence of heel pain is more in females and precautions should be taken by farmers by modifying their work strategies to avoid further damage.

Keywords: *Heel pain, Farmers, Musculoskeletal Condition.*

Introduction

Foot and ankle health is important because pain in this region can make it difficult to accomplish day to day jobs. Heel pain is also can impair the quality of daily activities, state of mind and performance of an individual. Most common causes of heel pain are:

1. Plantar fasciitis
2. Retrocalcaneal bursitis
3. Achilles tendinopathy and some other conditions also can cause heel pain.[1,2]

• **Plantar fasciitis-**It is a major cause of heel pain. It is mainly seen in occupations which are included prolong standing or walking. It can worsen when repeated stresses are given to them leading to worsening of heel pain. It is a result of inflammation of plantar aponeurosis at the point of it's attachment to calcaneal tuberosity. In this condition early morning pain is common.[1,9] Tightness and pain is experience in early morning and pain improves after walking and doing some activities. Self stretching can improve the pain but worsening can cause calcaneal spur.

• **Retrocalcaneal bursitis-**Retrocalcaneal bursa is situated behind the Achilles tendon where it is attaches to heel bone. When this bursa is inflamed then it is called as retrocalcaneal bursitis. It causes swelling around the back of heel area, pain and stiffness, loss of movements, redness and warmth of back of heel. It is also caused by overuse of heel and ankle area.[3,8]

• **Achilles tendinopathy**-It is a condition which can occur because of greater amount of strain produce on Achilles tendon and it can be due to old or poor quality footwear. And it also can occur because of walking on uneven surfaces. This condition also produces morning stiffness, tenderness of Achilles tendon to touch or gently squeezed. Audible clicking when ankle is moved

is also seen sometimes. [10]

All these conditions can occur due to occupation related to foot overuse such as agricultural industry prolong standing.

Major population in India work for agricultural industry but this is most hazardous industry as it requires various processes that can lead to injuries. In agricultural industry there are more chances of foot and ankle injuries because of nature of their work.[4,5,6] As farmers have to work on uneven lands and slippery areas, sometimes on larger fields and hard surfaces.[12] It is suggested in studies that frequent deep dorsiflexion movements can cause retrocalcaneal bursitis and farmers are doing frequent foot dorsiflexion in altered way, because of that they can suffer from such conditions.[1,7] And because of barefoot walking, standing for long time, walking on uneven surfaces they are also more likely to suffer from heel pain.[10,11]

Method

This study is cross sectional study undertaken to find out prevalence of heel pain in farmers and to create awareness about it in them. Farmers with age group of 30 to 60, both males and females were included. Farmers already undergone from foot and ankle related injuries and those who are unwilling to participate are excluded. Written consent of the patient was taken. The study is ethically approved. The Foot Pain Questionnaire is used as study tool.

The sample size was calculated by foot/leg pain taken at 50%(as a study has shown as prevalence of leg/foot pain in rice farmers is 48.7% therefore 50% was taken into consideration for heel pain. Hence for calculation of sample size p=50% and q=100-p=50% sample size $n=4pq/L^2$ therefore n=100.The simple random sampling is used to select the subjects for study and it is conducted in and around Karad Taluka.

Result

The study was conducted among 100 participants in Karad of Satara District in Maharashtra. 44 females and 56 males participated among which 30 farmers belong to age group of 30 to 40 years, 50 farmers to 41 to 50 years and 20 farmers are of 51 to 60 years.

According to this study it was found that 34(68%) subjects have pain since last 2 years, 9(18%) have pain since 2-4 years, 4(8%) have pain since 4-6 years and 3(6%) have pain since 6-8 years. Side of the pain was also asked and it was found that 12(24%) subjects have pain in only right side, 15(30%) subjects have pain in only left side and 23(46%) subjects having pain in both the sides. Level of pain is measured by giving the subjects a 10 point numerical scale in which 0 is no pain and 10 is absolutely intolerable pain. 34(68%) subjects rated their pain in between 3-6 that is moderate pain and 16(32%) subject have pain above 6 that is severe pain. Standing is affected in 40(80%) subjects and both sitting and standing positions were affected in 10(20%).

3(6%) subjects have improvement from their pain but 25(50%) subjects worsened their pain and pain remained same in 22(44%) subjects. Standing and walking are the most affected activities in which standing was affected in 26(52%) subjects and walking is affected in 24(48%) subjects. Different remedies were used by the subjects to reduce the pain such as 35(53%) subjects used rest as a treatment, 3(4%) subjects bought new shoes, 15(23%) subjects applied ice, 8(12%) took injections and 5(8%) took anti-inflammatory medications. 24(24%) subjects show positive results for heel pain and 76(76%) does not have pain.

Farmers also face some major issues which are the main cause of difficulty in daily work and those are represented in following graph with further details.

Issues of farmers and their distribution

Graph 1: According to the graph above 50(60%) subjects have pain as a main problem for approaching the doctor and in those subjects 26(52%) subjects had pain in hindfoot, 10(20%) had pain in midfoot and 14(28%) subjects had pain in ankle. 12(14%) have uncomfortable shoe wear as a main issue , 2(2%) have instability, 17(20%) have sprain and 3(4%) have recent injuries.

Based on this study it was found that heel pain in farmers is statistically significant ($p< 0.0001$).

Discussion

The aim of this study was to find out the prevalence of heel pain in farmers. The farmers with age group of 30-60 years, both males and females and participants those are willing to participate are included. The patients with red and yellow flags, Farmers already undergone from foot and ankle related surgeries were excluded.

Study was conducted with 100 subjects in and

around Karad. Subjects were selected as per inclusion and exclusion criteria and written consent was taken. Both males(56) and females(44) subjects were included for study. Subjects were explained about procedure of study and written consent was taken from them and they were also asked if they suffered any musculoskeletal problems. Then they were assessed with help of foot pain questionnaire, survey was done according to results obtained the conclusion was given.

Farming Industry require a lot of work which is done bare foot in our country. This is the major cause of ankle and foot related injuries. Farmers are prone to develop these conditions as they have to work on uneven fields, slippery surfaces and hard grass.

Work in farms put a lot of stress to ankle and foot structures and it leads to injuries like ankle sprains, instability, heel pain and sometimes deformity. Many studies are conducted for overall musculoskeletal injuries in farmers and studies related to instabilities and malalignments. But very few studies are conducted only in heel related problems.

In previous studies are carried out to see prevalence of and characteristics of musculoskeletal pain in Korean farmers by **David Min,** the purpose of this study was to investigate the prevalence and characteristics of musculoskeletal pain in results it shows that 43.3% farmers has leg or foot related condition.

So in farmers there may be significant heel pain, that's why it is necessary to find prevalence of heel pain in farmers. This study is even help to create awareness amongst farmers about heel pain and its risk factors which can affect their work and benefit for betterment of their lifestyle.

In this study we came to know that females are primarily affected by foot conditions. Heel pain was also found statistically significant in present study. It was shown that 24% subjects are having heel pain and they are in the age group of 41-51 years.

Conclusion

After analysing the data, it was found that there is a prevalence of heel pain in farmers. 24% of subjects are having heel pain and 76% of subjects do not have heel pain. 46 % of males and 54% of females have heel pain. 29% pain distribution in 30 to 40 yrs population, 54% pain distribution in 41 to 50 yrs population,17% pain distribution in 51 to 60 yrs population is seen.

Conflict of Interest: There were no conflicts of interest in this study.

Ethical Clearance: Ethical clearance was taken from institutional committee of Krishna Institute of Medical Sciences, Deemed to be University, Karad.

Psychosocial Health Status of Adolescent Girls in a Rural Area of Guntur District

Geethika Koneru[1], Samson Sanjeeva Rao Nallapu[2], Swapna B[3], T.S.R.Sai[4]

[1]PG, [2]Professor, [3]Professor, [4]Professor & HOD, Dept. of Community Medicine, NRI Medical College, Guntur District, Andhra Pradesh

Abstract

Background: Adolescence is a distinct phase of complex developmental and psychological needs. UNICEF states that suicide is the second leading cause of death in this age group of young girls. A myriad of social, economic and health factors undermine the ability of the adolescents to lead full and productive lives. There is a need to study these factors as they are bound to health-related outcomes.

Objective: To assess the psycho-social health of adolescent girls (15-19 years) living in a rural area using WHO HEEADSSS questionnaire and to compare their psychosocial risk profiles and demographic profiles to identify important risk factors.

Methodology: This cross-sectional study was conducted from April to August 2017 on a convenient sample of 180 adolescent girls of 15-19 years residing in the rural field practice area of NRI Medical College, Guntur. The WHO's HEEADSSS (Home and Environment, Education and Employment, Activities, Drugs, Sexuality, Suicide & Depression and Safety) questionnaire was used to assess the psychosocial risk profile of the subjects. The findings were subjected to multiple regression and chi-square test at 5% level of significance.

Results and Discussion: Only 6.11% of the girls had scores within the normal range. 10% were at severe risk and 1.11% were in the very severe risk category. The following factors accounted for 75% of the psycho-social risk: Age, Marital Status, Occupation, Positive History of Smoking or Alcohol intake in Family, Having Sleep Problems, Thoughts of inflicting self-hurt and Thoughts of inflicting physical hurt on others.

Conclusion: HEEADSSS questionnaire is a useful tool to assess the psycho-social health of adolescent girls. Most girls didn't have adequate knowledge regarding family panning methods or STDs. Qualitative methods would give further insight into these issues.

Keywords: *Adolescent girls, HEEADSSS, psychological, social, health, rural*

Introduction

Adolescence is a phase separate from both early childhood and adulthood. It is a transitional period that requires special attention and protection. Children go through several transitions physically while they mature. The brain also undergoes considerable development in early adolescence affecting emotional skills as well as physical and mental abilities [1].

In India, adolescents constitute around 22% of the population[2]. Though adolescents are generally considered as adults, they are known to suffer significant morbidity due to their risk-taking behaviour and inadequate access to healthcare[3]. In India, a myriad of social, economic and health factors undermine the ability of the adolescents to lead full and productive lives [4].

Amongst the adolescent girls, the age group of 15-19 years is commonly involved in teenage pregnancies. 11% of all births worldwide are to girls aged 15-19 years[5]. However, these girls are not physically or psychologically ready to bear the burden of motherhood.

The HEEADSSS Assessment is a systematic process for assessing a young person's psychosocial status and identifying underlying health concerns and risk factors. One can obtain a profile of the young person's psychosocial health, the overall level of risk of the young person, specific risk factors in their lives – as well as protective factors and areas for possible intervention[6].

Objectives

To assess the psycho-social health of adolescent girls (15-19 years) living in a rural area using WHO HEEADSSS questionnaire and to compare their psychosocial risk profiles and demographic profiles to identify important risk factors.

Methodology

This cross-sectional study was conducted from April to August 2017 and involved a convenient sample of 180 adolescent girls of 15-19 years residing in the villages Venigandla and Pedaparimi, which fall under the rural field practice area of NRI Medical College, Guntur. All the adolescent girls available in the villages during the study period were included. The World Health Organization's HEEADSSS (Home and Environment, Education and Employment, Activities, Drugs, Sexuality, Suicide and Depression and Safety) psycho-social interview / questionnaire was used to assess the psychosocial risk profile of the subjects. The questionnaire also included demographic questions pertaining to age, marital status, socioeconomic status, religion and caste. The findings were subjected to statistical tests such as multiple regression and chi-square test at 5% level of significance. Microsoft Excel and R software, with EZR package were used to carry out the statistical analysis.

Results

Out of the 180 girls included in the study, 27.8%, 13.9%, 13.9%, 15.6% and 28.9% were 15, 16, 17, 18 and 19 years respectively. The majority were Hindus 31.6% were Christians and 11.6% Muslims. 15% of the girls were married. Analysis using Kuppuswamy Socioeconomic Scale revealed that 2.22% belonged to Class I, 28.33% to Class II, 22.22% to Class III, 43.33% to Class IV and 3.89% to Class V. 31.11% belonged to Backward Castes, 28.88% to Scheduled Castes, 17.77% to Scheduled Tribes and 22.22% to Other Castes.

Table 1 shows the distribution of the average HEEADSSS scores obtained in the study in each of the components. The categorization of the study subjects according to the risk of developing future mental health issues has been enumerated in Table 2.

Home: 98.9% had satisfactory relationships with all the members of their homes and 83.9% felt they were closest to their parents. 31.11% had to live away from home for more than six months. None of the girls had ever run away from home. 7.22% said there were subjected to physical violence at home. 3.33% girls did not feel safe in their home.

Education & Employment: 24.45% girls had dropped out of school due to their own reason or due to pressure from family. 6.43% had to repeat a class. 44.29% had changed schools recently. 85.7% were attending a co-education school. 6.43% of the girls currently attending school had considered dropping out. 5.04% did not have future educational or employment goals. 5.56% were working 4-6 hours per day.

Eating: 68.9% girls said they ate meals in front of TV or computer. 22.8% reported having had a decrease in their weight. 3.33% felt their eating was out of control. 17.8% had done dieting in the past year in order to reduce their weight. 86.11% of the girls did not do regular exercise. 32.2% girls said they would like it if they decreased 5 kgs.

Activities: 59.4% did not participate in sports. 81.7% did not have hobbies. 30.6% watched TV for more than 4 hours per day. 57.2% did not know how to use a computer and internet. 88.9% did not have any productive activity they did when they met with their friends. 52.8% just gossiped with family members during leisure time.

Drugs & Alcohol: None of the girls had ever smoked or taken alcohol or drugs. 40% had a family member who smoked or drank alcohol or both.

Sexuality:17.78% had a romantic relationship or used to have one. 16.67% had been involved in sexual relations. 10.56% were aware of safe sexual practices. 11.67% had been pregnant or were currently pregnant.

7.14% were using a scientifically sound method of birth control. 29.63% admitted to not being satisfied with the birth control they were using. 73.89% had inadequate knowledge of sexually transmitted diseases (STDs).

A significant association was found between married and unmarried girls regarding romantic and sexual relations and satisfaction with birth control.

Suicide & Depression: 27.22% girls said they felt sad constantly. 27.78% said they felt bored most of the time and had comparatively increased risk scores. 18.33% admitted to having sleeping problems and having disturbed sleep patterns. 11.11% stated they had lost interest in things they used to enjoy before.

None of the girls admitted to trying to kill herself. 3.33% admitted to having wanted to hurt themselves in the past. 9.44% said they had wanted to hurt others in the past.

Safety: 4.44% girls had been injured in the past. 10.56% said there was violence at home. None of the girls admitted to having been subjected to repeated physical abuse or sexual abuse. Four girls said they had gotten into physical fights in the neighborhood. Two girls said they still got into physical fights in the neighborhood.

The factors found to have a significant association with the HEEADSSS scores obtained have been listed in Table 3, along with the Chi-Square values and p values obtained. Multiple Linear regression showed that the following seven factors accounted for 75% of the HEEADSSS psycho-social risk scores: Age, Marital Status, Occupation, Positive History of Smoking or Alcohol intake in Family, Having Sleep Problems, Thoughts of inflicting self-hurt and Thoughts of inflicting physical hurt on others.

Table 1 : Distribution of HEEADSSS score by components (n=180)

S.No.	Components of HEEADSSS	Maximum possible score*	Study group average score
1	Home	13	1.51
2	Education & Employment	14	4.14
3	Eating	8	2.7
4	Activities	8	4.58
5	Drugs	15	0.4
6	Sexuality	12	3.4
7	Suicide	16	2.09
8	Safety	14	0.62

**Contribution of each parameter to the HEEADSSS total score of 100*

Table 2 : Categorisation of the adolescent girls by HEEADSSS psychosocial score (n=180)	
Psycho-Social Risk Categories (Scores)	**No. of study subjects (%)**
Normal (0 -10)	11 (6.11)
Mild risk (10.1 - 20)	101(56.11)
Moderate risk (20.1 - 30)	48 (26.67)
Severe risk (30.1 - 40)	18 (10)
Very severe risk (>40)	2 (1.11)
Total	180

Table 3 : Significant factors affecting adolescent girls

S.No	Significant Risk Factors in adolescence	Average HEEADSSS Score	Chi Sq	p Value
1	Age - 18 & 19 years	21.92	21.72	< 0.0001
2	Religion - Christian	21.45	6.98	0.03
3	Caste - ST	27.11	40.65	< 0.0001
4	SES – Lower socio-economic class	25.04	16.07	0.007
5	Marital Status - Married	29.09	42.98	< 0.0001
6	Occupation – school drop out	27.45	65.78	< 0.0001
7	Not participating in Sports	21.89	27.21	< 0.0001
8	Not having Hobbies	20.54	9.98	0.02
9	Experienced Forced sex	33.75	4.68	0.03
10	Having sleep problems	25.02	15.48	< 0.0001
11	Have hurt themselves	36.55	9.52	0.002
12	Wanted to hurt others	31.45	23.49	< 0.0001
13	Get into physical fights	35.44	6.28	0.01
14	Family History of Alcohol	22.08	5.59	0.01

Discussion

The commonly found psychiatric disorders found in adolescents are anxiety and depressive disorders and behavioural issues[7,8]. However, reporting systems for adolescent psychiatric disorders are mostly inadequate[9]. Only 6.11% of the girls had scores within the normal range. 82.78% fell under the mild and moderate risk categories. 10% were at severe risk and 1.11% were in the very severe risk category. In a similar study, 40%, 43.6% and 11.75% girls were categorized as mild, moderate and severe risk respectively for psychological problems [10].

7.22% of the girls said that they were subjected to physical violence and 3.33% girls did not feel safe in their home. Home is meant to be a safe haven for every individual and this finding is of great concern.

Educating the girl child would play a major role in averting adolescent maternal deaths [11]. In this study, it has been found that the girls who had dropped out of school on their own due to family pressure had much higher risk scores. However, the drop out percentage was lower than what has been found in other similar studies; 30.64% [12] and 37.4% [13].

Higher risk scores were seen in girls attending a co-education school (85.71%), those who had considered dropping out (6.43%) and those who did not have future educational or employment goals (5.04%).

There wasn't much difference between the risk scores of the girls who worried about their weight and those who did not, probably due to influence of other components of the questionnaire. Most of them did not do regular exercise. It was seen that the girls in this study

had more body image issues than was found in a study conducted in urban slum in northern India [14].

The difference in risk scores between the girls having hobbies and playing sports and those who were not was found to be statistically significant. Higher risk scores were seen in girls who stated that they did domestic work during leisure time.

Only 10.56% of the girls were aware of safe sexual practices. Many did not feel the need to understand or practice safe sex. It has been found that 56% of abortions of adolescents were carried out by unqualified personnel at unapproved centres[15]. Adolescent girls contribute to 17% of the total fertility rate and are most of these births are unplanned. In this study, only 7.14% were using a scientifically sound method of birth control. Unable to discuss birth control with their partners was an important cause for not using birth control, as has been suggested in other studies[16]. Three girls had been forced to have sexual relations and they had very high risk scores. The sexual abuse was by their husbands or family members as has been found in other studies [17]. When probed further, it was clear that these encounters had a major effect on the girls' trust in adults.

The girls had poor knowledge of STDs. 26.11% of the girls were aware of HIV/AIDS which is lower than findings in similar studies [17,15,18,19]. Urban adolescents have better knowledge regarding HIV/AIDS compared to their rural counterparts[18]. A similar picture was seen in a study conducted in rural adolescent girls in Bangladesh[20]. There is a need to correct this as 2.2 million adolescents are living with HIV world-wide and 60% of them are girls [21].

Girls who had higher risk scores said they felt sad constantly, felt bored most of the time, had sleeping problems, and had lost interest in things they used to enjoy before. In India, suicide among adolescents is higher than other age groups[9]. Pre-marital sex, sexual abuse and physical abuse have been found to be important pre-determinants for suicidal behaviour in a study done in Goa[10].

10.56% of the girls said there was physical violence at home. The victim was usually the mother. None of the girls admitted to having been subjected to repeated physical abuse.

Girls in rural India shoulder a disproportionate burden of domestic work and childcare. They are denied equal participation in decision-making. There is a need to transform societal structures that tolerate discrimination against girls in homes and other places [22].

Conclusion

HEEADSSS questionnaire is a useful tool to assess the psycho-social health of adolescent girls. It was found that age, marital status, occupation, positive history of smoking or alcohol intake in family, having sleep problems, thoughts of inflicting self-hurt, thoughts of inflicting physical hurt on others were the factors that contributed to 75% of the psycho-social risk scores. Thus, an adolescent girl having these findings should be given special attention and counselled. Most girls didn't have adequate knowledge regarding family panning methods or STDs. Qualitative methods would give further insight into these issues.

Case Report on Medial Swivel Dislocation of Ankle

Gireesh Khodnapur[1], Dayanand B. B[2], Abhishek Shenoy[3], Siddhant Gandhi[4]

[1]Senior Resident, [2]Professor, [3]Junior Resident, [4]Junior Resident, Department of Orthopedics, Shri B M Patil Medical College Hospital and Research Centre, BLDE (Deemed to be University), Vijayapura

Abstract

A rare type of Chopart dislocation called swivel dislocation has been reported. This injury presents as dislocation of the talonavicular joint, but the calcaneocuboid joint remains unaffected. There is a typical rotational movement without inversion or eversion in the foot. The axis of rotation is the interosseous talocalcaneal ligament, which remains unaffected. We report the case of an 18-year-old male who had experienced a medial swivel dislocation of the talonavicular joint associated with displaced fracture of the base of fifth metatarsal. The occurrence, features, and method of treatment of this rare injury are presented.

Key Words : *Swivel Dislocation, Talonavicular Joint Dislocation, 5Th Metatarsal Base Fracture,Tarsal Dislocation*

Introduction

Midtarsal dislocations of the foot are unusual injuries, talonavicular dislocations occurring without an associated fracture of this joint or of the calcaneocuboid joint are very unusual.

Main and Jowett [(1)] found that injuries normally occur to the talonavicular and calcaneocuboid joints together. However, they also identified a "swivel dislocation" (12% of their series) in which the talonavicular joint dislocates, usually medially, and the calcaneus swivels under the talus, with the calcaneocuboid joint intact. The axis is the interosseous talocalcaneal ligament [(1)]. We report a case of medial swivel dislocation of talonavicular joint caused by a laterally directed force applied to the forefoot after the fracture fifth metatarsal

Isolated dislocation of talonavicular joint without associated subtalar joint dislocation or fracture of tarsal bones is rare. These injuries are caused by severe abduction or adduction force applied to the forefoot. A case of medial swivel dislocation treated by open reduction k-wire fixation is reported here.

Case Report

An 18-year-old male had injured his right foot during a motorcycle accident. He accepted emergency service and complained of pain along the medial aspect of talonavicular joint and on fifth metatarsal. Physical examination revealed an obvious deformity with medial displacement of the foot on the head of talus with severe edema and hematoma with the fifth metatarsal. A neurovascular deficit was not found.

FIG 1

FIG 2

FIG. 1 AND FIG. 2: PRE OP PICTURE AND RADIOGRAPH

FIG 3

FIG. 3: 3D RECONSTRUCTION OF ANKLE

Under spinal anesthesia, closed reduction was attempted, but it failed. Hence, open reduction was done. Under tourniquet control, a 6 cm anteromedial longitudinal incision was made centering the talonavicular joint. Extensor hallucis longus tendon and dorsalis pedis artery were retracted medially, and extensor digitorum long-us tendons were retracted laterally, exposing the dislocated talonavicular joint. The impacted fracture in talus was visualized, which

was less than 1 cm size, in all dimensions.

The talonavicular joint dislocation was reduced by traction and lateral rotation of the forefoot. The talonavicular joint was stabilized with 2-mm k-wires introduced from the dorsum of the foot transfixing the talonavicular joint. The wound was closed in layers. The foot was immobilized using below knee cast for 6 weeks. After 6 weeks, k-wires were removed, and weight-bearinFIG. 5 FIG.6

FIG. 5 AND 6 : SHOW PATIENT AT 6 MONTHS FOLLOW UP AND X-RAY AT 6 MONTHS FOLLOW UP

Discussion

The midtarsal joint includes talonavicular and calcaneocuboid joints, which lie in a transverse plane across foot. Main and Jowett[1] classified midtarsal injuries according to direction of deforming force and displacement into five groups (medial, longitudinal compression, lateral, plantar, and crush).[1,2] Medial and lateral midtarsal injuries are further divided into fracture, sprain, fracture subluxation or dislocation, and swivel dislocation.[1]

In the swivel injuries, the deforming force applied to the forefoot disrupts talonavicular joint, rotating the foot, causing rotatory subluxation of subtalar joint on the axis of intact interosseous talocalcaneal ligament. In medial swivel injuries, the deforming force is directed medially and talonavicular joint dislocates medially rotating the foot medially, whereas the calcaneocuboid joint is intact. In lateral swivel injuries, the deforming force is directed laterally, dislocating talonavicular joint laterally and rotating foot laterally. It is usually associated with impacted fracture of calcaneocuboid joint (nut cracker fracture)[3]. Swivel injuries differ from subtalar joint dislocation in that the deforming force probably falls more anterior to that which produces subtalar and ankle injuries.[1,2]. The talocalcaneal interosseous ligament is

intact.

Pehlivan et al[4] reported a single case of isolated medial dislocation of the talonavicular joint. They treated the deformity using open reduction and percutaneous fixation. At the last follow-up visit, they found that the patient had a small residual functional defect; however, lateral column pain with long distance ambulation was the only significant complaint[4].

It is important to distinguish between medial subtalar dislocation and swivel dislocation of medial type. Medial subtalar dislocation is reduced by traction and eversion, whereas swivel dislocation is reduced by traction and lateral rotation of foot. Obstruction to closed reduction in subtalar dislocation can be caused by interposed tibialis posterior tendon or interlocked or impacted fracture of articular surfaces of talus/navicular bone, which is not found in swivel type of dislocation.

In general, most investigators have advocated the use of internal fixation stabilization of the acutely dislocated Chopart joint because of the potential for vascular compromise [5,6,7,8]. Williams et al [9] described closed reduction without the need for percutaneous fixation in a single case report of a medial swivel dislocation. In their case, the dislocation was reduced intraoperatively and, under stress radiograph evaluation, was determined to be stable. The patient was placed in a cast after the reduction [9]According to the published data, swivel type injuries are associated with fewer complications than pure dorsal dislocations because of the lower degree of ligamentous structure involvement. Thus, very few attempts should be made at closed reduction of the deformity

Conclusion

We recommend closed reduction of medial swivel dislocation of the talonavicular joint first, with open reduction only after failure of an attempt at closed reduction. We suggest anatomic reduction for fracture of the fifth metatarsals if a medial swivel-type talonavicular dislocation is also present, such as in our case. The present case was reported because of its rarity, to report the features of treatment, and because of the excellent treatment outcome.

The Impact and Perspicacity of National Eligibility cum Entrance Test among Dental Undergraduates in India

Guruprasath Selvakumar[1], N. DivyaLalitha[2], Prabu.D[3], Sunayana Manipal[4], Rajmohan[4]

[1]Undergraduate, [2]Postgraduate, [3]Professor & Head, [4]Reader, [5]Senior Lecturer, Department of Public Health Dentistry, SRM Dental College, Ramapuram, Chennai

Abstract

Background: National eligibility cum entrance test (NEET) was first proposed in the Vision 2015 by Board of Governors (BOGs) in India. This exam was supposed to be a single window for admissions into medical colleges and dental colleges. NEET-UG (Undergraduate) was put into action in order to reduce stress of multiple examinations which was conducted in different states within India. **Aim:** The aim of this study is to assess the impact of National eligibility cum entrance test (NEET) among the first and second year undergraduates studying in various dental colleges in Chennai, India, qualified through the NEET examination. **Materials and Method:** A cross sectional questionnaire study was conducted among 17 to 22 year old dental undergraduate students. 110 participants were recruited by simple random sampling. A pre tested self- administered questionnaire was distributed to all the participants and data were obtained about NEET. Data was collected during the period of September to October 2017.Descriptive statistics and SPSS version 23.0 was used to analyze the data. **Results:** Out of the total 110 participants, 55 (50%) were males and 55 (50%) were females. 71(64.5%) chose dentistry by choice. 75 (68.2%) studied state board syllabus. A significant p value (0.005) was obtained while assessing the association between difficulty of NEET and efficiency of syllabus. **Conclusion:** It is evident to a certain extent that the system has attained stability and the admission procedures have become easy and transparent for the students as well as for the institutions.

Keywords: *Dentistry, NEET, Syllabus, Career*

Introduction

The choice of dentistry or rather career is one of the most important decisions of one's life. The students have many career options and it is extremely difficult to choose the best one out of them which would satisfy their passion, income, increase their credibility and respect in the society. [1] Choosing a Professional career or a 'White collar Job' always kept motivating the students in choosing dental education.

"The Joy of providing beautiful smiles on earth is one of the important accomplishments of a dentist which cannot be measured". [2]

Corresponding Author:
Dr. Divya Lalitha. N
SRM Dental College, Ramapuram, Chennai-600089
Ph no: 8056215655, Email: diyan2409@gmail.com

The Motives for choosing dentistry is multifactorial which includes financial rewards, secured life, social status, credibility, nature of the occupation, interest and passion in research field, familial interest etc. [3]

So what is dentistry?

Dentistry is a rewarding profession where we get to help others and regularly change people's lives for the better. Dentists play an equal role concerning your health alike your family doctor by looking after your general oral health instead of specializing in a specific area.

NEET-UG (Undergraduate) was put into action in order to reduce stress of multiple examinations, to ensure minimum competence and more importantly with the purpose to weed out corruption in medical education across the country. NEET-UG was first proposed in the Vision 2015 by Board of Governors (BOGs) appointed

after by Government of India after dissolution of medical council of India (MCI). This exam was supposed to be a single window for entry into a medical college and dental colleges across India.[4]

NEET-UG replaced the All India Pre Medical Test (AIPMT) and all individual exams conducted by states or colleges themselves for admissions. However, many colleges and institutes took a stay order and conducted their own private examinations for admission to courses. Nevertheless, many other reputed institutes such as the Armed Forces Medical College and Banaras Hindu University have opted to admit students on the basis of the NEET-UG now. [4]

The least that is expected to happen through NEET is to identify the best possible candidates who have the right skills for science and an attitude for hardwork. There is also a need for uniform distribution of the limited seats, which are in such high demand year after year. These could possibly be the fundamental reasons to seek National Eligibility-cum-Entrance Test (NEET) across the country. [5]

Before National eligibility cum Entrance Test (NEET) came into action, the system was lacking transparency in admission procedures. [6] As NEET came into effect, the pathways were opened up to question the validity of other qualifying exams conducted by state governments and private institutions. On the other hand, the conflicts arise due to insufficient syllabus, difficulty in attempting the exam for students, favorable to particular board of education was also seen among the students. There is a mixed reaction toward NEET, whether it is the ideal gateway to get admission in colleges.

In the era of modern education which is mainly knowledge based to lead an economic life, a person has to clearly show the required skills to lead a healthy professional life. [7]

Inspite of various exams and boards of education owing to test the person, the need for a single portal has always been a void in education system of India. Dental schools, on the other hand requires a proper medium to decide, if the student is eligible or has the skill to get admitted in their respective dental schools. So, it is inevitable for the society to depend on Knowledge and skill based qualifying exam.

The aim of this study is to assess the impact of National eligibility cum entrance test (NEET) among the first and second year undergraduate students studying in various dental colleges in Chennai, Tamilnadu, qualified through the NEET examination conducted in the academic year of 2016-2017 and 2017-2018.

Materials and Method

The present cross-sectional questionnaire study was conducted among the NEET qualified candidates who had successfully affiliated themselves to undergraduate (Bachelor of Dental Surgery) degree.

The sample size was conscripted to 110 students based on simple random sampling among the students pursuing the undergraduate dental degree among various dental colleges in Chennai. The samples were recruited within the age interval of 17-21 years. The sample included 55 male and 55 female undergraduate dental students who gave concern to participate in the study. This study was conducted during the period of September to October 2017.

The inclusion criteria included all the candidates who are pursuing BDS after their admission in the academic year of 2016 and 2017 and who gave consent to participate in this study. Candidates who did not give concern to participate in the study, who did not fill the questionnaire were excluded from the study. This study was approved by the Institutional Review Board, Department of Public Health Dentistry, SRM Dental College, Chennai.

A self-administered pre-tested questionnaire containing 14 questions was given to all sample recruited for the study. The first 11 questions were close ended and final 3 questions were open ended. Sociodemographic details of the participants like name, age, gender, address were collected. Close ended questions were about asked about the state, need for NEET in vernacular language, state influence on NEET, Efficiency of the standard twelve syllabus, need for coaching centers, fees structure after NEET etc. Open ended questions were used to know the overall opinion of the student about NEET.

The questionnaire was administered to all the 110 participants in person and the data was collected. The questionnaire consisted of demographic details (Name, age, and gender), their opinion on NEET examination, the influence of syllabus and state which they studied, and their outlook of dentistry.

Descriptive statistics was done and the association was assessed using Pearson's Chi Square test. Statistics was done using SPSS version 23.0 and the p-value was set at 0.05.

Results

The study was done to assess the impact of National eligibility cum entrance test (NEET) among the first and second year students studying in various dental colleges in Chennai, Tamilnadu qualified through the NEET examination conducted in the academic year of 2016-2017 and 2017-2018.

Table 1: Distribution of participants based on choice of dentistry, need for coaching center and productivity of syllabus

		N	**PERCENTAGE (%)**
1. Choice of Dentistry	**Choice** **Chance**	**39** **71**	**35.5** **64.5**
2. Productivity of syllabus	Sufficient Insufficient Indifferent Others	43 49 14 4	39.1 44.5 12.7 3.6
3. Need for coaching centre	Needed Not needed Needed but expensive Expensive not needed	28 19 57 6	25.5 17.3 51.8 5.5

Table 1 shows distribution of participants based on Choice of dentistry, need for coaching center and productivity of syllabus and difficulty of NEET. Totally 55 females and 55 males participated in the study. 71(64.5%) answered that they chose dentistry by chance and 39(35.5%) answered that dentistry was their choice. 75 (68.2%) studied state board syllabus, followed by students who studied CBSE, 29(26.4%) and students who studied in ICSE and other medium of studies were equal in number. 49 (44.5%) of them reported that the syllabus is insufficient to attempt NEET whereas 43(39.1%) of them reported that the syllabus what they studied is sufficient enough to attempt NEET. 57 (51.8%) reported that a coaching center for NEET is needed but it is expensive and only 6(5.5%) participants feel that it is expensive and not needed. 47(42.7%) participants reported that the difficulty of NEET is medium whereas 42(38.2%) feel that it is hard.

TABLE 2: ASSOCIATION BETWEEN PRODUCTIVITY OF SYLLABUS AND NEED FOR COACHING CENTER

Need for coaching centre	Productivity of Syllabus				Total	P value
	Sufficient	Insufficient	Indifferent	Others		
Needed	15	11	1	1	28	0.08
Not needed	9	7	3	0	19	
Needed but expensive	17	30	7	3	57	
Expensive not needed	2	1	3	0	6	
Total	43	49	14	4	110	

Table 2 shows association between productivity of syllabus and need for coaching center. Majority of the participants , 30(27.3%) feel that the efficiency of the syllabus is insufficient to take up NEET and a coaching center is needed but it is expensive. 17 (15.5%) participants feel that the efficiency of the syllabus what they studied is sufficient but still a coaching center is needed but is expensive. On the other hand 15(13.6%) participants said that the efficiency of their syllabus is sufficient but a coaching center is needed for them to attempt NEET.

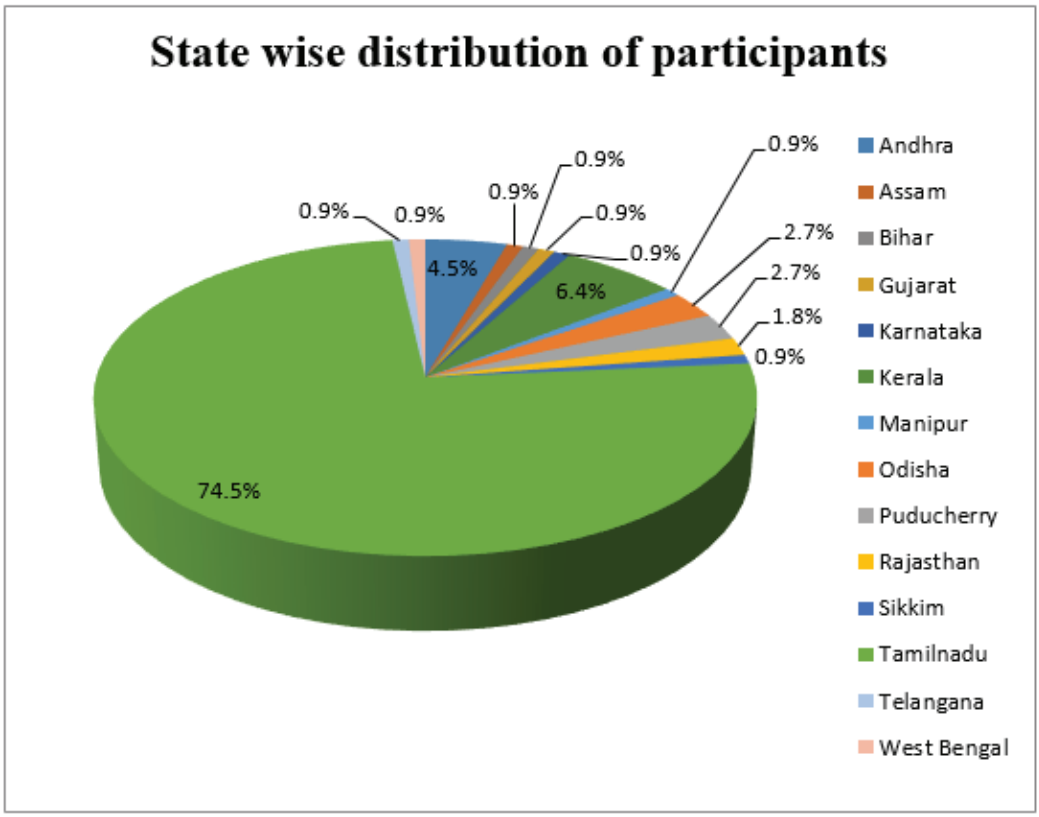

Figure 1: State Wise Distribution of Participants

Figure 1 shows state wise distribution of participants. Majority of them were from Tamil Nadu 82 (42.5%), followed by Kerala 7(6.4%), Andhra 5 (4.5%), Orissa and Pudhucherry 3 (2.7%), Rajasthan 2(1.8%) and then others states 1(0.9%).

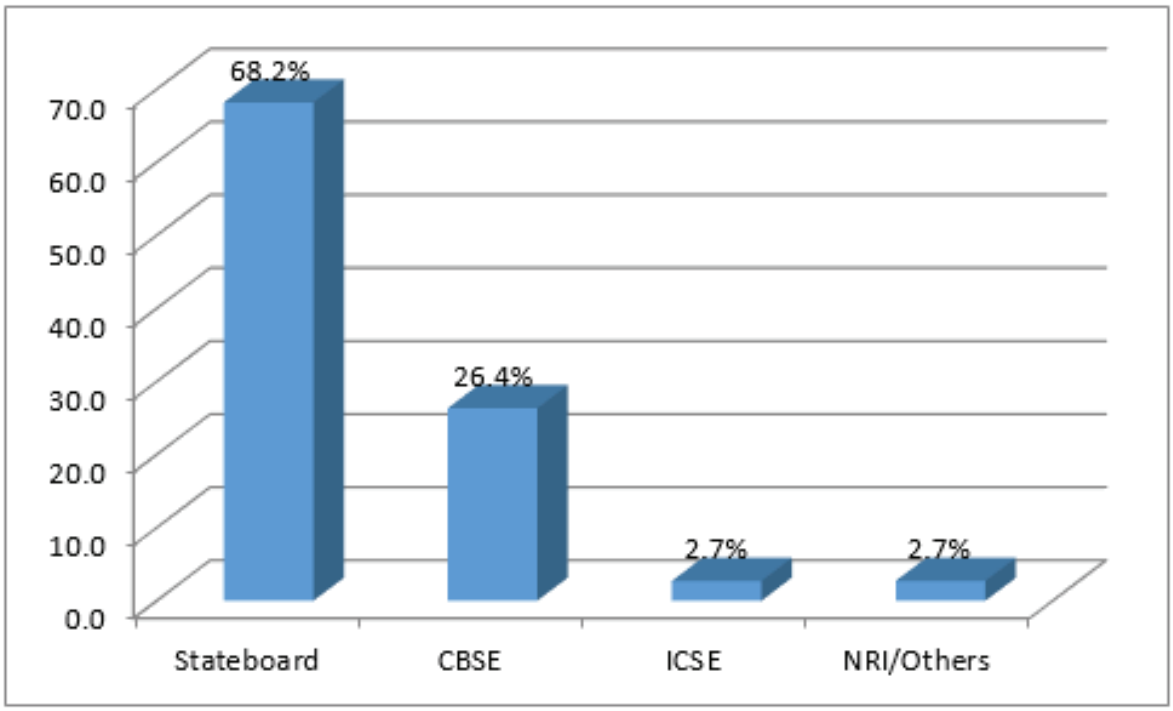

Figure 2: Distribution of Participants According to Syllabus of Study

Figure 2 shows distribution of participants according to their syllabus of study. 75 (68.2%) participants studied stateboard syllabus, 29 (26.4%) studied CBSE, 3 (2.7%) studied ICSE and 3 (2.7%) NRI/others.

Discussion

Although there are many fields in medical sciences, over the past few years, reasons behind students choosing dentistry as a profession have not been well documented by dentists or any others, especially in the developing countries. The motivational factors that influence students in entering dentistry, as well as the selection procedures, vary considerably between countries and even within a single country even between states. These situations pose great responsibility on dental colleges to select the appropriate applicants, both professionally and socially, for the ultimate benefit of the country. [8]

A study done by Kobale et al stated that, majority of students who choose dentistry as their carrier, because of someone encouraging them to do so in their family particularly in India. [9]

Before NEET (National Eligibility Cum Entrance Test) the admission to dental course lacked transparency. But now the system has attained some stability. Students who qualify in the NEET can only be admitted in the dental colleges.

The result of a study done by Rashmi et al found that 38.83% participants first choice was dentistry but in contradiction 64% participants in the present study chose dentistry by chance. [3]

According to a study done by Priya et al, the various reasons for the students dentistry were inability to get medical seat , 224 graduates (47%) followed by choice out of own interest, 175(37%) and family pressure , 76(16%). [1]

A study done among Iranian dental students, revealed that 93.2% students opted dentistry in their initial selection. Among these 82.5% chose it because they feel dentistry is a job which is an insurer of financial independence. [10] In a study done by Anbuselvan et al in Tamilnadu, majority of the students opted dentistry out of self interest. [7]

In one another study which was done among first year dental students, the reason for the students to select dentistry as their career was that it has regular working hours than other health related professions and they can make more money. [11] In a study done by Gallagher et al, 91% of the dental students said that they chose dentistry because of regular working hours. [12]

A significant results (p value=0.0005) was obtained in the present study in correlation of difficulty of NEET and the efficiency of the syllabus which the participant studied. Table 3 shows that, Majority of them (25 participants) feel that efficiency of the syllabus is insufficient so it was hard to attempt NEET. The quality of the syllabus must be improved to help the students. A universal syllabus system can be made so that all the students will get sufficient knowledge out of their own syllabus itself to attempt NEET.

When a question was put forward to the participants on their overall opinion about NEET, we got a mixed response. Few participants answered it is not useful whereas some answered it as it will be useful if all the students in India follow the same syllabus. Other few commented that it's a confusing fact.

Limitations of Study

Since the study was done in private dental colleges, all the participants were from private schools, none were from government schools. The level of difficulty of NEET would be different for a government school student than a private school student, which was not elicited in the study. Perception of postgraduates who came through NEET-PG was not assessed because it was beyond the scope of study. First and second year undergraduate students who took up the NEET exam in the year 2016 and 2017 only were included in the study because they are the students who will know the impact of NEET.

Recommendations

Students in India study different syllabus namely state board, CBSE, ICSE etc. but the syllabus of NEET is different. So there is a difficulty between different syllabus students to attempt NEET. Government school students find it more difficult because of lack of proper coaching. So the syllabus of NEET examination must be standardized to help each and every student be it government or private schools. Separate coaching for NEET can be encouraged in schools to improve the student's performance in NEET.

Conclusion

This was the first study which was conducted to analyze the pre and post NEET changes and opinion of the students among various dental colleges in Chennai. Although there was a mixed response about NEET in the present study, it is slightly evident that the system has attained stability and the admission procedures have become easy and transparent for the students as well as for the institutions. The coaching centers can provide good quality coaching for reasonable fees for the needy students in order to sort this issue. The syllabus can be standardized all over India so that all the students get the equal opportunity to prepare for NEET and to crack it.

Minimization of Heart Rate Bias in the Estimation of Heart Rate Variability

Jitendra Kumar Jain[1], Ranjan Maheshwari[2]

[1]Government Engineering College Bikaner, Karni Industrial Area, Pugal Road, Bikaner, Rajasthan, India,
[2]Rajasthan Technical University, Kota, Rawatbhata Road, Kota, Rajasthan, India

Abstract

Background: Heart Rate (HR) is a time varying signal indicating the beating activity of the heart, whereas Heart Rate Variability (HRV) is a noninvasive tool to evaluate the cardiac autonomic regulations. The HRV is widely used to evaluate cardiac/autonomic health in normal healthy as well as chronic diseased population. The HR and HRV are significantly connected with each other. HRV is dependent on the average HR as well on the Autonomic Nervous System (ANS) activity. To make the HRV a potential marker of ANS activity, the influence of HR must be reduced. The present study is designed to minimize the effect of HR on HRV by normalization of the RR interval tachogram.

Method: Forty six young adults participated in the non-invasive and benign study. 10 minutes of Electrocardiogram (ECG) lead II was recorded in each case in supine position. The electrocardiographic records of the subjects were divided into three groups based on their HR viz., slow, moderate and fast HR. The HRV indices were extracted at pre and post HR bias minimization.

Results: The improved HRV was observed with HR bias minimization in all three categories of HR. The reduced HRV was found with increasing heart rate even after HR bias minimization.

Conclusion: Significant impact of normalization was found on moderate and fast HR subjects. This suggests that the HRV studies would yield better results with HR bias reduced, thereby improving health monitoring systems based on HRV.

Keywords: *Heart rate; Heart rate variability; Normalization; HR bias.*

Introduction

Heart rate (HR) is a time varying signal and its variations may contain indications of various cardiac and non cardiac conditions[1]. The instantaneous HR can be calculated from the time between any two QRS complexes of the Electrocardiogram[2]. The Greek physicians were the first to measure the pulse rate and its variation with respiration was first observed by R. Stephen Hales[3]. Dyer et al. reported that high heart rate may be an independent risk factor from sudden death due to both cardiovascular and non-cardiovascular diseases[4]. The excess cardiovascular deaths with more rapid heart rates were also observed in a Framingham study of 5209 men and women for 30 years[5].

The HR is regulated by the natural pacemaker in the heart[6]. The HR is not constant but depends upon sinus node cycle length (CL) which is further under the control of autonomic nervous system (ANS)[7]. The CL variations result into beat to beat fluctuations in the HR which provides a noninvasive measure of cardiovascular control system; the sympathetic and parasympathetic systems[8]. Thus heart rate variability (HRV) is defined as the fluctuations of the RR intervals under the influence of ANS where short term variability mediated by parasympathetic system and long term variability by both sympathetic and parasympathetic pathways[9]. With the application of digital signal processing techniques, the HR and HRV and their relationship with health and diseases was explored[10-12]. The HRV has become a powerful and popular tool for the assessment of cardiovascular autonomic regulation. So far, more than 17000 PubMed listed HRV related articles have been published[13].

The HR and HRV both are strongly correlated. Their inverse correlation was reported by Ungi et al.[14]. The relationship between HR and HRV was further explored in various studies[15-16]. They demonstrated that the association between HR and HRV can be determined both physiologically and mathematically. The physiological association is manifested in ANS activity whereas mathematical association is observed by inverse relationship between HR and RR interval.

Monfredi et al. presented the increased HRV for slow HR (large RR interval) and decreased HRV for fast HR (small RR interval) and therefore concluded that HRV of two different average HR subjects cannot be compared[13]. In support to this, Kazmi et al. investigated the relationship between HR and linear/nonlinear HRV indices and concluded that HRV is dependent on HR and thus, HR should be considered while HRV analysis is performed in evaluation of cardiac ANS activity[17].

To overcome the influence of HR bias in HRV, Sacha et al. investigated the HRV relationship with HR by normalization of the RR interval with respect to the average value[18]. Their study revealed significant differences in the correlation between HR and HRV with normalization of the HR. Thus reducing the HR bias in HRV could metamorphose HRV in a significant manner for ANS activity. However the HR characterization in reducing HR bias is still to be explored. So, the present study was designed to investigate the effect of slow, moderate and fast HR bias minimization in HRV.

Materials and Methods

Study population

A number of college students were invited to take part in the study. Details of the study, procedure and objectives were given to the subjects prior to the data acquisition and written consent was obtained. Volunteers were examined for the following inclusion criteria:

1. Systolic blood pressure <140 mmHg and diastolic blood pressure <90 mmHg.

2. No history/treatment of any cardiovascular disease, diabetes or any other abnormality that would interfere with cardiac autonomic function.

Based on these inclusion criteria, forty six young individuals with age ranging from 18 to 39 years were chosen who met the criteria to participate in this study. The distribution of the population is shown in Table 1.

Table 1 Distribution of population

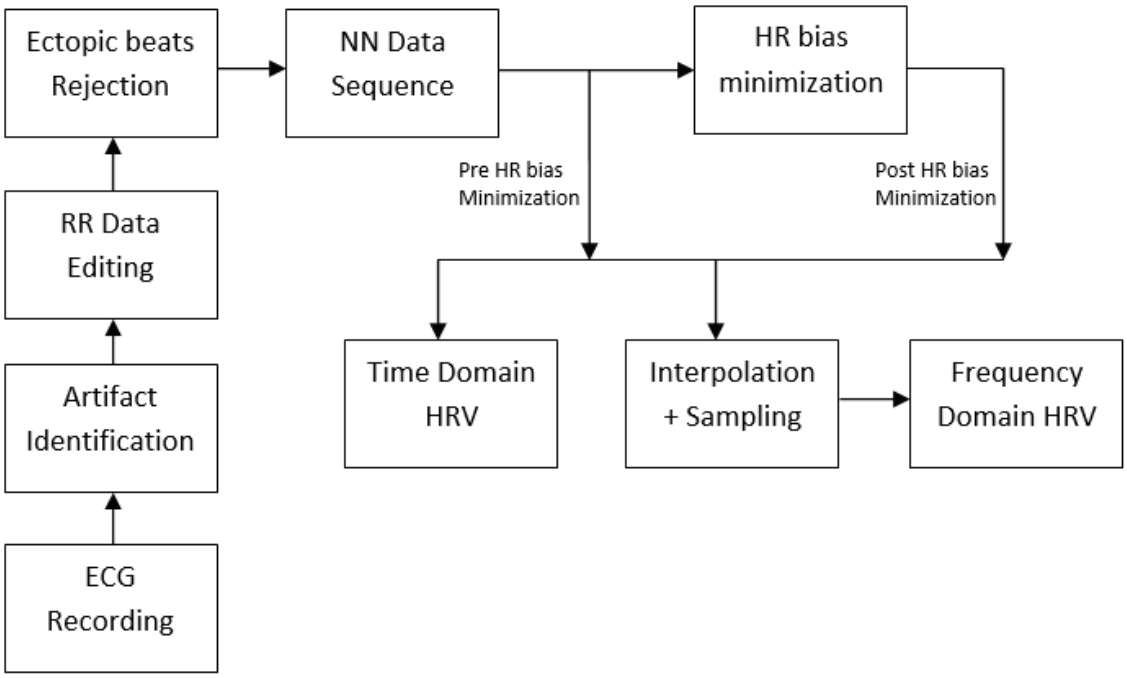
Parameters	HR (BPM)		
	Slow (HR<65)	**Moderate (65≤HR≤85)**	**Fast (HR>85)**
N	16	15	15
Age(years)	23.4±6.09	22.4±5.4	24.5±6.9
HR(BPM)	61.1±3.6	74.9±3.1	88.8±2.6
SBP(mmHg)	119.12 ± 5.75	120.31± 5.92	118.92±9.51
DBP(mmHg)	75 ± 3.18	79.1±4.92	77.1±5.99

Values are shown as mean±SD.
Abbreviations: N, No. of subjects; HR, heart rate; SBP, systolic blood pressure; DBP, diastolic blood pressure

Procedure

The ECG lead II was recorded in supine position for 10 minutes duration with a PowerLab26® and LabChart8.0® software (AD Instruments, Australia). The ECG data acquisition system along with flow chart of the study is shown in Fig. 1.

Fig. 1 Experimental setup and flow chart of the study



Data processing

Out of 10 minutes of ECG recording; smooth, 5 minutes duration of ECG was selected. The HRV module detected beats by detecting R waves in the ECG signal. The beats were classified as normal or ectopic beat based on preset limit. The ectopic beats were identified if the inter beat interval (IBI) differs more than ±30% from mean[19]. The cubic spline interpolation method was used to replace the ectopic beats with interpolated values based on weighted average of nearby accepted values.

The study population was divided into three categories based on the HR viz., slow HR (HR<65 BPM), moderate HR (65 BPM ≤HR≤ 85 BPM) and fast HR (HR>85 BPM). Time domain and frequency domain HRV indices were obtained from HRV module of the LabChart8.0® software[20-21]. For HR bias minimization, the RR interval tachogram was normalized with average RR interval for each subject. The normalization process neutralizes the mathematical inverse relationship between HR and HRV. The HRV parameters were extracted at pre and post HR bias minimization states from recorded Electrocardiographic data.

The data are expressed as mean±SD. Student paired t test was used to compare the difference between HRV parameters of slow, moderate and fast HR cases. Differences were considered significant at the level $p<0.05$.

Results

The time and frequency domain HRV parameters were obtained with LabChart8.0® software. The average values of HRV measures were obtained for slow, moderate and fast HR at pre and post HR bias minimization and presented in Table 2. The improved HRV was observed for all three HR categories with HR bias minimization. However, the impact was more significant in moderate and fast HR cases.

	p value	<0.05*	<0.05*	<0.05*	<0.05*	<0.05*	<0.05*

Values are shown as mean±SD. *Statistically significant at $p<0.05$

Abbreviations: t stat, student t test statistics; SDNN, standard deviation of NN intervals; RMSSD, root mean square of differences of successive RR intervals; pNN50, percentage of RR intervals greater than 50 ms; LF (ms2), low frequency power; HF (ms2), high frequency power; TP, total power.

The SDNN was increased at post HR bias minimization. The changes were not statistically significant for slow HR subjects (+2.7%, p=0.23) whereas statistically significant changes were observed for moderate and fast HR subjects (+19.8%, 31.9%, p<0.05) respectively. The RMSSD also increased with HR bias minimization. However the changes were significant only for moderate and fast HR subjects (+22.7 %, 37.9, p<0.05) respectively whereas changes were not significant for slow HR subjects (+2.8%, p=0.16). The pNN50 count also had similar trends. It increased significantly with HR bias minimization in moderate and fast HR subjects (+46.2%, +83.4%, p<0.05) respectively whereas insignificant variation was observed for slow HR subjects (+4.3%, p=0.09).

The HR bias minimization also improved frequency domain HRV measures. The LF power increased with HR bias minimization. The statistically significant changes were observed for moderate and fast HR subjects (+69.3%, 88.4%, p<0.05) respectively. The impact of HR bias minimization on HF power was also significant for fast HR subjects (+61.6%, p<0.05). However the changes were substantial for moderate subjects as compared to slow HR subjects. The TP also increased with HR bias minimization. It increased significantly for moderate and fast HR subjects (+43.4%, +71.8%, p<0.05) respectively.

The scatter plot between HRV indices and HR at pre and post HR bias minimization is presented in Fig. 2. An exponential trending was estimated on the scatter plot. It can be observed a less exponential decay for post HR bias minimization indicating an improved HRV with HR bias minimization. Negative decay of the exponent indicates that HRV decreases with increasing HR, even after HR bias minimization. The similar trends can be observed for all time and frequency domain HRV indices with HR. The two exponent curves are in close proximity at slow HR region depicting less impact of HR bias minimization on slow HR subjects. As HR increases, both the exponent curves moves apart depicting significant impact of HR bias minimization on moderate and fast HR subjects.

Discussion

In this study, the effect of HR bias minimization on HRV measures was presented. The HR bias is present due to inverse mathematical relationship between HR and HRV. To minimize the HR bias, the RR interval was normalized with average RR interval. The normalization procedure do not changes information about signal oscillations. It just changes the oscillations relative to signal average value.

The HR bias has also effect on the QT interval i.e. faster the HR, shorter the QT interval and vice versa. HR dependency on the QT interval has been presented early in 1920 by Bazett and Fridericia and established HR correction formulae[22]. These formulae adjust the QT interval for HR, if it is deviated from 60 beats per minute. The adjustment of the QT to varying HR is a dynamic phenomenon consisting of slow and fast adaptation phases and depends upon nature of HR changes. Repolarization adapts faster to increasing HR than it does to decreasing HR[23]. As the QT prolongation is associated with risk of cardiac arrhythmias and mortality, a correction for HR is warranted for QT interval[24].

Similar to this, correction for HR is also needed in HRV analysis. In this study, the HR bias minimization by RR interval normalization with average RR interval also sets the HRV measures for HR at 60 beats per minute. The HRV measures were improved after HR bias minimization. The HRV measures were found lower at higher HR even after HR bias minimization. This indicates a strong correlation between HR and HRV and the results obtained are in line with numerous studies[13,17,25]. Reduced HRV may be a natural response of ANS in higher HR; however reduced HRV has been also reported in many cardiovascular diseases. Therefore the HRV of two subjects with different average HR cannot be compared. It may lead to draw inappropriate inferences.

In this study, the HR was further characterized as slow, moderate and fast HR. It is proposed that,

(1) The heart rate has significant effect on HRV, particularly in moderate and fast heart rate cases. So, the

effect of heart rate bias minimization is more significant on moderate and fast HR as compared to slow HR.

(2) HRV has inverse relationship with heart rate even after HR bias minimization. It can be attributed to the natural response of ANS at increased heart rate.

Is Violin String Players Having Longer Left Fingers?

Joyanta Sarkar[1], Anil Rai[2]

Abstract

Bones are a form of specialized tissue. They are very strong and durable. Bones in our body will elongate and grow starting from the time we are born until adolescence. The rate of development of our bones will also depend on, amongst other things, the amount of nutrition, exercise and exposure to sunlight. Sunlight helps us produce vitamin D - which is important for absorbing calcium. Our bones provide the frame and structural support required to hold our flesh, organs and muscles together. They also provide protection for our vital organs. For example the ribcage protects the heart and lungs, while the skull protects our brains. Bone marrow found at the core of our bones, is used to produce blood cells and to store fat. Bones also act as a reservoir for calcium storage. In this paper, we propose, whether the experienced violinists have longer fingers on their left hand or not. This paper involved violinists who have been playing the instrument for more than 5 years.

Introduction

The violin, sometimes known as a fiddle, is a wooden string instrument in the violin family. Most violins have a hollow wooden body [1]. It is the smallest and highest-pitched instrument in the family in regular use. The violin typically has four strings, usually tuned in perfect fifths with notes G3, D4, A4, E5, and is most commonly played by drawing a bow across its strings, though it can also be played by plucking the strings with the fingers (pizzicato) and by striking the strings with the wooden side of the bow.

Violins are important instruments in a wide variety of musical genres. They are most prominent in the Western classical tradition, both in ensembles (from chamber music to orchestras) and as solo instruments and in many varieties of folk music, including country music, bluegrass music and in jazz. Electric violins with solid bodies and piezoelectric pickups are used in some forms of rock music and jazz fusion, with the pickups plugged into instrument amplifiers and speakers to produce sound. Further, the violin has come to be played in many non-Western music cultures, including Indian music and Iranian music [2]. The name fiddle is often used regardless of the type of music played on it.

The violin was first known in 16th-century Italy, with some further modifications occurring in the 18th and 19th centuries to give the instrument a more powerful sound and projection [3].

Violinists and collectors particularly prize the fine historical instruments made by the Stradivari, Guarneri, Guadagnini and Amati families from the 16th to the 18th century in Brescia and Cremona (Italy) and byJacob Stainer in Austria [4]. According to their reputation, the quality of their sound has defied attempts to explain or equal it, though this belief is disputed. Great numbers of instruments have come from the hands of less famous makers, as well as still greater numbers of mass-produced commercial "trade violins" coming from cottage industries in places such as Saxony, Bohemia, and Mirecourt. Many of these trade instruments were formerly sold by Sears, Roebuck and Co. and other mass merchandisers.

The parts of a violin are usually made from different types of wood. Violins can be strung with gut, Perlon or other synthetic or steel strings. A person who makes or repairs violins is called a luthier or violinmaker. One who makes or repairs bows is called an archetier or bowmaker [5].

Etymology

The word "violin" was first used in English in the 1570s. The word "violin" comes from "Italian violino, [a] diminutive of viola". The term "viola" comes from the expression for "tenor violin" in 1797, from Italian viola, from Old Provençal viola, [which came from] Medieval Latin vitula" as a term which means "stringed instrument," perhaps [coming] from Vitula, Roman goddess of joy..., or from related Latin verb vitulari, "to exult, be joyful." The related term "Viola da gamba" means "bass viol" (1724) is from Italian, literally "a viola for the leg" (i.e. to hold between the legs)." A violin is the "modern form of the smaller, medieval viola da braccio." ("arm viola")

The violin is often called a fiddle, either when used in a folk music context, or even in Classical music scenes, as an informal nickname for the instrument. The word "fiddle" was first used in English in the late 14th century. The word "fiddle" comes from "fedele, fydyll, fidel, earlier fithele, from Old English fiðele «fiddle,» which is related to Old Norse fiðla, Middle Dutch vedele, Dutch vedel, Old High German fidula, German Fiedel, "a fiddle;" all of uncertain origin." As to the origin of the word "fiddle", the "...usual suggestion, based on resemblance in sound and sense, is that it is from Medieval Latin vitula."

Construction and Mechanics

A violin generally consists of a spruce top (the soundboard, also known as the top plate, table, or belly), maple ribs and back, two endblocks, a neck, a bridge, a soundpost, four strings, and various fittings, optionally including a chinrest, which may attach directly over, or to the left of, the tailpiece. A distinctive feature of a violin body is its hourglass-like shape and the arching of its top and back. The hourglass shape comprises two upper bouts, two lower bouts, and two concave C-bouts at the waist, providing clearance for the bow. The "voice" or sound of a violin depends on its shape, the wood it is made from, the graduation (the thickness profile) of both the top and back, the varnish that coats its outside surface and the skill of the luthier in doing all of these steps. The varnish and especially the wood continue to improve with age, making the fixed supply of old well-made violins built by famous luthiers much sought-after.

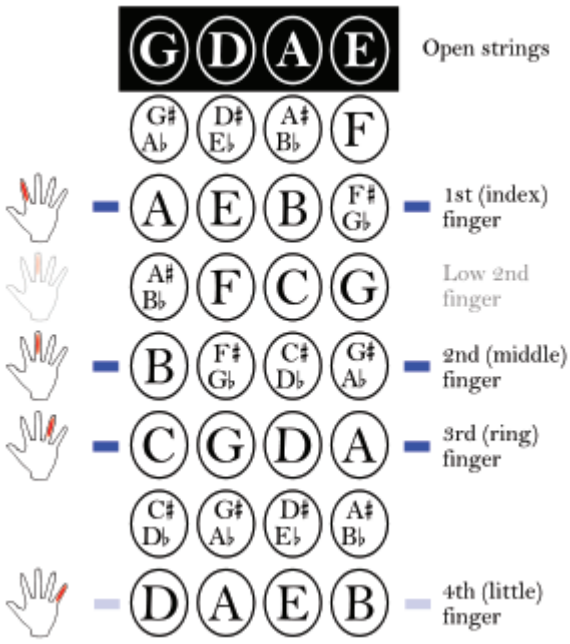
The majority of glued joints in the instrument use animal hide glue rather than common white glue for a number of reasons. Hide glue is capable of making a thinner joint than most other glues, it is reversible (brittle enough to crack with carefully applied force, and removable with very warm water) when disassembly is needed, and since fresh hide glue sticks to old hide glue, more original wood can be preserved when repairing a joint. (More modern glues must be cleaned off entirely for the new joint to be sound, which generally involves scraping off some wood along with the old glue.) Weaker, diluted glue is usually used to fasten the top to the ribs, and the nut to the fingerboard, since common repairs involve removing these parts. The purfling running around the edge of the spruce top provides some protection against cracks originating at the edge [6]. It also allows the top to flex more independently of the rib structure. Painted-on faux purfling on the top is usually a sign of an inferior instrument. The back and ribs are typically made of maple, most often with a matching striped figure, referred to as flame, fiddleback, or tiger stripe.

The neck is usually maple with a flamed figure compatible with that of the ribs and back. It carries the fingerboard, typically made of ebony, but often some other wood stained or painted black on cheaper instruments. Ebony is the preferred material because of its hardness, beauty, and superior resistance to wear. Fingerboards are dressed to a particular transverse curve, and have a small lengthwise "scoop," or concavity, slightly more pronounced on the lower strings, especially when meant for gut or synthetic strings. Some old violins (and some made to appear old) have a grafted scroll, evidenced by a glue joint between the pegbox and neck. Many authentic old instruments have had their necks reset to a slightly increased angle, and lengthened by about a centimeter. The neck graft allows the original scroll to be kept with a Baroque violin when bringing its neck into conformance with modern standards.

The bridge is a precisely cut piece of maple that forms the lower anchor point of the vibrating length of the strings and transmits the vibration of the strings to the body of the instrument. Its top curve holds the strings at the proper height from the fingerboard in an arc, allowing each to be sounded separately by the bow. The sound post, or soul post, fits precisely inside the instrument between the back and top, at a carefully chosen spot near the treble foot of the bridge, which it helps support. It also influences the modes of vibration of the top and the back of the instrument.

The tailpiece anchors the strings to the lower bout of the violin by means of the tailgut, which loops around an ebony button called the tailpin (sometimes confusingly called the endpin, like the cello's spike), which fits into a tapered hole in the bottom block. Very often the E string will have a fine tuning lever worked by a small screw turned by the fingers. Fine tuners may also be applied to the other strings, especially on a student instrument, and are sometimes built into the tailpiece. The fine tuners enable the performer to make small changes in the pitch of a string. At the scroll end, the strings wind around the wooden tuning pegs in the pegbox. The tuning pegs are tapered and fit into holes in the peg box. The tuning pegs are held in place by the friction of wood on wood. Strings may be made of metal or less commonly gut or gut wrapped in metal. Strings usually have a colored silk wrapping at both ends, for identification of the string (e.g., G string, D string, A string or E string) and to provide friction against the pegs. The tapered pegs allow friction to be increased or decreased by the player applying appropriate pressure along the axis of the peg while turning it.

Left hand and pitch production



First position fingerings. Note that this diagram only shows the "first position" notes. There are notes of higher pitch beyond those indicated.

The left hand determines the sounding length of the string, and thus the pitch of the string, by "stopping" it (pressing it) against the fingerboard with the fingertips, producing different pitches. As the violin has no frets to stop the strings, as is usual with the guitar, the player must know exactly where to place the fingers on the strings to play with good intonation (tuning). Beginning violinists play open strings and the lowest position, nearest to the nut. Students often start with relatively easy keys, such as A Major and G major. Students are taught scales and simple melodies. Through practice of scales and arpeggios and ear training, the violinist's left hand eventually "finds" the notes intuitively by muscle memory.

Beginners sometimes rely on tapes placed on the fingerboard for proper left hand finger placement, but usually abandon the tapes quickly as they advance. Another commonly used marking technique uses dots of white-out on the fingerboard, which wears off in a few weeks of regular practice. This practice, unfortunately, is used sometimes in lieu of adequate ear-training, guiding the placement of fingers by eye and not by ear. Especially in the early stages of learning to play, the so-called "ringing tones" are useful. There are nine such notes in first position, where a stopped note sounds a unison or octave with another (open) string, causing it to resonate sympathetically. Students often use these ringing tones to check the intonation of the stopped note by seeing if it is harmonious with the open string. For example, when playing the stopped pitch "A" on the G string, the violinist could play the open D string at the same time, to check the intonation of the stopped "A". If the "A" is in tune, the "A" and the open D string should produce a harmonious perfect fourth.

Violins are tuned in perfect fifths, like all the orchestral strings (violin, viola, cello) except the double bass, which is tuned in perfect fourths. Each subsequent note is stopped at a pitch the player perceives as the most harmonious, "when unaccompanied, [a violinist] does not play consistently in either the tempered or the natural [just] scale, but tends on the whole to conform to the Pythagorean scale." When violinists are playing in a string quartet or a string orchestra, the strings typically "sweeten" their tuning to suit the key they are playing in. When playing with an instrument tuned to equal temperament, such as a piano, skilled violinists adjust their tuning to match the equal temperament of the piano to avoid discordant notes.

The fingers are conventionally numbered 1 (index) through 4 (little finger) in music notation, such as sheet music and etude books. Especially in instructional editions of violin music, numbers over the notes may

indicate which finger to use, with 0 or O indicating an open string. The chart to the right shows the arrangement of notes reachable in first position. Not shown on this chart is the way the spacing between note positions becomes closer as the fingers move up (in pitch) from the nut. The bars at the sides of the chart represent the usual possibilities for beginners' tape placements, at 1st, high 2nd, 3rd, and 4th fingers.

Methodology

The materials required for this experiment: - 10 participants 12 to 20 years old who have played the violin for at least 5 years

- 10 participants 21 to 30 years old who have played the violin for at least 5 years

- 10 participants 31 to 40 years old who have played the violin for at least 5 years

- 10 participants 12 to 20 years old who are non-violinists

- 10 participants 21 to 30 years old who are non-violinists

- 10 participants 31 to 40 years old who are non-violinists

- 1 ruler

- 1 wooden block

Figure 1: Fingering Set-Up-1

Figure 2: Fingering Set-Up-2

Figure 3: Fingering Set-Up-3

Figure 4: Fingering Set-Up-4

1. For this experiment, the independent variable is the age of the participants and whether or not they have played the violin for at least 5 years. The dependent variable is the difference in the length of their left and right fingers. This is determined by measuring the length of their fingers using the ruler and wooden block. The constants (control variables) are the number of years for which they have played the violin and the method used to measure the length of the fingers. 2. Sixty participants are required for this project out of which 30 participants are required to have played the violin for at least 5 years and the remaining 30 participants are non-musicians. Out of the 30 participants, 10 of them will be from each of the age groups 12 to 20 years, 21 to 30 years and 31 to 40 years old. 3. The length of the participant's index, middle, ring and little fingers are measured on the left and right hand. The measurements are taken by placing a wooden block at the tip of the finger and using the ruler to measure the distance from the base of the finger to the edge of the wooded block. 4. The difference in length between the left fingers and right fingers is calculated as follows: Finger length difference = Length of left finger (index) – Length of right finger (index) The measurement is compared between the

same fingers, i.e. left index to right index finger. 5. The differences in finger lengths are recorded. After completing the measurements for all 60 participants, the average difference in finger length for each group is obtained by totaling the differences in finger length, and dividing the total by 10. The finger measurement which shows the most significant difference is used and the calculated results are recorded in the table given below.

Results and Analysis

It was observed that violinists have longer left fingers than their right fingers by about 7mm. Non-musicians have longer right fingers compared to their left fingers by about 8mm. Their age did not make a significant difference in finger length.

Table: Difference in left finger and right finger length for different age groups (mm)

Condition	Difference in left finger and right finger length for different age groups (mm)		
	Age 12-20	Age 21-30	Age 31-40
Violin players	6.7	7.0	7.1
Non-violin players	-8.0	-8.3	-8.4

The graph below represents the results of our experiment:

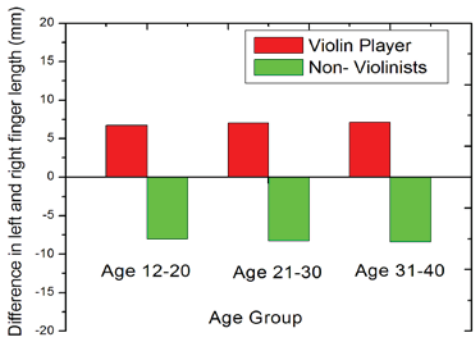


Fig: Finger length of Violinists and non-Violinists Player

Conclusion

Bones are a vital part of our body for many reasons. Involvement in sports and activities that result in stress on our bones, like baseball or playing musical instruments, are believed to increase the length and size of our bones. The hypothesis that violinists have longer fingers on their left hands, while non-violinists have shorter left hand fingers, is proven to be true.

A Study on the Effectiveness of Scapular Retraction Exercises on Forward Head Posture

K. Kirupa[1], S. M. Divya Mary[1], R. Nithyanisha[1], S. Navin Kumar[2]

[1]Assistant Professor, [2]Internee Student, Faculty of Physiotherapy, Dr.M.G.R Educational & Research Institute, Deemed to be University, Velappanchavadi, Chennai, Tamil Nadu, India

Abstract

Objective: The aim of the study is to find out the effectiveness of scapular retraction exercise for forward head posture.

Background of the Study: • Forward head posture is a condition often seen in person who were using computer and laptops for long hours. Forward head posture is the anterior positioning of the cervical spine. This posture is sometime called "text neck".

• It is a posture problem that is caused by several factor including sleeping with head elevated to high. Due to forward head posture the deep flexor muscle gets overstretched and weak thus resulting tightness of pectoralis muscle and over stretched to weak the rhomboid muscle.

• The purpose of this study was to investigate the effect of scapular retraction exercise on neck posture, muscle activity, pain and quality of life in individuals with neck pain and forward head posture.

Methodology: The study is experimental study with study set up at outpatient physiotherapy department of ACS Medical College and Hospital. 30 subjects are randomly selected with inclusion criteria of patient of both male and female, 18 to 30 years of age groups, IT job workers, often indulging in TV, Computer, Texting-neck, Driver's neck and exclusion criteria with Systemic illness, subject undergone surgeries, patient with congenital cervical deformities, Cervical fractures and the material used is adhesive skin marker, Measuring tape and Thera band and the outcome measures is VAS scale, Craniovertebral Angle (tragus right ear &midpoint of the C7) and NDI (neck disability index).

Procedure: 30 subjects with forward head posture were, included in this study. The Craniovertebral angle of all the subjects and were measured by using inch tape. The Craniovertebral angle was measured by angle between midpoint of the adhesive marker at tragus of right ear and midpoint of the reflective marker at C7. All the 30 subjects were received scapular retraction exercises as a common intervention

Result: There is significant effect of Scapular Retraction Exercises in reducing Forward Head Posture.

Keywords: *Forward head posture, Scapular Retraction Exercise, Neck pain, Postural Exercise.*

Introduction

One of the most common postural problems is the forward head posture(FHP) [(1)]. Forward head posture is the anterior positioning of the cervical spine occurring when the lower neck bone is bent and there is an extension of the upper neck bone and the head. This condition has increased and is exacerbated with the advancement in technology and the increasing use of computers and smartphones for extended periods of time. This posture reduces the dispersion of biomechanical loading and therefore causes degeneration of the neck muscles and structural changes in addition, compensatory actions, such as spinal actions, such as spinal curve changes, rounded shoulders and abnormal muscle activity can be observed[(2).]This posture is associated with weakness in the deep cervical short flexor muscles and mid-thoracic scapular retractor (i.e., rhomboids, serratus anterior, middle and lower fibres of the trapezius) and shortening of

the opposing cervical extensor and pectoralis muscles[3]. Forward head posture frequently appear in the patient with neck disorder. Most of the patient with forward head posture spend all day in prolonged sitting such as computer based work, industry related tasks and Bus drivers. Previous studies have shown that forward head posture leads to shortening of posterior neck extensor, tightening of the anterior neck and shoulder muscles and affects scapular position [4]. There is an incidence of 66% for forward head posture among people in age group of 20 to 50 years [5].

Neck pain is one of the most common musculoskeletal disorders, next to back pain. Many people seek medical centres for the treatment at least once in their life time. A review of different observational studies of neck pain around the world showed that is 1-year prevalence range from 16.7 to 75.1 percent for the entire adult population (aged 17 -70 years) with a mean of 37.2 percent [6].

Scapular retraction is an integral component of good trunk posture. Completing simple scapula retraction exercises can strengthen your muscles and improve your posture. These retractors are responsible for squeezing your shoulder blades together and pulling your shoulders back into upright positioning [7]. The two major scapular retractors are the middle trapezius and the rhomboids, but these two muscles vary somewhat in their actions. The middle fibres of the trapezius function as pure scapula and to rotate it to depress the glenoid fossa [8]. If imbalance in cervical muscle resulting from postural misalignment are prolonged an excessive load is imposed on the joint and muscle, thereby making the problem caused forward head posture chronic [9]. There are frequent occurrences of functional movement limitations or non-specific pain in the head and neck region in patient with FHP [10].

The smart phones have small monitors that are typically held downwards near the laps, users must bend their heads to see the screens, increasing activity in the neck extensor muscles overloading the neck and shoulders increases muscle fatigue, decreases work capacity and affects the musculoskeletal system [11]. There have also been concerns raised that the increasing use of computers may put children at higher risk of neck/shoulder problems -such as those commonly seen in adult computer users[12].The craniovertebral angle is identified as the intersection of a horizontal line passing through the C7 spinous process and a line joining the midpoint of the tragus of the ear to the skin overlying the C7 spinous process[13]. There are several exercises to engage the muscles used in retracting your scapula, and many of these exercise are almost strictly scapular retractions [14].

Methodology

The study is experimental study with study set up at outpatient physiotherapy department of ACS Medical College and Hospital. 30 subjects are randomly selected with inclusion criteria of patient of both male and female, 18 to 30 years of age groups, IT job workers, often indulging in TV, Computer, Texting-neck, Driver's neck and exclusion criteria with Systemic illness, subject undergone surgeries, patient with congenital cervical deformities, Cervical fractures and the material used is adhesive skin marker, Measuring tape and Thera band and the outcome measures is VAS scale, Craniovertebral Angle (tragus right ear &midpoint of the C7) and NDI (neck disability index).

Procedure:

Participants who reported to A.C.S medical college and hospital in outpatient physiotherapy department with forward head posture were screened for their eligibility depending on inclusion and exclusion criteria to participate in this study. Then the purpose of the study was explained and an informed consent was obtained. A standardized demographic information including age, gender, height, weight was collected.

All the subjects were asked to sit comfortably on back supported armless chair with both feet flat on floor, hip and knees positioned at 90-degree angle and buttock positioned against the back chair. The subjects were asked to rest their hands on their lap and to keep their shoulder against the back of the chair. Adequate exposure of neck up to shoulder level to clearly define anatomical landmark was done. The most prominent spinous process at the base of cervical spine was palpated. After it was identified, the cervical spine was passively flexed and extended to verify which one moved first, C6 vertebra should be more mobile whereas C7 should demonstrate less motion. Skin over the anatomical landmark was wiped with cotton soaked in spirit to remove skin secretions for proper fixation of adhesive markers. Anatomical landmarks were marked with marker pen; thereafter adhesive marker were fixed over the anatomical landmark. Then taken the measurement of the height between ground and C7 in sitting position of each subject was done with measuring

tape. The craniovertebral angle was measured by angle between mid-point of the adhesive marker at tragus of right ear and midpoint of the reflective marker at C7. After that all subject were asked to sit comfortably on back supported armless chair with feet flat on floor, hips and knees positioned at 90-degree angle hands on their lap.

Measurement of forward head posture: The method for finding the forward head posture, this is done with a tape measure or ruler (scale), ask the patient to lean on the wall in the relaxed position and measures the length between the wall and the head.A total of 30 volunteers meeting the inclusion criteria were selected and performed forward head correction program to 30 min. Forward head posture correction program, the exercises were done 3 weeks per day 2 sessions and 12 repetitions for each session.

Seated row- long sitting position, the patient is asked to take the Thera band to pull the lower sole of feet and grasping the Thera band end with hand, maintaining the shoulder level and head raise and pull the Thera band backward hold it for 2 secs and then relaxed.

Elbow push back- crook lying position, the shoulder kept 90º abduction, external rotation, the elbow push back against the floor and head is raised, both the shoulder retracted and maintain the position for 3 to 5 sec and the relaxed.

Scapular retraction activation- prone lying position, head raised, chintucked, both the arm abducted raising the shoulder from the floor maintain this for few seconds.

Arm slides – crook lying position the shoulder kept 90º abduction and external rotation,the arm slides upward and downward.

Lower trap row exercise - standing position, the Theraband wrapped the window pull the end of Thera bandand then relaxed.

Data Analysis

The collected data were tabulated and analyzed using both descriptive and inferential statistics. All the parameters were assessed using statistical package for social science (SPSS) version 24. Paired t-test was adopted to find the statistical difference within the groups.

Table - 1: Comparison of neck disability index score within group between pre & post test values

#NDI	Pre Test		Post Test		T - Test	Significance
	Mean	S.D	Mean	S.D		
GROUP	20.76	2.22	8.93	1.48	42.27	.000***

(*- P ≤ 0.001)**

The above table reveals the Mean, Standard Deviation (S.D), t-value and p-value between pre-test and post-test within Group. There is a statistically highly significant difference between the pre-test and post-test values within Group (***- P ≤ 0.001).

Table – 2: Comparison of visual analog scale within group between pre & post test values

#VAS	PRE TEST		POST TEST		t - TEST	SIGNIFICANCE
	MEAN	S.D	MEAN	S.D		
GROUP	3.76	.430	1.53	.507	28.43	.000***

(*- P ≤ 0.001)**

The above table reveals the Mean, Standard Deviation (S.D), t-value and p-value between pre-test and post-test within Group. There is a statistically highly significant difference between the pretest and posttest values within Group (***- P ≤ 0.001).

Table – 3 Comparison Of Craniovertebral Angle Within Group Between Pre & Post Test Values

#CVA	PRE TEST		POST TEST		t - TEST	SIGNIFICANCE
	MEAN	S.D	MEAN	S.D		
GROUP	47.11	.937	52.62	1.47	-25.59	.000***

(*- P ≤ 0.001)**

The above table reveals the Mean, Standard Deviation (S.D), t-value and p-value between pre-test and post-test within Group. There is a statistically highly significant difference between the pretest and posttest values within Group (***- P ≤ 0.001).

TABLE - 4: Pearson Correlation of Coefficient between Neck Disability Index and Craniovertebral Angle(CVA)

Parameters	Pearson correlation	
	'r' value	P value
NDI & CVA	-.147	>0.05

The above table reveals the Pearson Correlation of coefficient 'r ' value and p-value between Neck Disability Index and Craniovertebral Angle(CVA)

The value of R is -.147 Although technically a Negative Association and correlation between Neck Disability Index and Craniovertebral Angle(CVA)

Result

On comparing Neck Disability Index Score Pre test **20.76** and Posttest**8.93** Mean values within Group (Scapular Retraction Exercises) shows highly significant difference between Pretest & and Posttest Mean values at **P ≤ 0.001**

On comparing Visual Analog Scale Pre test **3.76** and Posttest**1.53** Mean values within Group (Scapular Retraction Exercises) shows highly significant difference between Pretest & and Posttest Mean values at **P ≤ 0.001**

On comparing Craniovertebral Angle Pre test **47.11** and Posttest**52.62** Mean values within Group (Scapular Retraction Exercises) shows highly significant difference between Pretest & and Posttest Mean values at **P ≤ 0.001**

The value of R is -.147 Although technically a Negative Association and correlation between Neck Disability Index and Craniovertebral Angle(CVA). The decrease in the values of Craniovertebral angle is associated with the greater level of Neck Disability.

Conclusion

In this study on comparing the values of Neck Disability Index Questionnaire, Visual Analogue Scale and Craniovertebral Angle within group, we conclude that Scapular Retraction Exercises are more effective in

reducing Forward Head Posture.

Discussion

The present study was to determine the effectiveness of scapular retraction exercises and forward head posture. This study was conducted on 30 subjects with forward head posture. Patients with forward head posture have rounded shoulders or poor back posture. Therefore, the scapula retraction exercise is applied to patients with forward head posture. Craniovertebral angle of all the subjects were measured using inch tape to assess the forward head posture. The scapular retraction exercises or Seated rows, Elbow push back, Scapular retraction activation, Arm slides and Lower trap row exercise. The outcome parameter is Visual Analogue Scale, Neck Disability Index Questionnaire and craniovertebral angle.

This study supports the findings of MELISSA SABO showed that completing simple scapular retraction exercises can strengthen your muscles and improve your posture. The posture, which is typically caused by weakness in the shoulder blade muscles, can lead to pain in the neck or shoulders if not addressed. Fortunately, shoulder retraction exercises can be helpful for strengthening these weak muscles and improving posture. Forward head posture is the anterior positioning of the cervical spine occurring when the lower neck bone is bent and there is an extension of the upper neck bone and the head. This condition has increased and is exacerbated with the advancement in technology and the increasing use of computers and smart phones for extended periods of time. This posture is associated with weakness in the deep cervical short flexor muscles and mid-thoracic scapular retractor (i.e., rhomboids, serratus anterior, middle and lower fibres of the trapezius) and shortening of the opposing cervical extensor and pectoralis muscles. The purpose of this study was to investigate the effects of scapular retraction exercise on neck posture, muscle activity, neck pain and quality of life in the patients with neck pain and forward head posture in the patient with forward head posture.

On comparing the mean values o of Neck Disability Index Score Pre-test 20.76 and Post-test 8.93 within group (Scapular Retraction Exercises) shows highly significant difference. On comparing the mean values of Visual Analogue Scale Pre-test 3.76 and Post-test 1.53 within group (Scapular Retraction Exercises) shows highly significant difference. On comparing the mean values of Craniovertebral Angle Pre-test 47.11 and Post-test 52.62 within group (Scapular Retraction Exercises) shows highly significant difference.

Therefore, by comparing the statistical values Scapular Retraction Exercises are effective in reducing Craniovertebral Angle and hence also reduces Forward Head Posture. Our data supports alternate hypothesis. Hence, null hypothesis is rejected.

Association between Stress Scores with Demographic Variables in Mothers of Children Attending Normal School and Special School

K. Maheswari,[1] G.Sasikala[2], P.Panneerselvam[3]

[1]Vice- Principal & Professor, Vinayaka Mission's Annapoorana College of Nursing, Salem, Tamilnadu, [2]Nursing Research Scholar, Vinayaka Mission's Research Foundation- Deemed to be University (VMRFDU), J-1 JMQ Sanatorium quarters, Perundurai, Erode, Tamil Nadu, [3]Assistant Professor, Dept of Physiology, Government IRT Perundurai Medical College, Perundurai, Erode, Tamil Nadu

Abstract

The present study was undertaken to observe the association between stress scores with demographic variables in mothers of children attending normal school and special school. The present study was a cross-sectional (comparative) study. 120 mothers were taken for the study, out of which 60 were mother of intellectually disabled children diagnosed with ID based on Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM5) criteria and 60 was mother of normal children. Stress inventory was used to determine the stress scores. The present study results showed that younger's are having less stress than others. It was confirmed using Chi square test. More income of mother of children attending Special school is having less stress than others. Further multi center studies are recommended in this area for better understanding of the association.

Key words: *Correlation. Stress, depression, mothers*

Introduction

As per Government data, every year new disability children been reported increasing Average -1534 per year in Erode district alone.[1] The aim of this study to compare the level of stress under Physiological, Emotional, Cognitive and Behavioural level between mothers of children attending Normal school Vs special school, considering their demographic background and planning early therapeutic interventions for these mothers to adopt appropriate coping mechanism to overcome their stress. Society plays an important role in the upbringing of their child. Some parents feel ashamed of their child and consider them as burden. Others consider it as their duty to take care of their children. Uplifting the parent's social and psychological well-being would help the parents to deal effectively with their children having problem.[2] Special measures like early diagnosis, prompt treatment and counseling for stress of the mothers of children attending Special school along with provision of need based rehabilitation services for the Intellectual disability children at different levels to reduce the stress of their mother. There is a great need to identify at an early stage which Mothers are at poor mental health and facing psychological problems, so that successfully targeted those mothers to modify their thinking style and living patterns Psycho-social intervention programs for family caregivers of children with Intellectual disability should incorporate building upon specific strategies to enhance their quality of life. The present study was undertaken to observe the association between stress scores with demographic variables in mothers of children attending normal school and special school.

Materials and Method

Study design: The present study was a cross-sectional (comparative) study

Study setting: The present study was conducted in

and around Erode district, Tamil Nadu.

Study participants: 120 mothers were taken for the study, out of which 60 were mother of intellectually disabled children diagnosed with ID based on Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM5) criteria and 60 was mother of normal children. A total of 60 mothers of intellectually disabled children were selected through convenient sampling method from those who referred to psychiatric clinics for children, specialists' offices, and also advisory centres of department of education and training centers–rehabilitation and organization for exceptional children of Erode district. The following inclusion and exclusion criteria was used in recruiting the participants.

Inclusion and exclusion criteria: Inclusion criteria were having a aged between 6 and 18 years old child, having just one child with intellectually disabled, the presence of both parents in the family, employment of the father and not facing any serious financial crisis, not having any other member in the family suffering from chronic physical-mental problems, not having the child admitted to a boarding school, not having serious marital conflicts during the past month, and no record of the death of a loved one during the past 3 months; also they should have been consent to participate in the study and in the case of mothers' unwillingness to cooperate for completing the questionnaires and giving full answers they would have been excluded from the study.

Outcome measures

Stress inventory: The questionnaire was standardized questionnaire. It consists of 30 items, under 4 parts namely, Physiological, Emotional, Cognitive and Behavioral. There are two possible responses to each item namely, 'Yes' or 'No'. The mothers were asked to tick any one, which applied to them the most. There was no time limit. But the mothers were asked to respond as quickly as possible. Scoring Key and Norms were provided by the authors. The validity of S.I. is 0.80 and the reliability by test retest method is 0.95.[4]

Data analysis: Data were analysed using SPSS software version 11.5 (SPSS Inc). Chi square test was used to detect the association. $P < 0.05$ was considered as statistically significant levels.

Results:

Table 1 shows the association between stress score and mothers of children attending Normal school Demographic variables. Younger's are having less stress than others. It was confirmed using Chi square test. Table 2 shows the association between stress score and mothers of children attending Special school Demographic variables. More income of mother of children attending Special school is having less stress than others. It was confirmed using Chi square test.

Discussion

Stress is most common and prevalent cause for many diseases and clinical conditions.[3] It is well associated with the demographic variables. The stress levels in females are still more when compared with males.[4] Further, the mothers those who have the children with disabilities either the physical or mental undergo enormous amounts of stress levels when compared with mothers of normal children.[5-9] However, it was also reported that the depression scores also higher in the parents of special children.[10] The present study was undertaken to observe the association between stress scores with demographic variables in mothers of children attending normal school and special school. Younger's are having less stress than others. It was confirmed using Chi square test. More income of mother of children attending Special school is having less stress than others. It was confirmed using Chi square test. Stress is found to be an important problem commonly found in parents of children with special needs. Being apprehensive clearly explains stress, anxiety and its repercussions are perceived in no less degree in mothers of children with special needs. A chain reaction to this is seen in their quality of life. It is the need of the hour to make a study on these mothers of children with special needs to manage their stress and anxiety about their children and to enhance their quality of life. Parenting stress can be defined as excess anxiety and tension specifically related to the role of a parent and to parent-child interactions.[3] Parent's psychological

well-being is considered to be very important in parent – child relationship because it is very important key to the success of a meaningful family relationship. Special measures like early diagnosis prompt treatment with rehabilitation to children and counselling to the mothers would help to develop a reasonable attitude rather than an emotional attitude towards the problem and pave way to enhance quality of life. Nurses should plan for various positive behaviour therapeutic interventions to them.

Conclusion

The present study results showed that younger's are having less stress than others. It was confirmed using Chi square test. More income of mother of children attending Special school is having less stress than others. Further multi center studies are recommended in this area for better understanding of the association.

Comparison of Parenting Stress and Quality of Life among Mothers and Fathers of Intellectual Disability Children in Erode, Tamilnadu

K. Maheswari,[1] G.Sasikala[2], P.Panneerselvam[3]

[1]Vice- Principal & Professor, Vinayaka Mission's Annapoorana College of Nursing, Salem, Tamilnadu, [2]Nursing Research Scholar, Vinayaka Missions University, Salem, Tamilnadu, [3]Assistant Professor, Dept of Physiology, Government IRT Perundurai Medical College, Perundurai, Erode, TamilNadu.

Abstract

The present study was undertaken to Compare Parenting stress and Quality of life among mothers and fathers of Intellectual disability children in Erode, Tamil Nadu. The present study was a cross-sectional (comparative) study. 60 couples having children aged between 2 and 18 diagnosed with ID based on Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM5) criteria formed the sample of this study. Case Study Schedule was used to get the needed information about the selected Parents of Mentally Challenged. The questionnaire was standardized questionnaire. It consists of 30 items, under 4 parts namely, Physiological, Emotional, Cognitive and Behavioral. The WHOQOL BREF questionnaire is used to assess the quality of life.[9] Prior permission was obtained to use the Tamil version of the questionnaire. The WHOQOLBREF is an abbreviated version of the original WHOQOL- 100. Very high level of stress was observed in mothers and high levels of stress was observed in fathers. Quality of life was more or less same in both mothers and fathers. There is a moderate negative correlation between fathers stress score and QOL score. It means stress decreases their QOL increases. There is a moderate negative correlation between mothers stress score and QOL score. It means stress decreases their QOL increases. The study recommends further multi center studies for better understanding and to plan adequate interventions.

Key words: *Quality of life, Mothers, Fathers, Stress*

Introduction

Mental retardation (MR) according to the World Health Organization has overall prevalence of 1-3% in the global scenario,[1] In India5.6 % has been reported and decadal change in disabled population in India is 22.4% .[2] This by itself suggests the magnitude of the problem in terms of the economy for a developing country like ours. MR also produces psychological, social and financial distress to the whole family, particularly parents, as they are usually the only constant caretakers.[3] Parents of children with intellectual disabilities frequently report symptoms of depression and anxiety. Studies have shown an association between parental distress and caretaking of children with developmental cognitive delays.[4] A large number of these children have behavioral issues, which can lead to higher levels of parental stress.[5] Parents reported more psychiatric symptomatology when the child showed a high level of dysfunction.[6] Treatment progress may need to address parental stress, which in turn will help optimize treatment outcome for the child and the family.[7] It is important to guide the provision of needed psychosocial, educational, and health services that can strengthen family coping and positive adjustment. Studies had suggest that the reduction of parenting stress is paramount in the enhancement of a child's family life and in the child's ultimate integration within society.There is little data in developing countries, such as India especially Erode district of Tamilnadu, concerning the impact of raising children with ID, upon the quality of life of parent and

Corresponding author:

Nursing Rearch Scholar in Vinayaka Missions University, J-1 JMQ Sanatorium Quarters, Perundurai, Erode, Tamilnadu-638053

their stress. Hence, the present study was undertaken to Compare Parenting stress and Quality of life among mothers and fathers of Intellectual disability children in Erode, Tamil Nadu

Materials and Method

Study design: The present study was a cross-sectional (comparative) study

Study setting: The present study was conducted in and around Erode district, Tamil Nadu.

Study participants: 60 couples having children aged between 2 and 18 diagnosed with ID based on Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM5) criteria formed the sample of this study. The schools meant for children with intellectual disability were chosen. Within a school, parents of children were chosen randomly. These schools are from Erode in Tamil Nadu.

Method:

Case study schedule: Case Study Schedule was used to get the needed information about the selected Parents of Mentally Challenged. Data was collected regarding the age, educational qualification, income, family type of parents, and number of children they have and level of retardation of the mentally challenged. It also assesses the negative emotions and symptoms of the parents of mentally challenged.

Stress inventory: The questionnaire was standardized questionnaire. It consists of 30 items, under 4 parts namely, Physiological, Emotional, Cognitive and Behavioral. There are two possible responses to each item namely, 'Yes' or 'No'. The mothers were asked to tick any one, which applied to them the most. There was no time limit. But the mothers were asked to respond as quickly as possible. Scoring Key and Norms were provided by the authors. The validity of S.I. is 0.80 and the reliability by test retest method is 0.95.[8]

WHOQOL BREF: The WHOQOL BREF questionnaire is used to assess the quality of life.[9] Prior permission was obtained to use the Tamil version of the questionnaire. The WHOQOLBREF is an abbreviated version of the original WHOQOL- 100. The WHOQOL is the only quality of life instrument that has been developed for wide range of cultures in 15 international field centers simultaneously including the Madras center presently Chennai, Tamil Nadu, India.

Data analysis: Data was analyzed using SPSS version 7.5. The results were expressed in terms of percentage, mean and SD. Students T test, Chi square test, were applied to compare the mean scores of different variables under the four domains. Karl Pearson correlation coefficient used to study the correlation between parent stress score and quality of life. A probability value of <0.05 is considered significant.

Results

Study results were presented in table no 1 to 5. There is a moderate negative correlation between fathers stress score and QOL score. It means stress decreases their QOL increases. There is a moderate negative correlation between mothers stress score and QOL score. It means stress decreases their QOL increases. Younger fathers are having less stress and better QOL than others. Mother who generates more income are having less stress better QOL than others. The results of the analysis of these data demonstrate that the families with a member with a disability report significantly greater stress, they also demonstrated that as stress increases the quality of life decreases. Governments need to address this problem if current policies of integrating people with intellectual disabilities into the community are to be successful.

Discussion

The present study was undertaken to Compare Parenting stress and Quality of life among mothers and fathers of Intellectual disability children in Erode, Tamil Nadu. There is a moderate negative correlation between fathers stress score and QOL score. It means stress decreases their QOL increases. There is a moderate negative correlation between mothers stress score and QOL score. It means stress decreases their QOL increases. Younger fathers are having less stress and better QOL than others. Mother who generates more income are having less stress better QOL than others. The results of the analysis of these data demonstrate that the families with a member with a disability report significantly greater stress, they also demonstrated that as stress increases the quality of life decreases.[9] Governments need to address this problem if current policies of integrating people with intellectual disabilities into the community are to be successful. Special measures like early diagnosis, prompt treatment and counseling for stress of the parents along with provision of need based rehabilitation services for the Intellectual disability children at different levels to reduce the stress burden of their parents.[10] There is a great need to identify at an early stage which parents are at poor mental health and facing psychological problems, so that successfully targeted those parents to modify their thinking style and living patterns Psycho-social intervention programmes for family caregivers of children with Intellectual disability should incorporate building upon specific strategies to enhance their quality of life. Parents of children with disability face multiple challenges due to their child's developmental difficulties.[11-12] Parents who adopt positive and problem-focused strategies report less stress and better well-being than those who often use emotion-focused coping strategies, which are ineffective and do not resolve the adverse situation that provokes the stress.

Conclusion

Very high level of stress was observed in mothers and high levels of stress was observed in fathers. Quality of life was more or less same in both mothers and fathers. There is a moderate negative correlation between fathers stress score and QOL score. It means stress decreases their QOL increases. There is a moderate negative correlation between mothers stress score and QOL score. It means stress decreases their QOL increases. The study recommends further multi center studies for better understanding and to plan adequate interventions.

Effectiveness of Mindfulness Life Intervention on Depression among Elderly Persons in a Selected Old Age Home of Pune City

Chhaya Misal[1], Sheela Upendra[2], Sheetal Barde[3]

[1]II year M.Sc (N), Symbiosis College of Nursing, [2]Associate Professor, HoD Mental Health Nursing, [3]Assistant Professor, Symbiosis College of Nursing, Symbiosis International (Deemed University) Pune, Senapati Bapat Road, Pune

Abstract

Background- Sadness, feeling down, having a loss of interest or pleasure in daily activities - these are symptoms familiar to all of us. But, if they persist and affect our life substantially, it may be depression**.** Studies on the elderly population, either in the community, inpatient, outpatient and old age homes have shown that depression is the commonest mental illness in elderly subjects. Prevalence rate of major depression in India amongst the elderly was 31.2 per 1000. **Objectives-** 1) To determine the level of depression among elderly persons at selected old age home in Pune. 2) To determine the level of depression post intervention among elderly persons at selected old age home in Pune city. 3) To evaluate the effectiveness of mindfulness life intervention on the level of depression among elderly persons at selected old age home of Pune city. 4) To find the association between post-test depression level and selected demographic variables. **Methodology-** A descriptive and a pre-experimental one group pre-test and post-test research design was adopted for this study. A non-probability purposive sampling technique was used to fetch a sample of 60. A modified geriatric depression scale (short form) was used to identify the depression in elderly persons of old age home. The reliability of Modified geriatric depression scale was found to be 0.92 by using Pearson's co-relation coefficient test. **Results-** out of 60 subjects, in pre-test, majority of 96.7% of the elderly persons from old age home had depression and 3.3% of them were normal. In post-test majority of 78.3% of the elderly persons from old age home had depression and 21.7% of them were normal. Average depression score in pre-test was 8.7 which reduced to 5.6 in post-test. T-value for this test was 10.6 with 59 degrees of freedom. Corresponding p-value was 0.000 which is small (less than 0.05). This indicates that depression of the elderly persons reduced remarkably after using mindfulness life intervention. **Conclusion-** This study concludes that mindfulness life interventions are effective in reducing depression of the elderly persons.

Keywords: *Effectiveness, mindfulness, depression, elderly person, old age home.*

Introduction or background

Depression (major depressive disorder) is a common and serious medical illness that negatively affects how you feel, the way you think and how you act. Fortunately, it is also treatable. It can lead to a variety of emotional and physical problems and can decrease a person's ability to function at work and at home.[1] Mindfulness is the psychological process of bringing one's attention to experience occurring in the present moment, which can be developed through the practice of meditation and other training. Mindfulness focus on becoming aware of all incoming thoughts and feelings and accepting them, but not attaching or reacting to them. [2] The mindfulness therapy was developed to help individuals who struggle with recurrent episodes of depression. Nandi studied psychiatric morbidity of the elderly population of a rural community in West Bengal. In a sample of 183 subjects (male 85, female 98) they found 60% of the population to be mentally ill with higher morbidity in women compared to men (77.6% and 42.4% respectively).[3]There was significantly more morbidity in population. 2 Studies on the elderly population, either in the community, inpatient, outpatient and old age homes have shown that depression is the commonest mental illness in elderly

subjects. Prevalence rate of major depression in India amongst the elderly was 31.2 per 1000.[4]

Material and Method

A descriptive and Pre-experimental research design was selected for this study. Under the pre-experimental research design one group pre-test and post-test design was adopted. Further, nonprobability purposive sampling technique was used to grab a sample of 60. The participant of this study comprised of elderly persons of Mamata Old Age Home, Pune. On day one of the study, a modified Geriatric Depression Scale was used to assess the depression in the elderly persons. Mindfulness life intervention steps taught and demonstrated to the experimental group. Post-test was conducted four weeks following the intervention using the same modified Geriatric Depression Scale. The collected data were analyzed, organized and presented. **Findings- The** analysis and interpretation of the data collected to determine the Effectiveness of mindfulness life intervention is carried out based on objectives set by the researcher taking the level of significance as 0.05. Researcher applied paired t-test for the effect of mindfulness life intervention on the depression among old age people.

Discussion

Alexander, Langer, Newman, Chandler & Davies compared no treatment to transcendental meditation, mindfulness training and relaxation in terms of their effects on longevity of human life and age related declines amongst 73 residents of nursing home. It was found that transcendental meditation group improved most followed by mindfulness training in contrast to relaxation and no treatment groups on cognitive flexibility, mental health, systolic blood pressure and behavioral flexibility.[5]

In study one group pretest post-test was done. A group of sixty elderly persons of old age home was considered as experimental group. It was found that mindfulness life intervention is effective in decreasing depression level of elderly persons.

Conclusion

This study concludes that mindfulness life interventions are effective in reducing depression of the elderly persons.

Interrater and Intra-rater Reliability of the Ball Speed Radar Gun Application to Measure Balling Speed in Cricket Ballers

Chinmoyee Panigrahy[1], Ujwal Yeole[2], Sakina Shaikh[3], Mittal Baish[3]

[1]Assistant Professor, [2]Associate Professor, MPT Dept. of Physiotherapy, [3]Intern, Dept. of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune

Abstract

Background: Balling in cricket is an action of propelling the ball towards the wickets defended by a batter and has always been given a special attention. The tools that measure balling speed are not easily accessible and are expensive and the accessible ones are not reliable. The aim of our study is to establish the Interrater and Intrarater reliability of one such application available on google play, the ball speed Radar gun.

Method: In our study we approached various cricket clubs and cricket set up in and around Pune out of which 30 players were selected based on inclusion and exclusion criteria. The balling speed was recorded by the Ball speed radar gun Application and Data was Collected whose Baseline data values in terms of Age in years (22.66±2.70), BMI in kg/m^2(23.12±2.98), Hours of practice in hours(4.12±1.31) and Years of Experience (2.93±0.91) are comparable at P=0.05 and analysed for Interrater and Intrarater reliability.

Result: In our study we established good Intrarater (k=0.988) and Interrater (k= 0.980) reliability at P=0.05 for the application.

Conculsion: From our study we conclude that Ball speed radar gun application is reliable to measure bowling speed.

Keywords: *Ball Speed Radar Gun, Balling Speed, Cricket.*

Introduction

Cricket is widely played throughout this country, yet there is little research done on the varied aspects of the sport. Cricket as a sport received considerable research attention which seems to have coincided with an increase in the worldwide audience for cricket. It consists of two team of 11 players, played by hitting the ball across the boundary and running between two sets called wicket. (1)

Balling in cricket is an action of propelling the ball towards the wickets defended by a batter and it is distinguished as throwing the ball by an angle in terms of action. Ballers are always given a special attention compare to their peers and according to speed of balling they deliver ballers are classified into Fast Bowlers are described as balling at a speed of 142+ kmph and medium fast bowlers are described as balling at a speed of above 96 kmph. The relationship between speed and techniques has received some attention with studies analysing techniques of balling unit but to evaluate and asses the players on the regular basis balling has to be assessed as an outcome measure. (2) (3)

For regular assessment and evaluation of the athlete's performance the balling speed needs to be assessed. Some of the techniques used includes, **The HAWKEYE** which is considered to be a gold standard in cricket. The basic idea is to monitor the trajectory of the cricket ball during the entire duration of play using 6 cameras to get the speed of the ball, It then calculates the data to track the ball path after the ball leaves the hand of the bowler until the ball stops, but due to its expensive setup and accessibility limited to elite players playing at level of National and International level and also decreased accuracy with factor as Wind, Bright

Tilak Maharashtra Vidyapeeth, Pune-4110372
Email: lituj5@gmail.com

sunlight, shadow, artificial floodlights, etc. possess a drawback. [4] **Snick-o-meter** consists of a sensitive microphone located in one of the stumps, which can pick up the sound when the ball hits the bat. It was invented by the scientist Allan Plaskett but the drawback is its reduced accuracy as it may record other sounds such as the ball hitting to batsman's pads or the bat hitting the pitch. [5] **Spider cam** is a film camera which move both vertically and horizontally over a pitch. These operates with 4 monitor winches, positioned at each corner at the base of cover area it requires expensive set up to record the balling speed. [6] **Ball spin RPM/ Rev Counter** is able to show a revolution per minutes (RPM) counter, showing how fast the ball is spinning after release. [7] **Speed Gun** is used to measure the speed of the ball from one end of the pitch to other. This technology allows calculating the speed gun gets mounted on a pole positioned next to the sight screen. The device relays a beam from the radar head to detect movement of across the entire length of the pitch, but as suggested most of these methods are expensive and there is always a time to time requirement of assessing the balling speed to evaluate the improvement in a performance of the athlete at a lower level, for the same there should always be a handy tool available which is inexpensive, easily accessible and reliable at the same time and one such tool is Ball speed radar gun application. [8] It is available for free at google play store. Measuring the velocity of the ball through Radar gun technology was developed in 1947 by John Baker, It works on the principle of Doppler Effect. It catches the echo of radio waves as ball travels through the air and uses a principle called doppler shift and classifies the ball between others object on the pitch and displays the speed of the ball. The radar gun reported ball speed to the nearest mph and the error in ball speed arising from misalignment of the radar gun was calculated to be less than 0.1 m/s. [9] [10] [11]But with an easily accessible method its reliability is also equally important leading to the aim of our study which is to establish the interrater and intrarater reliability of ball speed radar gun application.

Method

Study setting was sports clubs in and around Pune. Total number of 30 cricket players were selected between age group 18-30 years of both genders with more than 1 year of experience randomly. Permission was taken from the institutional ethical committee of Tilak Maharashtra Vidyapeeth department of physiotherapy and different centres were approached. Subjects were approached for data collection from cricket sport clubs in & around Pune city, India. The aims and methods of the study were explained and their written consent was taken, out of which 30 participants were selected randomly following the exclusion and inclusion criteria. The therapists used Tripod for stationary video recording of baller balling and distance from the pitch was kept at 50m. For intrarater reliability 30 players were assessed for balling speed on day 1 and were assessed again after a week by the same therapist, for interrarter reliability 15 players were assessed by therapist no.1, and assessed again by therapist no. 2 at a span of 1 week. A pilot study was conducted and errors were resolved.

Data management and Statistical Analysis:

The data was statistically analyzed using Excel sheet and medcalc and Tables and graphs were made using Microsoft word. The central tendencies were calculated for baseline demographic data for of Age (22.66±2.70), BMI (23.12±2.98), Hours of practice (4.12±1.31) and Years of Experience (2.93±0.91) which was found to be comparable at P=0.05.

To establish Interrater and Intrarater Reliability Cohen's kappa index for reliability was used within confidence interval of 95%.

Results

TABLE NO.1 shows the Average value of Age (22.66±2.70), BMI (23.12±2.98), and Hours of practice (4.12±1.31) and Years of Experience (2.93±0.91) comparable at 0. 05.

Table 1. BASELINE DATA OF THE SUBJECTS COMPARABLE AT P=0.05

VARIABLES	MEAN±SD
AGE	22.66±2.70
BMI	23.12±2.98
HOURS OF PRACTICE	4.12±1.31
YEARS OF EXPERIENCE	2.93±0.91

In our study, this application showed good inter-rater reliability (K=0.980) and intra-rater reliability (K=0.988) at P=0.05. (TABLE NO. 2, GRAPH 1 AND 2)

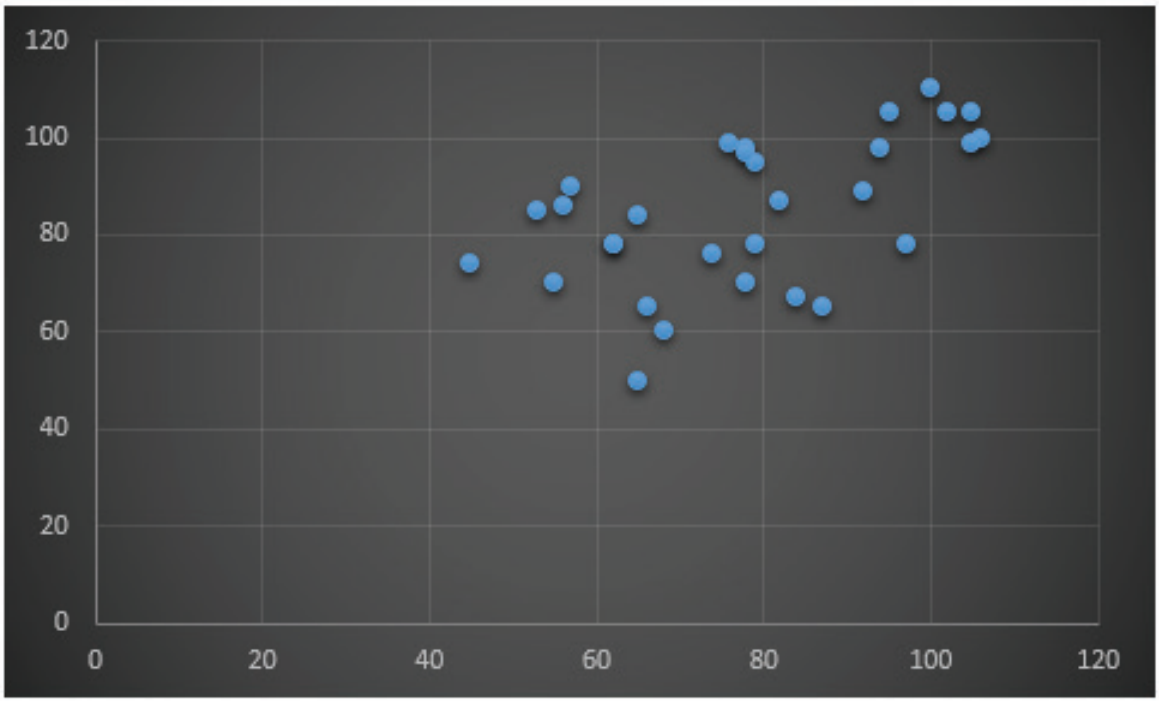

Figure 1: INTRARATER RELIABILITY OF BALL SPEED RADAR GUN AT A SPAN OF 7 DAYS FOR P=0.05, K=0.988

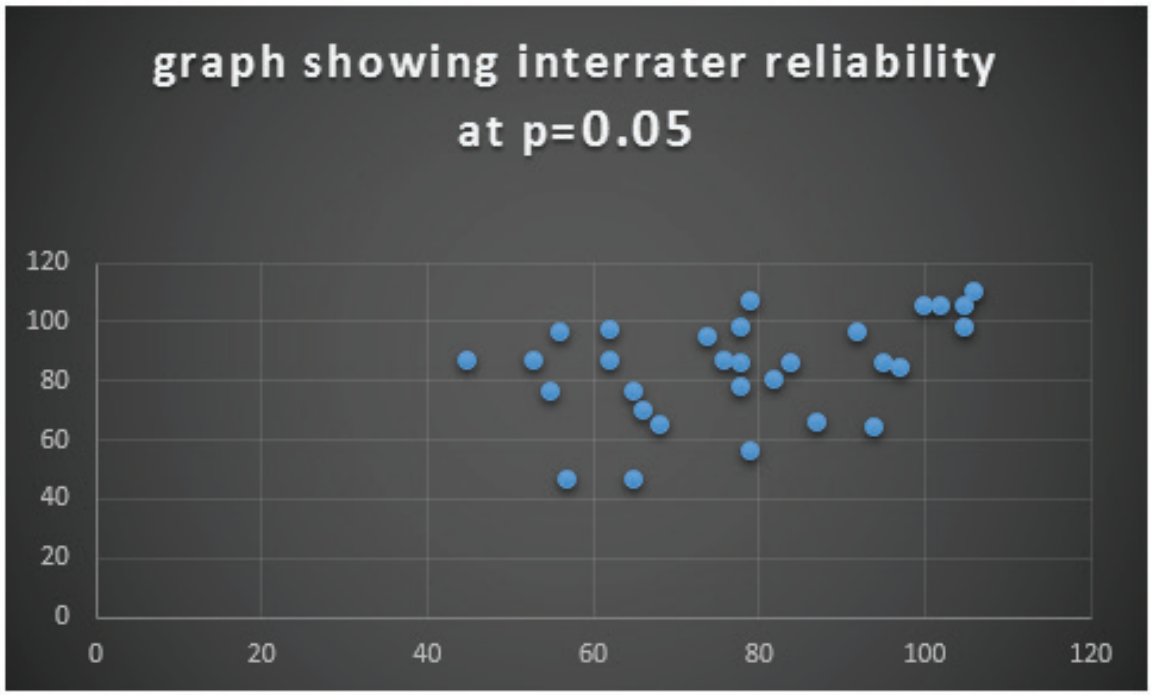

Figure 2 INTERRATER RELIABILITY OF BALL SPEED RADAR GUN AT A SPAN OF 7 DAYS FOR P=0.05, K=0.98

Table 2: TABLE SHOWING INTERATER AND INTRARATER RELIABILITY OF BALL SPEED RADAR GUN AT A SPAN OF 7 DAYS FOR P=0.05

INTERRATER RELIABLITY	K=0.980
INTRARATER RELIABILTY	K=0.988

Discussion

Reliability in psychometrics is the overall consistency of a measurement [12] [13]repeated over span of time. Various kinds of reliability coefficients, with values ranging between 0.00 (much error) and 1.00 (no error), are usually used to indicate the amount of error in the scores. [14] Reliability does not imply validity, that is measure is said to be reliable if it shows consistency used over a period of time. [15] Test-retest reliability is a measure of reliability obtained by administering the same test twice over a period of time to a group of individuals. The scores from time 1 and time 2 can then be correlated in order to evaluate the test for stability over time. [16] The time span in our study was kept at one week as, if the time interval is kept too long the therapist may forget how to perform a test or if the time span is kept too low, a carryover effect may occur, which would lead to a study bias. [17]

The Ball Speed radar gun Application detects the colour of the cricket ball to analyse the ball speed. The working of the APPLICATION is as follows:

Make sure camera is steady and not shaking/ moving while recording:

1. Play the video using open video button

2. Pause when ball is just released out of hand (in the air)

3. Click the "find speed" button and see the values detected

4. The camera is calibrated properly before measuring the speed for every baller.

5. The appropriate ball color is selected, else the app will not be able to track.

To Measure the bowling speed a phone is sufficient with the APP installed unlike the intricate machinery's also it can be assessed at the therapist's own comfort. This APP is can also measure the speed of a moving object and along with speed it also gives a complete analysis of bowling/pitching/serving/smashing action.

Camera calibration method

Point the camera at a player standing at the pitch or base where you want to measure the speed. Freeze the previous frame pause align / drag the two-red line to head and feet of the player standing at the pitch and enter the player's correct height. This way the application understands the pixel distance on phone screen vs the real players height. Then the application calculates you're the instantaneous speed (not average).

As explained earlier this application works on the principle of Doppler Effect that catches the echo. [9]This application can measure the instantaneous speed of a ball object using your phone camera and then the application calculates the instantaneous speed. [4]The possible bias that can be created in our text are the Researcher's lack of knowledge about the application use, Camera not being stationary , poor camera Quality, change in the Distance of the camera from rater to rater, within the rater or amongst the raters. To resolve these sources of error we did a pilot study. We found out that this application shows good inter-rater reliability (K=0.980) and Intra-rater reliability (K=0.988) at P=0.05.

The relationship between speed and techniques have received some attention with studies analysing techniques of balling unit but to evaluate and asses the players on the regular basis balling speed has to be assessed as an outcome measure. [2]There are many factors that affect bowling speed such as aerodynamics and techniques of swing used. [3; 18] [19]For regular assessment and evaluation of the athlete's performance of balling speed needs to be assessed. A timely evaluation of performance is not only helpful in understanding the athlete's game but also keeps the interest of the player in the game, hence this APP can be helpful in the lower levels to provide with a good performance review.

Conclusion

From our study we conclude that the Ball speed radar gun application which is available at the google play app store for free to assess balling speed is a reliable tool.

Effect of Yogic Practices with Sattvic Diet on Selected Bio Chemical Variable among Yogic Men Competitors

D. Chochalingam[1], P. Kaleeswaran[2]

[1] Research Scholar, [2]Assistant Professor, Alagappa University College of Physical Education,, Alagappa University, Karaikudi, Tamilnadu, India

Abstract

The purpose of the present study was to investigate the effect of yogic practices with sattvic diet on selected bio chemical variable among yogic men competitors. To achieve the purpose of the study thirty yogic men competitors were selected from Karaikudi, Tamilnadu, India during the year 2019. The subject's age ranges from 14 to 21 years. The selected subjects were divided into two equal groups consists of 15 men each namely experimental group and control group. The experimental group underwent yogic practices with sattvic diet programme for six weeks. The control group was not taking part in any training during the course of the study. High density lipoprotein was taken as criterion variable in this study. The selected subjects were tested on high density lipoprotein was measured through heparin precipitation method. Pre-test was taken before the training period and post- test was measured immediately after the six week training period. Statistical technique 't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference is found due to yogic practices with sattvic diet given to the experimental group on high density lipoprotein when compared to control group.

Keywords: *yogic practices, sattvic diet, high density lipoprotein and't' ratio.*

Introduction

Yoga is a great soul of the Universe. It can promote the social well being through limps of yoga (Asanas, Pranayama, Kriyas, Mudras and Meditations). To practising yoga regularly it can make you into sound body and sound mind. Yoga is the costless permanents treatment for more diseases, alaguraja, k.[1.] It is a practical holistic philosophy designed to bring about profound state as well is an integral subject, which takes into Consideration man as a whole, alaguraja, k. et.al., [2] One can start practicing Yoga at any given moment of time and you may start with meditation or directly with pranayama without even doing the asanas (postures), alaguraja, k. et.al,[3.] The science of Yoga Nidra is based on the receptivity of consciousness.

When consciousness is operating with the intellect and with all the senses, by making an individual think that he or she is awake and aware, but the mind is actually less receptive and more critical, yoga, p. et. al[4]. Training is a chain process that can be able to attain certain needs of the person's goal, alaguraja, k[5]. In the sports world, physical education is the most essential aspect due to the fact physical schooling increases the performance and the effectiveness of the sports, alaguraja, k. et.al.,[6] Today, sports have become a part and parcel of our culture. It is being influenced and does influence all our social institutions including education, economics, arts, politics, law, mass communication and even international diplomacy, alaguraja, k. et.al,[7]. The sports training can produce some physical fitness, Physiological and psychological benefits to the person and attain performance related task. It's also promoting the individual overall wealth to the sports person, alaguraja, k[8]. Yoga is a methodical effort towards self-perfection by the development of the potentialities latent in the individual, alaguraja, k. et.al, 2019 [9]. Today's there is an escalating emphasis on appearing smarter, feeling etter and living longer. In order to achieve these ideals as, scientific evidence tells us that one of the keys is high fitness and exercises, alaguraja, k. et.al,[10]. Asanas is a limp of Yoga practice it can make some health related gains to the individual who involved in yogasana practice regularly. Asanas can be used upon the needs

of the person. It's a scientific process the person must be follow the basic principles yogasana practice, alaguraja, k.[11]. Yoga is a practical aid, not a religion and its techniques may be practiced by Buddhist, Jews, Christians, Muslims, Hindus and Atheist alike. Yoga is union for all, selvakumar, k. et.al,[12]. Yogic action, or inner technique, such as breath control, parthasarathy., s. et.al,[13].

Research Methodology

Selection of subjects

The purpose of the study was to find out the effect of yogic practices with sattvic diet on selected bio chemical variable among yogic men competitors. To achieve this purpose of the study, thirty yogic men competitors were selected as subjects at random. The age of the subjects were ranged from 14 to 21 years.

Selection of variable

Independent variable

- Yogic practices with sattvic diet
- Dependent variable
- High Density Lipoprotein (HDL)

Experimental Design and Implementation

The selected subjects were divided into two equal groups of fifteen subjects each, such as yogic practices with sattvic diet group (Experimental Group) and control group. The experimental group underwent yogic practices for five days per week for six weeks. Control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following bio chemical variable namely high density lipoprotein was selected as criterion variable. All the subjects of two groups were tested on selected criterion variable high density lipoprotein was measured through heparin precipitation method at prior to and immediately after the training programme.

Statistical technique

The't' test was used to analysis the significant differences, if any, difference between the groups respectively.

Level of significance

The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

Analysis of the Data

The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent 't' test was used with 0.05 levels as confidence.

Table I: Analysis of t-ratio for the pre and post tests of experimental and control group on High density lipoprotein (Scores in mg/dl)

Variables	Group	Mean		df	't' ratio
		Pre	Post		
High density lipoprotein	Control Group	46.55	46.54	14	0.45
	Experimental Group	46.58	46.85		17.83*

**Significance at 0.05 level of confidence.*

The Table-I shows that the mean values of pre-test and post-test of the control group on high density lipoprotein were 46.55 and 46.54 respectively. The obtained 't' ratio was 0.45, since the obtained 't' ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of the experimental group on high density lipoprotein were 46.58 and 46.85 respectively. The obtained 't' ratio was 17.83* since the obtained 't' ratio was greater than the required table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant.

Result of the Study

The result of the study showed that there was a significant difference between control group and experimental group in high density lipoprotein. It may be concluded from the result of the study that experimental group improved in high density lipoprotein due to six weeks of yogic practices with sattvic diet.

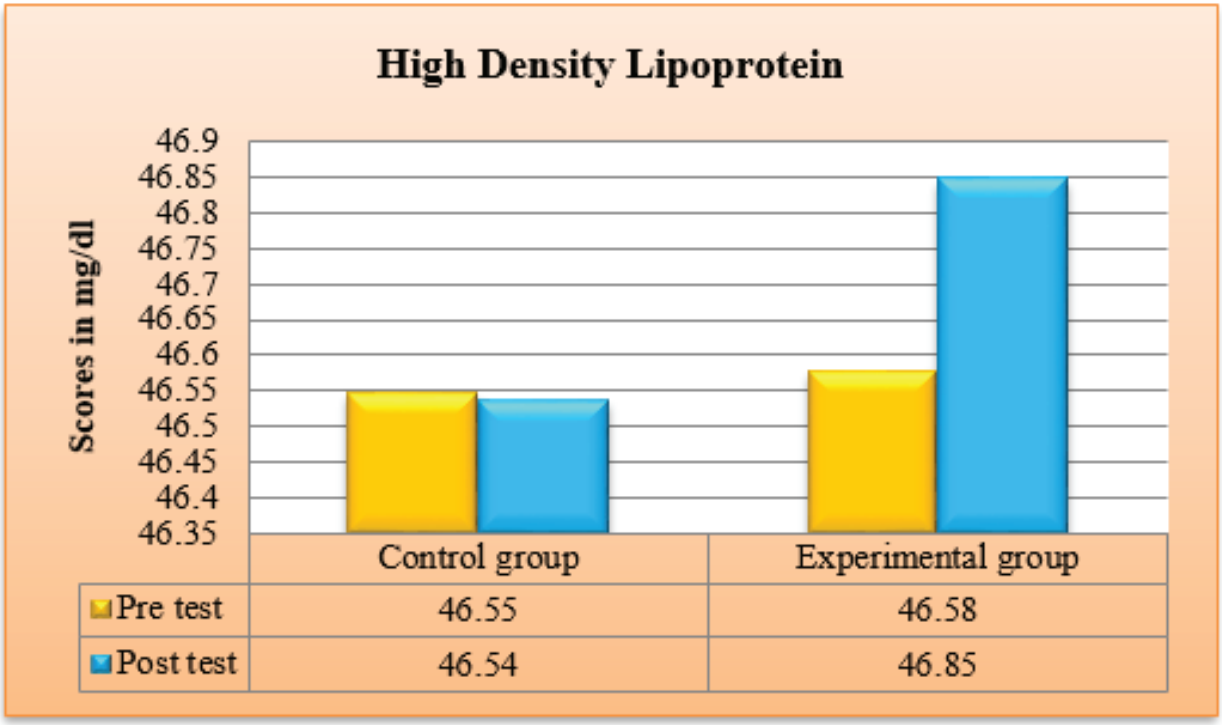

Figure-1: Bar Diagram Showing the Pre and Post Mean Values of Experimental and Control Group on High density lipoprotein

Discussions on Findings

The result of the study indicates that the experimental group, namely yogic practices with sattvic diet group had significantly improved the selected dependent variable, namely high density lipoprotein, when compared to the control group. It is also found that the improvement caused by yogic practices with sattvic diet when compared to the control group.

Conclusion

On the basis of the results obtained the following conclusions are drawn,

1. There was a significant difference between experimental and control group on high density lipoprotein after the training period.

2. There was a significant improvement in high density lipoprotein. However the improvement was in favor of experimental group due to six weeks of yogic practices with sattvic diet.

A Comparative Study on General Health of Adolescents

E. Manila Arouza Pai[1], R. Neelakandan[2], Ramaa Raju[3], M. Muthuraj[4]

[1]Research Scholar, [2]Assistant Professor, Department of Psychology, Annamalai University, TN, Associate Professor, Department of Psychology, Jyothi Nivas College, Bangalore, [4]Assistant Professor, Department of Physical Education, Annamalai University

Abstract

The purpose of the study was to analyse a comparative study on general health of adolescents. For the purpose of the study one hundred and twenty CBSE school students were selected as subjects (*sixty male and sixty female students*). The subjects' age ranged between eleven to twelve years. The general health selected as variable to compare the students. The collected data were analysed by the comparative T test to find out the difference between the male and female school students on general health. The result showed that there was a significant difference between male and female students on general health.

Key Words: *General Health, male, female and CBSE School Students.*

Introduction

The education which is associated with fitness is also called health training. Health training is a career of educating people about fitness.1 Areas within this profession encompass environmental fitness, physical health, social health, emotional health, highbrow fitness, and non secular fitness, as well as sexual and reproductive fitness schooling.2 Nutrition and exercising can appear enormously unimportant while younger, however building a regimen of wholesome behaviours at some stage in this time can serve us well within the long time. Work to keep away from the following problems many college students face as they stability coursework with other commitments and obligations. When students make time to have a look at and socialize, they lose sleep. Pulling "all-nighters," or staying up too overdue, takes its toll, leaving you with low levels of electricity and motivation.

Fast meals and comparable eating alternatives seem like time and money savers, adding too lots of those food to our food plan robs us of nutrients important to hold bodily robust and mentally alert. Throughout your academic career, tension will probable get up from assignments, assessments, and other necessities. With the addition of a difficult work schedule and different duties, the strain may additionally reach exceptional heights in scholar's existence.

Mental health additionally represents major situation for college students. Issues ranging from depression and anxiety to eating issues and dependancy can affect college students' lives in large and harmful approaches. Fortunately, colleges and universities provide a bunch of assist and related services; extra resources can be observed via country and neighbourhood places of work and independent corporations in our community. Physical fitness entails taking care of our body and ensuring it really works as intended.

Maintaining bodily health includes primary areas of awareness getting enough workouts and practicing top sleep behaviour. Look beneath to don't forget both the advantages of those sports and the resources available to assist the scholars.

Methodology

The purpose of the study was to analyse a comparative study on general health of adolescents. For

the purpose of the study one hundred and twenty CBSE school students were selected as subjects (*sixty male and sixty female students*). The subjects' age ranged between eleven to twelve years. The general health selected as variable to compare the students. The general health was assessed through the General Health Questionnaire developed by Goldberg (1988), it consist of 12 items, each assess the severity of the mental problem with using 4 point scale, score from 0 to 3, higher score indicate the worse condition of the health. The collected data were analysed by the comparative T test to find out the difference between the male and female school students on general health.

Results

General Health

The data collected from and female school students on general health were statistically analysed by comparative't' test and the results are presented in Table-1.

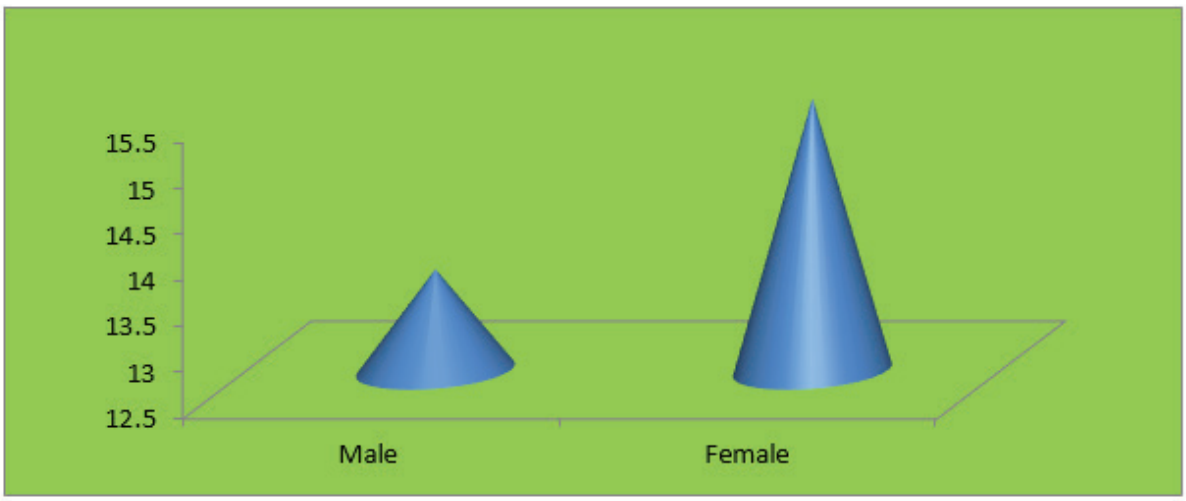
Table – 1 : Analysis of 't' test on general health of male and female school students

Group	N	Mean	SD	DM	't' - ratio
Male	60	13.60	1.23	1.86	7.83*
Female	60	15.46	1.35		

* Required table value for significance at 0.05 level of confidence for df of 59 is 2.00

Table – 1 gives the suggest and widespread deviation values on general health thirteen.60 + 1.23 and 15.forty six + 1.35 for male and woman college students respectively. Since the received 't' fee of 7.eighty three on fashionable health changed into higher than the specified desk cost of 2.00 for great stage zero.05 with 59 stages of freedom. It concluded that, there is sizeable degree of distinction on popular fitness between male and lady college students. Cone diagram for the male and female school students on general health.

Cone diagram for the male and female school students on general health



Discussion

The end result of the have a look at said that the there's giant level of distinction on fashionable fitness among male and female (adolescents) school students. Moreover the male adolescents are having higher trendy health conditions than the girl youngsters on the faculty stage. The following researches are helping this result. 3Astudy mentioned how college nurses promote intellectual fitness and subsequent educational success with the aid of screening and referral for children demonstrating mental fitness issues. They concluded that mental health problems can have an effect on school performance and academic fulfilment. 4A study attempted to difficult the relationship between instructional fulfilment and mental health of kids. Results without a doubt indicated that there's a quite vast relation

among educational fulfilment and positive dimensions of intellectual health namely standard adjustment and intelligence for the pattern as a whole.Conclusion

The conclusion of the study known that the there is significant level of difference on general health between male and female (adolescents) school students. Moreover the male adolescents are having better general health conditions than the female adolescents at the school level.

Ethical Clearance – Not required because, data collected through questionnaire.

An Epidemiological Study of Sputum Positive TB Patients & Burden of Tuberculosis amongst their Contacts in East District of Sikkim

Forhad Akhtar Zaman[1], Vijay Kumar Mehta[2], Shraddha Deokota[3]

[1]Professor, Department of Community Medicine, [2]Dean, [3]Assistant Professor, Sikkim Manipal Institute of Medical Sciences, 5th Mile, Tadong, Gangtok, Sikkim

Abstract

Background- Tuberculosis (TB) is a major public health problem all over the world and more so in India as it reports the highest burden of TB (both Drug sensitive and Drug resistant TB) globally. The magnitude of TB in Sikkim is enormous as is evident by the number of cases being reported (275 per 100,000 population) which is higher than the national average. It is a known fact that one single active case of TB can infect about 10 to 15 persons in a year. Early identification of the contacts ensures a better chance at cure and also helps to reduce the transmission.

Materials and Method - It was a cross sectional study conducted among all the Sputum Positive cases of Tuberculosis and their household contacts in East District of Sikkim that were registered with RNTCP for the first and second quarters of the year 2017.

Results- A total of 55 sputum positive cases of Tuberculosis and 196 household contacts were included in the study. Nearly 60% of the index cases reported having cough for more than two weeks along with fever in the beginning of their illness. On assessment of the past medical history of the contacts, it was observed that 8 (4.08%) had a history of TB in past. Almost a quarter of the contacts spent all their time in the same room as the index cases, another quarter spent only night time in the same room while about 61(30%) spend only daytime in the same room as index cases. Among the contacts, 5 were referred for sputum microscopy out of which 1 was found to be positive and 1 was negative. The remaining 3 didn't get themselves tested.

Conclusions- With the burden of TB being highest in India and having a goal to end TB by 2025, a more active approach to diagnose TB among contacts is the need of the hour which can led to early treatment and cut down transmission among the contacts.

Key words- *sputum positive cases of Tuberculosis, Contacts*

Introduction

Tuberculosis (TB) is a major public health problem all over the world and more so in India as it reports the highest burden of TB (both Drug sensitive and Drug resistant TB) globally. In 2017, the estimated number of cases in India was reported to be 2.74 million accounting for about 27% of cases in the world.[1] While TB is both curable and preventable; it is still among the ten leading cause of death in the world accounting for 1.6 million deaths in 2017.[2]

The magnitude of TB in Sikkim is enormous as is evident by the number of cases being reported (275 per 100,000 population) which is higher than the national average of 247 per 100,000 population. In 2016, total number of cases that were notified from Sikkim was

1539. Sikkim also reports a high number of MDR TB cases. [3]

TB is transmitted from person to person via droplet infection. It is a known fact that one single active case of TB can infect about 10 to 15 persons in a year. Therefore, the longer a case goes undetected, the more number of people they may infect.[4] Countries that have a high burden of TB report high prevalence of TB in contacts, particularly household members. Effective investigation and screening of such close contacts of TB cases will lead to early identification of a significant number of cases who can then be put on treatment. Early identification ensures a better chance at cure and also helps to reduce the transmission.[5] Many high income countries already have screening programmes for detection of TB in close contacts, however such a mechanism is often seen missing in the countries with highest TB burden.[5] Given the large burden of disease in the state of Sikkim, it is important to assess the burden of disease in the close contacts of an active TB case.

Aims and Objectives

The objective of this study was to assess the epidemiology of Sputum positive TB patients & the burden of Tuberculosis infection amongst their close contacts in the East district of Sikkim.

Materials and Method

It was a cross sectional study conducted among the Sputum Positive cases of Tuberculosis and their household contacts in East District of Sikkim. The study covered all the Sputum Positive cases of Tuberculosis and their close contacts (those sharing same household) that were registered with RNTCP for the first and second quarters of the year 2017. After obtaining the Institutional Ethics Committee clearance and permission from Govt. of Sikkim, the subjects fulfilling the inclusion criteria were first explained about the study in details and written informed consent of the subjects were taken. The study duration was for one year and a pre-designed questionnaire was used to collect information.

Two questionnaires were used: one for the sputum positive patient and another for the contacts. The questionnaire for the patient included information regarding their socio-demographic characteristics, details of household contacts, environmental sanitation, diagnostic and follow up investigations and treatment history. The second questionnaire for contacts collected information on whether they had experienced any symptoms of TB and their medical history. If the contact was found to have any symptom of TB, they were referred to the nearest designated microscopy centre to get their sputum tested and a chest x-ray was also done. The test results and whether or not treatment was started was also noted in the questionnaire. In case of paediatric contact, a history of Isoniazid prophylaxis was also taken.

In children up to 14 years of age, all eligible individuals were subjected to chest x-ray and the individuals showing signs and symptoms were further subjected to microbiological examination. For microbial confirmation, at least one positive sputum smear out of two was taken as a case. If sputum was not available or sputum microscopy failed to detect Acid Fast Bacilli then alternative specimen (like gastric lavage, induced sputum, broncho-alveolar lavage) was collected depending on feasibility and under the supervision of a paediatrician. Chest X-rays (PA view) were read by at least two experienced, independent and blinded readers. In case of discordant findings, the reading by a third expert reader was used.

All contacts regardless of their symptoms were given information on what to do if they developed any symptom.

After checking the questionnaire for completeness, the data was entered into a Microsoft Excel spread sheet and was analysed using SPSS version 20. Data was categorised and is presented in proportions.

ResultS

A total of 55 sputum positive cases of Tuberculosis and 196 household contacts were included in the study. Among the cases 23 (41.8%) were females while 32 (58.2%) were males, with 45.5% of them in the age group of 15 to 25 years.

Table 1: Socio-demographic characteristics of Index TB cases.

Age	**Male**	**Female**	**No (%)**
10-14	1	2	3 (5.45)
15-25	15	10	25 (45.46)
26-35	6	5	11 (20)
36-45	1	0	1 (1.82)
46-55	4	5	9 (16.36)
56-65	2	1	2 (3.64)
66-75	2	0	2 (3.64)
76-85	1	0	1 (1.82)
Religion			
Hindus	16	13	29 (52.73)
Buddhist	8	7	15 (27.73)
Christians	8	3	11 (20)
Educational status			
Graduate	0	1	1 (1.82)
HS	4	4	8 (14.55)
High School	11	6	17 (30.91)

Primary School	6	3	9 (16.36)
Illiterate	3	2	5 (9.09)
Type of family			
Joint	9		9 (16.36)
Nuclear	40		40 (72.73)
Three Generation	6		6 (10.91)
Occupation			
Semi professional	2	2	4 (7.28)
Skilled	5	0	5 (9.09)
Unskilled	6	0	6 (10.91)
Unemployed/housewife	19	21	40 (72.73)

Nearly 60% of the cases reported having cough for more than two weeks along with fever in the beginning of their illness, while about 10% reported having only fever and 30% reported having fever with other symptoms of Tuberculosis. A known history of contact was present in 40% of the cases. Among the cases, 23.6% reported consumption of alcohol and smoking, 12.7% were only smokers and 7.3% used smokeless tobacco while 5.5% took only alcohol. On assessment of housing parameters it was found that nearly 13% of cases lived in a kaccha house while 30% had mixed housing. Majority (81%) had adequate ventilation while more than half (52.7%) had overcrowding in the house. About a quarter of the houses did not have a separate kitchen and indoor air pollution was present in nearly 31% of the houses. The initial approach to diagnosis had been x-ray examination in most of the cases (63.6%) and sputum examination in 36.3%.

Table 2: Distribution of the TB cases as per determinants of the treatment adherence & outcome

Motivation for taking treatment				
Who motivated for taking treatment		Total	%	
Health Worker		6	10.92	
House-hold member		44	80	
Neighbor		2	3.64	
Self		3	5.54	
Sex distribution of the time lag between onset of symptoms and treatment				
Time lag	**Sex**		**Total**	**%**
	Male (%)	**Female (%)**		
Within first 2 weeks	13 (40.63)	14 (60.87)	27	49.09
From 2 weeks to 1 month	9 (28.13)	3 (13.04)	12	21.81
From 1 month to 3 months	8 (25%)	4 (17.39)	12	21.81
More than 3 months	2 (6.25)	2 (8.69)	4	7.27
Sputum result at the end of treatment				
Sputum at the end of treatment		**Total**	**Percentage**	
Positive		0	0	
Negative		12	21.82	
Died		1	1.82	
Not Known		42	76.36	

Out of the total 196 contacts included in the study, 48.5% were male and 51.5% were female. Most (20.9%) of the contacts belonged to the age group of 16 to 25 years followed by 20.4% in the age group 36 to 45 years. Paediatric contacts amounted to 6.1% in 0 to 5 years age, 7.6% between 6 to 10 years and 11.2% in age group 11 to 15 years.

Table 3: TB Symptoms screening among the Household contacts

Symptoms of TB	Number (%)
Cough	3(1.53%)
If Yes, < 2 weeks	1(0.51%)
>2 weeks	2(1.02%)
Blood stained	0
Fever	2 (1.02%)
Noticeable loss of weight (> 3 kg in a month)	0
sweating at night for 3 or more weeks in the last 4 weeks	0
swelling and/or lumps on your neck, arm pits, or groin	0

On assessment of the past medical history of the contacts, it was observed that 8 (4.08%) had a history of TB in past. All of them had been tested for HIV and 1(1.02%) came out positive. Diabetes was reported by 3 (1.53%) contacts and 98 (50%) reported having hypertension. Almost a quarter of the contacts spent all their time in the same room as the index cases, another quarter spent only night time in the same room while about 61(30%) spend only daytime in the same room as index cases. Two contacts shared the bed with the cases and 46(23.5%) slept in the same room but did not share a bed. Most of the contacts 137(69.9%) had been living in the same house as the index cases for more than five years. Among the contacts, 5 qualified for referral after screening and were referred for sputum microscopy out of which 1 was found to be positive and 1 was negative but the remaining 3 didn't get themselves tested. Among the paediatric contacts, none was referred as none was found to be chest symptomatic after screening all of them. Among them, 6 had started Isoniazid preventive therapy (IPT), 4 had completed and 3 were yet to start IPT.

Discussion

The present study identified 55 index cases of Sputum Positive TB & 196 household contacts. Along with sharing the same living space, the burden of care for the sick often falls on the household members. This means prolonged periods of close contact, putting the contacts at potential risk for developing Tuberculosis themselves.

In the present study there more male cases as compared to females with most of them in the age between 15 to 25 years. The findings are similar to studies conducted in other parts of the country except a higher proportion of cases in the age group below 14 years (5.5%). This difference may be due to the higher burden of TB in the state of Sikkim as compared to other parts of the country. [3,6,7] Overcrowding is a known risk factor for spread of respiratory illnesses especially tuberculosis and the present study report that almost half of the cases live in overcrowded houses. [8] Similar findings are reported by Singh et al.[6] Known history of contact with tuberculosis was present in 40% of the cases in the present study meaning that the index cases themselves had been contacts of cases of TB. On screening the contacts for symptoms, the commonest was found to be cough followed by fever, other studies also report similar findings with cough and fever being reported more than other symptoms like night sweats, weight loss or any swelling.[6] Among contacts in this study, 4.1% had TB in the past which is higher than that reported by Singh et al (0.8%), Lee et al (2%) and Nair et al (3.1%), which could be due to the higher burden of TB in the state of Sikkim. [6,7,9] Diabetes was reported in 1.53% of the contacts, similar to Lee et al (1.1%), putting these contacts at a higher risk of developing TB as Diabetes Mellitus triples a person's risk for developing TB.[10]

Sevaraju et al conducted a multi-centric cohort study and identified that contacts with age between 6 to 15 years, who are males and have long exposure to index patient per day had higher risk for TB incidence.[11] Similar report is given by Singh et al that male contacts had higher risk for developing TB.[6] The current study reports that 70% of the contacts have been living in the same house as cases for 5 years, almost half are males and 40% belong to age group 15 to 45 years, putting them at a considerable risk for developing TB.

This study could identify 1(0.5%) contact having sputum smear positive tuberculosis, which is comparable to that reported by Thanh et al (0.4%) and less as compared to other studies like Singh et al (6.8%), Nair et al (4.2%), Gupta et al (1.15%) and Fox et al (3%).[6,7,12,13,14] The difference can be attributed to the difference in the process of identifying and screening the household contacts. Some studies have employed more vigorous methods like offering screening to all contacts (Nair et al), use of a prospective study design was also seen with multiple follow up as in Singh et al and Gupta et al while Thanh et al relied on a self-referral mechanism according to the symptoms of the contacts.

Conclusion

With the burden of TB being high in India and having a goal to end TB by 2025, a more active approach to diagnose TB among contacts is the need of the hour which can led to early diagnosis & treatment and therefore cut down transmission.

Ethical Clearance- Ethical clearance was taken from Institution Ethics Committee (IEC) of Sikkim Manipal Institute of Medical Sciences (SMIMS), Gangtok, Sikkim.

Assessment of Cardiovascular Risk and Knowledge on Risk Factors among a Rural Population in Mangalore, Karnataka

G Shiny Chrism Queen Nesan[1], Rashmi Kundapur[2], G Rakesh Maiya[1]

[1]Assistant Professor, [2]Professor, Department of Community Medicine, Saveetha Medical College and Hospital, Chennai, [2]K. S Hegde Medical Academy, Mangalore

Abstract

Introduction: The major causes of CVD in low and middle income countries includes globalization, rapid unplanned urbanization and increasing sedentary lifestyle. Awareness of CVD and the risk factors of the same are significant in preventing and reducing CVD deaths.

Aims & Objectives: To assess the magnitude of association between the knowledge regarding the risk factors for cardiovascular disease and risk of developing CVD in next 10 years. **Methodology:** A cross sectional study conducted in Rural Mangalore among 230 participants, selected based on simple random sampling. A pre – validated, pre – tested and semi structured questionnaire to observe socio demographic characteristics, WHO/ISH Risk prediction algorithm was used to predict risk of CVD and likert scale was used to assess knowledge. Chi Square test was done to test the significance ($p<0.05$). **Results:** 64.8% had < 10% risk of which, 40.4% were males and 24.3% were females. 5.2% had > 40% risk which is the highest risk score of which 3.9% were males and 1.3% were females. Males (53.9%) had better knowledge on CVRF than females (28.3%). As age increases, knowledge decreases. **Conclusion:** Education was directionally proportional to the knowledge whereas age was inversely proportional to the Knowledge.

Key words: *CVD, Risk factors, Knowledge, Education, WHO/ISH chart*

Introduction

The Cardiovascular Disease is one of the major cause of disability and premature death throughout the world which includes coronary heart disease (CHD), stroke, peripheral vascular disease, congenital heart disease, endocarditis and many other conditions and it contributes to the increasing costs of health care, mortality, and morbidity.[1] The major causes of CVD in low and middle income countries includes globalization, rapid unplanned urbanization and increasing sedentary lives and it was noted that the morbidity due to CVD is 8 times higher compared to mortality.[2] Thus, it can be prevented and it is considered as a major public health importance. CVD risk factors tend to cluster in individuals rather than presenting as isolated risk factors.[3] Hence, rather to concentrate on a single risk factor, accounting the total risk a person carries will be more practical for the prevention of CVD. The WHO-ISH risk prediction chart[4] has been put together to assess various risk factors leading to the cardiovascular event and to predict the 10years risk of developing fatal and non-fatal MI or Stroke. Combining risk factors to assess and predict the total risk of CVD is a logical approach towards funneling the target for treatment. Awareness of CVD and the risk factors of the same are significant in preventing and reducing CVD deaths. Knowledge to make liable the risk factors is an important step in modification towards the lifestyle behaviors and conducive to optimal cardiovascular health in developing countries.[5] Thus, this study overall is done to predict the risk of developing CVD in the next 10 years among a selected population in a rural community and to assess their knowledge regarding the CVD risk factors as the knowledge of the patient's individual risk factors can play a useful role in clinical decision making regarding

Corresponding Author:
Dr G Rakesh Maiya
Assistant Professor, Saveetha Medical College and Hospital, Chennai, Tamil Nadu, India
Mail ID: rakeshmaiyag@gmail.com

the intensity of preventable interventions and in guiding individualized management and control of the factors.[6]

Aims and Objectives

To determine the risk of developing cardiovascular events (fatal and non-fatal MI or Stroke) among the individuals above 40 years of age in next 10 years by using WHO/ISH risk prediction algorithm and to assess the magnitude of association between the knowledge regarding the risk factors for cardiovascular disease and risk of developing CVD among the study population

Methodology

A cross sectional community health survey was conducted in a rural field practice area of Mangalore, Karnataka for 4 months among the individuals above the age of 40 years residing in that village. A previous study conducted in Puducherry, reported that 17% of subjects had moderate to high risk of developing CVD in next 10yrs.[7] With 5% allowable error and using formula $4pq/d^2$ the sample size derived as 225. Totally, 230 study participants were involved in the study using simple random sampling method to select the households for the study. A pre – validated, pre – tested and semi structured questionnaire was prepared to observe socio demographic characteristics and knowledge assessment was done using three points likert scale with options ranging between 'agree', 'disagree' and 'undecided'. WHO/ISH cardiovascular risk prediction algorithm for South East Asian region – Annexure 4[4] was used to predict 10 years' risk of developing MI or stroke. All people above 40 years and permanent residents of Bengre who were willing to participate in the study were included and those who are diagnosed with MI or stroke, mentally unstable and moribund subjects were excluded from the study. This study had obtained the ethical clearance approval from the institutional ethical committee. Written informed consent was obtained from all study participants. The collected information was summarized by using descriptive statistics such as frequencies and percentage. Chi square test was used for association between WHO Risk prediction scores and knowledge of CVD risk factors. P value < 0.05 was considered significant. Data management and analysis was done by using Microsoft excel and SPSS version 22.

Results

Among 230 participants, 64% were males and 36% were females. Majority of the males were in the age group of 40 – 50 years (26.1%) and majority of females were in the age group of 51 – 60 years (15.7%). Most of the study participants belonged to the socio-economic status of Lower middle class (43%), as per Modified B G Prasad socio economic classification scale, proposed in 2018. Among females 5.7% were unskilled workers which mainly involved bidi rolling in their homes itself. 33.5% of the study participants were Hypertensives, 30.4% of them had both Diabetes Mellitus and Hypertension and only 1.7% had Diabetes Mellitus. 27.4% of study participants had a strong family history of Hypertension and 24.8% of both Diabetes Mellitus and Hypertension.

Table 1 shows the listing of individual CVD risk assessment in next 10 years. It was observed that 64.8% had < 10% risk and 5.2% had ≥ 40% risk which is the highest risk score of which 3.9% were males and 1.3% were females. It was noted that the males had more risk of cardiovascular disease in future than females. Considering knowledge on risk factors for CVD among study participants, it was seen that majority of 82.2% of them considered stress as a major risk factor for CVD, followed by high lipid level (66.1%), hereditary (61.3%), smoking (60.9%), high blood pressure (60.4%), physical inactivity (42.6%), high sugar level (40.9%), obesity (38.7%), alcohol consumption (24.3%) and unhealthy diet (17.8%). The assessment was done over top five correct responses only.

On observing the knowledge on cardiovascular risk factors and gender distribution in **Table 2** it was noted that the males had better knowledge on the risk factors than females and these findings were statistically significant as observed in the table. The distribution of age and knowledge on risk factors of CVD in **Table 3**, it was noted that as the age increases the knowledge on risk factors decreased. These findings were significant for the knowledge on Stress, high lipid level, hereditary and smoking. In **Table 4** the socio-economic status and knowledge were compared, it was observed that most the participants from lower middle class families have correctly responded compared to upper middle class families for all risk factors mentioned in above table except Hereditary where upper middle class participants (26.5%) had responded correctly than lower middle class participants (19.6%) and this finding was statistically significant.

Table 5 shows the association between the knowledge on cardiovascular risk factors among the study subjects and the WHO/ISH risk prediction score

for next 10 years. It was observed that when the knowledge on cardiovascular risk factors was poor, the risk level of getting CVD was more. The table shows the significant associations for the knowledge on certain cardiovascular risk factors such as high lipid level, hereditary and high blood pressure. It was seen that 33.3% of participants who disagreed high lipid level was a potential risk factor was causing CVD had > 40% risk level of getting CVD than 4.6% of subjects who agreed to it.

Table 1: Distribution of WHO Risk prediction score in next 10 years (N = 230)

WHO SCORE**	MALES N = 147 N (%)	FEMALES N = 83 N (%)	TOTAL N = 230 N (%)
< 10%	93 (40.4%)	56 (24.3%)	149 (64.8%)
10 – 19.9%	25 (10.9%)	15 (6.5%)	40 (17.4%)
20 – 29.9%	13 (5.7%)	6 (2.6%)	19 (8.3%)
30 – 39.9%	7 (3.0%)	3 (1.3%)	10 (4.3%)
≥40%	9 (3.9%)	3 (1.3%)	12 (5.2%)

** WHO/ISH Risk prediction algorithm

Table 2: Knowledge of cardiovascular risk factors Vs Gender distribution (N = 230)

Risk factors	Knowledge on risk factors						P value#

$ Likelihood ratio ** WHO/ISH Risk prediction algorithm

Discussion

Our study showed that 9.50% had high risk (> 30%) of getting fatal or non-fatal MI or stroke in 10 years. This finding was less when compared to a similar study done by Gift Normal et.al[8] which showed an alarming 15.2% of high risk. Though both the studies have been conducted in Karnataka there is a difference in intensity of high risk, which may be due to the heterogenicity between two study settings based on dietary and working pattern.

In our study, it was observed that an average of 49.52% of participants only have responded correctly for the assessment of knowledge on risk factors asked to them. A similar study conducted by Omar et.al[9] revealed that only 41% of the participants surveyed had good knowledge on the risk factors which was slightly lesser than our finding. This shows that a significant amount of nearly half of our study subjects had poor or inadequate knowledge. A study conducted over American Indians in Arizona, Oklahoma, and South/ North Dakota[10] showed that 70% - 90% of their participants responded correctly for the risk factors analyzed.

In our study, only 40.9% were having knowledge that high sugar level may lead to CVD in future. Our results are consistent with previous study[11] conducted among Indians showed a low level of knowledge on DM. It was observed in our study that as the age increases the knowledge on the risk factors decreases, but it was observed in a study done by Potvin[12] among the Canadian population it was noted that mean knowledge scores progressively increased from the ≤ 30-year age group to >60-year group. This difference the level of knowledge was evident to show that the South Asian countries have a large knowledge gap when compared to the European countries

Conclusion

This study showed majority of the study subjects had <10% chance of getting CVD in next 10 years. The males had better knowledge on the CVD risk factors than the females. Education was directionally proportional to the knowledge whereas age was inversely proportional to the Knowledge.

Acknowlwdgement: We thank all the study subjects for their cooperation in this study.

A Study on Suicide Ideation among Medical Students in Mangalore

G Shiny Chrism Queen Nesan[1], Rashmi Kundapur[2], G Rakesh Maiya[1]

[1]Assistant Professor, Department of Community Medicine, Saveetha Medical College and Hospital, Chennai,
[2]Professor, K. S Hegde Medical Academy, Mangalore

Abstract

Introduction: Suicide is the second most common cause of death among adolescents in industrialized countries and high rates are being reported from India recently. **Objectives:** To determine the prevalence of suicidal ideation among students in a medical college in Mangalore and to associate the same with various socio demographic characteristics. **Materials & Methods:** A cross sectional (health survey) study done using pre-validated, structured and self-administered questionnaire based on Beck's scale of suicidal ideation, elicits questions on demography, life events and suicide ideation. Universal sampling method was followed and Chi Square test was done to test the significance ($p<0.05$). **Results:** Among 415 students, 179(43.1%) were males and 236(56.9%) were females. 3.6% and 8.9% had high and moderate risk of committing suicide respectively. 3.3% felt to attempt suicide at least once in last 12months and 27.9% did not care if they live or die. Suicidal Ideations were more significant among individuals with habits such as smoking and alcohol ($p=0.036$) and other addictions ($p=0.006$). Characteristics such as being neglected by parents, being physically assaulted by seniors, having psychiatric illnesses were more statistically significant to have suicidal ideas than other characteristics. **Conclusion:** Social factors have major impact on suicidal ideation among students. Identification of high risk adolescents is important to prevent suicides**.**

Key Words: *Suicide, Stress, Isolation, Medical students, Beck's scale, suicidal ideations*

Introduction

According to the WHO Suicide Prevention (SUPRE) Program, around one million people die due to suicide every year and this shows a worldwide mortality rate of 16 people per 100,000 or roughly one death every 40 seconds[1]. Suicidal ideation is defined as thoughts of harming or killing oneself[2] and it is an important factor of predicting suicide attempts and is considered as an index of the other mental health problems[3,4]. Suicide is the second most common cause of death among adolescents in industrialized countries and high rates are being reported from India recently[5]. Thus, Suicide is a major public health concern in India but there is only limited information available regarding suicide and suicidality in our community.

Some studies have shown that the level of suicidal thoughts among medical students and young physicians is very high.[6] Moreover, other overviews indicate an increased suicide rate in physicians and medical students. The estimated relative risk varied from 1.1 to 3.4 in male, and from 2.5 to 5.7 in female doctors, as compared to the general population[7]. Depressive disorders are often accompanied by suicidal thoughts, which are recognized as a risk factor for attempted suicide[8]. There are only few studies undertaken among the medical students and professionals to analyze this threatful situation and hence this study was conducted to have more clear view regarding the suicidal prevalence and thoughts among the medical students.

Aims and Objectives

To determine the prevalence of suicidal ideations among the under graduate students and to evaluate the association between suicidal ideations with various

socio demographic and influencing factors of suicides among study subjects.

Material and Method

A cross sectional health survey study was conducted among the undergraduate students in a medical college in Mangalore. The study was conducted from June to August 2017, among 3 batches of M.B.B.S students between 17 to 20 years. Considering a prevalence of life time suicidal cognition of, life not worth living was reported as 44.2%[9] With 5% allowable error and using formula $4pq/d^2$ the sample size derived as 395. Totally, 415 study participants were involved in the study using universal sampling method. A pre-validated, structured and self-administered questionnaire based on Beck's scale of suicidal ideation consisting 19 items, were given to each student. Each item in the questionnaire was scored based on an ordinal scale from 0 to 2 and the total score was considered as 0 to 38. The categorical score classifies individuals into three categories with suicidal ideations such as Mild: 0 – 8, Moderate: 9 – 19 and Severe: 20 – 38. The questionnaire also contains sections on socio demographic and other influencing factors for suicide. All students who were willing to participate in the study were included. This study had obtained the ethical clearance approval from the institutional ethical committee of K.S Hegde Medical Academy, Mangalore, Karnataka. Written informed consent was obtained from all study participants before eliciting the desired information. The collected information was summarized by using descriptive statistics such as frequencies and percentage. Chi square test (Inferential Statistics) was used for univariate analysis such as association between suicidal ideation scorings, sociodemographic and influencing factors for suicide. P value < 0.05 was considered significant. Data management and analysis was done by using Microsoft excel and SPSS version 16.

Results

Out of 415 participants, 179 (43.1%) were males and 236 (56.9%) were females. By nationality, 84.1% were Indians, 10.4% were NRIs and 5.1% were Foreigners. 85.5% were residing in hostel and 13% were coming from home. By religion, 60.2% were Hindus, 25.5% were Muslims and 11.8% were Christians. Among the participants, 33(8%) consumed alcohol 7(1.7%) were also smokers and 28(6.8%) mentioned to have addictions like substance abuse and pornography. Gender based suicidal scoring was done and it was observed that 87.5% of individuals had 'Mild' suicidal ideations of which 49.6% were females and 37.8% were males. Similarly, 8.9% (3.9% males & 5.1% females) of individuals had 'Moderate' and 3.6% (1.4% males & 2.2% females) had 'Severe' suicidal ideations.

Based on the general satisfaction in life, 24.1% of females were academically satisfied compared to 13.3% of males. 29.2% of females were satisfied with their extracurricular activities than 22.2% of males.40% of females had social life satisfaction than 30.6% of males and only 12.3% of males were satisfied with the pocket money they get from home than 20.7% of females. It is observed that 4.1% of females had suicidal thoughts often compared to 2.4% of males. 3.6% of males responded that they had courage to commit suicide compared to 2.2% of females.17.1% of females did not care to live compared to 11.3% of males. 8.4% of females were wishing they were dead compared to 4.3% of males. It was seen that 13 of them had strong intensity suicidal thoughts in past 12 months, 3 were ready to commit suicide if means available, 3 of them have completed preparation for suicide, 10 have completed suicide note and 7 of them have already attempted suicide.

The association between the suicidal ideation scoring and sociodemographic factors such as nationality, gender, religion, habits, addictions, residence and whom they stay with was observed. It showed that there was a significant association between suicidal ideations and individuals with habits such as alcohol and smoking (p=0.036) and addictions such as substance abuse and pornography (p=0.006). **Table 1** illustrates association between suicidal ideation scoring and factors which influences suicidal ideations showed that being physically assaulted by seniors, individuals who stay isolated, those who have low self-esteem on themselves, those who are having psychiatric conditions, being neglected by their parents and those whose parents who very demanding on academics were more significantly associated with suicidal thoughts and ideations compared to others.

Discussion

Suicidal ideations among young adults is an increasingly burdensome issue worldwide. Further, various studies have shown a very high prevalence of suicidal ideation in medical students, ranging from 9.1% to 48.2%[10,11]. Many factors contribute to the development of suicidal tendencies in this specific population including certain behavioral and personality traits, coexisting mental health problems, and stressful personal or academic events[6,12,13] Our study has briefly investigated over these factors and has found significant association over many.

Research done by Pickard M Bates et.al[14], Stockman J[15] and Arria et.al[16] had shown that the suicidal thoughts or wishes among females are more when compared to males which is similar to our study. In our study 5.1% of females had moderate suicidal ideations over 3.9% males and 2.2% of females had severe suicidal ideations over 1.4% of males. Few studies quoted that students with psychiatric stressors and therefore having anxiety and depression were susceptible for suicidal ideations[17,18]. A Study conducted by M.Esfahani[19] in 2015 showed a significant relationship between mental illness and suicidal ideation which was also significant in our study.

Other common traits that may contribute to suicidal thoughts in medical students include substance abuse, heavy curricular burdens, decreased life satisfaction, and certain personality traits including maladaptive behavior[6,20]. In our study addictions, such as substance abuse and pornography were significant to have suicidal thoughts and males had decreased life satisfaction when compared to females. A study conducted in 2014 showed that medical students do not look after their personal concerns and seek mental health treatment due to fears about stigmatization, confidentiality, and any impact such treatment may have on their future careers[12,21,22]. Additionally, certain personality traits make medical students more vulnerable to mental health stressors and suicidal ideation. These include neuroticism, introversion, and low self-esteem[23,24]. Several previous studies have shown that low self-esteem, which implies self-rejection, self-dissatisfaction, and self-contempt, is associated with suicidal ideation[25]. Like these studies our study has also shown that individuals with low self-esteem and those who always stayed isolated were significantly associated with having suicidal thoughts.

In our study, academic pressure was found to be a significant source of academic stress for many students along with parents' demands on academic excellence which was like the study done by Toero et.al in 2001[26]. According to our study, 1.7% of participants reported to have attempted suicide at least once in their life. Whereas a study done in 2015 reported 7% of individuals already have attempted suicide[19].

Conclusion

Our study shows that sociological and unsupportive environment at home play a major role in implication of the suicidal ideations among the students as these are an important source of comfort during stressful periods. It also revealed that students who stay depressed or isolated and those who are under psychiatric treatment had more suicidal tendencies than other students. Students who requested for support were taken care with utmost confidentiality.

Recommendations

This study calls for strategies to identify and refer high risk adolescents and young adults for mental health care and advices that it must be strongly implemented. Multi-faceted approach including mental health care services, academic support systems and counseling centers are necessary to prevent suicidal thoughts among the students.

Limitations:

The sample is not representative of the general population of Mangalore, and so the generalizability of the findings is rather limited. However, it can reflect the status in the population in a medical college in Mangalore. The clinical history of having psychiatric conditions and undergoing treatment for the same was based on the self-report of the participants only without any scope of verification. It is highly possible that people do not report their suicidal ideas or attempts.

Abstract

The present study was undertaken to observe the stress levels between mothers of children attending Normal school and Special school in Erode, Tamilnadu. The present study was a cross-sectional (comparative) study. The present study was conducted in and around Erode district, TamilNadu. 120 mothers were taken for the study, out of which 60 were mother of intellectually disabled children diagnosed with ID based on Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM5) criteria and 60 was mother of normal children. A total of 60 mothers of intellectually disabled children were selected through convenient sampling method. Stress inventory questionnaire was used to assess the stress levels. The major findings of this study are that mothers of children with intellectual disability experience stress. However, all the subjects experience higher level of Emotional, Cognitive, Behavioral stress than Physiological stress. Generalizations from this study are cautioned, due to the small volume of data and convenient selections of schools. Considering all that has mentioned above it has been shown that mothers of children with intellectual disability experience different levels of stress. Some relevant therapeutic interventions for these mothers and through methods of stress management interventions could be adapted to prevent many of these mothers' problems with their children. Special educations and early interventional measures should be more extensive in India and it should be available to educate and support mothers of intellectual disability children. The results of this study show that most of the mothers in our sample population must be referred to specialists for professional consultation on stress management.

Key words: *Stress, Mothers, special schools*

Introduction

Every child is special gift and blessing to their parents. But some children have special needs that challenge parents especially the mother to find ways to best prepare these children for their future and to handle any problem that may arise. The parents of children with special needs definitely face more difficulties than parents of normal children, which in turn affect their emotional well-being. Families of intellectually disabled children probably vary in their behaviour, social attitude and family relationships as compared to families who do not have disabled children. Understanding the emotional reaction and attitude of the parents as well as family members of intellectually disabled children are of great importance in the management. Children with intellectually disabled generally require more care, attention and direct supervision than children without disabilities.

Research demonstrates that these higher care giving demands are associated with poor psychological and physical health states for parents and other family members.[1] It is worrying fact that children of special needs are not given the attention they deserve. Despite modern human right attitudes, the idea that a disabled child is the result of the anger of God, or ancestors, the embodiment of sin in the family or the sin in itself, is widely prevalent. Endless research shows that parents

saipannsai@gmail.com

of disabled children feel guilty and sometimes take the blame for the impairment on themselves. Inevitably, the stigma and guilt result in isolation or segregation of the disabled child. In developing countries; the mother of the disabled child is abandoned by the husband forces the mother into either abandoning the child herself or becoming a beggar.[2] Society plays an important role in the upbringing of their child. Some parents feel ashamed of their child and consider them as burden. Others consider it as their duty to take care of their children. Uplifting the parent's social and psychological well-being would help the parents to deal effectively with their children having problem.[3] The present study was undertaken to observe the stress levels between mothers of children attending Normal school and Special school in Erode, Tamilnadu.

Materials and Method

Study design: The present study was a cross-sectional (comparative) study

Study setting: The present study was conducted in and around Erode district, Tamil Nadu.

Study participants: 120 mothers were taken for the study, out of which 60 were mother of intellectually disabled children diagnosed with ID based on Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM5) criteria and 60 was mother of normal children. A total of 60 mothers of intellectually disabled children were selected through convenient sampling method from those who referred to psychiatric clinics for children, specialists' offices, and also advisory centres of department of education and training centers–rehabilitation and organization for exceptional children of Erode district. The following inclusion and exclusion criteria was used in recruiting the participants.

Inclusion and exclusion criteria: Inclusion criteria were having a aged between 6 and 18 years old child, having just one child with intellectually disabled, the presence of both parents in the family, employment of the father and not facing any serious financial crisis, not having any other member in the family suffering from chronic physical-mental problems, not having the child admitted to a boarding school, not having serious marital conflicts during the past month, and no record of the death of a loved one during the past 3 months; also they should have been consent to participate in the study and in the case of mothers' unwillingness to cooperate for completing the questionnaires and giving full answers they would have been excluded from the study.

Outcome measures

Stress inventory: The questionnaire was standardized questionnaire. It consists of 30 items, under 4 parts namely, Physiological, Emotional, Cognitive and Behavioral. There are two possible responses to each item namely, 'Yes' or 'No'. The mothers were asked to tick any one, which applied to them the most. There was no time limit. But the mothers were asked to respond as quickly as possible. Scoring Key and Norms were provided by the authors. The validity of S.I. is 0.80 and the reliability by test retest method is 0.95.[4]

Data analysis: Data were analysed using SPSS software version 11.5 (SPSS Inc). Quantitative data were expressed as mean (standard deviation) and qualitative as number (percent). Analysis of variance (ANOVA) was used for comparing the stress score among between mothers of children attending Normal school and Special School in Erode with respect to each of the dependent variables. $P < 0.05$ was considered as statistically significant level.

Results

Table 1 compares the level of stress between mothers of children attending Normal school and Special school. Most of the mothers of children attending Normal school are 71.6% having low level of stress score , 16.7% of them are having moderate level of stress score, 11.7% of them are having moderate level of score and none of them are having very high level of stress score. Whereas mothers of children attending special school are none of them having low level of stress score, 16.7% of them are having moderate level of stress score, 71.6% of them are having higher level of score and 11.7% are having very high level of stress score. Table 2 shows the comparison of Mothers of children attending Normal school and Mothers of children attending Special school stress score.

Table 1: Comparison of level of stress score

Level of Stress score	MOTHER'S of children attending Special school		MOTHER'S of children attending Normal school		Chi square test
	n	%	n	%	
Low	0	0.0%	43	71.6%	$\chi 2$=17.85 P=0.001*** DF=2 not significant

(NOT SIGIFICANT P> 0.05 AT * significant at P≤0.05 ** highly significant at P≤0.01 *** very high significant at P≤0.001)

Discussion

The present study compared the level of stress among mother of children attending Normal school and Special school stress and also to investigate the potential effects of variables such as age, mother's education and income in the Erode society on these differences, our research data results revealed that None of the mothers of children attending Special school are having low level of stress score , 16.7% of them are having moderate level of stress score, 71.6 % of them are having high level of score and 11.7 % of them are having very high level of stress score. Statistically there is a significant difference between mothers of children attending Normal school Vs Special school, it was confirmed using chi square test very high significant (P=0.001). This confirms hypothesis I. This finding is in consonance with the findings of Rangaswamy and Bhavani [5] Parents with disabled child may have higher levels of stress and lower levels of wellbeing than with the normal children. Similar studies have also revealed that Lopez et al [6] also reported that parents of children with developmental delays experienced greater stress than children without delay. Floyd and Galladjhar [7] also observed that parents of children with intellectual disability often experienced considerable stress resulting from worries and demand related to their children. Similarly, Baker et al [8] found that parenting stress was higher for parents of pre-schoolers with delays than for parents of pre-schoolers without delays.

Stress is found to be an important problem commonly found in parents of children with special needs. Being apprehensive clearly explains stress, anxiety and its repercussions are perceived in no less degree in mothers of children with special needs. A chain reaction to this is seen in their quality of life. It is the need of the hour to make a study on these mothers of children with special needs to manage their stress and anxiety about their children and to enhance their quality of life. Parenting stress can be defined as excess anxiety and tension specifically related to the role of a parent and to parent-child interactions.[9] Parent's psychological well-being is considered to be very important in parent – child relationship because it is very important key to the success of a meaningful family relationship. The major findings of this study are that mothers of children with intellectual disability experience stress. However, all the subjects experience higher level of Emotional, Cognitive, Behavioral stress than Physiological stress. Generalizations from this study are cautioned, due to the small volume of data and convenient selections of schools.

Conclusion

Considering all that has mentioned above it has been shown that mothers of children with intellectual disability experience different levels of stress. Some relevant therapeutic interventions for these mothers and through methods of stress management interventions could be adapted to prevent many of these mothers' problems with their children. Special educations and early interventional measures should be more extensive in India and it should be available to educate and support mothers of intellectual disability children. The results of this study show that most of the mothers in our sample population must be referred to specialists for professional consultation on stress management

Source of Support: Nil

Conflict of Interest: The authors declare that they have no conflict of interest.

Ethical Approval: The study protocol was approved by institutional human ethical committee. All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional research committee.

Acknowledgment: We must thank here all the centers for education and rehabilitation of children with special needs, specialized school of the Erode city, and mothers of the disabled children whom their cooperation has made this research an easy job for us.

Abstract

Drug delivery is a method of administering a pharmaceutical compound to achieve a therapeutic effect in humans and animals. Conventional therapy is a classical method of achieving drug delivery. Where, it provides drug release immediately and causes fluctuation of drug level in in blood depending on the dosage forms compared to conventional, which improves the drug potency, controlled drug release to give a sustained therapeutic effect, provide greater safety and target a drug specifically to a desired tissue. It mainly includes targeted, controlled and modulated drug delivery systems. Hence, there is an increased interest towards the application of targeted therapies in medicine and dentistry and has proven to be successful in prevention and treatment of various oro-dental disorders.

Keywords: *Biodegradable; Carrier System; Nanoparticle; Target Drug*

Introduction

Targeted drug delivery is a special form of system, where the medicament is selectively targeted or delivered only to its site of action or absorption and not to the non-target organs or tissues or cells. It improves the efficacy and reduces the side effects [1]. The drug may be delivered, to the capillary bed of the active sites, to the specific type of cell or even an intracellular region, to a specific organ or tissue by complexion with the carrier that recognises the target. The main objective of a targeted therapy, is to mainly achieve a desired pharmacological response at a selected site, thereby the drug has a specific action with minimum side effects and better therapeutic index [1]. The main reason behind the targeting of the drug is in intervention, prevention or treating a disease. Conventional dosage forms have few drawbacks like, pharmaceutical drug instability, low absorption and high membrane bounding, biological instability. The drug delivered through conventional system, has a very low specificity, shorter half life, large volume of distribution and low therapeutic index. These challenges lead to increased interest towards a targeted therapy [2]

Requirements of drug targeting

For a drug to be targeted, it should have certain characteristics or requirements to be satisfied. Mainly it should be nontoxic, biocompatible, biodegradable and physico-chemically stable both invitro and invivo. The drug that has been delivered should be restricted to the targeted area and should have a uniform capillary distribution. It should be controllable and with predictable drug release. Amount of release is therapeutic, with minimal leakage during transit [3]. Carriers used must be bio-degradable or readily eliminated from the body without any problem. Although targeted therapy has several advantages, but still it has many limitations that hinder its application. The main disadvantage of this therapy is difficulty in predicting the exact action of drug at the specified site. Rapid clearance of targeted systems, immune reactions, insufficient localisation of targeted systems, possible toxic reactions in therapeutic dosages and tedious preparation procedures lead to decreased usage for day to day basis [4].

Carriers in targeted drug delivery:

Targeted drug delivery, can be achieved by using carrier system. Carrier is a special molecule or system essentially required for effective transportation of loaded drug to the selected site. Various pharmaceutical carriers used are polymers, microcapsules, microparticles, lipoproteins, liposomes, micelles. The important componential properties that influence drug targeting are mainly the drug delivered its concentration, particulate location and distribution, molecular weight, physicochemical properties and drug carrier interaction. In case of carrier molecule, its type, number of excipients, surface characteristics, size and density. In vivo electric field [5,6].

Various strategies in drug targeting [5] are, passive, active, ligand mediated, physical, dual, double inverse and combination targeting. Passive targeting utilises, the natural course of bio-distribution of the carrier. The colloids which are taken up by the reticulo-endothelial system can be ideal vectors for passive targeting. Active targeting involves the modification or functionalization of the drug carriers so that the contents are delivered exclusively to the site corresponding to which carrier is architectured. It can be affected at different levels like first order or organ compartmentalization, second order or cellular targeting, third order or intercellular organelles targeting. In first order targeting, there is a restricted distribution of drug carrier system to the capillary bed of a pre-determined target site, organ or tissue. In second order targeting, the drug is selectively delivered to a specific cell type such as tumor cells and to the normal cells. In third order targeting, drug is delivered to the intracellular organelles of the target cells. Inverse targeting is a reverse of passive system which avoids the passive uptake of colloidal carriers by the reticuloendothelial system. It can be achieved, by suppressing the function of reticulo-endothelial system by pre-junction of a large amount of blank colloidal carriers or macromolecules [5]. Ligands are carrier surface groups, which can be selectively direct the carrier to the pre-specified site, housing the appropriate receptor units to serve as homing device to the carrier or drug. The ligands confer recognition and specificity upon drug carrier and endow them with an ability to approach the respective target selectivity and deliver the drug. Physical targeting involves environmental changes like pH, temperature, light intensity, electric field and ionic strength. Dual targeting is an approach where, the carrier molecule itself, have their own therapeutic activity and thus increase the therapeutic effect of the drug. Double targeting is of two types, it can be achieved by spatial and temporal control. In spatial control, drugs are targeted to specific organs, tissues, cells or even subcellular component. In temporal control, the rate of the drug delivery is controlled to the target site. Combination targeting systems are equipped with carriers, polymers and homing devices of molecular specificity that could provide a direct approach to the target site [5,6, 7].

Delivery systems

Drug delivery, is a method or process of administrating a pharmaceutical compound to achieve a therapeutic effect. It is achieved through delivery systems, which help in delivering or carrying the drug to the specified site. The various delivery systems used are nanotubes, nanowires, nano shells, quantum dots, gold nano, dendrimers niosomes virosomes, liposomes, nanocrystals, magnetic nanoparticles, nanorobots [8]. Nano tubes are the hollow cylinder tubes made of carbon atoms, which can be filled and sealed for potential drug delivery they measure about 10 to 100 micrometers [9,10]. Nanowires are the thin wires which are usually microns in size, they localize the pinpoint damaged site. It has its wide applicating in patients with neurological disorders [8]. Nanoshells are the hollow silica spheres, covered with gold. Antibodies can be attached to their surfaces, enabling shells to target a particular cell in the body [8]. Quantum dots are miniscule silica particles, which are mainly the semiconductor particles, which are useful in various diagnostic and therapeutic purposes. Gold nano can be nanoparticles that are coated or made of gold particles. They are helpful in detection of DNA and protein markers. It has its wide applications in cancer treatment and genetic engineering [11]. Dendrimers are precisely defined [10,12]. Synthetic nanoparticles that are approximately 510nm in diameter. They are made up of layers of polymer surrounding a central core. They contain different sites to which the drugs are attaches and delivered. They have wide applications in gene transfection and medical imaging [8,9]. Liposomes are small microscopic vesicles in which an aqueous volume is entirely composed by membrane of lipid molecule. The drug molecules can either be encapsulated in aqueous space or intercalated into the bilayers [13,14,15]. Niosomes are non- ionic surfactant vesicles which can entrap both hydrophilic or lipophilic drugs either in aqueous phase or vesicular membrane made of lipid materials. It seems to have better stability than liposomes. Virosomes are immuno-modulating liposomes consist of glycoprotein

of viruses. They helpful in genome grafting and cellular microinjection [16,17,18,19]. Nanocrystals are nanoparticles with lesser than 100nm in diameter. Nanorobots include the technology of creating robots at nanoscale diameters, it is a hypothetical designing principle, which is still in research. It is claimed that they specifically delivered to certain areas and get targeted [8,9].

Applications of targeted drug delivery:

The applications of targeted drug delivery mainly include in treating oral mucosal lesions, in treating endodontic infections, cancer therapy and treating patients with periodontitis [20]. In treating oral mucosal lesions, various drugs are targeted using different strategies like usage of quantum dots, liposomes [13,14,15] which are bio-compatible, biodegradable and nonimmunogenic. Which ultimately reduce the toxicity and side effects of drugs. They have a wider role, with increased therapeutic effect as an antimicrobial, antiviral, antitumoral and also used in gene therapeutics. Folate targeting and sono poration have proven to be useful in treating patients with oral cancer. The major importance of nano particles, compared to the other conventional medicinal drugs is that the targeting of the nanoparticles to the specific tumor tissue. Compared to the microparticulate systems, nanoparticles can easily traverse in the blood vessels and the tumor tissue. In targeting the cancer tissue mainly by active and passive targeting modalities. In passive targeting, the injectable drug carriers have been surface modified to evade the reticule endothelial system. They are lived for longer time they have a greater advantage of reaching the blood vessels surrounding the solid tumors. The nanoparticulate molecules have enhanced permeability and retention. Active targeting is by conjugating a ligand to the surface of the particle, such ligand only target the specific cancerous tissue. Most of the studies till date, have focused on the tissue specific antigen mainly the tissue specific antigen. Liposomal carriers and the polymeric nanoparticles are the major important pathways of the targeted drug delivery [13]. Although other nanomicelle systems and studies are still being undertaken.

Periodontic and endodontic diseases are the conditions which mainly occur due to the inflammatory responses from the teeth and the supporting tissues. Endodontic and periodontal pathologies are both biofilm mediated diseases. Thus suppression of the microorganisms and the bio films is challenging. The recurrence of the infection is more common due to the adaptive nature of the microorganisms, protective extracellular polysaccharide matrix formation and development of resistance to microbial agents. To circumvent these challenges, nanomaterials in the form of nanofibers and nanoparticles have been considered in dental therapies. The micro and nano particles are used for localised delivery of the anti-infective agents for the periodontal and endodontic diseases. The micro particles seem to have a greater potential in improving the strategies in management of the endodontic and periodontal diseases. They are very effective when directed against the periodontal pockets and root canals as they have prolonged antibacterial effect and extremely effective. Among all the natural and synthetic polymers available, copolymers of lactic and glycolide family are the most studied and versatile with reference to its availability, release profile, biodegradation time and biocompatibility [21,22,23,24].

In controlling periodontal pathogens, various antibiotics such as doxycycline, tetracycline and minocycline are used. When these antibiotics, encapsulated with the polylactic glycolic acid blend spheres, it is observed the minimal inhibitory concentration was more than required in the gingival crevicular fluid, with continuous drug release up to a week. There was significant improvement in the plaque and gingival index scorings with relative attachment levels. Calcium hydroxide nanospheres are seen to be more effective in endodontic therapy compared to the conventional calcium hydroxide. The nanoparticles can also be used in dental materials, as nanoparticles, for improving the physicomechanical properties of the dental materials. Polymeric nanoparticles such as chitosan nanoparticles, serve as a prophylactic approaches for prevention of bacterial biofilm formation and possibility of penetration into the already formed biofilms. In addition to chitosan, polylactic glycolic acid and cellulose acetate phthalate nanoparticles have been used optimally as antibacterial agents for endodontic and periodontal disease management [25]. Charged and surface charged nanoparticles have direct interaction with the microorganisms and they are helpful in the selective eradication. It is a process where selectively the bacteria are eradicated by binding to the opposite charged bacteria or pathogens. The concept utilised in both endodontics and periodontics is by usage of the photosensitisers encapsulate with the nanoparticles, in the active photodynamic therapy to eradicate the microorganisms [25]. The principle is that

the photosensitiser is preferentially taken by the bacteria and the activation of the light generates free radicals and singlet oxygen which kills the microorganisms. Specific targeting nanoparticles is a strategy where a particular and specific pathogen can be identified and targeted. It is possible via conjugation of the antibodies with the respective nanoparticles. Immunoliposomes have been used to for the precise delivery of these Antimicrobial agents for specific plaque control. Although there are currently only a limited number of endodontic and periodontal nanodrug delivery systems, there is a future hope of developing and applying these nanoparticles in the endodontic and periodontal perspective [25,26].

Conclusion

Targeted drug delivery is an effective and alternative pathway for the modern dentistry. Although it is beneficial in several ways, the delivery systems still have to be I proved for they effective delivery into the targeted tissues. And there is a hope in near future that nano targeted dentistry will improve the treatment outcomes.

The Under 5 Age Children in Urban Area of Sangareddy, Telangana

Humera Abida[1], Batchu NagaGayathri[2]

[1]Assistant Professor, [2] Assistant Professor, Department of Community Medicine,, Mahavir Institute Of Medical Sciences, Vikarabad, Telangana, India

Abstract

Background: Diarrhoea is defined as the passage of three or more loose or liquid stools per day (or more frequent passage than is normal for the individual) [1]. Diarrhoea can last several days, and can leave the body without water and salts that are necessary for survival. In urban setting, diarrhoea is more common in the slum dwelling children who live in an environment with poor sanitary facilities and polluted water [2]

Aim and Objective: To estimate the prevalence of acute diarrhoeal diseases among the children below 5 years of age.

Material and Methodology: Cross sectional type of study conducted in children of 0-5 years of age using pre designed, pretested structured questionnaire. 402 children were selected for the study using convenient sampling technique. Study area was 5 Urban slum pockets in Urban Health and Training Centre(UHTC), Sangareddy, Department of Community Medicine, MNR Medical College, Telangana.

Results: Prevalence of acute diarrhoeal diseases was 15.7% among 402 under-fives children from the urban slum, over a recall period of 2 weeks. Among them 207 children were males and 195 were females, of which prevalence of diarrhea was observed more in females 33 (16.9%) when compared to males 30 (14.5%). About 90% of study participants belonged to nuclear family of which most of them belonged to class IV (upper lower) according to Modified Kuppuswamy scale[3]. Socio environmental conditions of these families were poor.

Conclusions: The study brought light on the unmet needs regarding poverty, sanitation, proper disposal of waste water and daily supply of safe potable drinking water and health care delivery.

Keywords: *Prevalence, diarrhoea, under 5 age children, environment.*

Introduction

Globally, four billion episodes of diarrhea were estimated to occur each year, with > 90% occurring in developing countries. Diarrhoeal disease is an important public health problem among children in developing countries.

According to WHO[4], 'Human faeces remains one of the most dangerous pollutant, spreading microbes causing various diseases like enteric fevers, diarrhoea etc. Rotavirus and Escherichia coli, are the two most common etiological agents of moderate-to-severe diarrhoea in low-income countries. Infection is more common when there is a shortage of adequate sanitation and hygiene and safe water for drinking, cooking and cleaning.

Diarrheoea can also spread from person-to-person, aggravated by poor personal hygiene. Food is another major cause of diarrhoea when it is prepared or stored in unhygienic conditions .Unsafe domestic water storage and handling is also an important risk factor.

In India especially poor sanitary conditions was the most important cause for most of ADD episodes. Health education on the etiology, prevention and management of the diarrhoea has the potential to establish productive contact between the health services and the community, to increase the capability of the families to recognize the

danger signs of diarrhoea in children and to encourage appropriate and early care seeking.

There is an imperative need to know about prevalence of diarrhoea and to assess the existing gap between knowledge and practice such as hand washing and use of sanitary toilet. There is also a need for supply of safe drinking water and maintenance of clean environment through provision of sanitary latrine and proper disposal of refuse. This is more important in case of mothers with under five children, in whom the morbidity and mortality to diarrhoea is very high.

Method

A community based cross sectional type of study conducted for a period of 12 months(January 2016-December 2016) . Study area is Urban slum area by name Marxnagar selected randomly from urban field practice area of Sangareddy. Out of 5245 population in urban slum, 681 under 5 age children are expected to be available to draw the adequate number of study population.

Out of 681 children only 402 children were taken for the study as per the calculations by using the formula for fixing the sample size as mentioned below n = (Z)2pq/ d2.

Where **Z**= percentage point corresponding to significance level. For significance level 5%, Z is1.96. **p** prevalence of diarrhea among under 5 children is 30%[5] q=100-p=70%

d is corresponding maximum error and is 15%. Hence n=1.96x1.96x30x70/4.5x4.5=398 i.e. rounded to 402 children < 5 yrs.

Data Collection:

Informed written consent was taken from the study participants prior to the start of the study. A pre designed, pre tested questionnaire was made as per guidelines given in basic biostatistics by A. Indrayen and L. Sathyanarayana . Pretesting of questionnaire was done in 40 samples selected randomly in 4 streets in the respective area of Sangareddy.

Data Analysis:

Statistical analysis was done using SPSS version 17.0 and the details regarding mother's knowledge and attitude regarding diarrhoea prevention was obtained. Data was summarized in percentages and proportions. Statistical associations was done using Chi square test wherever necessary with $p<0.05$ and considered statistically significant.

Results

Table 1: Distribution according to age & sex of under 5 age children

Demographic Characteristics		**No. of children**	**Percentage (%)**
Age Group	0-12 months	75	18.66
	13-24 months	108	26.86
	25-36 months	90	22.39
	37-48 months	71	17.66
	49-60 months	58	14.43
Sex	Males	207	51
	Females	195	49
Prevalence of Diarrhoea	Males	30	14.5
	Females	33	16.9

From the table 1, it was observed that, out of 402 under 5 aged children 108 (26.86%) children were from the age group of 13-24 months followed by 90 (22.39%). In the above table, majority of children were males 207 (51%)while females were 195 (49%).It was observed that prevalence of acute diarrhoeal diseases was more in females 33 (16.9%) when compared to males 30 (14.5%).

Table 2: Distribution according to Socio Environmental conditions of the families (n=255) of under 5 age children

Socio Environmental Characteristics		**No. of families(n=255)**	**Percentage (%)**
Type of family	Nuclear	235	92.3
	Joint	14	5.7
	Three generation	6	2
Socio Economic status	Class I (Upper)	5	1.96
	Class II (Upper middle)	31	12.15
	Class III (Lower middle)	56	21.96
	Class IV (Upper lower)	136	53.33
	Class V (Lower)	27	10.58
Source of drinking water	Municipal tap water	178	70
	Borewell water	77	30
Type of house	Kutcha	145	57
	Semi pucca	76	30
	Pucca	34	13
Sanitary facility	Present	41	16
	Absent	214	84
Garbage Disposal	Garbage pit	158	62
	House to house collection	18	7
	No facilities	79	31
Fly breeding	Yes	226	89
	No	29	11

From the table 2, it was observed that, majority of the families belonged to nuclear family 235(92.3%) and then followed by joint families (14%). Modified Kuppuswamy scale[6] was used to determine the socio economic status of the study population .Based on that majority of the families belonged to class IV (53.33%) followed by class III (21.96%).

Out of 255 families surveyed 178(70%) houses were receiving municipal tap water whereas 77(30%) houses were still receiving borewell water. Majority of the houses were kutcha type145(57%) followed by semipucca houses76(30%). Only a handful of houses 41(16%) had the sanitary facilities available.

Garbage pit was the major source of Garbage Disposal(62%) in the present study. Fly breeding was seen in approximately 90% of the houses.

Discussion

The present study was conducted in the urban field practice area of department of community medicine of MNR Medical College, Sangareddy, Telangana. For the purpose of study total 255 families were taken which had 402 under five age group children, who were enrolled in the study. The findings in this study document the prevalence of Diarrhoea among the under-five population of urban slum of Sangareddy.

Prevalence of diarrhoea in under five children in this study was found to be 15.7% .Similar findings were seen in studies conducted by Mishra CP[6] and Sudipta Basa[7].The study done in Aligarh of Uttar Pradesh by Ansari et al[8] has reported a prevalence of 16% which is comparable to our study.

In the present study it was observed that, males belonging to 13-24months age group was higher(30.9%) in number. Females belonging to 37-48months age group were higher (25.6%) in proportion than other age groups A cross-sectional study conducted to assess the prevalence of under-five diarrhea and socioeconomic factors by A.M. Elizabeth and Sherin Raj[9], the percentage of children suffering from diarrhea was highest among children aged 6-23 months (20.2%-20.6%) and lowest in the age group of 48-59 months (3.6%).

It was observed that sex ratio of the under five children in this study was 955 females /1000 males and it is slightly higher than the national average of 940/1000(NHFS-4).Prevalence of diarrhoea among under-five females was higher i.e. 33(15.9%) when compared to under-five males 30(14.5%) which is similar to study done by Sudipta Basa[10]

Majority of the under five children were from nuclear family 235(92.3%) and from joint family 14(5.7%). The majority of population was from urban areas and nuclear family culture was mainly followed in such part of country. It may be due to higher number of nuclear families in our study. A similar study done in Rural Community in the Jordan Valley by Abdelhakeem Okour, Ziad Al-Ghazawi, Muntaha Gharaibeh[11] showed no differences in diarrhoea due to type of family.

Source of drinking water in majority of houses 178(70%) was by municipal tap water followed by bore water i.e 77(30%). Among the 70% of water supplied by Corporation 75% were through corporation Lorries to the respective slums in the corporation council wards. Only 25% of the houses were supplied with regular water supply through taps. In a study done by Katharina Diouf[12], public taps were the most common source of drinking water (29.4%; n=162), which is similar to our study.

Out of 255 study families,136 (53.3%)families were belonging to class IV of Modified Kuppuswamy socioeconomic classification followed by 27(10.5%)%) families were of class V. Majority of children with diarrhea were from lower socioeconomic class with 35 children being affected from diarrhoea from class IV . Diarrhoea was higher in lower socio economic groups. It was found that there is a significant relation between socio economic status and prevalence of diarrhoea. ($p<0.05$) Similar findings were also reported by Sudipta Basa[10] in their study, with maximum number of study subjects 312 (44.8%) belongs to socio-economic class IV followed by class V 203(29.2%) which is statistically significant.

From Table no.2 which shows the environment of study area, the types of houses are mostly Kutcha houses(57%) and about 30% were Semi pucca. Only 13% were pucca houses . The environment around the Kutcha houses was poor with inadequate drainage facilities and the housing floor was in surface with street. About 84% of houses have no sanitary latrines and they are using either sulabh public toilet complexes or open air defecation. 40% of mothers said their family members use the near by play ground for open air defecation. Among 16% of houses having sanitary toilets, only 6% has latrine

with adequate water supply. Refuse disposal by most of households 62% were into garbage pits or cabin .About 88.81% of mothers complained about fly nuisance in their houses and they accepted it was due to improper refuse disposal. In a study done in Turkey[13] it was found that the association between family environment and diarrhoea is statistically significant (median 1.48+-0.12). The association between key health care practices and family environment in prevention of diarrhea .Village-level and township-level care were sought for childhood diarrhea by 67.02% of the caretakers[14].

Conclusion

Diarrhea is still the major killer of children under 5 years of age group, although its toll has dropped by a third over the past decade. It killed more than 1600 children under 5 years of age every day in 2012[15]. Hence, along with creating awareness regarding prevention and control of diarrhoeal episodes there is also a need for supply of safe drinking water and maintenance of clean environment through provision of sanitary latrine and proper disposal of refuse.

Comparison of Antibacterial Efficacy of Different Herbal Mouthwashes – An in Vitro Study

Ilakkiya Ezhil[1], Sri Sakthi[2]

[1]Undergraduate Student, Seethe Dental College, Saveetha University, Chennai, [2]Reader, Department of Public Health Dentistry, Saveetha Dental College, Saveetha University, Chennai

Abstract

Aim: To compare of antibacterial efficacy of different herbal mouthwashes

Background: Next to dentifrices, mouthwashes are one of the widely used modality to maintain oral hygiene. Chlorhexidine and Listerine are some of the commonly prescribed mouth rinses, but they come along with many disadvantages. To overcome this, in recent decade, the medical field has turned its attention towards indigenous techniques and medicines. Yet the efficacy needs to match the conventional products. Hence this trial was done to assess the anti bacterial efficacy of different commercially available mouth rinses.

Materials and Method: Three different herbal mouthwashes were taken. Saline was taken as control. 1000 µL of Himalaya herbal mouthwash, K.P Namboodiri herbal mouthwash, Orafrsh mourthwash and saline was pipetted into three cuvettes each . Cuvette was then incubated for 1hour at 37 degree Celsius at microbiology department, saveetha dental college, Nutrient agar was prepared. 10µL of sample was pipetted out from one cuvette and poured into one nutrient agar plate. Metal loop was heated to red hot and sample was streaked using metal loop. Nutrient agar plates was then incubated at 37 degrees Celsius for 24 hours. Agar plates were taken out of the incubator and bacterial colony count was done.

Results: The mean CFU/10 µL of streptococcus mutans in Himalaya herbals complete care mouthwash was 8 CFU/10µL. The mean CFU/10µL of streptococcus mutans in namboodiri's herbal mouthwash was 14.33 CFU/10µL. The mean CFU/10µL of streptococcus mutans in orafresh herbal mouthwash was 17.33CFU/10µL. Saline was compared as a control . The CFU/µL of streptococcus mutans in saline was 58.

Conclusion :The Antibacterial efficacy of different herbal mouthwash shows that Himalaya and namboodiri's herbal mouthwash has significantly antibacterial efficacy against S.mutans. Further research should be made against different organism and different herbal mouthwash.

Keywords*: Herbal, Mouthwash, Micro Organisms, Oral Health, S.mutans*

Introduction

Oral health can directly affect systemic health so prevention and maintenance of oral is very important. Products which are safe, effective and economical are necessary for improving oral health. Microorganisms are the main cause for disease of oral cavity. Use of dentifrice and mouthwash prevent the accumulation of plaque and calculus. Main method for prevention the progression of periodontal diseases is by use of mechanical methods like brushing and flossing. After brushing and flossing, use of mouthwash also help in prevention. Mouthwash can be used in mentally and physically challenged patients but it should be used along with brushing and flossing [1]. Mouthwash is an aqueous solution which is most often used for its deodorant, refreshing and antiseptic property or for control of plaque. Mouthwash contains alcohol, synthetic sweeteners, surface acting agents, coloring agent. Mouthwash contains anti microbial substances and hence proven to be effective in eliminating the microorganisms like streptococcus mutans (S. mutans), Lactobacillus, Enterococcus faecalis (E. faecalis) , Staphylococcus aureus (S. aureus) [2,3,4,].

Most of the commercially available mouthwash like chlorhexidine , Listerine contain alcohol leading

to side effects like brown staining of the teeth, changes in taste sensation, alter the oral mucosa leading to mucosal erosion, parotid swelling in rare cases and sometimes can also causes supra gingival calculus and burning sensation of mouth .The staining property of chlorhexidine can be due to degradation of chlorhexidine and release of parachloraniline, Maillard reaction ,metal sulphide formation with protein denaturation ,precipitation of dietary chormogens . Ethanol present in mouthwash can causes oral and pharyngeal cancer. Toxic metabolites of ethanol are formed from alcohol containing mouth and the concentration was similar to those after alcohol consumption. Mouthwashes which contain alcohol have also decreased the hardness of composite and resin restoration and also have altered the color of the composite restoration when it is used for a long time. Xerostomia can also be causes by alcohol present in mouthwash. Alcohol containing mouthwash is contraindicated in children as they can be toxic and even lethal if swallowed in large amounts. Sodium lauryl sulfate (SLS) is a chemical compound present in certain mouthwashes that has been proved to cause many health problem such as menopausal syndrome, premenstrual syndrome (PMS), decreased male fertility and also breast cancer .Benefit of alcohol in mouthwash is not yet scientifically proven.[5,6] Fluoride containing mouthwash is not recommended for children below 6 years because of the risk of fluoride ingestion .

New age medicine is most popular nowadays; new age medicine includes uses of herbal products. Herbal products have lesser side effects than others. Current research indicate that the polyphones, being secondary metabolites, are present in rich amount in various plants . Many of them possess antioxidant, anti-inflammatory, low antibacterial resistance and several others therapeutic properties than chlorhexidine mouthwash [4].

Mouthwash has been used for centuries for both medical and cosmetics purpose. Mouth rinsing was first described in Indian (Ayurveda) and Chinese medicine around 2700 BC. Ancient Indians and Chinese thought decay of the teeth was caused by worms and treatment included powder, tablet or ointments of various mixtures that contain different herbs, minerals, and esoteric agents like mouse bones. The Egyptians used honey, goose fat, cumin, and ochre for rinsing the mouth. Greeks recommended the uses of salt, alum, vinegar, leaves of olive tree, milk, pomegranate seed, and wine for rinsing the mouth. Tooth paste and mouth wash was first invented by Romans they used human urine in mouthwash and paste. Till 18 century urine was added in paste and mouthwash due to its high ammonia content [6 7]. At present there are several herbal mouthwash made out of neem, miswak, pomegranates extracts, papaya extract, clove, basil, lemon grass oil, peppermint , turmeric [4,8].

Use of herbal mouthwash is both promotive and preventive when used. In this method various plant and there extract are used to treat disease and to maintain good hygiene. Natural plants like neem ,clove, tulsi , jyestiamadh, pudina, triphala, ajwain and more plants can be used either as whole single herb or in combination . Herbal products have been scientifically proven to be safe and effective medicine against various oral health problems like gingivitis, periodontitis , halitosis, mouth ulcers and preventing tooth decay. The major strength of these natural herbs is that their use has not been reported with any side affects till date and by use of a herbal mouth rinse, ingredients which causes halitosis are avoided which itself is one step forward towards better oral hygiene and better health [7].

Streptococcus mutans is a, gram-positive coccus, facultative anaerobic. Main stains of S.mutans were isolated from the oral cavity .This microorganism was first described by J Kilian Clarke in 1924. S. mutans is stongly associated with dental caries and the primary causative agent [8].

Hence the aim of the study is to compare the antibacterial efficiency of different commercially available herbal mouthwash - An in vitro study.

Material and Method

Study design: In vitro, microbiological analysis

Inclusion criteria: Herbal formulations available in the market under mouth rinse category were to be included in the study.

(An online search was conducted to find out the commercially available herbal mouth rinse preparations, a total of 10 products were identified, of which 3 were selected for this study)

Exclusion criteria:

Any mouthwash containing alcohol, Chemical constituents as in conventional mouth rinses and fluoride containing mouthwashes were excluded from the study.

Products tested and composition

1) Namboodiri herbal mouthwash

K.P.Namboodiri'S herbal fresh mouthwash ingredients are as follows:

- Sorbitol,
- Licorice extract,
- polysorbate 20,
- Thymol,
- Tea,
- tree oil,
- extracts of clove,
- ginger,
- nutmeg,
- Cardamom.

2) Himalayan herbal complete care miswak and pomegranate mouthwash(Manufactured by the Himalaya Drug Company Makali, Bangalore 562123 (India)

Himalaya herbal complete care ingredients are as follows:

- Salvadora Persica extract ,
- punica granataum fruit extract ,
- Melisa Azadirachta leaf extract ,
- Sorbitol, citric acid.

3) Orafresh mouthwash - manufactured by charak

Orafresh Mouthwash Ingredients are as follows:

- Camellia sinensis 100mg,
- Triphala 100mg,
- Piper cubeba 70 mg,
- Melisa azadirachta 60 mg,
- Acacia catechu 40 mg,
- Mentha spicata 75 mg,
- Purified alum 50 mg,
- Eucalyptus globulus 5mg.

4) saline

Fig1: different herbal mouthwash

Armamentarium:

- Cuvette
- Cuvette stand
- Micropipette
- Petri dish
- Nutrient agar
- Spirit lamp
- Metal loop
- incubator
- saline
- Gloves

Method:

Three herbal mouthwashes were taken. 1000 µL of each herbal mouthwash was pipetted into three cuvettes saline was taken as control .1000 µL of saline was pipettes and poured into a cuvette. S. Mutants bacterial suspension was prepared. 10 µL of the prepared bacteria suspension was pipetted out and add to each cuvette. Cuvette was then incubated for 1hour at 37 degree Celsius at microbiology department, Saveetha dental college, poonamalle. Nutrient agar was prepared. 10µLof sample was pipetted out from one cuvette sand poured into one nutrient agar plate. Metal loop was heated to red hot and sample was streaked using metal loop. Nutrient agar plates were then incubated at 37 degrees Celsius for 24 hours. Agar plates were taken out of the incubator and bacterial colony count was done.

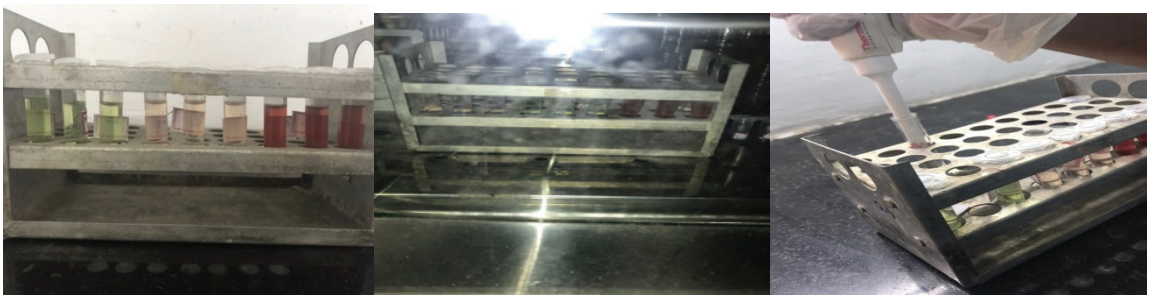

Fig2: depicts methods for identification of antibacterial effect of different herbal mouthwash

Flow chart 1: Method for indentifying antibacterial efficacy of different herbal mouthwash

Statistical Analysis

1) Data was entered in Microsoft excel spread sheet and analysed
2) Numerical data were presented as mean and standard deviation

Result

The CFU/µL of streptococcus mutans in different commercially available herbal mouthwash was given in table 1.

Himalaya herbal mouthwash had less number of bacterial colonies and oral fresh had high number of bacterial colonies, but all the herbal mouthwash has better Antibacterial effect Thant saline.

Table 1: S.mutans colony forming unit per µl of different herbal mouthwashes

Herbal mouthwash	Colony forming units per µL			Mean
	Sample 1	Sample2	Sample3	
Saline	58			
Himalaya	13	7	4	8
Namboodiri's	13	12	23	14.33
Orafresh	21	13	18	17.33

Discussion

In current study Streptococcus mutans showed 8 CFU/10µL in Himalaya herbals complete care mouthwash (miswak and pomegranate) and this result was similar to the results obtained from the study made by Charuta Sadanand Dabholkar, Mona Shah which also showed Himalayan herbal mouthwash exhibited anti bacterial efficacy against S.mutans. Study made by Jonathan E Sam also suggested that Himalaya herbal mouthwash significantly reduced the S.mutans count. Rupali Mahajan.et.al also suggested that Himalaya herbal mouthwash had the same effect of chlorhexidine [9, 10, 11].

Study done by Sanjukta also mentioned the anti bacterial effect of Himalayan herbal mouthwash HiOra R (manufactured by The Himalaya Drug Company, Bangalore, Karnataka, India). It is a herbal preparation, made from a combination of natural herbs with beneficial properties of antiacarcinogenic and anti-plaque due to the presence of Pilu (Salvadora persica) 5 mg, antibacterial, anti-inflammatory, and immunity booster due to Bibhitaka (Terminaliabellerica) 10 mg, antioxidant, antimicrobial, and plaque inhibiting properties due to Nagavalli (Piper betle) 10 mg. Essential oils of Gandhapurataila (Gaultheriafragrantissima) 1.2 mg possess antimicrobial, anti-inflammatory, and analgesic properties. Oil extracted from Ela (Elettariacardamomum) 0.2 mg is a potent antiseptic that is known to kill bacteriaaproducing bad breath. Peppermint satva (Menthaspp.) 1.6 mg acts as a natural mouth freshener. Yavanisatva (Trachyspermumammi) 0.4 mg also has antimicrobial properties. S. persica is one among the most commonly used antibacterial agent in traditional Ayurveda medicine. Its role as an anti-plaque agent has been reported extensively [12]

In the current study Streptococcus mutans showed 14.33CFU/10µL in namboodiri's herbal mouthwash and this result was similar to the result obtained from the study by sham .s butt results suggest that against Streptococcus mutans, K. P. Namboodiri's toothpaste was found to be the most effective followed by Colgate herbal toothpaste. K [6]

In current study orafresh herbal mouthwash showed 17.33 CFU/10µL this herbal mouthwash contain acacia catechu leaf extract which has high levels of Rutin and Epicatechin and the results was similar to the results obtained by Ezhil.I et.al. The results showed that epicatechin has no growth at 25 mg/ml tested against S. mutans and E. faecalis, chlorhexidine as positive control showed no growth in 10 mg/ml. Rutin showed no growth at 50 mg/ml against S. Mutans and at 25 mg/ml against E. faecalis. When compared to chlorhexidine the efficacy was less, but epicatechin and Rutin showed antibacterial activity against S. mutans and E. faecalis with a moderate action. Current research indicates that the polyphenols, being secondary metabolites, are present in rich amount in various plants. [13] .

The results obtained by Rakshana et.al showed that the herbal mouthwash made up of Ocimum sanctum tested showed significant antibacterial efficacy represented in. It showed no growth at 25 mg/ml tested against S. Mutans and 25 mg/ml against S. sanguis, and at 100 mg/ml against L. acidophilus. 10 mg/ml against S. salivations. Agar well diffusion method showed a maximum zone of inhibition against S. Mutans and S. Salivarius (19 mm and 22 mm), respectively [14]

In the current study use of herbal mouthwash was recommended but this was contradictory to the result obtained by Amir Moeintaghavi. This review showed that, when compared to herbal mouthwash , chlorhexidine mouthwashes provided better results in its antimicrobial efficacy against Streptococcus mutans. Further research could study the antimicrobial efficacy of herbal mouth rinse in greater depth and in vivo clinical testing is essential to confirm the in vitro results.[15,16]

There were few limitations associated with this study, colony forming units was only test in this study further study has to be made to identify the zone of inhibition of S.mutans against several herbal mouthwash.

There have been numerous in vitro studies that have investigated the activity of natural plant substances against oral bacteria. These studies have focused on bacteria known to be involved in the aetiology of oral and dental diseases. Early studies have clearly established that a number of herbal substances had potential to be utilized as mouthwash, given their activity against carcinogenic bacteria and those bacteria associated with periodontal diseases. certain plants and herb extracts like clove bud oil, cinnamon bark oil, and papuaamace extracts constituents of these extracts, such as cinnamic aldehyde and eugenol[17,18,19]

Use of different commercial brands of mouthwash, use of different ingredients may differ from study to study hence they affect the results. Presiding the ingredients, concentration, commercial brands can

help the researchers to identifying the main causes of differences in the results. [20]

Conclusion

The Antibacterial efficacy of different herbal mouthwash shows that Himalaya and namboodiri's herbal mouthwash has significantly antibacterial efficacy against S.mutans. Further research should be made against different organism and different herbal mouthwashes.

Post an Unforeseen Outcome of Serial Volunteering in Clinical Trials, What Does the Affected Community Want?

Irene Sambath[1], Thilagavathi R[2]

[1]MSc Biostatistics & Epidemiology, [2]Faculty of Biostatistics, School of Public Health, SRM Institute of Science & Technology, Kancheepuram, India

Abstract

Background and Aims: A disturbing trend is largely seen in clinical trials that recruit healthy volunteers, where vulnerable low-income groups are over-volunteering, leading to adverse health outcomes. There is a need for an awareness study of the affected rural community that has witnessed an unforeseen outcome of clinical trial participation.

Method: Data on knowledge, attitude, practice and educational materials about clinical trial participation using a semi-structured interview schedule was collected from 192 heads of households from Nagampet Village in Telengana state, South India, that had been making headlines in the news because of the death of one of its residents due to adverse effects of repeated participation in clinical trials. Descriptive and Multivariate analysis of variance was used.

Results: 99% of heads of household were married men with 69.8% belonging to Lower Middle Class and 34.9% less than a primary education. Majority (86.5%) were not aware about clinical trial process. 68.8% opined that family members should reject the individual's voluntary decision about taking part in clinical trials because they fear the death of the only earning member of the family due to any ill-effects from clinical trial participation.

Conclusion: This study brings out what the people want in order to avert another death or another unforeseen event in their village due to clinical trial participation. They want a professional such as teacher, doctor or nurse to explain to them the crucial steps in clinical trial participation during gram sabha and special village gatherings. Well-informed decision-making in clinical trial participation through reliable sources would encourage them to take medical help when in need and not to be lured by middle-men or agents.

Keywords**:** *Serial volunteering; Clinical Trial Participation; Awareness of Clinical Trial, KAP, Knowledge, Attitude, Awareness, MANOVA*

Introduction

Of recently, India's leading newspapers[1], local news channels and review journals[2] have brought to limelight that a growing number of low-income groups are over-volunteering for clinical trials to supplement for their income. Such serial volunteers are an especially vulnerable class of people because of their low levels of education, poverty and rural category[3,4].

Numerous studies, both quantitative[3,5,-10,] and qualitative [4,11,12], have explored the awareness, attitude and perception of general public and trial participants towards clinical research and the circumstances coercing the volunteers to partake in more than one clinical trial. Past studies conducted in North India were from urban and semi urban population and had contrasting results. Two studies[11,13] found majority knew nothing about clinical research while one KAP study[10] found that participants were aware of essential elements of clinical

School of Public Health, SRM Institute of Science & Technology, Kancheepuram 603203, India
e-mail: irene.sambath@gmail.com

trials. Results of all these studies show that healthy volunteers with minimal primary school education, who had taken part in clinical trials atleast once in their lifetime, did not know which trial they had taken part and did not fully participate in informed consent process.

A Korean study[14] replicated the PARTAKE Survey[13] and found a higher percentage of responders from Korea have heard of clinical research compared to India, attributing to high use of internet, media and smart phone in Korea.

The meta-analysis of qualitative studies of Indian clinical trials[9], systematic review of all phase I studies[15], case study of a CRO in Hyderabad[2] and review article of trial compensation in Telengana state[16] reveal that poverty compels many from the marginalised sector to over-volunteer in clinical trials. Similar finding is observed from the qualitative accounts of individuals of a longitudinal study in US[12,15].

What is missing from the past studies is an awareness study of the affected rural community that has witnessed an unforeseen outcome of clinical trial participation. This study aims (1) to explore the knowledge, attitude and practices about participating in clinical trials from this rural community who might be at risk of being lured into clinical trials (2) to find out directly from the people the information/educational materials they would like to have to increase their awareness about clinical trial participation and (3) to find the association between knowledge and attitude about clinical trial participation with socio-demographic variables using multivariate analysis.

Method

Study setting

This specific research was conducted in Nagampet Village of Jammikunta mandal in Karimnagar district located in Telengana state, South India in June 2018. One of the residents had passed away due to adverse effects of repeated participation in clinical trials. This village had been making headlines in the news for the past one year as pharma companies from Hyderabad in Telengana, Bengaluru in Karnataka and other areas attract healthy volunteers from remote areas.

Study design

The study design was cross-sectional and has Institutional Ethics Approval.

Sampling and Participants

The unit of analysis was head of household. Sample size n=221 was calculated with a proportion of 73% people not aware or heard of clinical trials [taken from PARTAKE study[13]], effect size = 0.06 assuming overall knowledge of community people fluctuates between 6% points (ie. 67% and 79%), $Z_{0.05}$ at 95% confidence interval and 5% non-response rate.

The village panchayat office had the list of households N = 406, which formed the sampling frame. Circular systematic sampling methodology was used. The sampling interval k=N/n = 406/221 = 1.8 ≃ 2. Random start from random number table was r = 2. Of the every second household visited, 12 refused, 10 consented but withdrew in the middle of the survey, 5 absent and 2 abandoned households. Data was collected from 192 heads of households after taking informed consent.

Material

The study tool was a semi-structured interview schedule on Knowledge, Attitude, Practice and Educational/Informational materials about clinical trial participation. A pre-validated questionnaire by Burt et al., 2013methodological, and operational reasons. There are indications that the public is unaware or misinformed, and not sufficiently engaged in clinical research but studies on the topic are lacking. PARTAKE – Public Awareness of Research for Therapeutic Advancements through Knowledge and Empowerment is a program aimed at increasing public awareness and partnership in clinical research. The PARTAKE Survey is a component of the program. Objective To study public knowledge and perceptions of clinical research. Methods A 40-item questionnaire combining multiple-choice and open-ended questions was administered to 175 English- or Hindi-speaking individuals in 8 public locations representing various socioeconomic strata in New Delhi, India. Results Interviewees were 18–84 old (mean: 39.6, SD±16.6[13] was used. It was reviewed for completeness, supplemental questions added and checked if it matches with this study's objective. The questionnaire underwent translation and back-translation from English-Telugu-English. Uday Pareek's socioeconomic scale and Kuppuswamy's monthy family income[17] updated for 2017 was used to collect socio-demographic information.

Data analysis

SPSS 16 was used to analyse data. The KAP component in Objective 1 and Objective 2 was analysed using Descriptive analysis. For Objective 3, the association between following variables was conducted using two-way multivariate analysis of variance (MANOVA). $P < 0.05$ was considered a significant difference.

Dependent variable 1	**Total knowledge score**
Dependent variable 2	Total attitude score
Between-group independent variables	Education Occupation Monthly family income Socio-economic status Willingness to participate in clinical trials

Results

Descriptive analysis

99% of heads of household were married men. 69.8% were Hindus. Half of the respondents belonged to Lower caste (50.5%), followed by Artisan caste (17.2%), Schedule caste (17.2%), Agriculture caste (14.1%) and Prestige caste (1%). Only 10.9% were graduates, 54.2% studied upto Middle and High School, and 34.9% had less than a primary education. In terms of occupation, majority were labourers (42.7%) with monthly family income in the range Rs. 6214 – Rs. 10356 (53.6%). Totalling the scores obtained using Modified Kuppuswamy Socio-Economic Status Scale revealed that 69.8% were from Lower Middle Class and 30.2% were from Middle Class.

The mean knowledge score was 22.24 ± 3.291 SD (n=192). Majority (86.5%) were not aware about clinical trial process. Almost all of them (96.9%) expressed that financial gain was the reason for taking part in clinical trials, a means of additional source of income. In the event of any side-effects from taking medicines during clinical trial participation, it is surprising to see that there were respondents who did not consider it important to take medical help. There were five respondents who felt that the volunteers of such clinical trials should keep it discrete and not tell anyone, for the fear of being scolded, rejected by family or treated differently by society.

The mean attitude score was 8.45 ± 1.439 SD (n=192). Though a majority of respondents (91.7%) considered experiments on humans essential to developing new treatments, they (76%) did not favour such experiments on humans. Most respondents (98.4%) said it is important to keep family members informed about clinical trial participation. Contrastingly, more than half the respondents (68.8%) opined that family members should reject the individual's voluntary decision about taking part in clinical trials. 77.6% respondents remarked such experiments are harmful to society. When asked, "given an opportunity, would they take part in clinical trials?" Majority (81.8%) said 'no'.

Regarding materials that educated them about participation in clinical trials, majority preferred to have messages through TV (17.2%), brochure (15.8%), messages in mobile (10.4%) and other means. The respondents wanted local government support in the form of monetary compensation for victims' family (10.9%) and panchayat meetings addressing this issue through expert advice (9.4%).

Two-way MANOVA

Two-way MANOVA is used to find out if there is an interaction between independent variables and the two dependent variables.

Checking correlation

The Pearson correlation for the dependent variables was within acceptable limits for MANOVA outcomes ($r=0.5$).

Checking assumptions

Levene's Test for homogeneity of variance assumption for dependent variables indicated that there is no homegeniety of between-group variance for knowledge ($p=0.001$) and attitude scores ($p= 0.008$). The Box's M value of 66.374 had a non-significant association with a p-value of 0.099. The covariance matrices between the groups were assumed to be equal.

Multivariate outcome

MANOVA was conducted to test null hypothesis that group mean vectors are all equal to one another. Wilks' Lambda is chosen. As shown in Table 1, a significant multivariate effect is obtained for the combined dependent variables of knowledge and attitude in respect of:

Education: λ = 0.868, $F(4,280) = 5.15$, p=0.001, partial eta squared = 0.069. Power to detect the effect was 0.868.

Occupation: λ = 0.852, $F(10,280) = 2.33$, p=0.012, partial eta squared = 0.077. Power to detect the effect was 0.852.

Education*Occupation: λ = 0.842, $F(14,280) = 1.79$, p=0.039, partial eta squared = 0.082. Power to detect the effect was 0.842.

Monthly family income*Willingness to participate in clincal trials: λ = 0.954, $F(2,140) = 3.34$, p=0.038, partial eta squared = 0.046. Power to detect the effect was 0.954.

Whereas, socio-economic status (p=0.194), monthly family income (p=0.269), willingness to participate in clinical trials (p=0.324) were not significantly associated with knowledge and attitude towards clinical trial participation.

Univariate statistics

Both dependent variables differed significantly in knowledge about clinical trial participation in respect of independent variables [education $F(2,141) = 9.886$, p<0.001) and occupation $F(5,141) = 4.64$, p=0.001)]. But not so with repect to attitude score [education $F(2,141) = 0.087$, p=0.917) and occupation $F(5,141) = 4.501$, p=0.775)].

Similarly, both dependent variables differed significantly in knowledge about clinical trial participation in respect of education*occupation*monthly family income $F(1,141) = 5.52$, p=0.02). Both dependent variables differed significantly in attitude score in respect of education*occupation*willingness to partcipate in clinical trials $F(1,141) = 5.069$, p=0.026).

Post-hoc analysis

Education

Since there did not exist equal variances across independent variables, Games-Howell outcome for knowledge and attitude scores is referred to. It indicated that graduates or those heads of households with higher levels of education were more knowledgeable (p<0.001; mean difference between 'graduates & above' and 'primary & below' is 8.32, 95% CI [6.97,9.67] whereas mean difference between 'graduates & above' and 'middle & high school' is 6.5, 95% CI [5.12,7.89]) and had better attitude towards clinical trial participation (p<0.001; mean difference between 'graduates & above' and 'primary & below' is 1.76, 95% CI [0.98,2.55] whereas mean difference between 'graduates & above' and 'middle & high school' is 6.50, 95% CI [0.66, 2.10]).

Occupation

As the hierarchy of occupation increases from low-skilled to professional jobs, there is an increase in knowledge score about clinical trial participation. Those in the Service sector, such as teaching and hospital have better understanding about clinical trial process than labourers. Mean difference between 'service-oriented occupation' and 'labourer' is 1.89, 95% CI [0.86, 2.93]

Table 1: Results of Multivariate Tests

Effect		Value	F	Hypothesis df	Error df	Sig.	Partial Eta Squared
Intercept	Wilks' Lambda	0.028	2.467	2	140	0.000	0.972
Education	Wilks' Lambda	0.868	5.154	4	280	0.001	0.069
Socio-economic status	Wilks' Lambda	0.977	1.659	2	140	0.194	0.023
Occupation	Wilks' Lambda	0.852	2.328	10	280	0.012	0.077
Monthly family income	Wilks' Lambda	0.964	1.304	4	280	0.269	0.018

Cont... **Table 1: Results of Multivariate Tests**

Willingness to participate in clinical trials	Wilks' Lambda	0.984	1.137	2	140	0.324	0.016
Education*Occupation	Wilks' Lambda	0.842	1.797	14	280	0.039	0.082
Monthly family income* Willingness to participate in clinical trials?	Wilks' Lambda	0.954	3.345	2	140	0.038	0.046

Discussion

While there had been studies in the past about awareness on clinical research with sampled population from general public and hospital patients who either had no knowledge[11,13,14] or some knowledge about clinical trial process[10], the very little knowledge that the heads of households of this study possessed about clinical trial participation is from the news that spread through the death of one of their residents in the neighbourhood who had secretly taken part in many clinical trials one after another, which made headlines in local news channels. With this, the villagers developed hatred towards pharma companies/CROs and felt that clinical trial volunteers are not taken care or treated properly by CROs.

This study brings out what the people want in order to avert another death or another unforeseen event in their village due to clinical trial participation. They want a professional such as teacher, doctor or nurse to explain to them the crucial steps in clinical trial participation such as informed consent, side effects, trial compensation, etc during gram sabha and special village gatherings. They would also like to have such information disseminated to them through radio, television and other means.

The multivariate analyses indicated that not all socio-demographic variables differed significantly in respect of a combination of knowledge and attitude towards clinical trial participation. Subsequent univariate analyses showed that there were significant effects for education and occupation in respect of knowledge and attitude scores. Games-Howell post hoc analyses suggested having educational qualification beyond high school and holding better jobs reflected in better knowledge and attitude about clinical trials process and participation.

Conclusion

The very few (13.5%) heads of households knew something about clinical trial process through word-of-mouth. They end up gathering wrongful information about clinical trials, developing negative attitude about it. This is reflected in victims fearing to take support from family or medics. One way to overcome this would be to disseminate the study findings to local village governance that will help in planning and conducting specific educational programs, tailored to appropriate cultural content and language and can be scaled to other rural settings in India with similar demographic and socio-economic characteristics.

Although the poor financial status of the family is the driving factor for the head of the household to discretely partake in clinical trials without his family's knowledge, it is not his socio-economic status that influences his awareness and perception about clinical trials but his education and occupational status. The educated masses from the community can be identified, training provided to them who in turn can educate the villagers, especially about making well-informed decision-making in clinical trial participation through reliable sources, encourage them to take medical help when in need and not to be lured by middle-men or agents.

Combination Of Walking Practices And Yogic Practices On Low Density Lipoprotein (Ldl) Among Middle Aged Women

James Rathinaraj. S[1]., P. Yoga [2], K. Alaguraja[3], K. Selvakumar[4]

[1]Research Scholar, [2]Assistant Professor, [3]Research Scholar, [4]Research Scholar, Alagappa University College of Physical Education, Alagappa University, Karaikudi, Tamilnadu, India

Abstract

The purpose of the present study was to investigate the efficacy of combination of walking practices and yogic practices on low density lipoprotein (LDL) among middle aged women. To achieve the purpose of the study thirty school students were selected from Karaikudi, Tamilnadu, India during the year 2019. The subject's age ranges from 35 to 45 years. The selected subjects were divided into two equal groups consists of 15 middle aged women each namely experimental group and control group. The experimental group underwent a combination of walking practice and yogic practices programme for six weeks. The control group was not taking part in any training during the course of the study. Low density lipoprotein was taken as criterion variable in this study. The selected subjects were tested on low density lipoprotein was measured through heparin precipitation method. Pre-test was taken before the training period and post- test was measured immediately after the six week training period. Statistical technique't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference is found due to combination of walking practice and yogic practices given to the experimental group on low density lipoprotein when compared to control group.

Keywords: *combination of walking practice and yogic practices, low density lipoprotein and't' ratio.*

Introduction

Everyday the human body have received some unwanted food store from the individual habits and its leads to some acute and chronic issues. Yoga is a great soul of the Universe. It can promote the social well being through limps of yoga (Asanas, Pranayama, Kriyas, Mudras and Meditations). To practising yoga regularly it can make you into sound body and sound mind. Yoga is the costless permanents treatment for more diseases, alaguraja, k[1]. It is a practical holistic philosophy designed to bring about profound state as well is an integral subject, which takes into Consideration man as a whole, alaguraja, k. et.al.,[2].

One can start practicing Yoga at any given moment of time and you may start with meditation or directly with pranayama without even doing the asanas (postures), alaguraja, k. et.al,[3]. The science of Yoga Nidra is based on the receptivity of consciousness. When consciousness is operating with the intellect and with all the senses, by making an individual think that he or she is awake and aware, but the mind is actually less receptive and more critical, yoga, p. et. al., 2019[4]. Training is a chain process that can be able to attain certain needs of the person's goal, alaguraja, k.[5]. In the sports world, physical education is the most essential aspect due to the fact physical schooling increases the performance and the effectiveness of the sports, alaguraja, k. et.al.,[6]. Today, sports have become a part and parcel of our culture. It is being influenced and does influence all our social institutions including education, economics, arts, politics, law, mass communication and even international diplomacy, alaguraja, k. et.al,[7]. The sports training can produce some physical fitness, Physiological and psychological benefits to the person and attain performance related task. It's also promoting the individual overall wealth to the sports person, alaguraja, k.[8]. Yoga is a methodical effort towards self-perfection by the development of the potentialities latent in the individual, alaguraja, k. et.al,[9]. Today's there is an escalating emphasis on appearing smarter, feeling etter and living longer. In order to achieve these ideals

as, scientific evidence tells us that one of the keys is high fitness and exercises, alaguraja, k. et.al,[10]. Asanas is a limp of Yoga practice it can make some health related gains to the individual who involved in yogasana practice regularly. Asanas can be used upon the needs of the person. It's a scientific process the person must be follow the basic principles yogasana practice[11]. Yoga is a practical aid, not a religion and its techniques may be practiced by Buddhist, Jews, Christians, Muslims, Hindus and Atheist alike. Yoga is union for all, selvakumar, k. et.al,[12]. Yogic action, or inner technique, such as breath control, parthasarathy., s. et.al,[13].

Research Methodology

Selection of subjects

The purpose of the study was to find out the effect combination of walking practices and yogic practices on low density lipoprotein (LDL) among middle aged women. To achieve this purpose of the study, thirty middle aged women were selected as subjects at random. The age of the subjects were ranged from 35 to 45 years.

Selection of variable

Independent variable

- Combination of walking practice and yogic practices

Dependent variable

- Leg Explosive Power

Experimental Design and Implementation

The selected subjects were divided into two equal groups of fifteen subjects each, such as a combination of walking practice and yogic practices group (Experimental Group) and control group. The experimental group underwent combination of walking practice and yogic practices for five days per week for six weeks. Control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following bio chemical variable namely low density lipoprotein was selected as criterion variable. All the subjects of two groups were tested on selected criterion variable low density lipoprotein was measured through heparin precipitation method at prior to and immediately after the training programme.

Statistical technique

The't' test was used to analysis the significant differences, if any, difference between the groups respectively.

Level of significance

The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

Analysis of the Data

The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent 't' test was used with 0.05 levels as confidence.

Variables	Group	Mean		Degree of freedom	't' ratio
		Pre	Post		
Low density lipoprotein	Control Group	101.11	101.16	14	1.37
	Experimental Group	101.18	100.70	14	15.87*

**Significance at 0.05 level of confidence.*

The Table-I shows that the mean values of pre-test and post-test of the control group on low density lipoprotein were 101.11 and 101.16 respectively. The obtained 't' ratio was 1.37, since the obtained 't' ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of the experimental group on low density lipoprotein were 101.18 and 100.70 respectively. The obtained 't' ratio was 15.87* since the obtained 't' ratio was greater than the required table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant.

Result of the Study

The result of the study showed that there was a significant difference between control group and experimental group in low density lipoprotein. It may be concluded from the result of the study that experimental group improved in low density lipoprotein due to six weeks of combination of walking practice and yogic practices.

Figure-1

Bar Diagram Showing the Pre and Post Mean Values of Experimental and Control Group on Low density lipoprotein

Discussions on Findings

The result of the study indicates that the experimental group, namely combination of walking practice and yogic practices group had significantly improved the selected dependent variable, namely low density lipoprotein, when compared to the control group. It is also found that the improvement caused by combination of walking practice and yogic practices when compared to the control group.

Conclusion

On the basis of the results obtained the following conclusions are drawn,

1. There was a significant difference between experimental and control group on low density lipoprotein after the training period.
2. There was a significant improvement in low density lipoprotein. However the improvement was in favor of experimental group due to six weeks of combination of walking practice and yogic practices.

Risk Factors Leading to Mental Illness among Patients: A Retrospective Study

Jiji Benny[1], Shivakumara J[2], Thereza Mathias[3]

[1]P G Student -M.Sc Nursing (Psychiatric Nursing),[2]Professor, [3]Professor and HOD, Department of Mental Health Nursing, Laxmi Memorial College of Nursing, A J Towers, Balmatta, Mangaluru

Abstract

Background: Mental disorder is a psychological factor reflected in the behavior, which affect the normal development of a person's culture. The burden of mental health problems is increasing globally. Most mental disorders are result of a combination of several different factors rather than just a single factor. Knowing the risk factors leading to mental illness, may help in future to reduce the incidences of mental illness by taking possible preventive measures.

Aim: The main aim of this study was to determine the risk factors leading to mental illness among patients.

Materials and Method: Case control study design with quantitative non experimental descriptive survey approach was used .Mini mental status examination tool was used to select 100 psychiatric patients based on inclusion criteria and 100 general populations to find the odds ratio. Data was collected using a demographic proforma and risk factors assessment check list.

Results: In biological, socioeconomic, environmental, psychological and personal factors, the highest value of the odds ratio of risk factors for mental illness is sleep disturbance (16.385), financial problems (3.149), slum area (3.162), feeling of loneliness (13.821) and chronic smoking (16.116) respectively; it is higher among patient with mental illness compared to the general population.

Conclusion: Most of the subjects are having one or other risk factors for developing mental illness**.** Hence we need to take care about risk factors and maintain good lifestyle to promote optimal mental health.

Keywords: *Risk factors of mental illness; psychiatric patients; general population; retrospective study.*

Introduction

Mental health as an adjustment of human being to the world and to each other with maximum of effectiveness and happiness.[1] Mental illness is often disorders of the brain that disrupts a person's thinking, feeling, mood, and ability to relate to others. Mental illnesses are of different types and degrees of severity. Some of the major types are depression, anxiety, schizophrenia, bipolar mood disorder, personality disorders, and eating disorders etc. [2]

The causes of mental disorders are complex and interact and vary according to the particular disorder and individual. Genetics, early development, drugs, a loss of a family members, disease or injury, stress, bereavement, relationship breakdown, physical and sexual abuse, unemployment, social isolation, and major physical illness or disability neuro cognitive and psychological mechanisms and life experiences, society and culture can all contribute to the development or progression of different mental disorders.[3] According to WHO, one in every four people develops one or more mental disorders at some stages in life. In India, the reported rate is 73 per 1000 population.[4]

The report of District Health and Family Welfare Office of Dakshina Kannada showed that nearly 238 neurotic and 300 psychotic cases of mental disorder were recorded during the year 2007-2008. Among these only 59 neurotics and 77 psychotic cases had approached for the treatment.[5]

The National Institute of Mental Health and Neuro Science (NIMHANS) report shows that in India 70 million people suffer from mental ailments and yet, 50-90% of them are not able to access corrective services due to less awareness and negative attitude or stigma towards mental illness.[6]

Community- based surveys conducted during the past two decades in India showed that the total prevalence of psychiatric disorder was around 5.8% and depression will be one of the biggest health problems worldwide by the year 2020.[7]

Materials and Method

The study was conducted over a period of two years at selected hospitals, Mangalore, India. Case-control study design with quantitative non experimental descriptive survey approach was used. Formal permission was obtained from the director and administrative department of selected hospitals. The researcher used the Mini Mental Status Examination tool for assessing the level of insight of the patients and followed by the researcher was selected 100 psychiatric patients who has the insight and 100 general populations in a similar background and setting by purposive sampling technique based on sampling criteria to find odds ratio of mental illness. The investigator used demographic proforma and risk factors assessment check list to determine the risk factors leading to mental illness.

Mini Mental Status Examination tool :(Folstein MF, Folstein SE and MC Hugh PR, 1987): It is a standardized tool for assessing the level of insight of psychiatric patients. The reliability of the tool was 0.98. It consisted of five characteristics namely, orientation, registration, attention and calculation, recall, language with total number of score 30 and it is graded as (24-30 no cognitive impairment, 18-23 mild cognitive impairment, 0-17 severe cognitive impairment).

Demographic Proforma: This is for assessing the background information of samples. Which consisted of 11 characteristics namely, age, gender, education, occupation, and marital status, types of family, number of children, number of siblings, birth order, duration of illness and number of previous admission in psychiatric unit.

Risk factors assessment checklist: To determine the risk factors leading to mental illness. Tool was prepared on five aspects of the risk factors such as biological factors (36 items), socio economic factors (9 items), environmental factors (5 items), psychological factors (24 items), and personal factors (15 items) with a total of 89 items in five areas with check responses provided as yes or no answers.

The gathered data was analysed using SPSS software system of version 16. Frequency and percentage distribution was calculated to analyse the sample characteristics and risk factors leading to mental illness. The chi-square test was computed to analyse the association of risk factors leading to mental illness with selected demographic variables. Odds ratio was calculated to compare the magnitude of various risk factors for that outcome.

Results

Section –1: Description of Sample characteristics

The study finding shows that highest percentages (27%) of the psychiatric patients were in the age group of 20-29 years in case group where as in control group, highest percentage (30%) of the samples were in the age group of 30-39 years' old. Majority (57%) of psychiatric patients were female where as in control group, majority (60%) of samples were female. Educational status of the psychiatric patients revealed that highest percentage (26%) of patients had studied up to secondary education where as in control group, highest percentage (27%) of them had studied up to secondary education. Majority (53%) of the patients were unemployed in case group where as in control group, highest percentage (38%) of them was unemployed. Most (69%) of the patients were married where as in control group, most (92%) of the patients were married. Majority (72%) of the patients belonged to nuclear family where as in control group, majority (73%) of them belonged to nuclear family. Majority (34%) of the patients had two children where as in control group, majority (44%) of them had two children. Number of the siblings of the psychiatric patients revealed that majority (52%) of the patients had more than 3 siblings where as in control group, majority (63%) had 3 siblings. Orders of birth in the case group, majority (42%) were first born where as in control group,

majorities (35%) were second child. Majorities (26%) of the patients were having mental illness for less than a year. Number of previous admission in the psychiatric unit revealed that majorities (41%) of the patients were admitted once to the psychiatric ward previously.

Section II: Assessment of Risk Factors Leading To Mental Illness

Table 1: Frequency Percentage Distribution of Risk Factors Leading To Mental Illness

Sl. No.	Risk factors	Case (N=100)	Control (N=100)	Chi-square value	df	P- value
		(f)	(f)			
I	**Biological factors**					
1	**Physical deprivation**					
1.1	Poor nutrition	7	0	0	0	0.014
1.2	Sleep disturbance	71	13	69.048	1	0.000*S
2	**Present physical illness**					
2.1	Hypertension	16	28	4.196	1	0.041
2.2	Epilepsy	9	2	4.714	1	0.030
2.3	Thyroid dysfunction	13	2	8.721	1	0.003
3	**Family history of Paternal**					
	Father	19	9	4.153	1	0.042
	Brother/sister	23	9	7.292	1	0.007
	Maternal					
	Uncle	6	1	3.701	1	0.054
	Cousins	8	2	3.789	1	0.052
	Brother/sister	9	0	0	0	0.003
II	**Socioeconomic factors**					
4	Financial problems	32	13	10.351	1	0.001
5	Joint family	24	11	5.853	1	0.016
6	Family migration	5	0	0	0	0.059
III.	**Environmental factors**					
7	Place of residence					
7.1	Slum area	26	10	8.672	1	0.003
8	Adverse influence of mass media (computer, radio, newspaper)	5	0	0	0	0.059
IV.	**Psychological factors**					
9	Stress full life events					
9.1	Love failure	8	0	0	0	0.007
9.2	Feeling of loneliness	22	2	18.939	1	0.000
10	Loss of a significant person					
	Father	18	3	0	0	0.001
V.	**Personal factors**					
11	Chronic smoking	14	1	12.180	1	0.000
12	Family conflict	13	3	6.793	1	0.009
13	Difficulty at school					
13.1	Fear of punishment	5	0	0	0	0.059

Data depicted in [Table 1] shows that the following risk factors are significantly predisposed to mental illness among cases (psychiatric patients) such as poor nutrition (P=0.014), sleep disturbance (P=0.000), hypertension (P=0.041), epilepsy (P=0.030), thyroid dysfunction (P=0.003), paternal-father (P=0.042), brother/sister (P=0.007), maternal-uncle (P=0.054), maternal-cousins (P=0.052), maternal-brothers/sisters (P=0.003), financial problems (P=0.016), family migration (P=0.059), slum area (P=0.003), adverse influence of mass media (P=0.059), work related stress (P=0.069), love failure (P=0.007), feeling of loneliness (P=0.000), loss of significant person (father) (P=0.001), chronic smoking (P=0.000), family conflict (P=0.004), and fear of punishment (P=0.054) along with case and control group.

Section III: Determination of Odds ratio of Risk Factors Leading To Mental Illness

Table 2: Odds ratio of risk factors for mental illness among psychiatric patients and general population n=200

SL. No	Risk Factors			Odds Ratio
		Case (100)	Control (100)	
I	**Biological factors**			
	• Sleep disturbance	71	13	16.385
II	**Socioeconomic factors**			
	• Financial problems	32	13	3.149
III	**Environmental factors**			
	Place of residence			
	• Slum area	26	10	3.162
IV	**Psychological factors**			
	• Feeling of loneliness	22	2	13.821
V	**Personal factors**			
	• Chronic smoking	14	1	16.116

Data in Table 2 shows that in biological, socioeconomic, environmental, psychological and personal factors, the highest value of the odds ratio of risk factors for mental illness is sleep disturbance (16.385), financial problems (3.149), slum area (3.162), feeling of loneliness (13.821) and chronic smoking (16.116) respectively; it is higher among patient with mental illness compared to the general population.

Section IV. Association of risk factors of mental illness with selected demographic variables.

Table 3: Association of demographic variables with risk factors of mental illness in case and control group n=200

Sl. No.	Demographic factor with Risk Factors	Case(100)		Control (100)	
		Chi-square value	P Value	Chi-square value	P Value
1	Occupation (sleep disturbance)	9.460	0.051*	3.057	0.548
2	Gender (diabetes mellitus)	0.672	0.412	4.001	0.045*
3	Age(hypertension)	9.008	0.016*	0.814	0.937
4	Marital status(hypertension)	15.534	0.004*	1.036	0.309
5	Education(epilepsy)	5.328	0.5036	16.667	0.020*
6	Type of family(epilepsy)	3.846	0.050*	0.548	0.459
7	Marital status(migraine)	9.789	0.048*	0.524	0.469
8	Age (thyroid dysfunction)	17.880	0.001*	2.211	0.697
9	Marital status (joint family)	5.606	0.231	6.238	0.013*
10	Type of family (joint family)	41.009	0.000*	25.612	0.000*
11	Type of family (riot prone area)	3.725	0.054*	1.118	0.290
12	Gender (work related stress)	6.206	0.013*	0.174	0.677
13	Occupation (work related stress)	20.572	0.000*	2.245	0.691

*- significant

Data presented in Tables 3 shows that there is a significant association between the risk factors of mental illness like sleep disturbance, diabetes mellitus (control), hypertension, epilepsy, (both case and control group) migraine, thyroid dysfunction, joint family (both case and control group), riot prone area, work related stress with selected demographic variables. Hence the null hypothesis is rejected and research hypothesis is accepted. There is no significant association found between the rests of the risk factors of mental illness with selected demographic variables.

Discussion

There is a paucity of literature looking to identify the various risk factors leading to mental illness. The present study intended to identify the risk factors leading to mental illness among patients in selected hospitals, Mangalore.

The present study findings are consistent with a longitudinal study conducted on sleep disturbances and depression: risk relationships for subsequent depression and therapeutic implications shows that 90% of patients with depression will have sleep quality complaints. About two third of the patients undergoing a major depressive episode will experience insomnia, with about 40% of patients complaining of problems initiating sleep (sleep onset difficulties), maintaining sleep (frequent awakenings), and/or early-morning awakenings (delayed or terminal insomnia), and many patients reporting all three. Hypersomnia occurs in about 15% of patients. Sleep problems sometimes emerge as a symptom of depression or as a side effect of treatment.[8]

The present study showed that in biological, socioeconomic, environmental, psychological and personal factors, the highest value of the odds ratio of risk factors for mental illness is sleep disturbance (16.385), financial problems (3.149), slum area (3.162),

feeling of loneliness (13.821) and chronic smoking (16.116) respectively; it is higher among patient with mental illness compared to the general population.

The study findings are supported by an epidemiologic study of sleep disturbances and psychiatric disorders shows that the risk of developing new major depression was much higher in those who had insomnia at both interviews compared with those without insomnia (odds ratio, 39.8; 95% confidence interval, 19.8 to 80.0).[10]

Study on loneliness in the general population: prevalence, determinants and relations to mental health shows that a total of 10.5% of participants reported some degree of loneliness (4.9% slight, 3.9% moderate and 1.7% severely distressed by loneliness). Loneliness declined across age groups. Loneliness was stronger in women, in participants without a partner, and in those living alone and without children. Controlling for demographic variables and other sources of distress loneliness was associated with depression (OR=1.91), generalized anxiety (OR=1.21) and suicidal ideation (OR=1.35).[11]

The present study shows that there is a significant association between the risk factors of mental illness like sleep disturbance, diabetes mellitus (control), hypertension, epilepsy, (both case and control group) migraine, thyroid dysfunction, joint family (both case and control group), riot prone area, work related stress with selected demographic variables. Hence the null hypothesis is rejected and research hypothesis is accepted. There is no significant association found between the rests of the risk factors of mental illness with selected demographic variables.

The study findings are supported by a study on relationships of occupational stress to insomnia and short sleep in Japanese workers shows that in men, high occupational stresses were significantly associated with insomnia, especially a high level of Effort Reward Imbalance (defined as the presence of high effort and low reward), had a remarkably higher odds ratio. In women, high occupational stresses were significantly associated with insomnia as well. High occupational stresses were significantly associated with short sleep in men. However, in women, only Effort Reward Imbalance showed a significantly association with short sleep.[12]

Conclusion

Most of the samples are having one or other risk factors for developing mental illness**.** Some of the most relevant risk factors are sleep disturbance, financial problems, slum area, feeling of loneliness, chronic smoking etc. Hence we need to take care about these risk factors and maintain good lifestyle to promote optimal mental health.

A Cross Sectional Study to Assess the Impact of Knowledge, Attitude and Practice (KAP) of Parents on Immunization Coverage of their Children

Juny Sebastian[1], Gurumurthy Parthasarathi[2], Mandyam Dhati Ravi[3]

[1]Lecturer, Department of Pharmacy Practice, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, Karnataka, India, [2]Director, Pharmacovigilance and Clinical Trials, Botswana Medicines Regulatory Authority, Gaborone, Botswana, [3]Professor, Department of Department of Pediatrics, JSS Medical College and Hospital, JSS Academy of Higher Education & Research, Mysuru, Karnataka, India

Abstract

Background: Many studies proved that, parents' knowledge on the risks and benefits of vaccination is directly proportional to the attitude and practice in immunizing their children. As parents are the decision makers, their KAP towards vaccination play a major role in achieving adequate immunization coverage of the community.

Objective: To assess the impact of parent's KAP on immunization coverage of their children.

Method: A cross sectional study enrolled parents of children aged 2-5 years visiting the pediatric department of JSS Hospital, Mysuru. A validated KAP questionnaire in local language was used as the study tool. Median split method was used to categorize the parent's KAP into adequate and inadequate. Statistical analysis was performed using independent t-test and One Way ANOVA.

Results: The mean KAP score of the study population was 15.25 and 56.54% (n=95) of them scored more than the mean KAP. The adequate KAP score was observed among 51.19% of the study population and 48.81% had inadequate KAP scores. The study identified a statistically significant association between the KAP scores of the parents and the immunization coverage of their children. Significant association was also observed between the KAP scores and factors such as number of kids, place of stay , educational and socioeconomic status of the parent.

Conclusion: It is important to understand the KAP of parents towards immunization of their children and develop and implement suitable interventions/strategies to improve the immunization coverage.

Key words: *Immunization coverage, Impact of education, Knowledge Attitude and Practice, Parental KAP, Vaccination*

Introduction

Immunization prevents 2-3 million deaths globally and an additional 1.5 million deaths could be avoided if the global immunization coverage improves.[1,2] With the exception of safe water, no other modality, have had such a contributing effect on population growth and reduction in mortality.[2] Globally, the number of infants missing basic vaccines were estimated as 21.8 million.[3]

Though there is slight improvement in the immunization coverage in recent years, still India, have 7.4 million unimmunized children and is responsible for more than five lakh deaths annually.[4] According to the United Nations International Children's Emergency

Fund and National Family Health Survey-4 (NFHS-4), the percentages of children fully vaccinated between the age groups of 12 to 23 months were only 62% in India and 55% in one of the south Indian state, Karnataka.[5,6]

Lack of awareness on benefits of vaccination and completion of vaccination schedule, wrong ideas on vaccination, child sickness, cultural diversity and conflicting priorities of parents and Adverse Events Following Immunizations (AEFIs) are some of the important barriers for India to lag behind in immunization coverage.[3] Another important reason for vaccine hesitancy among the parents is anti-vaccine movements, which encourage them to refuse vaccination for their children and lead to a reduction in the expected herd immunity.[7] Previous studies proved that the parents' knowledge on the risks and benefits of vaccination will directly influence the attitude and practice in immunizing their children.[8] This study was conducted to assess the impact of knowledge, attitude and practice (KAP) of parents on the immunization coverage of their children.

Materials and Method

This cross sectional study was conducted over a period of six months at the pediatric department of Jagadguru Sri Shivarathreeshwara Hospital, Mysuru, Karnataka, India. Ethical clearance was obtained from institutional human ethics committee before the commencement of the study. Study enrolled either of the parents of children aged between two to five years visiting the study site for any reason and who are able to provide the immunization card to the researcher. Eligible parents were counseled and enrolled in to the study after taking the informed consent.

Validated self-administered KAP questionnaire[9] was used as the tool to collect the data from the enrolled parents. If the child had received all immunizations required until the age of two as per the immunization card was classified under 'complete immunization' and others were under 'partial immunization'.[10] KAP questionnaire scoring was done by allotting zero and one point for each incorrect and correct answer respectively. Median split method was used to categorize the parent's KAP into adequate and inadequate.[9,11] Parents having an aggregate KAP score lower than 17, the calculated median, were categorized under inadequate KAP on immunization. Independent t test and one-way ANOVA were performed wherever necessary. *P* value of <0.05 was considered statistically significant with 95% confidence interval.

Results

From the total 168 parents enrolled in the study, 57.14% were males, 80.95% were from the rural area and 37.50% belonged to upper middle socioeconomic class. Mean age of the fathers and mothers enrolled in this study were 32.7 5.58 and 27.9 5.86 years respectively. Among the study population, 80.95% completed the vaccination schedule of their children as per the age of two years.

Knowledge Domain

The mean knowledge score of the study population was 9.79, which was 65.2% of the total score. The knowledge (11.61) level was high among the parents who had two children whereas the knowledge (5.84) scores were less among the parents having three children. People living in urban residential area (15.59) and the parents who were graduates or postgraduates (19.0) had better Knowledge scores when compared to others.

Practice domain

Among the study population, partial immunization coverage was identified in 19.05% of the study population. Various reasons for non- completion of immunization schedule was news about AEFIs [n=16(09.52%)], child sickness [n=08(04.76%)], child receiving many injections [n=08(04.76%)], forgetfulness [n=02(01.19%)] social or religion reasons/ lack of transport facilities / non availability of vaccines [n=01 (0.59%)each] and there was no specific reason among 02.97% of the study population.

Attitude Domain

Only 82.92% of population answered that they support immunization program of the country and 23.80% answered that they do not recommend immunization to others. Also, 82.15% of parents answered that they are favoring the immunization program of the country.

KAP Scores of study population

The mean KAP score of the study population was 15.25 and 56.54% (n=56.54%) of the study participants scored more than the mean KAP. The adequate KAP score was observed among 51.19% of the study population, whereas 48.81% had inadequate

KAP scores. 68.45% of parents who completed the immunization schedule had adequate knowledge and 31.54% of the parents who completed the immunization schedule had inadequate knowledge. The adequate KAP score was observed for the parents whose children completed the vaccination schedule [80.35%(n=135)] as per their age where as very low level KAP [07.73%(n=13)] was observed among the parents whose children didn't complete the schedule. KAP scores of the study population are presented in table I. There was statistically insignificant difference in the KAP scores of both parents, where as a significant association was identified between the KAP scores and the number of children, place of stay and the immunization status of the children (table II).

Discussion

The result of this study was similar to the findings of studies from various parts of the world.[7,11-14] Almost half of the enrolled study population had adequate knowledge on immunization. The percentage of parents in our study who knew that the vaccination prevents disease was 91.1% and a similar result was obtained from a study conducted in Pakistan (94%).[15] Studies from other Asian countries also had similar findings on knowledge of vaccination.[11,14] The study population was immunizing their children as a routine practice however their knowledge that the vaccination improves

the child's immunity against a particular Vaccine preventable diseases (VPD) was very less among the study population. One of the reasons for incomplete vaccination was the news about the occurrence of VPD even after the vaccination[15] that make them feel that the vaccine administered through EPI are not effective hence vaccination is not important.

History of severe allergic reaction during the previous dose of vaccine or to a component of vaccine is the only contraindication applicable to all vaccines.[15] The study participants, only 19.0% answered that any acute illness was a contraindication for vaccination and the remaining couldn't answer the question, similar to other published studies.[11,16] Only 65.5% of the parents answered that government provides many vaccines freely to Indian citizens, the others considered the consultation fee charged at the hospitals were the cost of the vaccinations.

The immunization status was categorized as complete vaccination among 75% of our study population and the finding is almost in line with other studies from other parts of India also categorized 78% of the children under the category of complete immunization.[10,13] In a study from Iraq, only 56.3% of the children were considered to have received complete immunization, the difference in the percentage may be due to the cultural and political situation in the country.[4,11]

Percentage of parents (82.15%) favoring the immunization program and recommending the vaccination to others (83.92%) was less in our study compared to an Iraqi study, where 94% and 96% of parents favoring the immunization program and recommending the vaccination to others respectively.[11] In a studies from Pakistan and Saudi Arabia, 57.7% and 89.3% of parents respectively recommended the vaccination to others though 96% and 100% respectively favored the vaccination program.[14,17] The difference in the attitude pattern could be related to the environmental and socioeconomic status prevailing in each of these countries.[11] There are studies published that describes the influence of religion on parental decision on vaccination as an excuse for non-vaccination.[18,19] However the current study couldn't assess the influence of religion on vaccination coverage, as there were no sufficient representative sample from different religion.

Previous studies conducted couldn't find a statistically significant association between the education status and socio-economic background of the children with the immunization coverage whereas our study showed a statistically significant correlation of KAP with educational status and socioeconomic background of parents.[17] Parents with more than three children had shown a better KAP scores in a previous study from Saudi Arabia.[20] Low education and low socio economic status might have contributed for the difference in the KAP score observed in our study when compared to the study from Saudi Arabia.[19] Similar to our study, the previous studies also found a significant association between the knowledge about vaccination and the completeness of immunization schedule.[11] This clearly describes the need of education to parents to improve the immunization coverage of the community. Study population answered that side effects of vaccines were one of the major reason for non-administration of vaccine in our population similar to previously published literatures.[20]

Conclusion

KAP of the parents about immunization is the key for the immunization coverage of their children. It is important to understand the KAP of parents towards immunization of their children and develop and implement suitable strategies to improve the immunization coverage. The strategies can vary based on the culture and education of the population. Personalized education to the parents may be useful in improving the KAP and there by the immunization coverage.

Limitations: The study represents the KAP of the parents who were literate. The illerate people were excluded from the study as the tools used for the study was a self administered questionnaire.

Abstract

Backgroun: Prevalence of oral cancer is high in India , other Asian countries, Brazil and France. Micro nutrients like copper and zinc are increasingly recognized for their role during the onset and progression of pre malignant and malignant oral lesions.

Aim -To determine serum levels of copper and zinc among oral cancer patients

Objective -To estimate and compare the serum levels of copper and zinc in healthy and cancer patients and to derive Cu/Zn ratio, to establish a possible relationship between micro nutrients and oral cancer.

Materials and Method - 25 patients clinically diagnosed with oral cancer (study group) and 25 healthy individuals (control group) in the age group of 30-50 years were included in the study. Blood samples were collected and serum copper and zinc values for both cancer and control group were estimated using ERBA CHEM 5 semi auto analyser. Mean and standard deviation of serum copper and zinc values for both the groups were determined and compared. .

Results- Significantly higher values ($p < 0.04$) were noted for serum copper level (mean value 249.39 ± 58.3 µg/dl) for study group compared to control group (123.95 ± 16.2 µg/dl). However there was no significant difference in serum zinc values between both the groups.

Cu /Zn ratio of 1.43 and 2.86 for control and study group respectively was derived from the above estimated value

Conclusion -Mean serum copper value in study group was significantly higher than in the control group mean may be considered as a biological marker for oral cancers.

Keywords : *Zinc, copper , oral cancer , serum levels, micronutrients*

Introduction

Oral cancer is one of the most prevalent and 6th most common type of cancer in the world [1]. Prevalence of oral cancer is higher in, India, Asia Brazil and France compared to other countries globally. Incidence and distribution vary by age, ethnic group, culture and lifestyle associated factors [2]. Alcohol, viruses, genetic mechanisms, candida, and chronic irritation have modifying effects on the etiology of oral cancer .Tobacco can cause genetic damage and can lead to development of oral cancer. Smoking and alcohol consumption are major risk factors [3]. It mostly affects the tongue, buccal mucosa, gingivae, lips, and palate [4] .It was also found that higher intake of fruits and vegetables had lower risk of oral cancer but an unbalanced diet has been related to an elevated risk. [5]

Clinical and histopathological examination of oral lesions plays a major role in the diagnosis of oral cancer. In addition, it has been reported that levels of trace elements or micro nutrients such as copper, zinc, iron

Corresponding author:

and selenium are altered in serum, plasma and tissues of pre malignant oral lesions [2] [6]

Copper, zinc, iron are chemical elements required in minute quantities for vital biochemical reactions such as free radical formation and cellular homeostasis[2]. The enzymes of trace elements are an important part of certain biological and chemical reactions. [7]. Zinc is also an important constituent of biological bio membranes and contributes to membrane stability. It modulates activities of ribonucleic acid and deoxyribonucleic acid polymerase enzymes [8, 9].The need of zinc for a healthy immune system, cell division, skin, hair, and muscle growth cannot be overemphasized.

Copper is involved in the release of energy during cell formation of red blood cells, collagen production, and iron absorption.

However, it was found that there is a potential link between trace elements and carcinogenesis. The ratio of copper to zinc is also believed to be a reliable biomarker in the development and progression towards malignancy [10]. Copper and zinc are often recognized for their possible role in the prevention and modulation of diseases but recent studies have proved increased level of copper and decreased level of zinc in cancer [11].

The present study was undertaken to evaluate and compare the levels of copper and zinc in the blood serum of normal and patients with oral cancer.

Materials and Method

The sample for the present study consisted of 50 individuals. 25 healthy individuals from the outpatient clinic accepted to participate in the study as controls. 25 patients diagnosed with oral cancer were included as the observational study group from the outpatient department, Oral Cancer Institute of Sabetha dental college. The study was approved by the Institutional Ethical Committee and informed consent was obtained from the patients prior to the blood sample collection. The participants were chosen based on the following inclusion and exclusion criteria. Inclusion criteria included patients diagnosed with carcinoma, in the age group 30 – 50 years, and for control group, healthy individuals with no history of systemic disorders were chosen. Exclusion criteria included immuno compromised adults, patients diagnosed with endocrine disorder, coronary artery disease and infectious diseases like tuberculosis or syphilis. Methodology included collection of 5ml of blood sample under absolute asepsis and transferred to acid washed test tubes .The blood collected was centrifuged at 2500rpm for 15 minutes and preserved in a frozen state until analysis. The samples were then analyzed using ERBA CHEM 5 semi auto analyzer. Serum levels of zinc and copper were assessed with the help of reagents provided.

The data obtained, was statistically analyzed using the SPSS software. Range of values of all the samples for serum copper and zinc were evaluated and grouped (Tables Me, II). Mean and standard deviation for serum copper and zinc of both the groups were determined and compared for statistical significance $p<0.05$ (Table III). Cu/Zn ratio was then derived from the above estimated value.

Results

Analysis of the data revealed that serum zinc values ranged from 60 µg/dl to 119 µg/dl in both the groups. (Table I). However a maximum of 8 samples were in the range of 100- 109 µg/dl in controls , and a maximum of 7 samples were in the range of 90 - 100 µg/dl in the study group. The mean value for serum zinc in control group was 86.64±17.4 µg/dl ,while the serum zinc level in the study group was found to be 85.17±14.98µ/dl (Table III). There was no statistically significant difference in the mean serum zinc values between study and control groups.

Table 1 Frequency table and range of serum zinc values

Zinc serum level observed in the study	No. of samples in cancer study group (n=25)	No. of samples in control group (n=25)
60-69 µg/dl	3	3
70-79µg/dl	2	4
80-89µg/dl	4	5
90-100µg/dl	7	5
100-109µg/dl	3	8
110-119µg/dl	6	0

On the contrary, the serum copper level ranged from 180-340ug/dl in study group while in the control group it

varied from 110-160ug/dl. (Table II). A maximum of 8 samples were in the range of120-129 µg/dl in the control and a maximum of 8 were in the range of 300-339 µg/dl in the study group. The mean serum copper values were found to be higher in study group 249.39±58.3 µg/dl, compared to that of healthy control group 123.95±16.2 µg/dl. (Table III). Mean serum zinc levels showed no changes.

Cu /Zn ratio was1.43 and 2.86 for control and study group respectively.

Table III: Mean values and standard deviation of serum copper and zinc values

Table II a	
Serum copper level in control group	**No of samples (n=25)**
110-119µg/dl	4
120-129µg/dl	8

Discussion

Trace elements Copper (Cu), zinc (Zn), selenium (Se) and molybdenum (Mo) are required in small concentration and have important role in many biochemical reactions. They are essential for proper functioning of life supporting processes and are an essential component of biologically active constituents [13, 14]. Copper is found in plasma (90-95%) as part of oxidative enzyme ceruloplasmin [15]. It is also a part of various enzymes like tyrosinase, cytochrome oxidase etc., and participates in oxidative process in cell metabolism. Zinc another micro nutrient is essential for gene transcription and cell multiplication and critical for activation of RNA and DNA polymerase activity. Decreased zinc levels are associated with increased oxidative stress at cellular level [16].

The normal serum copper and zinc levels are 0.6 - 1.6µg/ml and .6 -1.5µg/ml respectively where atomic absorption spectrometry has been used for analysis [17]. Others [10] have reported 114.20±38.69 mg/dl, 64.57±31.54 mg/dl as copper and zinc values respectively in their control sample by means of calorimeter. The values of these trace elements estimated in the present study were performed with ERBA CHEM 5 semi auto analyzer.

Concentrations of copper when exceeds the optimal level turns toxic. It breaks down the DNA strands or modifies the bases and deoxyribose. [12]. Sliwinski et al observed that zinc did not induce DNA damage in normal cells but exerted a protective effect against DNA damaging agents but increased cytotoxic effect on cancer cells[11] . A number of studies have estimated copper and zinc levels in serum, blood and saliva in various carcinomas especially oral squamous carcinoma and have established a positive correlation with the incidence of malignancy. Significant alteration in serum levels of the trace elements have been reported in head and neck cancer, lung and breast cancer [2, 18]. The increased levels of copper and zinc in cancer reported earlier have been 209.85± 160.28 mg/dl, 113.51± 52.30 mg/dl respectively [10] . In the present study, copper showed a significant increase [249.39±58.3µg/dl] in oral cancer group compared to control group [123.95± 16.23µg/dl]. Similar findings have also been reported by Khanna et al, Amitkumar et al, Yunus et al, Ayinam pudi BK, Jayadeep A et al and Shetty SR et al. [2, 6, 10, 17, 19, 20, and 21] they observed increased copper levels in sera of patients in oral pre malignant and malignant patients.

The increased level of serum copper in OSMF patient was attributed by Khanna et al to high copper content in areca nut, the major physiological factor in the pathogenesis of OSMF [17] it initiates fibrin genesis and inhibit collagen degradation. It has also been explained that increase in serum copper levels in cancer patients is a consequence of increased production of copper containing ceruloplasmin an oxidative enzyme which is precipitated by an inflammatory response to cancer or decrease in catabolism by serum ceruloplasmin [16] . Jayadeep et al also suggested that rise in copper levels might be due to increased turnover of ceruloplasmin, a copper carrying globulin with oxidative activity [19] .

Review of literature indicates low serum zinc level in several forms of cancer like cancer of breast, gallbladder, lung, colon and oral cancer [22, 23] . Serum zinc level in a present study did not reveal a similar finding. The serum zinc level among cancer patient in the present study was marginally lower or similar to control group. Contrary to this finding statistically significant decrease in mean serum zinc levels have been reported by various other studies [18, 20, and 24]

Amit kumar et al [6] suggested that zinc deficiency impair protective mechanism designed to protect against DNA damage, enhance susceptibility to DNA damaging agents and ultimately increased risk of cancer

Increased copper zinc ratio seen in oral sub mucous fibrosis (OSMF) and oral squamous cell carcinoma (OSCC) was also noticed in patients with pancreatic cancer, breast cancer, lymphoma etc. Yunus et al concluded that alterations in serum copper, zinc, copper zinc ratio can be used as potential biomarkers in early detection of oral pre cancerous lesion and their malignant transformation to frank cancer at early stages [2].In the present study the ratio was 1.43 in control, and increased to 2.86 in the study group, probably due to increased copper values. Other reports have shown that Cu/Zn ratio was 0.97 in health and 1.10 in cancer patients, but the diff was not statistically significant [17,25].

This study confirms the earlier reports on the possible relation between serum copper level and oral cancer and can be considered as a biochemical marker for oral cancer, but needs further evaluation on a larger sample including patients with oral premalignant lesions.

Conclusion

Trace element copper level in oral cancer patients did

show a significant increase compared to control group. Serum zinc level however did not show any difference between study and control groups. Alterations in serum copper level are suggestive of its important role in oral carcinogenesis and needs further research on larger population.

Prevalence of Black Stains in School Going Children in age Group 6-12 Years

Leya Meriam Mathews[1], Dhanalakshmi Ravikumar[2]

[1]Graduate Student, Saveetha Dental College, Saveetha University, Chennai, [2]Senior Lecturer, Department of Paedodontics, Saveetha Dental College, Saveetha University

Abstract

Introduction: Black stains are extrinsic discoloration in primary dentition that can also occur along with dental caries. It clinically presents as pigmented, dark lines or as an incomplete coalescence of dark dots rarely extending beyond the cervical third of the crown. This has often been a concern of dental aesthetics and its frequent recurrence, makes it necessary to find the causative factor and the treatment needed.

Materials and Method: In this cross sectional study, 93 children aged between 6-12years were examined clinically for the presence of black stains using mouth mirror and dental probe by one examiner. The DMFS / deft index were recorded in children with and without black stains.

Results: In the limited sample size recorded, it was observed that 11 children had black stains. Black stains were also found along with dental caries in 3 children. The p value was 0.85373, found to be insignificant

Conclusion: The prevalence rate of black stains is estimated to be 10% from the sample size, as per data collected, Black stains can occur along with caries but the incidence is less. In conclusion , the results of our study , indicates the prevalence of caries along with the black stains in children within the age group 6-12 years , highlight the need to do further investigations

Introduction

Tooth discoloration can be defined as any change in the color, hue or translucency of a tooth due to a cause. It is an altered physical appearance of the tooth which is a common clinical finding and a concern of aesthetics, found more often among the children thereby having significant effects on their personality and self-confidence. There are several causes of tooth discoloration like food, drinks, poor dental hygiene, and medications [1].

Tooth discoloration can vary based on their location, etiology, appearance and composition. Historically, tooth discoloration can be classified, based on their location, to extrinsic, intrinsic and internalized [2]. Intrinsic Discoloration refers to the change that occurs due to the disturbance in the structural composition or thickness of the dental hard tissues. It occurs when the tooth structure is penetrated by pigmented materials, usually during tooth development. Extrinsic discoloration refers to the deposit or stain that occurs on the surface of the tooth or in the acquired pellicle. The origin of the stain might be metallic or non-metallic. Internalized discoloration is the presence of an external stain within the tooth following dental development. It is mostly seen in case of any enamel defects and in the porous surface of dental caries. This stain or discoloration can also be an acquired defect due to tooth wear, gingival recession and restorative materials [3, 4].

A common extrinsic discoloration is the black stain which appears as a dark line or an incomplete

coalescence of dark dots formed on the cervical third of the tooth and following the contour of the gingival margin, firmly attached to the tooth surface. It affects mostly the primary dentition and its prevalence seen in both the sexes [5]. Black stain is a form of dental plaque that covers a great surface of the tooth including the grooves, pits and fissures.

According to Ried et.al, the black pigmentation is considered to be an insoluble ferric compound, most likely a ferric sulfide, which arises from the interaction in the saliva or gingival fluid between hydrogen sulfide produced by the bacteria present in the periodontal environment and iron [6]. The microbiological composition of Black stain is hypothesized to be bacterial strains of Acitnomycetes, Lactobacillus and prevotella melaningenica [7].

The origin of Black stain has been discussed for over a century, since 1890. However, the criteria to diagnose the black stain have still not been established. Shourie used the following criteria for classifying black stain: 1) no line 2) incomplete coalescence of pigmented spots and 3) a continuous line formed by the pigmented spots. Further additional classification by Koch et.al, depending on the size of the spots and the presence of cavitation on the tooth surface, and, depending on the area of the tooth surface have also been used in different studies [8].

Tooth discoloration has been frequently associated with medical problems and sometimes due to certain medications or even restorative treatment. Few of the conditions like malnutrition, rubella, measles, and developmental disorders like gametogenesis imperfect show black stain as one of the manifestation. Another important differential diagnosis is the dental caries. Most of the studies show the occurrence of Black stain with lower caries experience which could imply that caries resistance in children with black stain could be a result of lower caries activity than a localized effect [9].

This study was done to find the prevalence of black stain in school children, aged 6-12 years, among the Chennai population. The children were also asked about their families and their place of residence to help evaluate the risk factors associated with the black stain.

Materials and Method

Sample Selection

A total of 93 children were aged from 6-12 years of age, were examined for black stains from the areas of Old Washermenpet and Perangallthur, Chennai. None of the children had any systemic or infectious diseases and were both physically and mentally well. A written informed consent was obtained from the parents of all the children enrolled in this study. The inclusion criteria and exclusion criteria were as follows;

Inclusion Criteria

- Age group 6-12 years
- Children with black stains

Exclusion Criteria

- Immunocompromised Patients
- Children with any systemic disease
- Enamel hypoplasia

Clinical Examination for Black Stains

The Clinical examination was performed under natural light with plane mouth mirrors and dental probe in the community halls of the respective places. The diagnosis of the black stains was examined based on the criteria given by Shourie and Koch et.al. [8].

A record was maintained for every child with Black stain, where the vestibular and the palatal surface was registered for the maxillary teeth and the vestibular and the lingual surface was registered for the mandibular teeth. In order to record the pigmentation location and extension, every tooth surface illustrated was segmented into three sectors – gingival, middle third and the incisal or occlusal surface.

The DMFS/deft index was recorded in children with and without black stains. The PUFA/pufa index was also recorded to check for any visible pulp, ulceration of oral mucosa, fistula and abscess, if present.

Statistical Analysis

After the examination, the data was processed and a statistical analysis was done using the Social Science Statistics Software for Windows, Version 20.0. Statistical Significance was considered at 5%.

Results

Out of 93 children examined, black stains were

observed in 11 children, 10.23 % of the sample size. 7 children belonged to the age group 6-9 years and 4 of them in the 10 -12 years of age. 82 children did not have any black stains, 76.26% of the sample size. Black stains were found to be more prominent in the lower age group as shown in Table 1

Table 1 - Number of children with Black stains and without

Age group	Black stains (%)	Non - Black stains
6years-12years	7 (6.27)	46 (46.73)
10years-12years	4 (4.73)	36 (35.27)

Dental caries were observed in 3 children black stains. It was observed that in Children without any black stains, dental caries were present in 45 children. (Table 2). The prevalence of caries was found to be insignificant ($p>0.05$)

Table 2 – Prevalence of caries and p value in children with and without black stains

	Black stains	Non - Black Stains	P value
Caries Present	3 (5.68) [1.26]	45 (42.32) [0.17]	0.853
Caries Absent	8 (5.32) [1.35]	37 (39.68) [0.18]	0.853

Discussion

This study was done to estimate the prevalence of black stains in children aged from 6 to 12 years. Additionally, this study helps to show the association between black stains and dental caries in a population based study. Out of 93 children examined, only 11 children were observed with black stains, indicating this type of condition, as a rare disorder, as shown in Table 1. This rare condition observed in this study agrees with other studies which showed similar results [10, 11]. Most of the studies took place in 1970's in different countries. Brazilian studies show a prevalence of 9.3 % of black stains for children aged from 6-13 years of age and 2.5 % for children aged from 3-5 years from different areas of the country [12]. Koch et.al reported a prevalence of 19.9% for school children, aged 7-15 years in Switzerland and 4.6% for children aged 6-10 years in Germany [8]. The different prevalence recorded in different studies could be due to different habitats and lifestyles of different populations, which could be possible etiological factors.

Though etiology behind the formation of black stains still remains unknown, studies show a possible correlation between various risk factors and black stains. Various etiological factors include gender, socioeconomic factors like maternal education, family income, and diet and fluoride level in water consumed. These factors were also commonly associated with the development of caries [13]. With this understanding, Franco et.al found a significant association between black stains and lower income. Children from families with lower income showed a higher prevalence of black stains [14]. Consumption of vegetables, fruits and dairy products also consume black stains development. Certain studies contradict to the fact with the association between sex and black stains prevalence. However, due to insufficient data, the etiology still remains unclear making it difficult to distinguish factors associated with its formation [15, 16].

The association between dental caries and black stains is debatable because of the varying results from different studies. Gallardo et.al stated that there is no association between dental caries and black stains [13]. Contradicting to this, other studies show similar findings demonstrating lower level of caries experience along with black stain Gasparetto et al. Showed a negative correlation between black stains and dental caries, but

did not find any association between the presence of black stains and caries prevalence. Similarly, Koch et al. found a tendency for children with black stains in primary dentition to present less dental caries, but the difference was not statistically significant [8,17] . Other Findings show that both black stains and dental caries had common co-variables, like socioeconomic factors and behavioral which could be reasonable enough to help hypothesize that there could be a possible association [12].

The results of our study suggest that black stains can occur along with dental caries as shown in Table 2. The data revealed that the prevalence of caries in this study was lower among the children with black stains (0.3%) than those of without black stains (36%) ,this finding is in accordance with study done by Gasparetto A et al.10 , Koch et al.8. and Sutcliffe [18] . The mean DMFS values were found to be statistically significant between children with black stains and those without black stains. The mean value of DMFT was 1.5 ± 0.7, which is a bit higher than the mean value observed in another study done in Udaipur for the same age range, which tells us the need for further exploration to find the causative factors responsible [19].

Various hypotheses relating to caries development and black stains have been put forward to understand the biological interaction between microbiota related to the extrinsic pigmentation. Morphological stains reported by Ried et.al and Thaelide et.al confirmed that this kind of stain is a special kind of dental plaque characterized by its flora and its tendency to calcify . The most prominent organisms involved are Actinomyces and Prevotella melaninogenicus. The tendency towards calcification within the black material benefits a high level of calcium and phosphate that gives to a reduction in the enamel dissolution and an increase in the buffering capacity [6, 20]. The saliva of the children with black stains showed a higher content of total calcium, inorganic phosphates, copper, sodium and total protein and less glucose than in controls [21].

With this understanding, and the inverse relationship between dental caries and calculus stated by Duckworth and Hunnigton, Gasperrato et.al proposed that calcium and phosphate are part of the reaction for black stain formation and together with fluoride and pH conditions are the main tooth remineralization components. Because caries development is a demineralization process due to the acids produced by oral bacteria, the presence of a larger amount of minerals in the oral cavity – which could be the case in children with black stains – increases the remineralization process, to keep the oral cavity in a balanced equilibrium and reducing the risk for caries development [12].

Another hypothesis states that low cariogenic oral micro flora is associated with the presence of black stains. The bacteria related to black stains could establish a competitive environment for bacteria related to caries development, impairing the adhesion of these bacteria to dental surfaces or changing the characteristics of the dental biofilm, reducing the potential for caries to develop [22].

The management of extrinsic stains involves proper diet and maintaining oral hygiene. Whitening toothpastes with abrasives help remove extrinsic stains. Other methods include Selective polishing , where polishing is done over a specific tooth using prophylactic angle and rubber cup , with the right toothpaste and use of prophylactic paste , air jet polishing , ultrasonic scaling etc. . However, due to unclear etiology, black stains have a tendency to recur and frequent use of these modalities can lead to enamel removal, which is highly undesirable [23].

In conclusion , the results of our study , indicating the prevalence of caries along with the black stains in children within the age group 6-12 years , highlight the need to do further investigations and statistical analysis with multivariable analysis to help understand the biological mechanism. This in turn will help find a possible solution to help treat this condition.

Complications of Root Canal Irrigation - A Review

Leya Meriam Mathew[1], Jayalakshmi Somasundaram[2]

[1]Graduate Student, Senior Lecturer,, Department of Conservative and Endodontics, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Root canal irrigation plays an important role in the debridement and disinfection of the root canal. Most commonly used irrigants have good benefits of tissue dissolving and disinfection capability. However, it also produces toxic effects on the vital tissues resulting in ulcer, necrosis etc. The aim of this review is to analyze the factors causing or affecting the Root canal irrigation during a root canal treatment.

Keywords : *Root canal , irrigants , infection, microbial , complications, toxicity .*

Introduction

The main aim of a root canal treatment is to ensure complete removal of connective tissue and destruction of residual microorganisms found in the infected root canals[1]. The complexity of root canal system, presence of numerous dentinal tubules in the roots, invasion of the tubules bymicroorganisms and preservation of healthy dentin after achieving the primary objectives of complete shaping and cleaning of root canal systems are done with the help of a proper irrigation [2]. However many mishaps can occur while cleaning and shaping the root canals with irrigating solutions ranging from damage to the patient's clothing, splashing the irrigant into the patients or operators eye, to allergic reactions. The ideal properties of an irrigant [3] include, a potent tissue debris solvent ,low toxicity, low surface tension, lubricant, sterilizing agent, removal of smear layer, low cost and inactive endotoxin

Endodontic Irrigants

Non-bactericidal irrigants

Some general dental practitioners either use saline, local anaesthetics and/or distilled water. These have no antibacterial action and will not lessen bacterial significantly. These irrigants may be used regularly as they are easy to use, readily available and safety. However, irrigants have no role in handling infected root canals..

Bacteriostatic/bactericidal irrigants

These include a collection of solutions which also kill bacteria or enable their death by allowing other irrigants to come into contact with the bacteria.

Sodium Hypochlorite (NaOCl)

Sodium hypochlorite was first recognized as an antibacterial agent in 1843 and used as a hand wash . Its advantages are pulpal dissolution and antimicrobial effect. Studies show that a decrease in microbial numbers is achievable when using NaOCl for endodontic treatment of teeth with apical periodontitis. It was used as an endodontic irrigant ,with low viscosity ,effective antimicrobial properties but low tissue dissolving capabilities acceptable shelf life , easily available and inexpensive [4]. The mechanism of action involvesbreak down of protein by dissolution of amino acid content of vital and necrotic tissue by the available free chlorine in NaOCl

However, certain disadvantages of this irrigant are the toxicity to the vital tissues which includes cytoxicty, foul smell and foul taste, fabric bleach on accidental spillage and corrosive on metals [5].

Hydrogen Peroxide

Hydrogen peroxide (H_2O_2) is a colorless liquid and has been used in dentistry in concentrations varying from 1% to 30% [6]. H_2O_2 degrades to form water and oxygen. It is active against microbes via the production of hydroxyl free radicals which attack proteins and DNA [7]. It has been shown that NaOCl, combined with H_2O_2, is no more effective against E. faecalis than NaOCl alone [8] , however, CHX combined with H2O2 was a better antimicrobial agent than either one on their own.

Chlorhexidine

Chlorhexidine digluconate is widely used in disinfection because of its excellent antimicrobial activity. It is highly antimicrobial especially at pH 5.5-7.0 and is known for its longlasting effectiveness even after the removal of the solution [9] .It is a positively charged hydrophilic and lipophilic molecule which relates with phospholipids and lipopolysaccharides in cell membranes. Consequently, there is disruption of the cell membranes which allows CHX molecules to enter the cell to cause intracellular toxic effects, such as coagulation of the cytoplasm. Other advantages include available in acceptable flavor and not injurious to the surrounding tissues. Chlorhexidine has a persistent residual antimicrobial action.. Commonly, Chlorhexidine is used in conjunction with NaOCl as an irrigant as it raises the effectiveness of the irrigation protocol [10] .

However, in spite of the advantages chlorhexidine cannot be considered as an ideal root canal irrigant because of its inability to dissolve necrotic tissue remnants [11] .But capable of dissolving the smear layer [12] . Additionally studies have revealed the presence of desquamategingivitis, discoloration of teeth and tongue or dysgeusia associated with it .Laboratory findings showed chlorohexidine to be highly cytotoxic to human periodontal cells, fibroblast via inhibition of protein synthesis [13] While it does not appear to cause any long term damage to host tissues, it may still cause an inflammatory response in these tissues if expressed beyond the root canal [14] .

MTAD

MTAD is a mixture of 3% doxycycline, 4.25% citric acid and detergent developed by Torabinejad et.al. The irrigant has a combination of both chelating and antibacterial properties [15] . The citric acid may serve to remove the smear layer, allowing doxycycline to enter the dentinal tubules and exert an antibacterial effect [16] MTAD is considered to be more superior to Cholorhexidine in antimicrobial activity and is also7more biocompatible and enhances bond strength [17] . MTAD was seen to be less toxic than eugenol, 3% H2O2, CA (OH) 2 paste, 5.25% NaOCl, Peridex (a CHX mouthwash with additives) and EDTA, however, was more lethal than NaOCl in absorptions of 2.63%, 1.33% and 0.66%. The procedure for clinical use of MTAD is 20 minutes with 1.3% NaOCl followed by 5 minutes of MTAD . This irrigant is based on a tetracycline isomer; there may be problems with staining, resistance and sensitivity.

EDTA

Ethylenediaminetetraacetic acid (EDTA) is a synthetic amino acid and the sodium salts of EDTA (Na2EDTA) are used in dentistry. It is often used as a chelating agent. EDTA is not bactericidal nor bacteriostatic but inhibits the growth of, and eventually kills, bacteria . EDTA at concentrations of 15–17% removes calcium from dentine leaving a softened matrix of dentine. It also emulsifies soft tissue and removes the smear layer with no deleterious effect to pulpal or periapical tissues. EDTA reacts with the calcium ions in dentine and forms soluble calcium chelates. It is reduces the intracranial microbial flora and also helps to detach biofilms adhering to root canal walls [18] However irrigation with 5%NaOCl or alternated with 17% EDTA, significantly increased the tooth strain .It reduces the chlorine in solution, rendering the sodium hypochlorite irrigant ineffective on bacteria and necrotic tissue [16] . A one minute application of 17% EDTA combined with ultrasonic is efficient for smear layer and debris removal in the apical region of the root canal [19]. EDTA is available in a liquid form for irrigation and a gel form for lubrication .

Other Irrigating Solutions

The other irrigating solutions are sterile water, physiologic saline, iodine compounds, ureaperoxide, etidronic acid, citricacid, maleic acid, tetraclean, chlorine dioxide etc [20]

HEBP is also known as etidronic acid or etidronate and has been proposed as an alternative potential alternative to EDTA or citric acid because it shows no reactivity with NaOCl [19] .It is nontoxic but h owever, the demineralization kinetics was lower than those of 17% EDTA.

Maleic acid is a mild organic acid used as acid conditioner in adhesive dentistry. Ballal et.al reported that the final irrigation with 7%maleic acid for 1minute was more efficient than 17% EDTA in the removal of smear layer [20]

Iodine Compounds are bactericidal, fungicidal, and virucidal. 2% iodine in 4% potassium iodide has been used in endodontics. It shows less toxicity and a

decreased tendency to stain dentine.. However it is not the first choice as an irrigant. Despite its antimicrobial activity, iodine is a very potent allergen thereby causing a risk for allergy [21]

Curcuma longa (Turmeric): Curcumin, possesses anti-inflammatory,anti-oxidant,anti-microbial andanti-canceractivity. In an in vitro study conducted by Prasanna Neelakantan, it has been shown that curcumin has significant anti-bacterial activity against E.faecalis and can be used as an alternative to sodium hypochlorite for root canal irrigation [22, 23] .

Complications during Root Canal Irrigation

Root canal irrigation is an integral part of the rootcanal treatment to ensure proper debridement and disinfection of the root canal system. A review of these complications have been described briefly below, which necessitates the need to carry out effective techniques in order to avoid complications .

Damage to Clothing

Sodium Hypochlorite, a common bleaching agent can cause a concern of damage. Accidental spillage of minute quantities can lead to rapid, irreparable bleaching [24, 25] . When using an ultrasonic device for root canal irrigation the aerosol may also cause damageto the clothing. These mishapsshould be prevented by proper shield of the patients' clothing. When using hand irrigation, oneshould reassure that the irrigation needle and syringe are tightly attached .

Damage to the Eye

Mild burns with the alkali such as sodium hypochlorite can result in significant injury causing blurring of vision and patchy coloration of cornea [26] .Irrigant in contact with patients or operators eyes can result in immediate pain, intense burning and erythema. Immediate ocular irrigation with large amounts of tap water or sterile saline should be performed by the dentist.

Damage to Oral mucosa and Skin

Skin injury with an alkaline substance requires an immediate irrigation with water as alkalis combine with proteins or fats in tissue to form soluble protein complexes or soaps which could further cause irritation to the mucosa. Accidental swallowing of irrigant by patient requires proper monitoring. It is possible that skin injury can result from secondary contamination [27, 28].

Allergic reactions

Various allergic reactions to Chlorhexidine have been described. It is known to elicit allergic contact dermatitis, generally after repeated application. It can also contact urticarial,photosensitivity, fixed drug eruption and occupational asthma [29] .

The allergic potential of sodium hypochlorite was first reported by Sulzberger when a 32 year old female reported a rapid onset of pain, swelling and difficulty in breathing [30] . A subsequent allergy skin scratch test performed two weeks later confirmed a positive result to sodium hypochlorite. Other symptoms include burning sensation, shortness of breath [31] .

Complications arising from the irrigant extrusion beyond root canal apex

Chemical Burns and necrosis

When sodium hypochlorite is extruded beyond the root canal into the periradicular tissues, the effect is a chemical burn leading to localized or extensive tissue necrosis. This can further lead to tissue swelling both intra orally and extra orally. The swelling could later produce a sudden onset of pain, associated bleeding, acute sinusitis, ecchymosis of the mucosa [32].

Neurological Complications

The major complications include parathesia and anesthesia affecting the mental, inferior dental and infraorbital branches of the trigeminal nerve.

Facial nerve damage was first described by Witton et al. in 2005, where the buccal branch of the facial nerve was affected in 2 cases. Both patients exhibited a loss of the naso-labial groove and a down turning of the angle of the mouth. Both patients were reviewed and their motor function, was regained after several months [33].

Upper Airway Obstruction

Without adequate tooth isolation, sodium hypochlorite can lead to the leakage of the solution into the oral cavity and ingestion or inhalation by the patient. This could result in throat irritation and the upper airway could be compromised [34]. Ziegler presented a case of a 15-month-old girl who presented a complication of root canal irrigation with acute laryngotracheal bronchitis, stridor and profuse drooling from the mouth as a result

of ingestion of a high concentration of household sodium hypochlorite.

Air Emphysema

Studies show cases of emphysema which occurs when the root canal is dried with compressed air after injecting hydrogen peroxide into it. Symptoms and signs include a rapid swelling and erythema in the region of the treated tooth, emphysema of the face, the suborbital region, and neck. The mainsymptom is a crepitus of the swelling [35] .

Flare up

An endodontic flare-up is a complication of endodontic treatment which is defined as an acute exacerbation of asymptomatic pulp, after the initiation or continuation of root canal treatment. Excessive pressure during irrigation will cause large amounts of irrigant to come in contact with the periapical tissues, thereby a possible etiological factor for Flare up [36].

Conclusion

Thus, it is important to carry out an effective technique in order to avoid complications. In the event of an accidental extrusion of any solution, treatment guidelines should be applied as may be relevant to each case.

Phytochemical and Antimicrobial Analysis of *Portieria Hornemannii*, A Marine Red Macro Algae

Louis Cojandaraj[1], Gurdyal Singh[2], John Milton[3]

[1]Assistant Professor, Department of Medical Laboratory Sciences, Lovely Professional University, Phagwara, [2]Plant Head, Affy Parenteral, Baddi, Distt. Solan, H.P. India, [3]Associate Professor, PG & Research Department of Advanced Zoology and Biotechnology, Loyola College, Chennai

Abstract

The present study was designed to evaluate the phytochemical activity of *Portieria hornemannii*. The primary metabolites from *Portieria hornemannii* were obtained by soxhlet extraction using various solvent like acetone, chloroform, ethyl acetate and methanol. The phytochemical analysis determined the presence of flavonoids, terpeniods Saponins, Phenol and Cardiac Glyciosides. The extracts of ethyl acetate exhibited a higher phenolic content of **764.413 ± 22.11 mg/GAE.** The antibacterial activity determined that the extracts of ethyl acetate exhibited a good zone of inhibition of 19mm and 14mm at 20µg against *Klebsiella pneumonia* and *Staphylococcus aureus.* and in the case of antifungal activity no zone of inhibition was obtained in any of the extracts.

Key words: *Portieria hornemannii, Seaweed, Phytochemical Analysis, Red algae, Antibacterial activity, anti-fungal activity.*

Introduction

Seaweeds are able to produce a great variety of secondary metabolites characterized by a broad spectrum of biological activities and because of these properties they are considered to be the most predominant source for bioactive compounds. Seaweeds during metabolic process, infrequently suffer serious photodynamic damage even though they grow in a harsh environment. This fact suggests that seaweed cells possess some protective compounds and mechanisms.[1] Marine algae, like other photosynthesizing plants, are exposed to a combination of light and oxygen that leads to the formation of free radicals and other strong oxidizing agents. However, the absence of oxidative damage in the structural components of macro algae (i.e., polyunsaturated fatty acids) and their stability to oxidation during storage suggest that their cells have protective anti-oxidative defence systems which are similar to vascular plants[1,2].

In developing countries diseases are the major cause of death and accounts to 50% of it. Antimicrobial agents are essentially important in reducing the global burden of infectious diseases. But pathogens with resistance develop and spread, because of which the effect of those antibiotic drugs is reduced. This kind of resistance by bacterial species to the antimicrobial agents invoke a serious threat worldwide[3,4]. Bacterial resistance to antibiotics increases mortality likelihood of hospitalization and also increases the period of hospitalization.[5] Hence, there occurs an urge of antimicrobials with alternate strategies.[6,7] It has been well established by several scientific teams that seaweeds belonging to all three major pigments exhibit inhibitory action against both Gram negative and Gram positive bacteria. Antibacterial activity of nine species of seaweeds belonging to all major pigmentations revealed that brown and red seaweeds had greater antibacterial activity than the green and brown algae.[8] This study reveals the antibacterial and the phytochemical aspects exhibited by the marine red algae. *Portieria hornemannii* is a small red marine algal species which is widely distributed in tropical and subtropical water bodies of the Pacific and Indian Ocean.[9] Portieria belongs to the family Rhizophyllidaceae. The family Rhizophyllidaceae

includes 4 genera Contarinia, Ochtodes, Nesophila and Portieria. The geographical distribution of the species belonging to the genera is interesting and exclusive.[10–12]with an evaluation of the ordinal classification of the Florideophyceae (Rhodophyta The present study was designed to investigate the presence of major phytochemical compounds present in *Portieria hornemannii*.

Materials and Method

The crude metabolites from the sample were extracted using Soxhlet extraction method using solvents like acetone, chloroform, ethyl acetate and methanol. The extracts were subjected to phytochemical analysis to detect the presence of following biomolecules using the standard qualitative and quantitative procedures as described by Trease and Evans[13] and Total phenolic assay was determined by using Folin-Ciocalteu assay.[14]

The screening of anti-bacterial and antifungal activity against fastidious pathogens was performed with extracts of *Portieria hornemannii* by determining the zone of inhibition using disc diffusion method.[15–17]

Result and Discussion

The phytochemical characters of *Portieria hornemannii* were determined for all the crude extracts derived from the solvents after condensation in rotary vacuum evaporator.[13] From the present study, it was observed that Flavonoids, Terpenoids, Phenol and Cardiac glycosides were present in all the four crude extracts derived from acetone, Ethyl Acetate, Chloroform and methanol. However, Saponins were present only in methanol and ethyl acetate extracts (Table 1).

Table 1: Qualitative analysis of Phytochemicals from*Portieria hornemannii.*

Phytochemicals	Solvents			
	Acetone	Methanol	Ethyl Actetate	Chloroform
Tannins	-	-	-	-
Saponins	-	+	+	-
Flavanoids	+	+	+	+
Terpenoids	+	+	+	+
Alkaloids	-	-	-	-
Cardiac Glycosides	+	+	+	+
Phenol	+	+	+	+

The seaweeds are known for their secondary active metabolites which are used in several medical and pharmaceutical industries. Metabolites like Tannins, Saponins, Flavanoids, Terpenoids, Alkaloids and phenolic compounds have a great medicinal value and are extensively used for the manufacturing of new drugs.[13] Saponins are widely used in the treatment of hypercholesterolaemia and hyperglycaemia. It is also used as a mild detergent. Apart from this saponins also possess several medical properties like anti-microbial, cholesterol lowering, anti-oxidant, anti-cancer, anti-carcinogenic, and immune modulatory activities. It also helps in the treatment of congestive heart failure by inhibiting Na^+ and Ca^{2+}antipotal by producing cytosolic Ca^{2+} which reduces congestive heart failure by strengthening heart muscles.[18]

Tannins possess antibacterial anti-cancerous and anti-viral activities, is also used for the inhibition of HIV replication.[19] Flavonoids also possess similar activities

like tannins like antioxidant, anti-inflammatory, anti-cancer, antimicrobial and anti-allergic activity.[20]

Determination of Total phenols

Earlier reports have stated that the polyphenols obtained from marine algae possess a good anti-oxidant property [21,22]. Total phenolic content of the extracts was calculated from the regression equation of calibration curve (Y = 0.001+ 0.25x; R2 = 0.966) and expressed as mg gallic acid equivalents (GE) per gram of sample in dry weight (Figure 1) The Results of the phenolic content of *Portieria hornemannii* determined the ethyl acetate extract has high phenolic content followed by methanol extract comparing to other extracts (Table 2; Figure 2). The differences between the content of phenolic compound between each solvents and extraction methods were statistically significant ($p < 0.05$) (Table 3). The presence of high phenolic compound could be useful for the prevention of oxidative activities of the extract.

Table 2. Mean ± SD of Total Phenolic Content of *Portieria hornemannii*

Solvent	Total Phenolic Content (mgGAE/g)
	Mean ± Std. Deviation
Acetone	486.206 ± 4.84
Methanol	696.146 ± 3.85
Ethyl Acetate	764.413 ± 22.11
Chloroform	449.026 ± 14.43

Table 3. Two way ANOVA Total Phenolic Content of *Portieria hornemannii*

	Sum of Squares	Degrees of freedom	Mean Square	F-Value	Sig.
Between Groups	216040.115	3	72013.372	391.723	0.000
Within Groups	1470.699	8	183.837		
Total	217510.814	11			

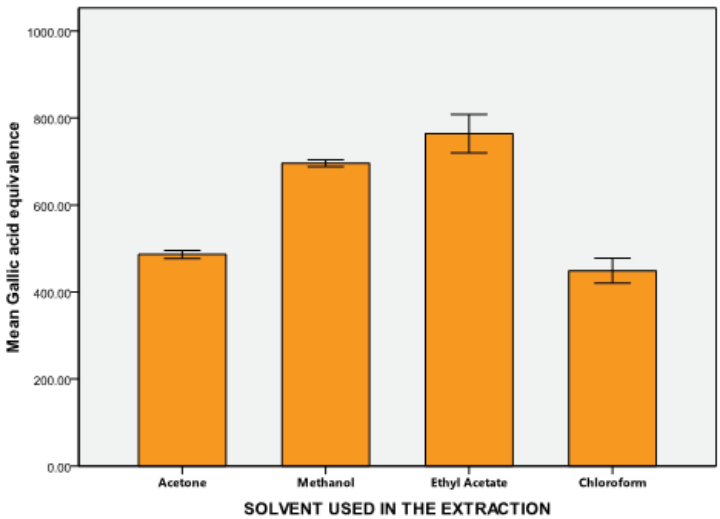

Figure 1. Mean ± SD of Total Phenolic Content of *Portieria hornemannii.*

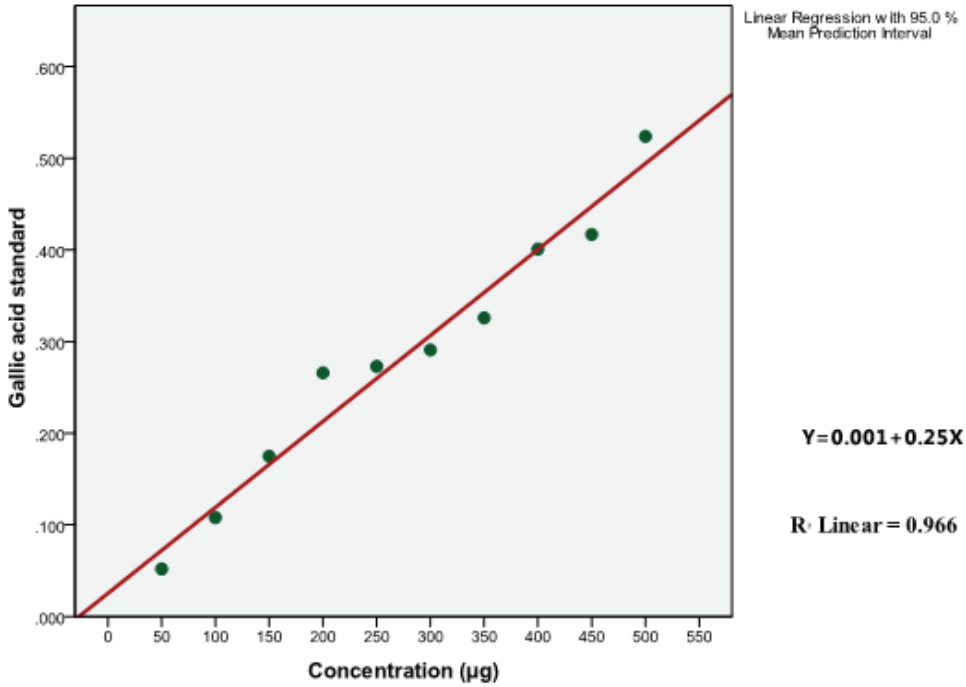

Figure 2. Gallic Acid Equivalence

Phenols are the most significant constituent in seaweed as of for their scavenging activity due to presence of the hydroxyl groups [23]. Pedersen reported that the increase in the phenolic content depends upon two major factors i.e. it increases with the aging of the tissue and also the salinity concentration of its habitat. [24] The bioactive compounds of macro algae is determined by certain aspects like environment, salinity, maturity of the algae and climatic conditions.[25] A lower phenolic content range of 1.5 to 4.1 mg GAE/g, with crude methanolic extracts of red seaweeds which is comparatively very lower with the range obtained with present study [26]. The Phenolic compounds derived from the marine algae play a vital role against the abiotic and biotic stress conditions through cell defense mechanism.[27]8 Phaeophyta and 23 Rhodophyta. In general, the biological activities of the seaweed are reflected by the phenolic compounds present in the seaweed.

Antimicrobial Activity

Antibacterial activity

In this present study the screening of the antibacterial activity was performed against five different bacterial strains *Bacillus subtilis, Staphylococcus aureus, Klebsiella pneumonia, Escherichia coli, Pseudomonas aeruginosa* under various concentration of each crude extracts ranging from 2, 5, 10, and 20µg. From the study, the zone of inhibition of *Bacillus subtilis* was obtained at a concentration range of 20µg only in chloroform extracts (10 mm). Whereas, in *Klebsiella pneumonia*, the zone of inhibition (10 mm and 19 mm) was obtained at a conc. range of 20µg in both the acetone and ethyl acetate extracts. Also, the zone of inhibition against, *Escherichia coli* was observed at a conc. range of 20µg in the extracts of ethyl acetate (11 mm), methanol (10 mm) and chloroform (12 mm). Apparently, the zone of inhibition against *Staphylococcus aureus* was observed at a conc. range of both 10µg and 20µg in the extracts of acetone (10 mm, 11 mm), and ethyl acetate (10 mm, 14 mm). Finally, the zone of inhibition against *Pseudomonas aeruginosa* was observed at a conc. range of 20µg only in the extracts of chloroform (10 mm) (Table 4). Therefore the highest zone of inhibition was seen only in the ethyl acetate extracts comparing with other extracts and also the ethyl acetate extracts inhibited the growth of three bacterial strains followed by acetone and chloroformic extracts which inhibited two bacterial strains and finally methanolic extracts inhibited only a single bacterial strain (Table 4).

Table 4. Antibacterial activity of *Portieria hornemanii*

Bacterial Species	Acetone				Ethyl Acetate				Methanol				Chloroform			
	Concentration in µg															
	2	5	10	20	2	5	10	20	2	5	10	20	2	5	10	20
Bacillus subtilis	-	-	--	--	-	-	--	--	-	-	--	--	-	-	--	10
Klebsiella pneumonia	-	-	--	10	-	-	--	19	-	-	--	--	-	-	--	--
Escherichia coli	-	-	--	--	-	-	--	11	-	-	--	10	-	-	--	12
Staphylococcus aureus	-	-	10	11	--	--	10	14	-	-	--	--	-	-	--	--
Pseudomonas aeruginosa	-	-	--	--	-	-	--	--	-	-	--	--	-	-	--	10

The acetone extract of Caulerpa scalpelliformis showed broad spectrum antibacterial activity when compared to other seaweed extracts.[28,29] But in the present study the maximum zone of inhibition was obtained from the extracts of Ethyl acetate. The maximum antibacterial activity was observed in the methanol extract of Caulerpa scalpelliformis against Salmonella typhi, Micrococcus sp., and Shigella bodii. [30]. Ely *et al*., studied with the methanolic extracts of *Chadophorea profileria* exhibited a moderate antibacterial activity against *Staphylococcus aureus* and *Vibrio cholera* [31].

Anti-fungal activity

In the present study the screening of the antifungal activity was performed by agar disc diffusion method against five different fungal strains *Aspergillus niger, Aspergillus flavus, Aspergillus fumigatius, Fusarium solanum, Exoserohium species* under various concentration of each crude extracts ranging from 2, 5, 10, and 20µg. From the study, the zone of inhibition was not observed in any of the concentrations.

In contradiction to this, the methanolic extracts of *Aspergillus taxiformis* showed inhibitory activity against fungal species like *Fusarium solanum, Aspergillus flavus,* and *trichoderma species*. The organic extracts obtained from *Aspergillus taxiformis* showed low inhibitory zone against *Aspergillus fumigatius* [32]. From the reports of El-Baroty *et al*., it was observed that the hexane and ethyl acetate extracts of *Aspergillus taxiformis* showed a good anti-fungal activity against *Fusarium oxysporees* [33] .

Conclusion

The phytochemical (Flavanoids, Terpenoids, Saponins, Phenols and Cardiac Glycosides) studies were determined for *Portieria hornemannii.* Ethyl acetic extracts showed a significant amount of phenolic content on comparing with other crude extracts. The antibacterial activity for different solvents extracts was measured in range of 10 mm to 19 mm. The extracts of ethyl acetate showed a maximum zone of inhibition against *Staphylococcus aureus, Klebsiella pneumonia, E. coli* at 10µg and 20µg/ml. It was followed by chloroform and acetone extracts. *Portieria hornemannii* was also analyzed for antifungal activity against five ocular pathogens. But, there was no significant zone of inhibition in any of the extracts at any concentration. This algal species possesses a good antibacterial activity

which can be used for the drug developmental against various fastidious bacterial strains.

Conflict of Interest: The authors declare no conflict of interest.

Ethical Clearance: Animal study was not involved in this research.

Transplantation of Human Organs: An Indian Legal Analysis

Hiranmaya Nanda[1], Shyamantak Misra[2]

Assistant Professor, Faculty of Legal Studies, Siksha 'O' Anusandhan University, Bhubaneswar, Odisha, India,
[2]Research Scholar, KIIT School of Law, KIIT University, Bhubaneswar, Odisha, India

Abstract

This article is an attempt made by the author to discuss the various aspects of transplantation of human organ and its legal features. Human organ and tissue transplantation was started in India in 1962. Earlier, the human organ transplant was unfettered, and human organ trafficking was rampant in the society. The parliament of India first drafted The Transplantation of Human Organ Act governing the transplantation which was passed in 1994. This act has been subsequently amended in 2011, and new rules came into force in 2014. This research paper discusses the significant mechanism of the act and spotlights on what all medical practitioners involved in transplant should know about the legal aspects of transplantation.

Keywords: *human organ, body, transplantation, medical*

Introduction

Transplantation of human organ is a great achievement in the medical history like the invention of antibiotics and anesthesia. The ancient Indian text and some of the Chinese literature narrated about the transplantation of organs. But first it was invented by a French surgon named Alexis Carrel who experimented in animals in the year 1902. The first human kidney was transplanted in the year 1946 and the liver in 1963 and the heart in 1967. After this many organs were transplanted like lung, pancreases, intestines etc. The WHO has now accepted transplantation of human organ as a well and standard recognized treatment. With the passage of time people have come forward for the donation of their respective human organs as a mark of true spirit of humanity and to save the precious lives. The Organ transplantation means "a medical procedure in which an organ is removed from one body and placed in the body of a recipient, to replace a damaged or missing organ. The donor and recipient may be at the same location, or organs may be transported from a donor site to another location." There are two parameters to get the consent for removal of organs from dead individuals firstly "the presumed consent in the absence of objection from the deceased when he was alive or from family members of the deceased, secondly informed consent based on the express consent of the deceased or the family members." The law relating to transplantation of human organs have been passed in Denmark, France, Sweden, Italy and Israel. Moreover "the permission of the relatives of the deceased unless the deceased has forbidden in his lifetime is assumed." For the first time in India, the Transplantation of Human Organ Bill was introduced in the parliament on 20th August 1992 and subsequently became the Transplantation of Human Organ Act in 1994.

Death and Transplantation in India:

According to the section 46 of the Indian Penal Code, 1860 it provides that, death denotes "death of a human being unless the contrary appears from the context." The definition of life in the context of death means the span of animate existence and the period between birth and death. Under the Part III of the Indian Constitution Article 21 broadly enumerates the meaning of life and guaranteed as a fundamental right of every citizen. Right to life includes right of the individual of his body in its completeness and without any dismemberment. The prohibition of any parts of the body or injury of the body/organ life cannot be enjoyed and is a violation of basic fundamental right.

Organ Transplantation has raised many ethical, moral, religious and legal issues. Science has advanced and biotechnology has also made a great contribution in the field of medicine. This organ transplantation is also very expensive procedure in India. Besides the cost of surgery the therapeutic care cost is added to the expensiveness.

Transplantation of Human Organ Act

This is an act "to provide for the regulation of removal, storage and transplantation of human organs for therapeutic purposes and for the prevention of commercial dealings in human organs and for matters connected therewith or incidental thereto." This act also "to provide for the regulation of removal, storage and transplantation of human organs for therapeutic purposes and for the prevention of commercial dealings in human organs"

The provision mandated that the donor must not be less than eighteen years of age and must voluntarily give his/her consent which is as understood from the Indian Contract Act, 1872. Section 12 of the Act also provides the consent of the donor must be informed consent. Section 3(4) of the act prohibits other than the medical practitioners no one can remove any organ from the donor. The most important of the guideline which prescribes that "no human organ removed from the body of a donor before his death shall be transplanted into a recipient unless the donor is a near relative of the recipient." The near relative means may be son, daughter, brother, sister, father, mother & spouse.

Section 6 of the act prescribes for Authority for removal of human organs from bodies sent for post mortem examination for medico-legal or pathological purposes that "where the body of a person has been sent for post-mortem examination- (a) for medico-legal purposes by reason of the death of such person having been caused by accident or any other unnatural cause; (b) for pathological purposes, the person competent under this Act to give authority for the removal of any human organ from such dead body may, if he has reason to believe that such human organ will not be required for the purpose for which such body has been sent for post-mortem examination, authorize the removal, for therapeutic purposes, of that human organ of the deceased person provided that he is satisfied that the deceased person had not expressed, before his death, any objection to any of his human organs being used, for therapeutic purposes after his death or, where he had granted an authority for the use of any of his human organs for therapeutic purposes after his death, such authority had not been revoked by him before his death."

Section 7 of the Act Provides for Preservation of human organs that, "after the removal of any human organ from the body of any person, the registered medical practitioner shall take such steps for the preservation of the human organ so removed as may be prescribed."

Prevention of Commercial Dealings in India

Commercialization of Organs in India is increasingly common. Many of the cases and instances have been reported relating to transplantation of human organ. This is seen almost in Rich & Poor Context. The poor who cannot fed his/her hungry stomach are easily ready for selling their one kidney by approaching the needy rich people. However Section 19 of the Act provides Punishment for commercial dealings in human organs that "whoever – (a) makes or received any payment for the supply of, or for an offer to supply, any human organ; (b) seeks to find person willing to supply for payment any human organ; (c) offers to supply any human organ for payment; (d) initiates or negotiates any arrangement involving the making of any payment for the supply of, or for an offer to supply, any human organ; (e) takes part in the management or control of a body of persons, whether a society, firm or company, whose activities consist of or include the initiation or negotiation of any arrangement referred to in clause (d); or (f) publishes or distributes or causes to be published or distributed any advertisement- (a) inviting persons to supply for payment of any human organ; (b) offering to supply any human organ for payment; or (c) indicating that the advertiser is willing to initiate or negotiate any arrangement referred to in clause (d), shall be punishable with imprisonment for a term which shall not be less than two years but which may extend to seven years and shall be liable to fine which shall not be less than ten thousand rupees but may extend to twenty thousand rupees: Provided that the court may, for any adequate and special reason to be mentioned in the judgment, impose a sentence of imprisonment for a term of less than two years and a fine less than ten thousand rupees."

Role of Judiciary on Transplantation of Human Organ

There are many cases discussed by the judiciary to tackle with the challenging issues of the transplantation

of human organs. In the case of *Aukland Health Board v. Attorney General,*[1] the court held that, "the values of human dignity and personal privacy belonged to everyone whether dead or alive. There are essentially two parameters to draw consent for removal of organs from a deceased person, (1) presumed consent, in the absence of objection from the deceased when he was alive or from family members, (2) informed consent, based on the express consent of the deceased or the family members." Generally the strict requirement of the consent is superseded by empowering the family to consent on behalf of the deceased. Medical hospitals that need an organ ask the permission of very close relatives of the deceased patient as normal procedure.

In an another case *Arup Kumar Das v. State of Orissa*,[2] the court observed that, "it is essential to point out various objectives of the Transplantation of Human Organ Act, 1994 and the intention of the legislature in enacting the present legislation appears to have not been properly understood by the statutory authorities who have been vested with the responsibilities of enforcing the said act. What have been prohibited under the statute is commercial dealings in authorization must be prevented and the commercialization dealings in human organs is prohibited, yet bona fide applicants may not be viewed in a suspicious manner since the act itself permits not only the donors from within the family but also permits non relative donors."

In an another case of *Jeewan Kumar Raut v. Central Bureau of Investigation*[3], the court observed that, "TOHO is a special Act. It deals with the subjects mentioned therein, viz., offences relating to removal of human organs, etc. Having regard to the importance of the subject only, enactment of the said regulatory statute was imperative. TOHO provides for appointment of an appropriate authority to deal with the matters specified in Sub-section (3) of Section 13 thereof. By reason of the aforementioned provision, an appropriate authority has specifically been authorized inter alia to investigate any complaint of the breach of any of the provisions of TOHO or any of the rules made there under and take appropriate action."

In another case *Mukesh Gandhi v. Deputy Secretary (Health) Medical Education and Research,*[4] the court held that, "as such there cannot be compulsion on the part of the recipient to have the liver transplanted in the very hospital, where it has been harvested. As observed earlier, situation of preservation of human organ through scientific mode is conceived under the Act. Therefore, there could be a transplantation of such human organ in different hospital than the hospital at which organ is removed. But of course with the requirement to be followed for ensuring that the preservation is under accepted scientific method and the viability for the purpose of transplantation is not lost. It is also required to be ensured that the transplantation takes place in the body of the recipient only, so that the purpose of donor for therapeutic use is fulfilled. What measures may be required to be undertaken are generally left to the authorization committee to decide and in any case, it would be required for the authorization committee also to ensure that, as and when such permission is granted, well accepted scientific methods are complied for preservation of such human organ, and the same is transplanted in the body of the recipient through recognized hospital having expertized for such purpose, and there is no misuse by any party during the course of transplantation."

Conclusion

Donation of human organ by a person who is dead or alive is considered to be the highest sacrifice. This sacrifice is for a giving life to other person. The transplantation act has evolved over last few decades and it is still in force. All the stakeholders who are part of this process, may it be Doctor, Doner, Donee & the relatives should aware of these rules & regulations so that misuse of human organs can be checked in the society.

Ethical Clearance: Not required, as the research article is based on Transplantation of human organ and its legal provisions. The research is doctrinally undertaken.

Factors Related to the Wasting in Child Under-Five Years in the the Sungai Bilu Public Health Center Working Area 2019

Ika Nirmala Febriyanty[1], Roselina Panghiyangani [2], Lenie Marlinae [3], Husaini [1], Meitria Syahadatina Noor[2]

[1]Master of Public Health Science Study Program, Faculty of Medicine, Lambung Mangkurat University, Banjarmasin, Indonesia, [2]Medical Education Study Program, Faculty of Medicine, Lambung Mangkurat University, Banjarmasin, Indonesia, [3]Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Banjarmasin, Indonesia

Abstract

Sungai Bilu Public Health Center report in 2018 noted that there were 24 people who received complementary feeding packages from 78 wasting cases recorded in the E-PPGBM report. The children under-five years who got this complementary feeding were indicated to experience wasting nutritional status (Z-score <-3SD) which was 30.77%. This study aims to analyze the risk factors associated with the incidence of wasting in child under-five in the Sungai Bilu Public Health Center in 2019. The design of this study was observational analytic, using a case control study research design. This research was conducted in the Sungai Bilu Public Health Center working area. The total sample in the study was 72 people. Primary Data using the 2016 Ministry of Health Nutrition Monitoring Questionnaire. The factors associated with the incidence of wasting in children under-five in Sungai Bilu Public Health Center are age, mother's education level, history of exclusive breastfeeding, history of complementary feeding and number of children. The sex factor is not related to the incidence of wasting in children under-five of Sungai Bilu Public Health Center working area. Mother's education level are the factors that most influence on the incidence of wasting in children under-five in the Sungai Bilu Public Health Center working area.

Keywords*: age, mother's education level, history of exclusive breastfeeding, history of giving complementary feeding, number of children, wasting*

Introduction

Children under-five years from poor families have the potential for greater malnutrition, it is estimated that more than one third of under-five deaths are due to malnutrition.[1] In 2011, around 52 million (8%) children around the world suffered from wasting, more than half of them living in South Asia.[2] The prevalence of wasting in South Asia is above 15%, meaning that the wasting has become a critical public health problem. According to the 2014 Global Nutrition Report (GNR) shows that Indonesia is included in 17 countries among 117 countries that have high nutritional problems in infants, one of which is wasting 12.1%.[3]

The Local Government has a community nutrition improvement program in Banjarmasin City where wasting children under-five years receiving additional food in 2018 have reached 100% of the target of 838 people more than in 2017 (252 people). This shows the increasing cases of wasting in the city of Banjarmasin. The children under-five years who got this complementary food were indicated to experience very thin nutritional status (Z-score <-3SD) which was 30.77%. Waluyo's research (2017) shows that the age of giving MP-ASI that is not good <6 months has a 1.35 times chance of wasting compared to the age of giving MP-ASI good at age 6 months.[4] According to data from the annual report from Sungai Bilu health centers 2018 show that low educational level is still there which is about 34.7%.[5] The average number of people in a family

Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Jalan A. Yani, Km.36, Banjarbaru, Kalimantan Selatan, Indonesia,
email: bintangara@ulm.ac.id

in Sungai Bilu Sub-District is 3.44% out of 2805 Family Heads.[6] According to the 2018 Sungai Bilu Public Health Center Annual Report shows that there are still 34.7% of families with more than 2 children.

Materials and Method

The design of this study was observational analytic, using a case control study research design. This research was conducted in the Sungai Bilu Public Health Center Working Area. The population is all wasting children under-five years that are found in the EPPGBM data December 2019 who are domiciled in the working area of the Sungai Bilu Public Health Center who lived at the time of the interview with 508 people. Samples taken from the existing population determined by purposive sampling. Case group are mothers with children under-five and wasting. Control was determined based on cases for one control (1:1) with the provisions of data on mothers with children under-five with normal nutritional status based on the body weight/height index with age 659 months, then matching with the closest address to the case or still in one neighborhood association area. The total sample in the study was 72 people. Primary data using the 2016 Ministry of Health Nutrition Monitoring Questionnaire. Data were analyzed using chi-square test and multiple logistic regression tests.

Findings and Discussion

Table 1. Characteristics of Respondent

Variable	Case		Control	
	F	%	F	%
Children under-five years Age				
High risk	28	77.8	11	30.6

Relationship between age of children under-five years with wasting

Based on the results of the study, there was a relationship between the age of the child with the incidence of wasting in children under-five years in the Sungai Bilu Public Health Center. The results of this study are similar to studies conducted by Mgongo et al (2017) which states that children under-five year age is associated with wasting events (p-value = 0.0001).[7] Devitasari›s research (2018) shows that children under-five years with poor nutritional status and psychomotor development that are not in accordance with their developmental age because of the mother›s ignorance of the importance of consuming nutritious food to achieve psychomotor development that is appropriate to the age of development and providing stimulation and monitoring of development that not do by old.[8]

The age groups most vulnerable to malnutrition are children who are growing up. As a child gets older the more the body needs the nutrients needed by the body to support the increasing and increasingly diverse physical activities. [9]

Relationship between the sex of children under-five with the incidence of wasting

Based on the results of the study, there was no relationship between the sex of children with the incidence of wasting in children under-five years in the Sungai Bilu Public Health Center. The results of this study are in line with research conducted by Putri (2013) which shows that there was no significant relationship between sex and wasting status, but the proportion of child wasting is slightly greater in the group of boys (15.7%) compared to the group of female children (14.8%).[10] Lestari (2016) shows that the analysis of the relationship between sex and wasting shows that there was no significant relationship between sex and nutritional status of children (p value = 0.528).[11]

Gender is related to values towards a child. Gender inequality occurs when there are different assessments between boys and girls in a community that cause boys and girls to get different treatment, different health care, and different accessibility of resources. The lack of correlation in this study can be caused due to no existence of differences in view of the value of the adopted family to the presence of a child male and female of this region, so that treatment of the family in terms of patterns of parenting, giving meal, the opportunity to access sources of health is equal to boys and girls.

Relationship of mother's education level with the incidence of wasting in children under-five years

Based on the results of the study, there was a relationship between the level of maternal education with the incidence of wasting in children under-five years in the Sungai Bilu Public Health Center. This study is in line with Khikmah's research (2014) which states that there was a relationship between maternal education and nutritional status of children.[12] Mothers who are highly educated are more likely to make decisions to improve nutrition and health in children, besides that mothers are also the primary caregivers for children so that the level of mother's education influences the incidence of stunting in children under-five years.[13]

Relationship history of exclusive breastfeeding with the incidence of wasting in children under-five years

Based on the results of the study, there was a relationship between the history of exclusive breastfeeding with the incidence of wasting in children under-five years in the Sungai Bilu Public Health Center working area. The results of this study are in line with research conducted by Rochmawati (2016) which shows that there was a significant relationship between exclusive breastfeeding and the incidence of underweight nutrition in the work area of the Saigon and Perumnas II Public Health Center (p-value = 0.021).[14] Children who get exclusive or predominant ASI have better nutritional status than partial breastfeeding or who are given additional food/drink <6 months and who have never been breastfed.[15]

Relationship of complementary feeding giving history with the incidence of wasting in infants

Based on the results of the study, there was a relationship between a history of breastfeeding with the incidence of wasting in children under-five years in Sungai Bilu Public Health Center. This is in accordance with research conducted by Hariani et al. (2016), that the pattern of complementary feeding, is associated with infant growth. The better the pattern of complementary feeding, the better the children under-five years growth chart.[16]

Food plays an important role in the growth and development of children. Because children are

growing, their needs for food are different from those of adults. Lack of nutritious food will cause growth retardation of children, so that it can cause an increase in child morbidity and mortality.[17] Complementary feeding for children under-five years is nutritional supplementation in the form of complementary foods with special formulations and fortified with vitamins and minerals targeted at children under-five years group for recovery or fulfillment of nutritional status.[18]

The relationship between the number of children and the incidence of wasting in children under-five years

Based on the results of the study, there was a relationship between the number of children with the incidence of wasting in children under-five years in Sungai Bilu Public Health Center. The number of children under-five years in the family will affect parenting because the time and attention of the mother to the child is divided, which in turn will affect the nutritional status of the child. The number of children in families with sufficient socioeconomic conditions will result in reduced attention and affection received by children, especially if the child is too close. As for families with poor socioeconomic conditions, the large number of children will result in a lack of affection and attention to children, as well as primary needs such as food, clothing and even housing not being met. The birth distance between two babies that is too close causes the inability of the family to care for the children properly. In order for mothers to breastfeed their children during this time, an effort must be made at least 18 months to two years between the birth of one baby and the subsequent pregnancy.[9]

The most influential factor with the incidence of wasting in infants

Based on the results of the study, maternal education is the most influential factor on the incidence of wasting in children under-five years in the Sungai Bilu Public Health Center working area (Exp. B = 31.919). The results of this study are in line with Rahayu's research (2018) which shows that there was a significant relationship between maternal education and nutritional status of children (OR = 2.36). Children under-five years with less nutritional status coming from groups of mothers with less education than with a group of highly educated mothers.[19]

The level of education affects a person in receiving information. People with better levels of education will be easier to receive information than people with less education levels. This information is used as a provision for mothers to care for their children under-five years in their daily lives. Perception itself can be interpreted as a person's perspective on something after gaining knowledge both directly and indirectly.[20]

Conclusion

The factors associated with the incidence of wasting in children under-five in the Sungai Bilu Public Health Center are age, mother's education level, history of exclusive breastfeeding, history of complementary feeding and number of children. The sex factor is not related to the incidence of wasting in children under-five years in the Sungai Bilu Public Health Center working area. Education mother factors are the factors that most influence on the incidence of wasting in children under-five years in the Sungai Bilu Public Health Center working area.

Ethical Clearance: Before conducting the data retrieval, the researchers conducted a decent test of ethics conducted at the Faculty of Medicine, Lambung Mangkurat University to determine that this study has met the feasibility. Information on an ethical test that the study is eligible to continue. The feasibility of the research was conducted to protect the human rights and security of research subjects.

Source Funding: This study was done by self-funding from the authors.

Conflict of Interest: The authors declare that they have no conflict interests.

Bifid Rib with Additional Oval Intercostal Space: A Rare Case of Anterior Chest Wall Deformity

Ishwar B. Bagoji[1], Gavishiddappa A. Hadimani[1], Ravi S. Bulagouda[2], Shardha Bai Rathod[3]

[1]Assistant Professor, [2]Professor & Head, Dept. of Anatomy, [3]Lecturer, Dept. of Dentistry, Sri B M Patil Medical College, Blde (Deemed To Be) University Bijapur, Karnataka, India

Abstract

Morphological variations in the anterior osseous thoracic skeleton are a rare entity. Its incidence includes accessory bones atypical fusion or non bony fusion of ribs and accessory foramina. Knowledge of these rare skeletal variants is vitally important for surgeons and radiologist performing thoracic surgeries and counting ribs, because such anomaly could mislead them during the procedure. During the routine dissection of adult male cadaver for undergraduate medical students, we observed a variation of bifurcation of anterior end of right third rib and corresponding costal cartilage. These bifurcated ends were joined together to form oval additional intercostal space. Bifid ribs are usually asymptomatic, and usually detected during routine radiographical procedures. It is peremptory that detection of bifid rib can help early diagnosis of Gorlin's syndrome.

***Key words**: Bifid ribs, Intercostal space, Radiographs, Gorlin's syndrome.*

Introduction

Ribs contribute majority of the thoracic skeleton in the mammals, which are twelve pairs of elastic arches that articulate ventrally and dorsally by sternum and vertebral column respectively, forming normally eleven fair of intercostal spaces. These osseochondral spaces contain thin multiple layers of muscular fibres from outside inwards intercostalis externa, interna and intimi respectively, and intercostal nerves and vessels courses through the intercostal groove formed between intercostalis interna and intimi[1]. The ribs are derived from ventral development of the sclerotomic mesenchyme that designs the vertebral arches, initially ribs develop as part of the cartilage model for each vertebra, but in the thorax region, the rib portion separates from the vertebra by the seventh to eighth week. The ossification of the rib takes place in the cartilage model, except for the anterior portion, which remains as the costal cartilage. Growth of the cartilage models for the ribs, sternum and vertebrae allow the enlargement of the thoracic cavity by providing the protection to vital organs. The thoracic skeleton act as dynamic, as it moves at is its various joints, increasing or decreasing the various diameter of the cavity for an extremely important process of respiration. A bifid rib is a congenital neuroskeletal abnormality of the anterior chest wall, which occurs in about 1.2% of humans[2]. Incidence of bifid rib is more common in male than female [3]. Additional intercostal space results from incomplete fusion of cephalic and caudal segments of sclerotomic mesenchyme during 4th to 6th week of intra uterine life[4]. During the mesenchymal and chondrogenic state of development, faulty fusion or anomalous chondrification may give rise to unusual fusion deformities of the ribs[5].

Case Report

During routine dissection for medical students in Department of Anatomy, BLDE Deemed to be University's Shri B M Patil Medical College and Research Centre, Vijayapura. Right sided anterior chest wall variation was observed in a 68 year old male embalmed cadaver. Additional oval intercostal deformity was examined in detail and morphological measurements were recorded. Bifid third rib was present enclosing an

additional intercostal space. Its bifurcation point was near its costochondral junction, the dimensions of the additional space were about 3.4 cm in transverse length and 0.7 cm in vertical length. The upper arched bony bar above the window at costochondral junction measured 1cm in length and the lower arched bony bar below the window at costochondral junction measured 1.3 cm in length. The intercostal space between second and third rib was 1cm at costochondral junction and intercostal space between third and fourth rib costochondral junction was 1.8 cm. The additional external intercostal space was covered by thin fibrous external inter costal membrane. Deep to the membrane the internal costal space was covered by internal inter costal muscle, fibres running down and laterally. Posterior to the internal inter costal muscle, fibres of Sternocostalis muscle were extending over this region. The intercostal vessels were entering additional intercostal space from right internal thoracic artery. The 3rd intercostal nerve running in costal groove was giving a twig to additional intercostal space.

Figure 1 Dissection of Cadaveric thorax of right side showing oval intercostal space intervening between second and third intercostal spaces, encircled by bifid third rib and bifid third costal cartilage

Discussion

Skeletal anomalies in the bones of thorax are recognized as potential cause of thoracic out let syndrome (TOS). Bifurcation of ribs and presence of supplementary intercostal spaces is a very rare variation of the thoracic skeleton. This may be due to gene mutation that strongly alters the anatomy of bone development [6], and bifid rib immensely linked to the alteration of rib development during embryogenesis [7]. The ribs develop from sclerotomal cells of somite at approximately 7th to 8th weeks of gestation, and play a crucial role in subsequent body patterning by governing the formation of all adult segmented structures, the vertebrae and the intervertebral discs, the ribs, muscles, tendons, ligaments, dorsal root ganglia, peripheral spinal nerves, and blood vessels of the adult vertebrate trunk. Disturbance in the segmentation process in vertebrates can result in conditions characterized by fusion of the ribs and spinal deformities or truncations[8]. The segmental border of a somite is defined under the influence of Mesp2, a transcription factor that acts by suppressing the Notch signaling pathway [9], involved in the pace of somite formation. Each somite in the thoracic region

forms the caudal part of one rib and the cranial part of the next caudal rib. Finally, after their formation from unsegmented somatic mesoderm (PSM). Occurrence of congenital skeletal malformation in patients with mutations in Notch-associated genes which exhibit a short trunk due to multiple hemi vertebrae formation accompanied by rib fusions, bifurcations, and deletions. The dermomyotome derived from one somite contributes to the intercostal muscle [10]. Aberrations of ribs probably occur during the process of segmentation and re segmentation of the developing of costal processes from the somites [2]. Mesp 2 also plays a crucial role in defining these regions, by establishing the gene expression pattern within the two halves [9]. The formation of a rib follows a complex pattern that involves the caudal half and the rostral half of two adjacent somites, in children, the bifid and fused ribs are associated with pathologic malformations such as Gorlin-Goltz syndrome [3], which is a rare, autosomal dominant inherited condition. Rib anomalies are generally more common in females than in males, occur more frequently on the right side and usually they are asymptomatic. Studies reported that genetic background influence negative impact on rib development in children, such as trisomy 18, neurofibromatosis, achondroplasia, thalassemia major and mucopolysaccharidosis can increase the relative risk of ribs malformations. Progressive loss of bone matrix and demineralization occurs in case of overactive (hyper) parathyroid gland and vitamin D deficiency, also known as rickets happens when the there is hepato renal dysfunction. Prostaglandins medication, used to treat heart disease in children can also cause abnormal rib development; Additional intercostal space in our case gets nerve supply from 4th intercostal nerve. This indicates that the muscles of this additional space are originated from muscles of the fourth intercostal space. Development of the bifid rib is probably due to disrupted interactions between cephalic and caudal segments of sclerotome during embryogenesis, occurring around the 4th-6th week of fetal life[11].

Conclusion

Skeletal variations in the anterior chest wall may indicate underlying systemic disease. Mal-development of rib at upper end of thoracic cage is due to defective bone segmentation and also associated with variation in disposition of vessels and nerves. Identification of rib anomalies can yield important diagnostic clues in the work-up of patients with congenital bone dysplasia, acquired metabolic diseases, iatrogenic conditions, trauma, infection, and neoplasm's. Awareness of such variations is necessary for physician's radiologist and surgeons during clinical diagnosis and treatment.

Clinical Profile and Short-Term Outcomes of Neonates in Material Eclampsia

Jagjit Singh Dalal[1], Monika Dalal[2]

[1]Associate Professor, Department of Neonatology, [2]Associate Professor, Department of Obstetrics and Gynaecology, Pt. B.D. Sharma Post Graduate Institute of Medical Sciences, Rohtak, Haryana, India

Abstract

Introduction: Maternal Eclampsia has shown to contribute to neonatal mortality and morbidities. Aim of the study was to determine the clinical profile and short-term outcomes of neonates born to women with eclampsia at a tertiary care hospital

Method: In this retrospective study case records of all eclampsia mother and their newborn babies were analyzed, Data were recorded from case sheets of mothers, delivery register and baby files. Details were recorded till discharge/death of babies.

Results: Out of 11,661 deliveries there were 113 cases of eclampsia mothers (0.96%). Majority of newborn were born to unbooked mother (95.57%). 57% babies were born by Caesarean section. Out of 113 births, 80.5% babies were live born and 19.5% were still born. Perinatal deaths due to eclampsia was 23%. Out of 91 live births, 45 (49.4%) babies admitted to Neonatal intensive care unit. The common reasons for admission were small for gestational age (43.9%) and low birth weight, hypoglycemia (5.4%), respiratory distress (15.3%), severe birth asphyxia (7.6%) and 4 (4.3%) babies had neonatal death. 87/91 (95.6%) newborns were discharged.

Conclusion: Maternal Eclampsia is one of the prominent etiological factors for neonatal morbidity and mortality. Prematurity, growth restriction and low birth weight are the common neonatal complications seen in babies born to mothers with eclampsia.

Keywords: *Eclampsia, neonatal outcome, morbidity, morbidities, clinical profile*

Introduction

Fetal and neonatal outcomes related to hypertensive disorder varies widely across the world.

Perinatal mortality is higher where lack of neonatal intensive care facilities are Eclampsia is defined as the onset of seizure during pregnancy or postpartum in patients of preeclampsia with >20 weeks gestational age. Eclampsia is life threatening complication of pregnancy worldwide.[2,3] Study (GBD 2015 It is 10 times more in India and is known to contributes to maternal and perinatal mortality[4] Approximately 12-25% of the small of gestational age (SGA) and 15-20% of all preterm birth are attributable to preeclampsia[5]. This study was done to analyze the short-term outcome of babies born to eclampsia mothers.

Objective: To Study the clinical profile and short-term outcomes of neonates born to women with eclampsia at a tertiary care hospital

Method

In this retrospective study case records of all eclampsia mother and babies were analyzed for period of January 2018 to December 2018 at PGIMS, Rohtak, India. All the babies born to eclampsia mothers during this period were included in the study. If mother was

E-mail: jagjit.dr@gmail.com

a known case of seizure disorder was excluded from study. A total of 113 babies born with maternal history of eclampsia were included in this study. Information were collected from case sheet, delivery register and discharge cards. Information in detail of maternal profile and neonatal outcome were noted. Study variable of eclamptic patients like age, parity, booking status, gestational age at the time of admission, type of eclampsia, delivery; various perinatal and maternal outcomes e.g. Still births, maternal complications during the delivery were recorded. Neonatal weight, gestation, mode of delivery, apgar, growth category, and complications like respiratory distress, meconium aspiration, hypoglycemia, hypocalcemia, mortality etc were recorded. Data were collected till the time of discharge/death of babies.

Results

A total of 11661 patients delivered within the study period, out of which 113 patients developed eclampsia. The prevalence of eclampsia came out to be 0.96%. The age of eclamptic women in our study varied from 17 years to 32 years (Table 1). Eclampsia was found to be more common in young patients with age < 25 yrs. (74.2%).

Table 1 Maternal characteristics (N=113)

Maternal characteristics	**Percentage (n/N)**
Age < 20yrs	21(18.5%)
21-25 yrs	63 (55.7%)
26-30 yrs	26 (23%)
30-35 yrs	3 (2.6%)
>35 yrs	0 (0%)
Booked	5 (4.43%)
Unbooked	108(95.57%)
Caesarian	65(57.5%)
Vaginal	45(39.8%)
Instrumental	3(2.6%)
primigravida	66 (57.5%)

Maximum patient (57.5%) were primigravida in our study and 71% patient had antepartum eclampsia and only 27 % had postpartum eclampsia. 43% patient were in between gestational age group of more than 36 weeks and only 3.5% patients were <25 week. Most of the mothers were unbooked (95.6%). Fetal distress was the most common indication of caesarean section. (Table 1) Out of 113 babies, 91(80.5%) babies were live born and 22 (19.5%) were still born. Total percentage of perinatal deaths due to eclampsia was 23%.

Table 2 Clinical profile and short-term outcome of live birth babies

Variable	**Vaginal group (n= 91)**
Gestation (wks) mean	36.1±4.8
Birth weight (g) mean	2267
Intra-uterine growth categories Weight < 10th centile, n (%) Weight 10th- 90th centile, n (%) Weight >90th centile, n (%)	 40 (43.9) 49 (53.8) 2 (2.2)
Male gender, n (%)	51 (55)
Meconium stained liquor	10 (10.9)
Severe birth asphyxia	7 (7.6)
Hypoxic Ischemic Encephalopathy	3 (3.2)
Hypoglycemia	5 (5.4)
Hypocalcemia	2 (2.1)
Mortality	4 (4.3)
Respiratory distress	14 (15.3)
Clinical Sepsis	15 (16.4)
Bronchopulmonary dysplasia	3 (3.2)
Discharged	87 (95.6)

Out of 91 live births, 45 (49.4%) babies admitted to NICU and 4 (4.3%) babies had neonatal death. Causes of death include severe birth asphyxia (n=1), prematurity (n=1) and sepsis (n=2). 87/91 (95.6%) newborns were discharged normal. Postnatal complications observed in babies were jaundice, sepsis, meconium aspiration, hypocalcemia, syndrome, hypoglycemia and asphyxia.

Discussion

The prevalence of eclampsia in current study was 9.6 per 1000 deliveries. Higher rates of eclampsia at our center may be related to high referrals received from community health centers, primary health centers, rural hospitals, district hospitals and also from private hospitals.

43.9% babies had intrauterine growth restriction (IUGR) in the present study. Maji[6] showed 65% babies with low birth weight. A study by Kumari A et al[7] showed that a statistically significant higher incidence of number of low birth weight babies (61.8%), IUGR babies (47.2%), preterm deliveries (28.1%) , stillbirths (14.5%) and neonatal mortality (10.9%) in their study. Also similar to our study they also found poor perinatal outcome was associated most commonly with factors such as IUGR, prematurity and low birth weight. Study by Choudhary P et al[8] had stillbirths (14%), neonatal deaths (6%). Still births were lesser than our study but the neonatal death were slightly less in our study.

Study by Haque et found that 60.86% newborn were preterm and 56.52% were low birth weight. In half number of their newborns, Apgar score at 5 minutes was less than 7 but in our study, we had lesser incidence of severe birth asphyxia (7.6%). Birth asphyxia was recorded in 39.1% and low birth weight in 25.8% in another study[10]

Study by Pokharel et al[11] showed that abnormal fetal heart rate, still birth, intrauterine fetal death, birth asphyxia(46.7%), need for resuscitation, low birth weight (33.3%) and intrauterine growth retardation were significantly higher in cases than controls. Our study had 19.5% still born and 80.5% live babies and only 4.3% babies had neonatal death. Neonatal death were 10.9% in study by Kumari et al[7] which was higher than our study. The causes of perinatal death were prematurity, fetal growth restriction, fetal asphyxia and sepsis in our study. Many studies have shown a higher risk of low birth weight and fetal death in eclampsia[8,11–13] similar to our study. The babies also had more respiratory distress in our study possibly because of more IUGR babies who had poor lung growth and also because of meconium. The complications noticed in babies of eclampsia mother were on higher side than the general incidence in neonatal period. Antenatal care, early diagnosis, primary management and referrals need to be improved as in our study most of the mothers were unbooked. There is need to spread awareness and encourage the general public for antenatal care visits and institutional delivery[6].

V. Conclusion:

Eclampsia continues to be one of the prime etiological factors for fetal and neonatal morbidity and mortality. Booking and improved antenatal care of mothers can improve perinatal outcomes. Prematurity, growth restriction and low birth weight are the common neonatal complications seen in babies born to mothers with eclampsia.

Effectiveness of Mother as a Rehabilitative Aid (MARA) Program in the Recovery of Children with Cerebral Palsy-An Assessor blinded Randomized Controlled Trial

Jayashree K R[1], Kovela Rakesh Krishna[2], Ajay Thakur[3], Pamidigantam Raghava Priya[4]

[1]Undergraduate Student, [2]Associate Professor, [3]Professor and Principal, [4]Lecturer, Vikas College of Physiotherapy, Mary hill, Airport Road, Mangalore

Abstract

Background: Cerebral Palsy is a non-Progressive neuromotor disorder which leads to various impairments and disabilities. There are evidence based Paediatric Physiotherapy approaches for rehabilitating the same. In the recovery of the child literature suggests that home program plays a major role.

Objectives; Till date there is a dearth in the literature which quantifies the home program. To provide Mother as a Rehabilitative Aid Program (MARA) to parents of children with cerebral palsy. To compare the effectiveness of MARA with traditional home program.

Methodology: Mother as a Rehabilitative Aid (MARA) is a unique program which helps the mothers to be a part of rehabilitative team. It is a quantified tailor made treatment protocol to be effectively used by the mothers. The present study aims to see the effectiveness of MARA over traditional approaches for home program in children with spastic diplegic Cerebral palsy children of age 5 to 10 years. The study design is Assessor Blinded Randomized Controlled Trial. The study population divided into MARA group and Controlled group

Results: MARA proved to be effective than traditional home program. T test was used in the statistical analysis. GMFM-88, PBS, Gait parameters all were statistically significant in MARA group than Control group.

Discussion: This study is correlated with previous studies and found to give a clear explanation for parent oriented program with quantifiable outcome measures.

Conclusion: It can be incorporated in the treatment of cerebral palsy children. Students Communication skills improved, Their Practical skills and service oriented mindset generated. They will get good ideas and can able to feel different problems that parents are facing and they got chance to plan their treatment accordingly. For Parents it generates hope and Trust on our profession. Their involvement will be more when their suffering is shared. Parents came to know different other challenges faced by other parents and they Got to know various other methods to overcome. This study leaves a benchmark for more high quality studies on MARA.

Introduction

Physiotherapist will come across many children with disability and it's a daily routine that providing treatment and educating parents regarding the treatment and ask them to continue at home. Family centered home program for children with disability plays a

major role in their improvement.[1] Parents especially mother takes care of children most often in Indian scenario. We have noticed that Mothers were not able to give appropriate home program because of lack of quality in providing home program which gives them a clear idea of managing children at home. Mother's perceptions should be unique and focused for their child's improvement.[2,3]Thus we thought of conducting a program which empowers mothers and make them understand their abilities in providing appropriate home program for the early recovery of child suffering with cerebral palsy. Mother as a Rehabilitative Aid (MARA) Program idea was developed by Kovela Rakesh Krishna which gives tremendous insights into carryover and treatment follow up of children with disability.[4] Till date no high quality studies were done on MARA. If MARA is proved to be effective then it will help in setting a bench mark for home program for all the disabled children to have a faster recovery and thus reduces burden of parents. It will also help in maintaining continuity in the treatment as changes in the child will become quite evident. Objectives of the study are to provide Mother as a Rehabilitative Aid Program (MARA) to parents of children with cerebral palsy. To compare the effectiveness of MARA with traditional home program.

Methodology

Study setting was Paediatric Physiotherapy Unit of Vikas College of Physiotherapy. Mothers of Children with Spastic Cerebral Palsy were study population. Study Type was assessor blinded Randomized Controlled trial and Sample size was 30 (15 in each group)Study duration was 2 months, Sampling method was simple random sampling, Randomisation was computer generated random number table and allocation was sequentially numbered opaque sealed envelope. Inclusion Criteria was 1. Mothers of spastic cerebral palsy children of age 5-10 years either gender with GMFCS level I and II. 2. Mothers who are willing to spend time in giving home program and give a feedback every day and should maintain continuity coming to the department. 3. Mothers who can understand local language (Kannada, Tulu) Exclusion criteria: Mothers of Cerebral palsy children will be excluded if the children are suffering with fixed deformities, With recent surgeries involving spine and limbs, Under anti-epileptic medication.

Procedure: Institutional Ethical approval was received, children with spastic cerebral palsy visiting our department were screened for their GMFCS levels[5] and inclusion criteria. Once they met our inclusion criteria an informed consent and assent were taken from parents and children respectively. Parents of the included Cerebral palsy children were divided into two groups through computer generated random number table and allocation by sequentially numbered opaque sealed envelope (SNOSE) into Experimental and control groups. Experimental group received MARA program primarily aiming Gross motor function, balance and gait parameters and control group received traditional home program for one hour a week, for 8 weeks. On the first day of program and on the last day of program assessment was taken by blinded assessor experienced in taking outcome measures through GMFM-88, PBS, Cadence, Stride length and Gait Velocity.

MARA Program: All the mothers of the Cerebral palsy children in the experimental group (15) were asked to assemble in a room. Primary investigator with the help of the guide elaborated the present condition of each child through PPT presentation. Co-investigator elaborated the changes and rationale behind changes. Balance, Gait parameters and Gross motor function were given priority throughout the program. Mothers were given chance to ask their queries regarding treatment. Once their queries are answered, the primary investigator demonstrated the home program through charts with exercises, video recordings and practical demonstrations. Home program which requires minimal handling from mothers were taught to maintain professional integrity. Mothers are made to perform the exercises minimum five times in front of the concerned physiotherapist. Exercises to be done at home were drawn and given to mothers through charts. Mothers were requested to take video recordings every day while giving home program. They are also instructed to maintain a diary. After 8th week comparison was shown to each parent individually about the development of the child and ease in functional activity performance of their child. Finally after 8 weeks, Gross motor function, balance and gait parameters were measured and post treatment outcome measures of Gross Motor function, Balance and gait parameters were taken.

Traditional Home Program, Control group: Mothers in the control group were given home program and asked to give all exercises which are taught to them without fail for 5 days a week, for 8 weeks.

Outcome measures: To measure balance, Paediatric balance scale (PBS)[6] is used. To measure Gait

parameters, Cadence (steps/min), Stride length (cm)and Gait velocity(m/min)[7] was used. To measure Gross motor function, Gross Motor Function Measure (GMFM-88)[8] was used. To measure Lower extremity function, Gross Motor Functional Classification System (GMFCS) was used.

Discussion

Results were analyzed using T tests and SPSS 21 Software. Boys were more in number than girls. Mean age group was 7. Results of control group are shown in tables 1-3. Results of Experimental group shown in tables 4-6. GMFM 88 D&E, Goal % were significantly improved in MARA Group than Traditional group. PBS and gait parameters were also significant in MARA than traditional group. This is the first study in MARA program with outcome measures.

Previous study by Racic M related to home program were shown that it is cost effective and easy to deliver.[9]

Previous study by Arthasarathy states that children with special needs have intimate relationship with parents with higher levels of motivation and protection, in which mothers have more role than fathers.[10] The results of the present study also proves the same that mothers have strong belief and can work harder to gain benefit in their children.

A study by Domenech Et al states that mother caregivers have a positive perception of the physical therapy treatment. They value and recognize the benefits of the treatment, by emphasizing that it provides for the physical, psychological and social recovery of their children.[11] the present study has proved that the mothers have positive perception and positive inclination to home program.

Effectiveness of Drumstick Leaves Juice on Hemoglobin Level among Reproductive Age Group Women in A Selected Community Area, Bathinda, Punjab

Jayasree GS[1], Shridhar.K.V[2], Mandeep Kaur[3], Simranjit Kaur[4]. Anita Rani[5]

[1]MSc. Nursing, Adesh College of Nursing, Adesh University, [2]Profesor Adesh College of Nursing, [3]Asst.Professor Adesh College, [4]Asst, Professor Professor Adesh College of Nursing

Abstract

Anemia is considered as most common cause of malnutrition and it has great significance in public health affecting children adolescents and reproductive age group women in worldwide.[1] **Objectives:** To assess the level of hemoglobin level among women in reproductive age group, before administration of drumstick leaves juice supplementation for both experimental and control group. To assess the effectiveness of drumstick leaves juice supplementation on hemoglobin among women in reproductive age group in experimental group. **Method:** The research approach was a quasi experimental study was done by one month of period, in 60 reproductive age group women (15-45) in the army cantonment area Bathinda Punjab. Drumstick leaves juice was freshly prepared and administer for 30 days .pre test and post test estimation of hemoglobin was done be using cyanmethamoglobin method. **Result**: The mean hemoglobin level of experimental group before administering 100ml drumstick leaves juice was 11.43 with a standard deviation ± 0.91 The mean hemoglobin level of experimental group after administering 100ml drumstick leaves juice was ±12.36 with a standard deviation is ± 0.69.the p value is 0.69. **Conclusion:** Comparing to control group the hemoglobin level of experimental group is improved.

Key words: *anemia, drumstick leaves, reproductive age.*

Introduction

Anemia is one of the most common nutritional disorders and it has public health importance in developing countries like India where it is the most widespread nutritional problem in adolescents and women of reproductive age.[2] WHO has estimated that prevalence of anemia in pregnant women is 14% in developed countries and 51% in developing countries while it is 65-75% in India. As a result, about one-third of the global population (over 2 billion) is anemic.[3] According to world health organization (WHO) the hemoglobin level should be 12 g/dl for women's. When the hemoglobin level less than 12 g/dl is considered as iron deficiency anemia.[4] WHO/UNICEF/ UNU graded the hemoglobin level . The most common type of anemia is due to nutritional factors and is also found especially among women of childbearing age group (15-49 years), pregnant, and lactating mothers.[5] Nutritional anemia is a worldwide problem, with the highest prevalence in developing countries. The etiology of anemia in India is not well established and the information available is limited in representativeness of the whole country.[6]

Objectives

1. To assess the level of hemoglobin level among women in reproductive age group, before administration of drumstick leaves juice supplementation for both experimental and control group.

2. To assess the effectiveness of drumstick leaves juice supplementation on hemoglobin among women in reproductive age group in experimental group.

3. To compare the level of hemoglobin among women in reproductive age group between control group and experimental group after post test.

Method

A quasi experimental (one group pre-test and post-test with control) design including demographical

variables and the hemoglobin level was assessed by cyanmethemoglobin method. The researcher approached the reproductive age group eligible women and those who were willing to participate in the study. Pre- test was conducted in the first day of data collection and Followed by that 100 ml of freshly prepared drumstick leaves juice was administered to the experimental samples. **Intervention**: Drumstick juice is prepared by boiling 1 kg of drumstick leaves with 4.5 liter of water and makes it boil 45 minutes and strain it well. It will give 4 litre of drumstick leaves juice then add two drops of lemon juice in it for every 100 ml of drumstick leaves juice**.** The juice administered continuously for 30 days and followed that 30th day hemoglobin level again assessed by same clinical method. Post- test was conducted for both experimental and control group

Design:

Quasi experimental (One group pre-test and post-test control group design)

Setting of The Study

Staff residence of cantonment, Bathinda

Sample Size

60 reproductive age group women.

Inclusion Criteria:

1. The reproductive age group women of 15 – 45 years.

2. Women who are willing to participate

3. Women who are having hemoglobin level between 7-13 gm/dl

Exclusion Criteria:

1. Persons who are having hemoglobin level less than 7 and above 13 gm/dl

2. Women who are having any other blood disorders such as sickle cell anemia,

And thrombocytopenia.

Tools and Methods of Data Collection

The data was collected by using standardized estimation of hemoglobin level by cyanmethemoglobin method.

Descriptive Statistics

Mean, medium and standard deviation

Inferential Statistics

Chi - Square

Results

1. Before administering drumstick leaves juice by conducting pre test estimation of haemoglobin was found that the mean value of hemoglobin in experimental group was 11.43 with a standard deviation is ±0.91 and control group mean haemoglobin level was 11.40 with a standard deviation was ±0.92

2. After the administration of drumstick leaves juice ,the mean haemoglobin value of The mean value of hemoglobin level for experimental group is 12.36 with a standard deviation is±0.69 and the control group mean value is 11.41 with a standard deviation is ±0.92.The p value is significant at **<0.001 level** of significance.

3. **T**here is a significance difference between pretest hemoglobin level mean value is (11.43) with a standard deviation (0.91) and posttest level of hemoglobin mean value is (12.36) with a standard deviation is (0.69).

4. In the present study paired t- test was done to compare between pre- test and post- test to compute the mean haemoglobin level. The results showed a significant difference, **(p<0.05)**.

Conclusion

- This study shows the effectiveness of drumstick leaves juice on hemoglobin level among reproductive age group women. The results provided valuable information to the effectiveness of drumstick leaves juice on improving haemoglobin level. And effectiveness of administration of drumstick leaves juice was seen from the results of post- test depicts that there was significant increase in the level of haemoglobin among reproductive age group women.

- This study concluded that the administration of drumstick leaves juice an effective way to improve the haemoglobin level in reproductive age group women.

Discussion

The mean hemoglobin level of experimental group before administering 100ml drumstick leaves juice was

11.43 with a standard deviation ± 0.91 and in control group mean was 11.40 with a standard deviation ± 0.92. There is no significance difference between the hemoglobin level and the women in reproductive age group before administration of drum stick juice (p value is 0.899). In present study during the comparison of hemoglobin level before and after administering100ml drumstick leaves juice, it was found that there was a significant difference between mean hemoglobin level before and after administering the drumstick juice was present.

It was observed that the administration of the drumstick leaves juice on hemoglobin level among reproductive age group women had a significant increase in their post test estimation of hemoglobin. In present study during the comparison of hemoglobin level before and after administering 100ml of drumstick juice, it was found that there was a significant difference between mean hemoglobin level before and after administering100ml of drumstick juice in experimental group. The P value is significance at <0.001 level of significance.

This finding was supported by a Quasi experimental study which was conducted to evaluate the effectiveness of drumstick leaves juice to increase the hemoglobin level among adolescent girls with anemia in selected homes at Madurai, The sample size was 40 which was selected by using the non probability purposive sampling method. The pre intervention level of hemoglobin was done and the drumstick leaves juice was administered for 15 days and the post intervention level of hemoglobin was done. The results shown that, in the level of hemoglobin 23 (57.5 %) had mild level of anemia and 17 (42.5 %) had moderate level of anemia in the pre-test and 24 (60 %) had mild level of anemia and 16 (40 %) had no anemia in the post-test. It shows that there is a difference between the pre and post level of hemoglobin. That shows that there is a significant difference between the mean score after the intervention. The obtained "t" 9.44 value was found to be extremely significant at the level of $p < 0.01$. It was observed that the administration of the drumstick leaves juice for adolescent girls with anemia had a significant increase in post test estimation of hemoglobin.[8]

RECOMMENDATIONS

On the basis of the findings of the study the following recommendations have been made:

1. Similar study can be undertaken with a large sample to generalize the findings.

2. The study can be conducted in different settings with similar facilities.

Morbidity, Physical Disability and Health Security of the Greying Population in India: Distributional Profile and Implications

K Gangadharan[1], Sajith Kumar S[2]

[1]Project Director, [2]Research Associate, ICSSR IMPRESS Research Project, Department of Economics, Kannur University Dr.Janaki Ammal Campus, Palayad

Abstract

Ageing involves multidimensional changes including those in the biological, psychological and social spheres of a person's existence. Based on the IHDS 2011-12 the study tries to analyse the morbidity/ disability status and the income and expenditure coverage incurred for treatment of the 60 plus folks in the country. High Blood Pressure, diabetes and Asthma are the most prevalent morbidity types among the aged people and these are suffered through out of the rest of life. The inadequate care and support in the older age creates stress and makes the infirmity problem more severe. Accessibility and quick improvement in health condition become the major reason for preferring the allopathic treatments. Availing any sort of pension or health insurance schemes is the possible way that makes the elderly more independent and stable. However the data reveals that the percent of elderly availing these services are slight in number. Financial burden and dependence force them to skip their treatment or to ignore the affliction, this makes their health condition more severe and further leads to more illness.

Key Words: *Health, Health care, Health Security, Ageing*

Introduction

The world is greying rapidly with the rate of growth of ageing population exceeding the general population[1]. Ageing refers to the process of growing old or changes that occur with the passage of time. It involves multidimensional changes including those in the biological, psychological and social spheres of a person's existence. The elderly form a high risk group for multiple morbidity; physical, mental and social among others. Chronic and degenerative diseases, physical defects continue for a long period making health maintenance difficult for the aged. Ageing, as it is fraught with many unpleasant changes like disease, disability, dependence, frailty and the prospect of dying, may induce anxiety and apprehension. Thus ageing is a source of stress by means of physical, social and economic perspectives[2]. The higher degree of tolerance to disease conditions in old age as something normal is also a contributory factor to the prevalence of improperly treated disease conditions in old age. Therefore, there is an urgent need for propagation of proper attitudes and health behaviour in old age and change the negligent outlook both in the elder himself and the significant others around who care for him[3].

Quality of life at any age is influenced by the health status and health is considered a significant personal and social resource. A significant relationship between poor health and low satisfaction and psychological distress has been found in earlier studies on older persons. It implies that, chronic illnesses and disability increase with age. The proportion of persons with chronic illness rises from 38 percent in the 60 + group to 45 per cent in the 65+ age group to 54 per cent in the 70+ group. Nearly 60 per cent of the subjects above 60 year of age suffered from some long term illness that required frequent visits to doctors[4].

The difference between the number and proportion of old people must be borne in mind as the former has economic implications while the latter defines requirements for amenities and services. In the coming decades, the elderly population will constitute a large proportion of the population. This will create more burden on the existing health care service availability

and utilization. The general health care delivery system in India is itself very inadequate[5]. In this backdrop this paper seeks to review the current state of art in the area of health care, morbidity and health security among the elderly. It is primarily concerned with identifying the morbidity and disability status of the aged with respect to their financial status in terms of pensions and health insurance availability.

Objectives of the Study

The study points to evaluate the following objectives

(i) To examine the morbidity and disability status of the elderly population in India

(ii) To examine the pattern of health security and health expenditure for outpatient care for the elderly population across treatment.

Materials and Method

The study uses the extracted data from Indian Human Development Survey (IHDS 2011-12), conducted by National Council of Applied Economic Research and the University of Maryland. It involves a large scale national representative data that covered all Indian states and 4 union territories of India. The number of elderly respondents covered in the study is 21922.

Results and Discussion

The problems of the aged are truly multidimensional and call for a multi- sectoral approach involving health, social, economic and other disciplines almost simultaneously. The most common chronic health problems of the aged in the developed world include hearing impairment, cardio vascular diseases, diabetes, dementia and cognitive functions and cancer. But for countries like India, we need to add blindness, respiratory disorders, nutritional deficiencies etc. Over 75 percent the elderly in India are from the rural areas and over 80 percent come from the unorganized sector underlining the fact that meeting health care needs of the aged folks become a serious problem in terms of access, availability and health security. Table 1 presents the age and gender status of the 60 plus respondents surveyed in IHDS 2011-12.

Table 1. Gender wise Age status of the respondents

Age Category	Gender		Total
	Male	Female	
60-69	6262	6665	12927 (59.0)
70-79	3064	3351	6415 (29.3)
80-89	989	1717	2106 (9.6)
90-99	207	267	474 (2.2)
Total	10522 (48)	11400 (52)	21922

Source: IHDS 2011-12[6]

Figures in parenthesis are percentage to total respondents (N)

The survey conducted among 21922 respondents aged 60 years and above, out of this 52 percent are female and 10522 are male. Almost 59 percent of the total respondents belongs to the 60 to 69 age group; possibly the younger and most active group among the elderly. The representation of female respondents in all the four age group is evident from the table.

Table 2 reveals the major morbidity type among the 60 plus respondents considered for the study.

Table 2. Major Morbidity problems among aged respondents

Morbidity type	Status (Number of Respondents)		
	No	Relieved	Yes
TB	21705 (99.0)	53 (.2)	164 (.7)
BP	19157 (87.4)	31 (.1)	2734 (12.5)
Heart Diseases	21224 (96.8)	26 (.1)	672 (3.1)
Diabetes	20311 (92.7)	20 (.1)	1591 (7.3)
Cancer	21862 (99.7)	8 (.0)	52 (.2)
Asthma	20952 (95.6)	13 (.1)	957 (4.4)
Paralysis	21445 (97.8)	19 (.1)	458 (2.1)
Epilepsy	21830 (99.6)	3 (.0)	89 (.4)
Mental Illness	21807 (99.5)	3 (.0)	112 (.5)

Source: IHDS 2011-12

Table reveals that Blood Pressure, diabetes and Asthma are the most severe/prevalent morbidity types among the aged people. The low values corresponding to the morbidity relieved group indicates the long term vulnerability of diseases in the old age. Ailments in the old age are a type of morbidity trap and they can't revive from the ill health condition.

More than the long term morbidity the physical disabilities like infirmity in Hearing, walking, speaking and vision affects the normal life and routine of the aged person. Since all these problems are associated with the older age, the exposure such disabilities are prolonged. Many elderly in their later years suffer from disability either physical or mental or both. Physical disability refers to impairment of skills in performing personal, self-help activities and psychological disability manifests due to impairment in cognitive functions viz., memory, understanding ability, concentration etc. Assessment of disability is important to take decisions about the chronicity of disablement of a person or the need for financial assistance. These physical and mental disabilities increase the incapacity in performing self-help activities and dependency. As a consequence, the transition from illness to disabilities and imposed functional limitations, the burden on the caregiver increases. The disability status of aged respondents with respect to their social background is presented in the Table 3.

Table 3. Disability status of the 60 plus respondents

Variables	Category	Type of disability and the number and percent of Disabled					Total *
		Hearing	Speaking	Far sight	Short sight	Walking	
Age	60-69	677 (5.24)	364 (2.82	1742 (13.48	1456 (11.26)	1934 (14.96)	12927
	70-79	848 (13.22)	411 (6.41)	1379 (21.50)	1208 (18.83)	1761 (27.45)	6415
	80-89	498 (23.65)	255 (12.11)	689 (32.72)	601 (28.54)	893 (42.40)	2106

Source: Authors calculation based on IHDS 2011-12 Figures in parenthesis are percentage to row total. *Total respondents in each category including persons with no disability. **Total respondents within each disability group and the figures in parenthesis are percentage with row total (N).

It is a general belief that disability increases with increase in age. The table make sense to this belief and a higher level of disability rate is found among respondents with more age; seniors of the senior citizens. Mobility and vision are the two factors that help elderly maintain their independence in old age[7]. However, the table reveals that disability in walking and far sight are the most severe problem found among the older respondents. It is highly evident from the study that, compared to the aged male, females are more subjected to all these disabilities. Also, there was a greater rise in disability among the females than the males. Some of the reasons for this include the neglect in healthcare, poor workforce conditions, and gender-based violence. Physical disability status of aged people in rural and urban area does not derive too much difference, though, a detailed analysis reveals that rural people age more prone to all these difficulties. While analysing the disability status of the aged respondents it is a noteworthy mention that higher level of disability is found among unmarried and widowed/separated respondents. The inadequate care and support in the older age creates stress and makes the infirmity problem more severe. Thus it is evident that lack of care, dependence and support is the major cause for wide spread disability among the older persons. Social and health morbidity is found to be associated with low socio-economic status and the female gender

The increasing level of morbidity and disability among the aged creates a more dependence on public and private health care delivery mechanisms. The coping capacity of these health system services is a matter of worry. Most of the elderly lacks enough financial support and are dependent on their family. The increased medical expenditure forces them to skip from treatment or ignore the vulnerability. Thus, the cost for treatment also play an important role in deciding the accessibility of health care utilization and the severity of morbidity condition. The table 4 analyse the cost of morbidity treatment for major treatment type and services and the availability of medical insurance to cope with the ever increasing health care expenditure.

Table 4. Cost for different treatment type and insurance coverage

Treatment Type	Doctor/hospital Fee		Medicine Cost		Travel Expenditure		Expenditures covered by Medical Insurance	
	A*	B**	A	B	A	B	A	B
Allopathic(Pain killer/ Cough syrup)	276	8407.63	276	2386.89	276	382.79	271	22.36
Allopathic (Antibiotic)	1264	6806.95	1264	3655.64	1263	623.42	1223	365.68

Source: Authors Calculation from IHDS 2011-12 data

A* Number of respondents availed services, B** Mean Expenditure incurred,

#Number of respondents availed treatment/services

The table makes it clear that allopathic treatment is the most preferred method among the elderly population. Accessibility and quick improvement in health condition become the major reason for the dependency on pain killer and antibiotic in allopathic treatments. Sugary is the most expensive treatment however, allopathic treatments require more expenditure for medicine. The average cost for travel or the expenditure for travel incurred by the patients is higher for surgery and homeopathic treatments than in allopathic. The repeated visit for check-ups and treatment make them more expensive than the rest of the items.

Various health/medical insurance helps the patients to cover a part of their burden of medical expenditure. The table 4 makes it clear that the number of respondents availing the service of medical insurance is too meagre. Patients opting allopathic treatment and surgery avails the majority of the insurance coverage. It is a positive sign that the patients incurring higher treatment expenditure avails significant part of the medical insurance.

The financial status of the aged person is always become a trouble and majority depends on their children/family for meeting their financial needs. Govt Implements various social security measures like pensions to ensure minimum financial security to the aged and vulnerable sections of the society. Every elder persons is eligible for old age pension if he does not avail any other financial support from authorities. The table 5 presents the status of availing various pension by old age people.

Table 5. Number of Aged people availing any sort of pension

Pension Type	Response	Number of Respondents	Percent
Old Age pension	No	17864	81.5
	Yes	4058	18.5
Widows Pension	No	20768	94.7
	Yes	1154	5.3
Disability Pension	No	21847	99.7
	Yes	75	.3
Annapurna	No	21884	99.8
	Yes	38	.2
Other Government	No	21909	99.9
	Yes	13	.1
NGOs	No	21908	99.9
	Yes	14	.1
Any Other	No	21882	99.8
	Yes	40	.2
Total Respondents		21922	100

Source: Authors Calculation from IHDS data

From the table it is clear that the number of respondents availing any sort of pension is too small. Old age pension is the most received source of income followed by widow pension and the contribution from the rest of schemes is insignificant. The level of disability in the old age is higher in age compared to the other age groups, even though the number of people availing disability pension is also meagre.

Suggestions and Conclusion

The level of disability and morbidity among the aged person is very high compared to the counterparts. This makes a very high rate of dependents on health care institutions and the cost for treatment in the form of fees, medicines and transportation is also very high. The financial status of most of the aged respondents is too poor and majority of them are financially dependent on their family. Availing any sort of pension or meeting the health expense from various health insurance schemes is the possible way that makes the elderly more independent and stable. However the data reveals that the percent of elderly availing these services are minor in number. Financial burden and dependence force them to skip their treatment of to ignore the morbidity/disability affliction, this makes their health condition more severe and further leads to more illness.

Appropriate health education of all age groups with an emphasis on their contribution to good health in old age is the only way of forestalling disease, disability and dependence in old age. An appropriate health attitude and health practice programme becomes an integral part of coping with ageing ensuring better health in old age. The State supported health care programmes targeted for the elderly are quite inadequate due to economic constraints is well known. Geriatric health care yet does not figure top on the nation's health agenda even while there are more urgent issues like cataract, a serious social and economic liability crippling over 11 million elderly yet to be completely addressed.

Significance of Chemical Composition Analysis in Urolithiasis

Karanpreet Bhutani[1], Upinder Singh[2], Punam Rani[3]

[1]Assistant Professor, Biochemistry, MMIMSR, MMDU, Mullana, [2]Consultant Orthopedician, Prime Hospital, Patiala, [3]M.sc Medical Biochemistry, MMIMSR, MMDU, Mullana

Abstract

Introduction: Urolithiasis is the formation of stones in the urinary tract. Between 1% and 15% of people globally are affected by kidney stones at some point in their lives. Knowledge of chemical composition of Renal stones may be helpful in clinical management of patients as well as in reducing risk of prevalence and recurrence of stones in this region.

Aims and Objectives: To analyse the chemical composition of Urinary tract stones.

Material and Method: The present study included 100 uroliths obtained by surgical intervention of Urolithiasis patients diagnosed at MM Institute of Medical Sciences, MMDU , Mullana from August 2018 to October 2019. The powdered form was qualitatively analyzed for their chemical composition adopting standard methods.

Results: In the present study, out of total 100 patients, the incidence of urolithiasis was more in males (72%) compared to females(28%).Distribution of stones based on their location, showed a high incidence of stones in the ureter (42%), followed by Bladder (26%) and Urethra (19%). Calcium oxalate was the most predominant chemical composition in the stones analyzed (63%), followed by Uric acid (18%). Calcium carbonate, Calcium phosphate and Magnesium Ammonium phosphate were predominant in 8%, 6% and 5% of stones respectively.

Conclusion: Analysis of the chemical composition of stones and knowledge of its etiology will help in improving the management of patients with Urolithiasis.

Key Words: *Urolithiasis ; Chemical ; Ureter; Calcium; Oxalate*

Introduction

Urolithiasis is the formation of stones in the urinary tract.A small stone may pass asymptomatic[1] If a stone grows to more than 5 millimeters, it can cause blockage of urinary tract, resulting in severe pain in the lower back or abdomen.[1][2] A stone may also result in hematuria, vomiting, or painful urination.[1] Risk factors for stone formation include high urine calcium levels, obesity, certain foods, medications like calcium supplements, conditions like hyperparathyroidism, gout and not drinking enough fluids.[1][3] Stones form in the kidney when minerals in urine are at high concentration such as Calcium, Magnesium, Oxalate, Carbonate, Phosphate, Urate etc. Between 1% and 15% of people globally are affected by kidney stones at some point in their lives. [3] High incidence of urolithiasis with varied chemical composition of calculi has been reported from different regions of India [4].Generally, more men are affected than women.[1]

There is limited data on the analysis of chemical composition of renal calculi in the population in and around Mullana. So the present study was undertaken to qualitatively analyse the renal stones. Knowledge of chemical composition of Renal stones may be helpful in clinical management of patients as well as in reducing risk of prevalence and recurrence of stones in this region.

Aims and Objectives

To analyse the chemical composition of Urinary tract stones.

Material and Method

The present study included 100 uroliths obtained by surgical intervention of Urolithiasis patients diagnosed at MM Institute of Medical Sciences, MMDU , Mullana from August 2018 to October 2019. The stones obtained from the Surgery Department to Clinical Biochemistry Laboratory were washed with distilled water to remove the debris, dried completely and weighed. The stones were cut and crushed, the powdered form was qualitatively analyzed for their chemical composition adopting standard methods [5] using chemicals of Analytical reagent grade. The research project was approved by the ethical committee of institute.

Inclusion Criteria

Patients above 14 years were included in the study

Results

In the present study, out of total 100 patients, the incidence of urolithiasis was more in males (72%) compared to females(28%). The highest percentage of urolithiasis was found in the age group 31-45 years in both the sexes(51%). (Table 1)

Distribution of stones based on their location, showed a high incidence of stones in the ureter (42%), followed by Bladder (26%) and Urethra (19%). Males showed high incidence of Ureteric stones while females had high incidence of bladder stones.(Table 2) All the stones analysed were of heterogenous mixed type. Calcium oxalate was the most predominant chemical composition in the stones analyzed (63%), followed by Uric acid (18%). Calcium carbonate, Calcium phosphate and Magnesium Ammonium phosphate were predominant in 8%, 6% and 5% of stones respectively. (Table 3)

TABLE 1: Occurrence of Urolithiasis in relation to age and sex of the patient

Age group (in years)	No. of cases (Male) (n=72)	No. of cases (Female) (n=28)	% of Occurrence
15-30	12	03	15%
31-45	32	19	51%
46-60	18	05	23%
>60	10	01	11%

Table 2 : Distribution of stones according to their site of Occurence

Location	No. of Males	No. of Females	% of Occurrence
Renal	07	06	13%
Ureteric	39	03	42%
Vesicle/Bladder	08	18	26%
Urethral	18	01	19%

Table 3 : Chemical composition of the urinary stones

Composition of Stone	**No. of stones**	**%**
Calcium Oxalate	63	63%
Calcium Phosphate	06	6%
Calcium Carbonate	08	8%
Uric Acid	18	18%
Magnesium Ammonium Phosphate	05	5%

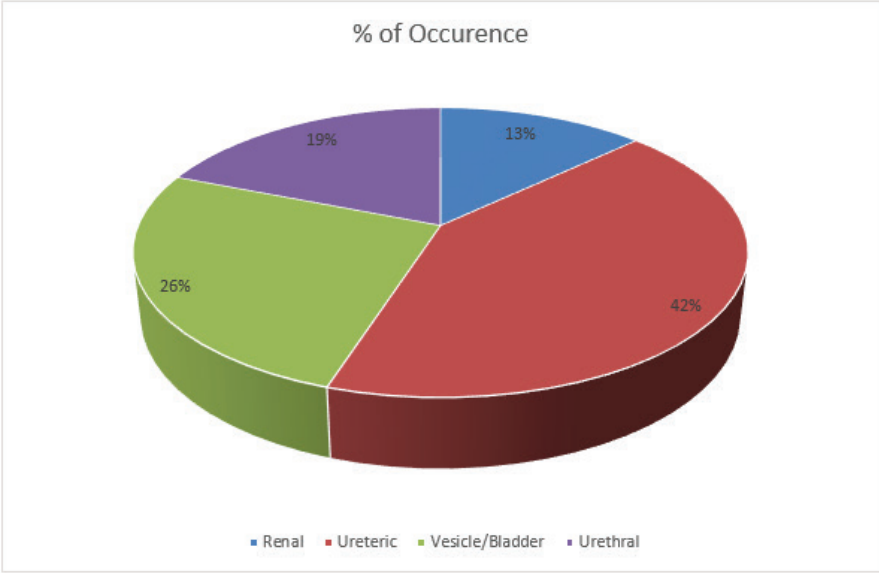

Figure 1 showing percentage occurrence of stones according to location

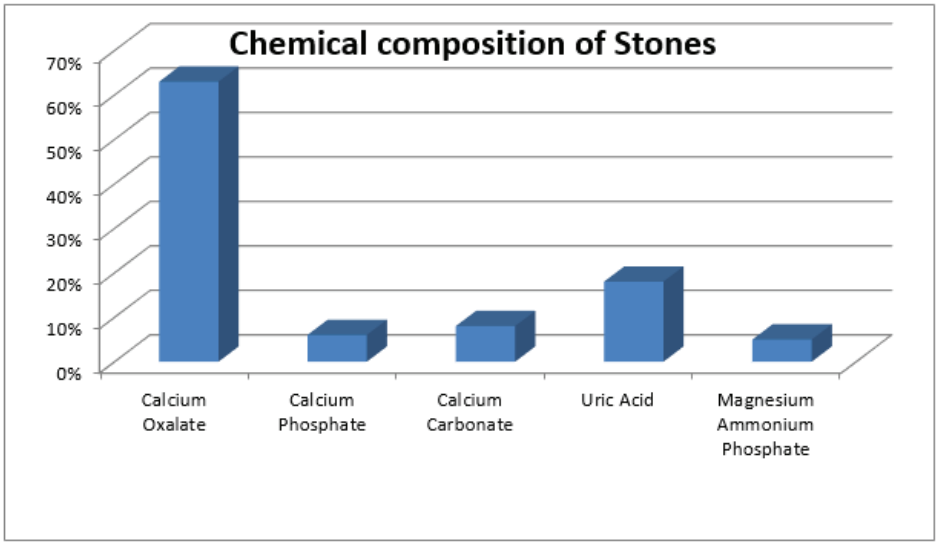

Figure2 showing chemical composition of stones

Discussion

Kidney stones affect all geographical, cultural and racial groups. [6] Stones result when urine becomes too concentrated and substances in the urine crystallize to form stones. [7] In the present study, the urolithiasis was predominant in males compared to females. Our findings were similar to study by Rafique et al [8] who found the incidence to be three times in males compared to females. Smaller diameter and increased length of urethra or large muscle mass in men may be the reason behind higher incidence in males compared to females. [9] Tissue breakdown on daily basis contributes to metabolic waste and a tendency towards formation of stones. [10] The type of diet consumed in the area is reflected by the composition of urine which in turn indicates the type of stones formed. Poor drinking leads to low urine volume which in turn contributes to stone formation . [11] In the present study, Calcium oxalate stones were predominant. Our findings were similar to the stone analysis study done in Manipur by P.P Singh et al who found calcium and oxalate in all the 196 stones analysed. [12] Ureteric stone analysis done in Jodhpur also reported a similar finding.[13] Hypercalciuria and hyperparathyroidism are the risk factors for calcium stone formation. Excessive consumption of Oxalate containing foods or excessive absorption of oxalate in enteric diseases or ileojejunal surgery or Vitamin C supplementation [14] contributes to oxalate stone formation. [9]

Excessive consumption of meat causes over acidification of urine leading to increased excretion of calcium, oxalate and uric acid and thus an increase in the kidney stone formation.

The composition of stones , urinary risk factors and analysis of diet suggest that urinary tract infections, nutritional habits and poor fluid intake contribute to urolithiasis. Therefore, sufficient intake of fluids can prevent stone formation and its recurrence. [15]

Conclusion

Analysis of the chemical composition of stones and knowledge of its etiology will help in improving the management of patients with Urolithiasis. The high incidence of renal stones in this area can be reduced by planning preventive measures and also the recurrence of stone formation can be prevented in the patients of urolithiasis by advising them on diet modification.

Assessment of Awareness and Practices in Management of Childhood Diarrhoea among Caregivers of Under Five Children in Urban Field Practice Area of KIMS, Hubballi

Kashavva B Andanigoudar[1], Laxmikant Lokare[2], Dattatreya D Bant[3],

[1]Post Graduate, [2]Associate Professor, [3]Professor and HOD, Dept of Community Medicine, KIMS KIMS Campus, Vidyanagar, Hubli

Abstract

Background: Diarrhoea is one of the leading causes of childhood mortality and morbidity. Diarrhoea leads to dehydration and causes significant mortality and morbidity in under five children. Most of the childhood diarrhoea cases can be treated by Oral Rehydration Therapy and Zinc supplementation. Hospitalization for childhood diarrhoea can pose significant burden to health systems and households. Therefore, it is necessary to assess the community-based management followed for the same. The objective of this study was to assess the awareness and practices for management of childhood diarrhoea among the caregivers of under five children.

Method: A Community based Cross sectional study was conducted among 203 caregivers of under five children residing in urban field practice area of KIMS, Hubballi, during June-July 2018. Study participants were selected by convenient sampling. After obtaining informed oral consent, data was collected using self-administered, semi structured questionnaire by house to house visits. Information about the sociodemographic profile, episodes of diarrhoea and management for same was collected.

Results: The prevalence of diarrhoea in under five was 21.8% in preceding two weeks. 78.8% of the caregivers were aware of ORS.73% of caregivers used ORSand 6.41 % used Zinc in the treatment of diarrhoea in their children. Awareness about sanitation and hygiene was not satisfactory in the current study.

Conclusion: Appropriate use of ORS and Zinc therapy can reduce burden of diarrhoea. Awareness regarding safe drinking water, excrete disposal and personal hygiene needs to be improved to reduce diarrhoeal diseases.

***Key words**: Diarrhoea, ORS, Zinc, childhood, KIMS, Mortality, Morbidity*

Introduction

Diarrhoea is one of the most common childhood illness, in both developing and developed countries. It is the second leading cause of childhood mortality in India and is responsible for 9% of all deaths per year among children under 5 years of age [1]. It is estimated that approximately 1.6 million die each year from diarrhoea in the developing world[1].

The standard definition of diarrhoea could be passing of three or more liquid stools in a 24hour period[2] . They are generally characterized as acute watery diarrhoea, persistent diarrhoea and dysentery.

Global incidence of diarrhoea among under five children is 1.731 billion episodes per year[3] . Approximately 480,000 children of age under 5 years die every year due to diarrhoea all over the world[4] .In India incidence of diarrhoea among under 5 children was estimated to be 1.71 and 1.09 episodes per person

Corresponding Author:
Dr.Laxmikant Lokare,
Associate Professor, Dept of community Medicine, Campus, Vidyanagar, Hubli-580022. Email ID: drlaxmikant25@gmail.com, Mobile:9886104302

per year in rural and urban areas and total number of diarrhoeal deaths among under five children were estimated to be 158,209 per year as per 2015[5,6].

Interventions to prevent diarrhoea including safe drinking water, use of improved sanitation and hand washing with soap can reduce disease risk. An optimal strategy for the case management of diarrhoea in children includes correct fluid therapy, proper feeding habits, appropriate use of antibiotics, no use of anti-diarrhoeal and effective education of mother or care taker.

Oral rehydration therapy (ORT) is the management of diarrhoeal disease through the administration of plenty of fluids, in an effort to maintain or replenish proper levels of hydration in the body[7] .

In India, incidence and deaths due to diarrhoea has declined over the years due to several programmes inculcated from the grass root level. Some of the programmes include Intensified Diarrhoea Treatment Fortnight (IDCF), National Diarrhoeal Disease Control Programme (NDDCP), Rotavirus vaccination etc.

The main objective of this programme is to improve usage of ORS and Zinc for childhood diarrhoea by pre-positioning ORS at household level. The activities under this programme mainly include intensification of advocacy and awareness generation activities for diarrhoea management, strengthening service provision for diarrhoea case management, establishment of ORS-zinc corners, prepositioning of ORS by ASHA in households with under 5 children and awareness generation activities for hygiene and sanitation[8].

The studies on the diarrhoeal diseases among under five children have been scarce in this region despite high occurrence of diarrhoea among under five children. Therefore, this study on diarrhoea among under five children and initiatives to reduce the burden of diarrhoea is necessary to provide evidence-based platform for intervention.

Objective: Assessment of Awareness and Practices in Management of Childhood Diarrhoea among Caregivers of under five children.

Materials and Method

This was a community based Cross sectional study, conducted by Department of Community Medicine, Karnataka Institute of Medical Sciences (KIMS) Hubballi after taking Ethical clearance. Based on the previous study, the prevalence of diarrhoea in under 5 children was 14.8% and taking absolute precision as 0.05, sample size was calculated using the formula: $N = 4PQ/d^2$. The final sample size was taken as 203. 203 caregivers, selected by convenience sampling. The study was conducted for 1 month (8^{th} June to 5^{th} July 2018) in urban field practice area Karnataka Institute of Medical SciencesHospital (KIMS), Hubballi of Dharwad District, Karnataka, India. Caregivers of under five children residing in study area, who gave consent participated in the study. Caregivers of children with congenital anomalies and children with special needs were excluded from the study. Semi-structured, pretested questionnaire. Ethical clearance was obtained from institutional ethical committee of Karnataka Institute ofMedical Sciences(KIMS), Hubballi.

Method of data Collection

Caregivers of under 5 were identified by house to house visit in the area. The questionnaire was pretested in 10% of the sample size in one randomly selected urban area. The primary respondents were mothers of the under 5-year children and in cases where a mother was not a caregiver,another primary caregiver was interviewed. After taking the oral consent, the participants were interviewed using the questionnaire. Information about sociodemographic details, past episodes of diarrheal, awareness and practices about its prevention, control and management was collected.

Data Analysis

Data was entered and edited in Microsoft Excel and analysed usingStatistical Package for Social Sciences (SPSS) Version 21.Continuous data was expressed as the mean and standard deviation.Categorical data was expressed as proportions. Appropriate tests of significance were used.

Results

A total of 203 caregivers were interviewed. Majority of the study participants belonged to Muslim religion. Most of the participants were from lower middle class of socio-economic status according to modified B G Prasad's classification. 1.29% of the care givers reported at least one episode of diarrhoea in their child in the past one year and 7.9% of the caregivers reported at least one episode of diarrhoea in the preceding fortnight (figure 1).

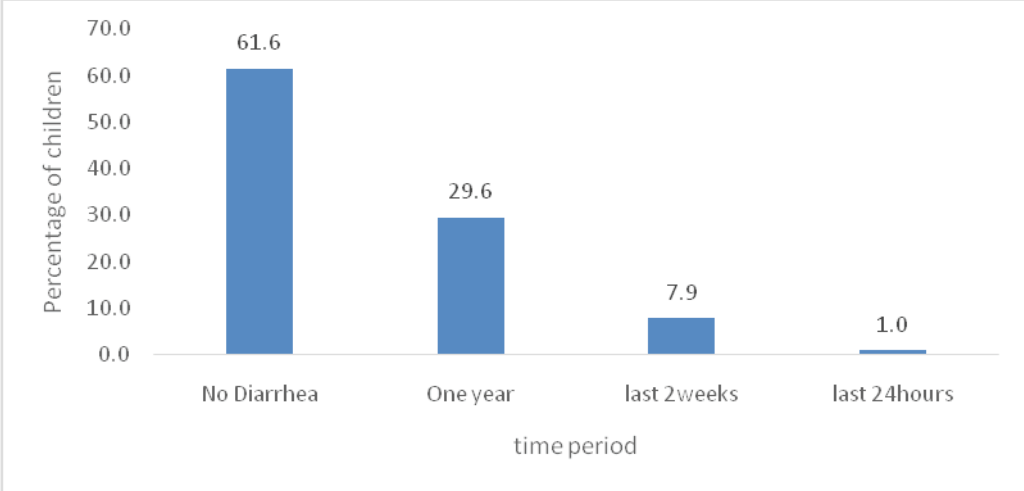

Figure 1: Distribution of number of children with episodes of diarrhoea in the past.

Table 1: Treatment approaches employed by the caregivers for management of diarrhoea in children.

Treatment approach	**N**	**%**
Managed with ORS at home	12	15.4
Managed with Home available fluids(other than ORS)	3	3.8
Went to hospital	63	80.8
Total	78	100

Table 2: Knowledge about the use of Oral Rehydration Therapy and Zinc in treatment of diarrhoea in children among the caregivers.

Variables	**Categories**	**N**	**%**
Knowledge about use of ORS	Yes	160	78.8
	No	43	21.2
Knowledge about use of Zinc	Yes	14	6.9
	No	189	93.1

The most common treatment approach for treatment of childhood diarrhea among caregivers was visiting hospital. The most common health facility approached and preferred by the caregivers was private clinic. Only 15% of the caregivers used ORS at home for diarrhoea in the children (Figure 1).

All the caregivers were aware of ORS and 78.8% were having knowledge about the correct method of use of ORS for diarrhea in their children. Only 6.9% of the caregivers were aware about zinc and its usage in episode of childhood diarrhoea. (Table 2).

All the caregivers practiced handwashing with soap and water before cooking food, before feeding the child

and after using toilet, but most of them were not aware about the proper handwashing technique and steps in hand washing. The awareness about sanitation and hygiene practices were found to be poor in most of the caregivers.

Table 3: Factors affecting the use of ORS and Zinc in the treatment of diarrhoea in children.

Variables	**Categories**	**Use of ORS n(%)**		**Chi square**	**p value**
		Used ORS	**Did not Use ORS**		
Socioeconomic status	>/=class 3	23(13.1)	152(86.9)	6.562	<0.05
	<class 3	9(32.1)	19(67.9))		
Education of the mother	>/=High school	32(27.8)	83(72.2)	29.069	<0.001
	<High school	1(1.13)	87(98.87)		
Awareness about the use of ORS	yes	31(19.4)	129(80.6)	7.419	<0.05
	No	1(2.3)	42(97.7)		
Hospital care seeking for diarrhoea	Present	27(84.3)	5(15.7)	50.5	<0.001
	Absent	135(78.9)	36(21.1)		
Variables	Categories	Use of Zinc n(%)		Chi square	p value
		Used Zinc	Did not Use Zinc		
Socioeconomic status	>/=class 3	13(7.4)	162(92.6)	0.559	>0.05
	<class 3	1(3.5)	27(96.5)		
Education of the mother	>/=High school	12(10.4)	103(89.6)	5.172	<0.05
	<High school	2(2.3)	86(97.7)		
Awareness about the use of Zinc	yes	12(7.8)	141(92.2)	0.528	>0.05
	No	2(4)	48(96)		
Hospital care seeking for diarrhoea	Present	5((3.6)	135(96.4)	7.768	<0.01
	Absent	9(14.3)	54(85.7)		

The factors found to be significantly associated with the use of ORS for childhood diarrhoea were lower socioeconomic status, education of the mother, awareness about the use of ORS in childhood diarrhoea and hospital care seeking for treatment of diarrhoea. The factors found to be significantly associated with the use of zinc were higher socioeconomic status, education of the mother, awareness about use of zinc and hospital care seeking for treatment of diarrhoea (Table 3).

Discussion

Diarrhoea is one of the major problems faced by children under five of developing countries like India. Recurrent infections in childhood significantly hamper the growth and development of preschool children[9].

The proportion of children with at least one episode of diarrhoea in our study was 38.4%, with almost equal distribution of cases among the age groups 1- 3 years and 3- 5 years. In another study done by Negi in rural

community of Varanasi, diarrhoea prevalence was 60.24% amongthe children of age group 10-25 months[10] . This difference in the most affected age group could be explained on the basis of a difference in study areas, feeding practices and sanitary conditions.

Of the total diarrhoeal episodes, 60.2 % of the cases occurred in the families of lower socio-economic status (class 4 and class 5) and this finding was significant. A similar study conducted by Walia et al in-pre-school children reported that poor socioeconomic statusand poorsanitation were important factors responsiblefor high diarrhoeamorbidity due to ease of transmission of infection[11] .

Only 6.9% of the caregivers were aware about the use of zinc in the treatment of diarrhoea and its additional benefits, while about 78% of the caregivers had knowledge about the use of ORS. A similar study conducted in urban slums of Delhi reported 71% awareness about ORS among care givers[12] .

The main finding is that about 81.8% of under 5 children with acute non bloody diarrhoea sought care from health facilities. This might be due to more severity of the episode or reduced awareness about the management of diarrhoea by home available fluids (HAFs). Out of those who sought care, utilisation of private facilities was preferred by the majority of care givers.

In a UNICEF 10 district survey in New Delhi, 79 % of mothers sought treatment from private medical sector for management of diarrhoea in their children[13]. From this it is quite evident that there is an over dependence on private sector. As medical expenses are more and more expensive in this sector the financial burden on families will be tremendous during course of treatment. In spite of the same facilities being offered free of cost in the government sector and offered at the door steps by health workers, they are not being utilized well by people.

Conclusion:

There was high prevalence of diarrhoea and most of them sought care from private health facilities. Cost of treatment can be significantly reduced by continuous health education in the community about the usage of zinc and ORS for treatment of diarrhoea. Health providers should spend more time to emphasize on use of ORS, Zinc and HAFs in prevention and treatment of dehydration. Awareness regarding safe drinking water, excrete disposal and personal hygiene whichcan reduce burden of diarrhoeal diseases is recommended.

R. Avenue, Kolkata, India

Abstract

Thalassemia is the most common genetic blood disease in the world and varies in different population group in the world. In thalassemic patients liver damage is augmented when age of the patients are increase. These are due to increasing age with advancement of disease progression, repeated blood transfusion, less use/ intolerance of iron chelating agent, decreased activity of hepatocyte to rescue them in such excess billirubin and iron flood. Secondary to hypersplenism.

Iron overload due to frequent transfusions in β-thalassemia results in abnormal organ function tests. Proper and timely screening of these parameters can help in early diagnosis & prevention of iron overload. Iron overload is a main leading cause of elevated liver enzymes, and presence of HCV infection is significantly related to the increased iron overload[14]. Liver injury whether acute or chronic, eventually results in an increase in serum concentrations of Alanine transaminase (ALT) and Aspartate transaminase (AST). In transfusion dependent thalassemia patients iron overload is often inevitable and exposed to transfusion-associated infections. Apart from these when the age is more, the disease progresses with their complication like hepatic injury. The thalassemia patient develops liver fibrosis as a result of iron overload due to excessive blood transfusion and also from excess intestinal absorption. N Sultana et al.[6] showed that serum ferritin and serum bilirubin parameter of iron over load and jaundice are correlated.

Key Words: *Thalassemia, liver function test, ferritin.*

Introduction

Thalassemia, the most common hereditary disorder worldwide[1].Approximately 7% of the global population is carrier for hemoglobin disorder[2].Beta-thalassemia syndromes are a group of hereditary blood disorders characterized by reduced or absent beta globin chain synthesis, resulting in reduced Hb in red blood cells (RBC), decreased RBC production and anemia. It is mostlyinherited as recessive traits [3]. Hemoglobinopathies are characterized by the production of structurally defective hemoglobin due to abnormalities in the formation of globin moiety of the molecule [4].Beta-thalassaemias are heterogeneousgroup of disorders and has three types, beta-thalassemia minor or beta-thalassemiatrait, beta-thalassemia intermedia and beta-thalassemia major. Beta thalassemia occurwidely in a broad belt, ranging from theMediterranean and parts of north and West Africa through the Middle East and Indian subcontinent to South East Asia[4].Hb-E beta-thalassemiais the commonest severe form of thalassemia in South East Asia and part ofIndian subcontinent.Hb-E isineffectively synthesized and hence, when itinherited together with beta-thalassemia there ismarked deficiency of beta-chain production [5].It is also divided into mild, moderateand severe form clinically. Clinical presentation of severe form is similar with beta-thalassemia major. These patients can survive long with the bettertreatment [6]. They need alifelong repeated blood transfusion to

Tel. No.-+91-8981856735. West Bengal, India

maintaintheir hemoglobin level around 12g/dl, but multiple transfusion will cause an accumulationof iron in various tissue accompanied by anincrease serum iron level[7].In thalassemia, iron over load occurswhen iron intake is increased over a sustainedperiod of time, either from the transfusion of redcells or because there is increased absorption ofiron from digestive tract. As there is nomechanism in human to excrete the excess iron, it has to be removed by chelating agent[8]. Iron can deposit in different visceral organs mainly in heart, liver and endocrine glands causing tissuedamage and most of the mortality and morbidity associate with thalassemia. Iron is stored in the body as ferritin mainly within the reticuloendothelial system and its overload may promote hepatic injury and fibrogenesis [9]. Furthermore blood transfusion dependent thalassemia are also liable to infected with Hepatitis B and Hepatitis C if proper screening is not done which can cause hepatic fibrosis and cirrhosis[10]. So thalassemia patients must be routinely checked for liver function, cardiac function, endocrine function and also serum ferritin and they should be treated accordingly for the maintenance of healthy life.

Materials and Method

The study was conducted in the Hematology Department, Calcutta school of Tropical medicine,from September 2018 to May 2019. This study was designed on the basis of retrospective observational type of study.This study was conducted on consecutive 64 transfusion dependent thalassemia patient. Thalassemia diagnosis was confirmed by examining hemoglobin electrophoresis. A pre-designed Proforma was used to collect information from the hospital records. By using the proforma which included sex, age at presentation, age at diagnosis, ferritin level, body weight, pre-hemoglobin and clinical symptom at presentation.

Inclusion criteria

Patient over 2 years to 30 years of age with confirmed thalassemia by examining hemoglobin electrophoresis. Those having symptom of clinical jaundice with or without history of chronic blood transfusion.

Exclusion criteria

Age more than 30 years

Statistical Analysis

Data were analyzed using the statistical software SPSS (version 21). All the variables were tested for normality, so that suitable parametric statistical tools could be used. Analysis of variance (ANOVA) of the data was used to detect overall difference in group means.

Observation and Results

Clinico-hematological study of Thalassemia was done on 64 patients during the period of 2018-2019.

AGE and SEX:-

Mean (±SD) age in total 64 patients between the age group 1 to 10 years was 5.70 ± 2.084, between 11 and 20 years mean was 15.76 ±3.562 and between age 21 to 30 years was 25 ± 2.8982 were include in the study. Our study based on 64 Thalassemia patients. Sex distribution in different patients shown in Age and sex distribution in different patients shown in **Table 1:**

Table1: Group statistics of LFT with AGE and SEX distribution

subject		Frequency	Percent (%)	Valid Percent	Cumulative Percent
Age group	1-10	17	26.6	26.6	26.6
	11-20	25	39.1	39.1	65.6
	21-30	22	34.4	34.4	100.0
	Total	64	100.0	100.0	
Valid	F M Total	35 29 64	54.7 45.3 100.0	54.7 45.3 100.0	54.7 100.0

Corelation Between Lft and Age:-

A Pearson product- moment correlation is run to determine the relationship between Total Billirubin and AGE. There is low correlation is found between TBill and AGE, which is statistically insignificant (r=.111, n=64, p=0.384).

SGPT-

The descriptive table show below some useful descriptive statistics like Mean, std. Deviation, and 95% confidence Interval for dependent variable (SGPT) for different age group (1-10,11-20,21-30) .**Table 2:**

Table 2:The descriptive table show below the SGPT Level of different age group

	N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Minimum	Maximum
					Lower Bound	Upper Bound		
1-10	17	50.335	46.4452	11.2646	26.455	74.215	10.0	159.0
11-20	25	54.160	41.2530	8.2506	37.132	71.188	9.0	169.0
21-30	22	45.182	29.8530	6.3647	31.946	58.418	5.0	121.0
Total	64	50.058	38.8359	4.8545	40.357	59.759	5.0	169.0

The table shows the output of the ANOVA analysis and whether there is a statistically significant difference between our group means. We can see that the P-value (Sig value) is .737, which is above 0.05. So there is no Significant difference found in SGPT with three age groups (1-10,11-20,21-30). Similar analysis was done for SGOT of different age group, and shows that the p-value(.479), that was also insignificant.

Independent samples t-test of SGPT on different sex

The table below shows independent samples t-test. Our level of significance is 0.05.and equal variance assumed. Our null hypothesis is mean SGPT for male and female are equal, and alternative hypothesis is mean SGPT of male and female is not equal.

		(1) Levene's Test for Equality of Variances		(2) t-test for Equality of Means						
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	95% Confidence Interval of the Difference	
									Lower	Upper
SGPT	Equal variances assumed	.082	.776	.043	62	.966	.4210	9.8301	-19.2291	20.0711
	Equal variances not assumed			.043	60.372	.966	.4210	9.8301	-19.1887	20.0306

Table 4: FERITINCAT * AGECAT Cross tabulation

			AGECATEGORY			Total
			0-10	11-20	21-30	
FERRITIN CATEGORY	0-1000	Count	12	19	14	45
		Expected Count	12.0	17.6	15.5	45.0
	1000-2000	Count	3	4	5	12
		Expected Count	3.2	4.7	4.1	12.0
	2000-3000	Count	2	2	3	7
		Expected Count	1.9	2.7	2.4	7.0
Total		Count	17	25	22	64
		Expected Count	17.0	25.0	22.0	64.0

Table 5: **Chi-Square Tests**

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	.907a	4	.924
Likelihood Ratio	.911	4	.923
Linear-by-Linear Association	.215	1	.643
N of Valid Cases	64		

When reading this table we are interested in the results of the "**Pearson Chi-Square**" row. We can see here that $\chi(4) = .907$, $p = .924$.This tells us that there is no statistically significant association between FERRITIN CATEGORY and AGE CATEGORY. Here we can see that ,The strength of association between two variables is very weak.

Table 6 : ANOVA table showing SGPT of different ferritin group					
	Sum of Squares	**df**	**Mean Square**	**F**	**Sig.**
Between Groups	2432.310	2	1216.155	.801	.453
Within Groups	92585.967	61	1517.803		
Total	95018.276	63			

From the above table we can see that the significance value is 0.453(p-value), which is above 0.05, and therefore we can conclude that there is no significant difference found in SGPT with three ferritin group.

Discussion

Regular blood transfusion and iron chelation therapy have improved the life expectancy in patients with transfusion dependent thalassemia and now they survive beyond the third decade of life. Liver derangement is becoming an important cause of morbidity and mortality in these patients. Viral infections (mainly hepatitis B and C) causing chronic hepatitis and/or severe iron overload are both important causes of liver pathology. Iron chelation with Deferasirox (DFX), an oral single dose therapy, has improved the compliance to chelation which reduces excessive body iron [11].

Liver enzymes are raised and indicative of liver injury in transfusion dependant β-thalassemia major patients [12]. In thalassemia, abnormal liver function

appears to be related to the high ferritin levels and the age when transfusions was initiated.[13-17]In thalassemia, liver is the earliest organ affected by iron and serum SGOT and SGPT are raised due to peroxidative injury and direct toxic effect of iron on liver cells[12]. So this study was conducted to know the derangement of liver enzymes and their correlation with the age and serum ferritin levels.

In our study on 64 thalassemic patient, we found raised SGOT and SGPT only in 33 and 31 patients respectively. They had no correlations with age with p value0.479 and0.737 respectively.

Reduction of serum ferritin concentration was associated with a significant decrease in serum ALT, AST and ALP concentration[11]. In a study by Soliman A et al, they found a significant correlations between serum ferritin concentrations and ALT and AST levels ($p < 0.01$)[11].

Another study by Suman RL et al showed as Iron deposition in liver takes place, its functions are affected which are predicted by raised SGOT and SGPT. SGOT and SGPT were raised significantly (p Value <0.05) and continue to rise as ferritin crosses 1000 ng/ml. There was a positive correlation between serum ferritin and liver enzymes (Pearson's bivariate correlation coefficient r=+0.87±84)[12].

But in our study we found raised ferritin level(1000- 2000 ng/ml) in 12 patients and 7 patients in 2000 -3000 ng/ml. Still we could not found any correlation of it with LFT (Mainly transaminases). The p value was 0.453 for SGPT.

In those two studies, they found raised SGOT and SGPT as their ferritin level were very high in all patient, whereas we found raised ferritin level in very few patient. It may be due to our all patients are routinely checked for serum ferritin and they received chelation therapy when ferritin level goes above 500 ng/ml.

Conclusion:

Iron overload can cause liver injury which causes raised liver enzymes. We failed to show this. Like us, some investigator also found such weak correlation [18] as exact mechanisms are still unclear. So, further detailed studies needed to find out the promising correlations in transfusion dependent thalassemic patients.

Construction of Human Development Index (HDI) for districts of Karnataka based on NFHS-IV data

Keerthan Rao Y[1], Ravishankar. N[2]

[1]MSc Bio-statistics, [2]Assistant Professor, Department of Data Science, Prasanna School of Public Health (PSPH), Manipal Academy of Higher Education (MAHE), Manipal

Abstract

Background: The Human Development Index (HDI) is a composite measure of life expectancy, education and per capita income indicators, which are used to rank countries. A country scores higher HDI when lifespan is higher, literacy rate is higher and GDP per capita is higher.

Objective: To construct HDI for districts of Karnataka based on NFHS-IV data.

Methodology: Based on the district level NFHS-IV household data, HDI scores were calculated. The methodology put forward by United Nations Development Programme (UNDP) was adopted. Health index is measured in terms of life expectancy at birth. Education index is calculated based on adult literacy rate. Living standard index is measured in terms of availability of resources like water, toilet, cooking fuel, electricity, type of house and income level .The HDI is computed as the geometric mean of these three indices.

Results: Based on the HDI scores, districts are ranked. The number of districts belonging to very high, high, moderate and low human development are 3 (10%), 13(43.3%), 13(43.3%) and 1(3.3%) respectively. Udupi district ranked first in terms of overall human development where as Yadgir ranked least.

Keywords. *Human development index; Life expectancy*

Introduction

Human Development Index (HDI) is a composite measure of indicators of basic human needs namely health, education and per capita income.[1] The index was first developed by Pakistani economist Mahbub Ul Haq in 1990 and later by Indian economist Amartya Sen. This index helps to assess the performance of a country with respect to other countries in terms of development. United Nations Development Program (UNDP) publishes global HDI report where countries are ranked according to their development. A country with a higher development will have a better rank in HDI. India ranks 130 out of 189 countries according to UNDP's HDI report 2019. In India HDI for states is published by NITI aayog.

Karnataka is one of the 29 states of India. It is located in south western part of India. It was formed in November 1, 1956, originally known as the State of Mysore. The capital of Karnataka is Bengaluru. Karnataka comprises of 30 districts with 227 talukas. As per the information from Census 2011, Karnataka has population 6.11 crores. The area of the state is about 190000 sq.km as it is 8th largest state of India in terms of area.[2]

The National Family Health Survey (NFHS) is one of the largest surveys conducted in India by International Institute of Population Sciences (IIIPS), Mumbai. NFHS provides information about population, health and nutrition status for all the states and union territories of India. Its recent round is NFHS-IV, which was conducted in 2015-16. Fieldwork of NFHS-IV was conducted from 20 January 2015 to 4 December 2016 covering 601509 households, 699686 women and 112122 men. It collected data on 114 key indicators. NFHS-IV provided

the district level data for important indicators.[3]

Human Development Index measures the average achievement in human development and assigns ranking to countries.[4] Similarly, human development index can be calculated for states, districts and talukas. In this paper, human development index for districts of Karnataka is constructed based on district level data from NFHS-IV.

Objective:

To construct human development index for districts of Karnataka based on NFHS-IV data.

Data and Methodology:

The National Family Health Survey-IV (NFHS-IV) district level household data was used to construct Human development index for 30 districts of Karnataka state. For the statistical analysis, Microsoft Excel-2007 and EZR version 1.37 were used.

The methodology put forward by United Nations Development Programme (UNDP) was adopted for the construction of HDI. The human development index is computed based on three indices namely Living standard index (LSI), Education index (EI) and Health index (HI). The geometric mean of these three indices gives the Human Development Index (HDI).[4]

$$HDI = (LSI \times EI \times HI)^{1/3}$$

Living standard index (LSI) is computed as geometric mean of 6 dimensions. The 6 dimensions are proportion of households having source of water facility (l_1), proportion of households having toilet (l_2), proportion of households having access to electricity (l_3), proportion of households having access to cooking fuel (l_4), proportion of households having pucca house (l_5) and proportion of households having at least middle class status (l_6).

$$LSI = (l_1\, l_2\, l_3\, l_4\, l_5\, l_6)^{1/6}$$

Education index (EI) is computed in terms of proportion of literates among population aged 7 and above (proportion ranging from 0 to 1).

Health index (HI) is measured in terms of life expectancy at birth (LEB). It is calculated as follows:

Where, max (LEB) is maximum life expectancy at birth that is 85 years and min (LEB) is minimum life expectancy at birth that is 25 years. Life expectancy at birth was computed by constructing complete life tables using age at death of each district.

Interpretation of HDI

Human Development Index ranges from 0 (minimum human development) to 1 (maximum human development). Further, HDI value of 0 – 0.540 signifies low human development, 0.541 – 0.699 signifies moderate human development, 0.7 – 0.79 signifies high human development and 0.791 – 1 signifies very high human development.

Results

The HDI for 30 districts for Karnataka is provided in table 1. Among the 30 districts, 3 (10%) belonged to very high human development, 13 (43.33%) belonged to high human development, 13 (43.3%) belonged to moderate human development and 1 (3.3%) district belonged to the category of low human development. From the table 1, it can be seen that, HDI score is maximum for Udupi and minimum for Yadgiri, which is the only district belonging to low human development category. Living standard index score is maximum for Bengaluru and minimum for Yadgiri. Health index score is maximum for Ramanagara and minimum for Bengaluru Rural. Education index score is maximum for Bengaluru and minimum for Yadgiri.

Table 1: HDI for districts of Karnataka

DISTRICT	LSI	HI	EI	HDI	RANK
UDUPI	0.891	0.863	0.761	0.837	1
BENGALURU URBAN	0.962	0.689	0.866	0.831	2
DAKSHINA KANNADA	0.884	0.804	0.793	0.826	3
UTTARA KANNADA	0.789	0.781	0.745	0.771	4

Discussion

Human Development Index (HDI) reflects the status of well-being and economic development of a geographic entity – country, state, district etc relative to others. Many policy decisions are made looking into the HDI. In this study HDI was constructed for 30 districts of Karnataka state using NFHS-IV as the data source. This index can be used to identify where the districts are lagging behind in developmental process.

As per the HDI, Udupi district was ranked first among all the 30 districts of Karnataka state. This can be attributed to presence of good quality health care facilities, educational institutions and better transport facilities. Further, Udupi is one of the best tourist hotspots and religious destinations of India. Yadgiri was ranked last as it has least HDI value. This may be due to the fact that Yadgiri is recently formed district, developmental programs are still at infancy.

As per the Human Development Index across districts of Karnataka, 2011 reported in Economic Survey of Karnataka 2015-16,[5] Bengaluru Urban has been ranked first among 30 districts with HDI score of0.928, whereas Udupi is positioned at 3rd place with HDI score 0.675. Raichur is in the last place with HDI score 0.165. In Economic survey of Karnataka 2015-16, living standard indicators used were access to cooking fuel, toilet, pucca house, water, electricity, percentage of non-agricultural workers to total workers and taluk level per capita income. Education indicators used were literacy rates and gross enrollment rates. Health indicators used were child mortality rate and maternal mortality rate. The methodology used in this paper is almost same as that of Economic Survey of Karnataka 2015-16, except in health index, instead of maternal mortality rate and child mortality rate, life expectancy at birth is used and in education index, only literacy rates are used.

Ethical Clearance: not applicable as the study is based on a secondary publicly available/open source data

Association of Anthropometric Measurements and Lumbar Lordosis with Flexor and Extensor Trunk Muscle Endurance Along with Gender Based Differences in Young Adults

Manoj Purohit [1], Shabnam Joshi[2], Rekha Chaturvedi* [2], Sivachidambaram Kulandaivelan[2]

[1]Student, MPT, [2]Assistant Professor, Guru Jambheshwar University of Science and Technology Hisar, Haryana.

Abstract

The goal of the study is to see the association of anthropometric measurements and lumbar lordosis with flexor and extensor trunk muscle endurance along with gender based differences in young adults. **Study design**: Cross sectional observational study. **Sampling**: Systematic random sampling **Sampl**e: 354 participants of age group 18-28 years based on inclusion and exclusion criteria. **Procedur**e: Age, BMI, Trunk flexor and extensor endurance, lumbar lordotic angle were measured and the association between these variables were calculated using chi square test and independent T- test. **Result**: Significant gender based differences were found in variables age, BMI, LLA and WC. Significant positive association of BMI and LLA, WC and LLA, FET and EET, age and FET, Negative association of EET and LLA, WC and FET was found. **Conclusion**: LLA and endurance of the trunk musculature are vital elements for good spinal health.

Trial Registration: CTRI/2019/04/018628.

Keywords: *BMI, Trunk flexor endurance, Trunk extensor endurance, Lumbar lordotic angle.*

Introduction

Low back pain has been a common problem contributing enormously to musculoskeletal problem that causes activity limitation and work absenteeism[1,2] and thereby causing enormous burden to the society [3]. Alteration in posture is one of the contributing factor of pain in the low back region. The variance of lumbar spine curvature because of irregularities in posture contributes significantly to low back pain. Studies have reported that excessive lumbar lordosis as a prime cause for pain and radiculopathy [4, 5] and the deficiency in endurance of trunk muscles has been recognized as a predictor for various conditions of the low back in people [6]. Studies have confirmed that the patients of low back pain have lesser abdominal endurance as compared to the healthy population[7-9] and the major element of low back pain is estimated to be the loss of muscle control leading fatigue in trunk muscles[10]. Thus the examination of the endurance of trunk muscles holds greater importance in prevention and rehabilitation of low back pain. The relationship of low back pain with the BMI is described in various studies suggesting increase in the bulk of the trunk area results in frequent ability to fatigue of the musculature[11]. Increase in BMI, because of diminished mobility act on pelvic, abdominal and thoracic area results in decrease range of motion. A decrease in flexibility of the trunk region and early fatigue is the complication of low muscle strength in some subjects. Decrease muscle flexibility and trunk strength have been found as risk factor for low back pain[12].The endurance of the musculature of the trunk also a vital element for mechanical support to spine[13]. The endurance of the musculature of the trunk muscles influences the pelvis and lumbar stability. A study suggests chief causes of postural deformation is the asymmetry between endurance of trunk flexors and extensors [14]. A study suggests that the endurance of back muscle is seen to be more in males as compared to females and has a negative co-relation between the core muscle endurance and lumbo-sacral angle in patients with chronic low back pain[15]. Factors like obesity, lumbar lordotic angle, poor

trunk and abdominal muscle strength, tight hamstrings and inequality of lumbar lordosis are interconnected factors contributing to decreased range of motion of lumbar spine[16]. So this study aims to see the association between anthropometric variables and lumbar lordosis with the trunk muscle endurance and to see the gender based differences in these variables in young adults.

Methodology

Study design: The present study is a cross sectional (Observational) design. The subjects were selected by systematic random sampling method. A total of 354 participants were selected out of 4992 participants residing in hostel of the University based on the inclusion and exclusion criteria. Sample size estimation was done with 95% confidence level and 5% margin of error. Inclusion criteria were: healthy young adults of age group between 18-26 years. Exclusion criteria: symptomatic back pain, pain in neck and thoracic region, history of any disease related to orthopedic, neurological and cardiopulmonary, any congenital or acquired chest wall deformity. Ethical approval was taken by Institute Ethical Committee (IEC) of Department of Physiotherapy of Guru Jambheshwar University of Science and Technology Vide letter no. PTY/2019/351. The protocol for the study was registered in CTRI (Clinical Trial Registration of India) Registration number CTRI/2019/04/018628 in accordance with the guidelines of ICMR (Indian Council of Medical Research)

Procedure:

The height and weight of all the participants of the study were taken using the weighing scale and stadiometer and the BMI was calculated. For measuring the Trunk flexor endurance Kraus-Weber Test was used[17]. For measuring the trunk extensor endurance modified Sorensen extension test was used. Palpations and marking of spinous processes was done by dry erase marker at the T12 and S1 spinous processes. Before measuring the lumbar lordosis angle of each subject the iPhone® has an inbuilt zeroing option for the application based inclinometer.[18]

Fig. 1 Kraus Weber test for Trunk flexor endurance

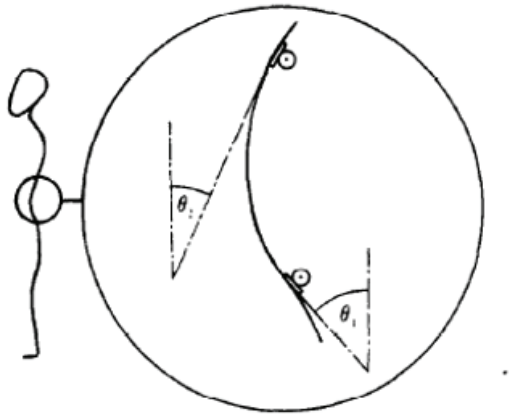
Fig. 2 Sorenson test for trunk extensor endurance

Fig. 3 Measuring lumbar lordosis using I Phone inclinometer

To measure the lumbar lordosis angle of subjects the instrument (iPhone®) was put with contact through the power on-off button on the body landmarks T12-L1 and

S1-S2 marked by a dry erase marker.[18]

Calculation of lumbar lordosis angle was done by the output from the instrument indicating the angles θ_1 (S1), and θ_2 (T12). The angles were recorded and added together. Lumbar curvature C is given by $C = \theta_1 + \theta_2$. [18,19]



Data analysis: Data was analyzed by the SPSS software (21.0 version). Mean and standard deviation (SD) of all the seven variables i.e. age, height, body mass index, waist circumference, flexor trunk muscle endurance (FET), trunk extensor muscle endurance (EET) and lumbar lordotic angle (LLA) in all male and female participants were calculated. The quartiles were formed from the values obtained from all variables to simplify the calculations. Independent T- test was used to find out the gender difference between the subjects and Chi-square test was used to find significance of association between the variables in both groups. The significance level was set at $p < 0.05$.

Result

The result of the study shows that there is significant gender difference in variables like age, BMI, LLA and WC. The male participants were taller, older and have more BMI and WC than their female counterparts. The females had more LLA as compared to the males. The characteristic of significant variables is mentioned in Table 1

Variables	**Mean ± SD**		**MD (95% CI)**	**t**	p
	Male	**Female**			
Height (m)	1.72 ± 0.05	1.59 ± 0.05	0.12 (0.11-0.13)	21.23	0.000
Age (years)	21.20 ± 1.89	20.81 ± 1.82	0.40 (0.01-0.78)	2.002	0.046
BMI (kg/m2)	22.33 ± 2.83	20.97 ± 2.93	1.36 (0.76-1.97)	4.436	0.000
FET (sec)	52.99 ± 19.92	51.27 ± 18.11	1.72	0.851	0.395
EET (sec)	75.75 ± 18.22	74.96 ± 17.57	0.79	0.414	0.679
LLA (o)	23.74 ± 2.72	26.13 ± 2.37	-2.39 (-2.93 to -1.86)	-8.824	0.000
WC (cm)	81.17 ± 7.50	76.44 ± 6.37	4.73 (3.28-6.19)	6.394	0.000

Table 2 Association between anthropometric variables and lumbar lordotic angle (LLA), trunk extensor muscle endurance test (EET), trunk flexor muscle endurance test (FET) using cross-tabulation

Variables	Df	Chi-square value	Significance
BMI_Quartiles*LLA_Quartiles	9	57.844	<0.001*
Age_Quartiles*LLA_Quartiles	9	15.764	0.072
FET_Quartiles*LLA_Quartiles	9	8.014	0.533
EET_Quartiles*LLA_Quartiles	9	22.689	0.007*
WC_Quartiles*LLA_Quartiles	9	23.904	0.004*
BMI_Quartiles*EET_Quartiles	9	11.441	0.247
Age_Quartiles*EET_Quartiles	9	5.380	0.800
FET_Quartiles*EET_Quartiles	9	137.188	<0.001*
WC_Quartiles*EET_Quartiles	9	16.172	0.063
BMI_Quartiles*FET_Quartiles	9	14.436	0.108
Age_Quartiles*FET_Quartiles	9	16.418	0.059*
WC_Quartiles*FET_Quartiles	9	20.607	0.015*

There was a positive correlation of BMI with the LLA. With the increase in BMI, LLA was also increasing. The extensor endurance showed a negative association with the LLA. When the LLA is decreased EET is also decreased. The result of the study showed significant positive correlation of LLA with the waist circumference. With the increase in WC, LLA is also increased. FET is also directly associated with EET. With the increase in flexor endurance , extensor endurance of the trunk muscle is also increased. The flexor endurance of the trunk muscle is also directly associated with the age. The flexor endurance is more in the participants of higher age. The result of the study also showed with the increase in waist circumference flexor endurance of the participants were decreasing. Decrease in extensor endurance is significantly associated with the history of back pain. The result of the study shows decrease in trunk endurance is most associated with low back pain as compared to flexor endurance (OR for FET is 2.42 and EET for 4.74). Point prevalence of low back pain in young adults aged 18-26 years is 4.5 % (95% 2.80-7.22) with females more prone to be affected. The use of high heels increases the lumbar lordosis and may contribute to low back pain. However, the result of the study shows no association between high heels use and lumbar lordotic angle, trunk flexors muscle endurance and trunk extensors muscle endurance.

Table 3 Association between trunk extensor endurance test (EET) and LBP in total population (n=354). The result shows there is a significant association of extensor endurance with history of back pain. The decrease in extensor endurance is directly associated with history of back pain.

EET	No Back Pain (n=338)	Back Pain (n=16)	Total
1st Quartile (n=72)	67 (93.1 %) 19.8	5 (6.9 %) 31.3	20.3
2nd Quartile (n=71)	64 (90.1 %) 18.9	7 (9.9 %) 43.8	20.1
3rd Quartile (n=81)	79 (97.5 %) 23.4	2 (2.5 %) 12.5	22.9
4th Quartile (130)	128 (98.5 %) 37.9	2 (1.5 %) 12.5	36.7

Discussion

The result of the study showed significant gender difference in the variables like age, body mass index, lumbar lordotic angle and waist circumference. The male participants were taller, older and have more BMI and waist circumference than their female counterparts. The lordotic angle was found to be greater in females as compared to the males (MD=7.7), this variation in the lordotic angle certainly reflects the gender differences in the shape of pelvis. There was a significant positive association of BMI with lumbar lordotic angle with the increase in BMI lumbar lordotic angle also increases. A study showed that people with normal BMI suffered from mild low back pain, whereas overweight and obese people complaint of severe low back pain, thereby showing positive correlation of BMI with low back pain significantly [20].The result of the study also showed that with the decrease in LLA, there is decrease in trunk extensor endurance. This relationship has been explained in various studies of low back pain. The patients of low back pain shows straightening of curvature of lumbar spine and thereby decrease in lumbar lordotic angle. A study has reported that acute LBP patients exhibits decrease in lumbar lordosis and lumbosacral angle, and increased thoracic kyphosis and backward displacement of COG and concludes that increased lumbar lordosis may result in pain in thoracic and lumbar region [21]. Another study has investigated the relationship between trunk muscle strength, lumbar lordosis and sacral angle in low back pain patients revealed that an imbalance in the trunk muscle strength may have a significant impact on the lumbar lordosis and could be a risk factor for possible low back pain[22]. Wallwork TL et al 2009 also reports decrease in the cross sectional area of the core muscles especially the multifidus and thereby compromising the extensor endurance of the back muscles in LBP patients [23]. The waist circumference shows significant positive co-relation with LLA, with the increase in waist circumference LLA also increases. Mainly the overweight females with a predominant abdominal fat mass having large waist circumference have been seen to have largely increased risk of low back pain. A study has shown that patients with BMI more than 24 kg/m2 or waist-hip ratio more than 0.85 can exaggerate the measurements of cobb's angle and sacrum slant angle. Increased lumbar lordosis and sacrum slant angle can be one of the causes for low back pain in a person with increased waist circumference [24]. Another study reported that females with a waist circumference greater than ninety centimeters have decreased muscular endurance as compared to the females with lower waist circumference [25]. The correlation of flexor endurance with extensor endurance shows direct correlation, with the increase in flexor endurance extensor endurance also increases. As the participants of the study are of age group between 18-26 years which is a high physical active group and the participants in the study complaining of low back pain were only 8.5% so, this

association is justified. Age is significantly associated with trunk flexor muscle endurance. This relationship can be further explored to know the exact mechanism for increase in the trunk flexor endurance. The point prevalence of LBP in the study was 4.5%, 95% CI (2.80, 7.22) with a female predominance and 84% of participants having weak extensor endurance and had history of back pain. The result of the study shows decrease in trunk extensor endurance is most associated with low back pain as compared to flexor endurance (odd ratio for flexor muscle endurance is 2.42 and for extensor endurance is 4.74).

Conclusion

The lumbar lordotic angle and the endurance of the trunk musculature as an essential element for maintaining good spinal health.

The Effectiveness of Autogenic Relaxation on Reducing the Level of Depression among Elderly People Residing in Old Age Homes

Mansi N. Patel[1], Deepak Krishnamurthy[2]

[1]2nd year M.Sc. Nursing student, [2]HOD of Mental Health Nursing, Manikaka Topawala Institute of Nursing, College address: Manikaka Topawala Institute of Nursing – A constituent of Charotar University of science & Technology, Changa, Taluka : Petlad, District : Anand, Gujarat 388421 India.

Abstract

Introduction:- Aging is a worldwide issue in our society, elderly people living in old age homes may suffer from sadness, pain, and isolation. Depression is a common condition in the elderly that negatively affects numerous parts of their lives. Autogenic therapy uses visual imagery and body awareness to promote a state of deep relaxation. A detached but alert state of mind called "passive concentration" must be achieved for autogenic therapy exercises to be carried out. DESIGN:- A quantitative approach using pre experimental one group pre test post test design. PARTICIPANTS:- 60 old age people were selected by using a purposive non-probability sampling technique. INTERVENTION:- Autogenic relaxation TOOL:- geriatric depression scale was used to assess the level of depression in old age people RESULT:- The Mean depression level before intervention is 14.23 while after intervention it is reduced to 11.83. It shows statistically significant change in the mean depression level before & after the autogenic relaxation session. CONCLUSION:- The findings of the study indicate that autogenic relaxation is effective in lowering the level of depression among old age people living in old age homes.

Key Words:- Autogenic relaxation, Level of depression, Old age people

Introduction & Background

Most commonly the depressive syndrome is observed among the elderly. Depression is a mental illness, which currently accounts for nearly 30% of people between the age of 45 and 75years in India.[1]

Approximately 15% of adults aged 60 and over suffer from a mental disorder. The most common neuropsychiatric disorders in this age group are dementia and depression.[2]

Depression is the frequent affective condition in elderly. In depression, the person is having symptoms like sad mood, despair, lower confidence, poor interest in routine activities and negativity. Depression in the old age people has an impact on the variables of physical problems, functional issues, and cognitive disturbances.[3]

The elderly people don't have other alternative but to live in old age homes, multiple times they feel loneliness, detachment, and depression. In addition to losing their privacy, most of their worldly possessions, they also lose their sense of self-worth and social support. They are dependent on others to meet their emotional and recreational needs. This inspires the researcher to perform a study to identify depression in the older adults living in old age care centers.[4]

Autogenic Relaxation provides an excellent strategy for managing depression, Autogenic relaxation is a psychophysiological type of psychotherapy based on autosuggestion, first developed by the German physician and psychiatrist J.H. Schultz in the early 20th century. It consists of the phased practice of six simple relaxation

responses. The first exercise that addresses muscular relaxation is performed by reiterating a formula to promote a sensation of heaviness in limbs, and subsequently, attention is focused inactively on sensing warmth, then on slow breathing, abdominal warmth, a calm heart beat, and a cool forehead. While progressing through these exercises, most people experience passive concentration, which allows the individual to break depression.[5]

Material and Method

Purpose of the Study

The purpose of the study is to evaluate the effect of autogenic relaxation on reducing the level of depression among old age people in old age homes.

Objectives of the Study

I. To assess the pre-test and post-test level of depression among elderly people.

II. To evaluate the effectiveness of autogenic relaxation reducing the level of depression among old age people.

III. To find the association between the level of depression with selected demographic variables.

Hypothesis

$1H_0$: There is no significant difference between the mean pre-test depression score and the mean post-test depression score. (at $p< 0.05$ level of significance)

$2H_0$: There is no significant association between pre-test depression level of elderly people and their selected demographic variables. (at $p<0.05$ % level of significance)

Delimitations

1) The study is limited to old age people who are between 60 to 72 years.

2) The study is limited to old age people residing at selected old age homes.

3) Limited uniformity in following the command of the therapist by all the participants.

4) This study is limited to a significant level of depression.

Operational Definition

1. Elderly people: The old age people aged 60 to 72 year who are residing in old age homes.

2. Level of depression: Depression is a loss of interest in pleasurable activities, feelings of worthlessness, helplessness, isolation, lack of interest in daily activities for at least two weeks in elderly people which is measured by the elderly depression scale. Grouping the depression scores obtained through observation rating scale on depression. It is divided in to normal, mild, and severe.

3. Effectiveness: It is the outcome of autogenic relaxation which will be appraised, validated by a decrease in depression level among elderly people. It is the difference between the pre-test and post-test level of depression and it is measured by the geriatric depression scale.

4. Autogenic relaxation: It is the kind of relaxation technique that involves six progressive steps Practicing for once in a day for 30 minutes during which elderly people focus on breathing, circulation and muscle relaxation. It is a non-pharmacological, non-invasive therapy used to decrease the level of depression among old age people.

5. Old age home: Old age home is a residence or institution where old people live and providing care to the elderly.

Research Approach

A quantitative approach was used to test the effectiveness of the intervention.

Study Design

The researcher used a pre-experimental research design for the present study.

Research Variables

Independent variable:-

In the present study independent variable was selected autogenic relaxation sessions.

Dependent variable:-

In present study dependent variable was level of depression among elderly.

Demographic variables:-

Demographic variables are characteristics or attributes of subjects that are collected to describe the sample. age, gender, religion, education, marital status, no of children, frequency of visit of children, Previous occupational status, Type of family, spouse alive or dead, any problem with a spouse were the demographic variables of the present study.

Setting of the Study

The research was done in selected 4 old age homes which include.

· Krishnahsray Ashram, Janhitarth charitable Trust, old Age Home, Mahelav

· Asahara Mahila Utkarsh Trust, old Age Home, Petlad

· Jalarambapa old age home, Pij

· Jivansandhya old Age Home, Ahmedabad

Population

Target population**:** Target population of the study was old age people residing at old

age home.

Accessible population**:** An accessible population is the aggregate of old age people that conform to designated inclusion or exclusion criteria and that are accessible as the subjects of study.

Sample

The participants were old age people with mild depression according to the Geriatric depression scale residing in a selected old age homes, those who fulfilled the inclusion criteria.

Sample Size

The sample size for the present study was 60 old age people who were residing in old age homes.

Sampling Technique

60 old age people were selected by using a purposive non-probability sampling technique.

TOOL

The tool used for the study was the Geriatric Depression Scale (30 points)**.** The investigator collected the data by used the geriatric depression scale. It was YES or NO question type. The items were assessed by the tool scores, which was given based on the nature of questions that is in a positive manner for positive type questions and in a reverse manner for the negative aspect questions. A total Score was provided which consists of one point from each depressive answer. Non-depressive answers were scored as zero and do not add to the total score. In scoring the Geriatric Depression Scale, each item is scored 0 or 1 depending upon whether the item is worded positively or negatively. The total score on the scale ranges from 0 to 30. For items 2-4, 6, 8, 10-14, 16-18, 20, 22-26, 28 the scoring is: Yes = 1 , No = 0 Items 1, 5, 7, 9, 15, 19, 21, 27, 29, 30 are reverse scored as follows: No = 1 , Yes = 0

SCORING INTERPRETATION	
0 - 9	No depression
10 - 19	Suggestive of mild depression
20 -30	Suggestive of severe depression

Criteria For Selection of Samples

Inclusion criteria

1. Elderly people who stayed in the selected old age homes in Gujarat.

2. Elderly people in the age group of 60 to 72 years.

3. Elderly people who can speak read and understand Gujarati.

4. Elderly people who are willing to participate in this study.

5. Elderly people who have mild depression according to the Geriatric depression scale.

Exclusion criteria

1. Elderly people who are not available at the time of data collection.

2. Elderly people with psychotic symptoms and other mental illness

3. Elderly people who are taking drugs for mental illness.

4. Elderly people with hearing problems and without

hearing aids.

SOURCE OF DATA

The data will be collected from the Geriatric people who were residing at selected old age homes.

The researcher chooses old age care centers with the use of simple random sampling technique (chit method) after getting approval from concerned authority and written consent from participants, GDS is utilized to check the depression. The participants comes in inclusion criteria are recruited. An autogenic relaxation session was provided for 7 days once in a day for 30 minutes preferably in morning 10 to 11 am. On 7th day geriatric depression, the scale is reapplied to assess depression level after autogenic relaxation sessions.

Findings

The investigator collected the data for analysis and interpretation, using post-test structured Performa. The majority of the old age people 25 [41.7%] were in the age group of above 68-72 years. While comparing the sex, the majority of the old age people 37 [61.7 %] were female and 23 [38.3%] were males.

Regarding religion, all the old age people 60 [100 %] were Hindus. Regarding the marital status majority of the old age people, 24[40%] were married, 9 [15%] were unmarried, 23[38.3%] widow/widower 4 [6.7 %] divorced.

While comparing family type 22[36.7%] belongs to the nuclear family, 25[41.7%] belongs to the joint family. While comparing the number of children 2[3.0%] had no children, 6[10%] had 1child, 19[31.7%] had 2 children, 17[28.3%] had 3 children, 7[11.7%] had more than 3 children.

Regarding the children visit time to old age home, 12[20%] not even visited once in a month, 22[36.7%] visited to old age home in monthly once, 10 [16.7 %] 2 times visited old age home in month , 5 [8.3%] visited old age home more than 2 times in month.

Regarding spouse 28[46.7%] had a spouse and 23[38.3%] had no spouse. While discussing any problem with spouse 6[10%] had a problem with their spouse and 22[36.7%] had no problem with the spouse.

Table 1: Frequency and percentage distribution of old age people according to the level of depression

N=60

Level of Depression	Pre Test		Post Test	
	Frequency	Percentage (%)	Frequency	Percentage (%)
No Depression	00	00	07	11.67%
Mild	60	100%	53	88.33%
Severe	00	00	00	00

The above table states that in the pre-test all the old age people 60 [100%] had a mild level of depression, in post-test 7 [11.67 %] had no depression and 53[88.33%] had a mild level of depression.

Table 2: Effectiveness of autogenic relaxation on depression among old age people N = 60

	N	Mean	Standard Deviation	SE Mean
Depression Level- Pre	60	14.23	2.174	0.281
Depression Level- Post	60	11.83	2.195	0.283
Difference	00	02.40	-0.021	-0.002

The Mean depression level before intervention is 14.23 while after intervention it is reduced to 11.83. It shows statistically significant change in the mean depression level before & after the autogenic relaxation session.

Table no. 3 Level of depression before and after an intervention N=60

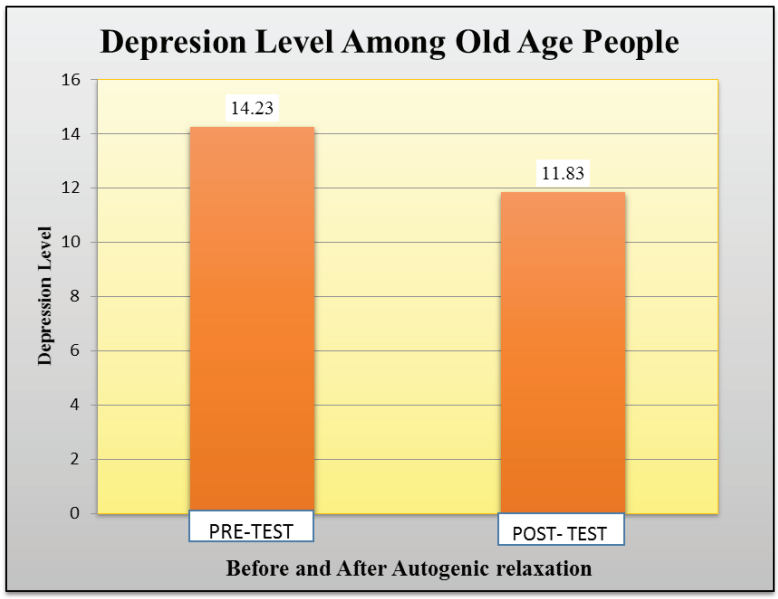
		Mean	Std. Deviation	Std. Error Mean
Pair 1	Pretest	14.23	2.17	0.28
	Posttest	11.83	2.19	0.28

Data presented in table no 4 depicts mean pre-test depression score is 14.23 & SD is 2.17 and the mean post-test depression score is 11.83 & SD is 2.19. It indicates that there is statistical significant difference found on depression level before and after intervention.

Table no. 4 Effectiveness of Autogenic Relaxation on Depression level

	Paired Differences					t	df	Sig. (2-tailed)
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
				Lower	Upper			
Pair- 1 Pretest Posttest	2.40	0.88	0.11	2.17	2.62	20.96	59	.0001

Data presented in table no 5 indicate that the mean difference between pre-test and post-test is 2.40 & SD is 0.88 and the calculated T- value is 20.96 which is more than t table value hence we reject null hypothesis so it concludes that autogenic relaxation is effective intervention on reducing the level of depression.



The above graph shows that in the experimental group the Mean depression level in the pre-test is 14.23 while in post-test it reduced to 11.83. It indicates Autogenic relaxation therapy has a significant effect on depression levels among old age people.

The p-value association shows there was an association between the pre-test level of depression and age and there was no association found between the level of depression and other socio-demographic variables.

Discussion

Autogenic relaxation promotes deep relaxation. They used words like: "relaxed, rested, calmness, warmness, heaviness". Moreover, the physical sensations felt by some participants throughout the Autogenic relaxation sessions such as: tingling at fingertips, deep sleep, slow respiration, warm sensation.

However, considering the actual fact that Autogenic relaxation supports the present self-healing and sel-regulating physiological functions of varied body systems. Some of the participants even fell asleep often throughout the follow of Autogenic relaxation.

At the end of every Autogenic relaxation session, participants got an opportunity to speak regarding their experiences. They were assured that these sensations are normal and uncontrollable responses and that they can decrease in intensity and frequency with follow. For example, within the starting, many participants found it troublesome to prevent their mind from wandering off. They were reminded that passive concentration is new their brain which intrusive thought is sort of normal. At the end of the session, participants sometimes 'forget' to say their bodily complaints.

In this study, Autogenic relaxation did have a positive impact on Total psychological well-being among the experimental group over time. For the aim of this study, no comparisons were created across the genders due to the unequal distribution of woman to men. Additionally, age variations were conjointly not considered due to the small sample size.

Conclusion

From the results of this study, it is conclude that Autogenic relaxation considerably reduced the level of depression and Total psychological well-being among the experimental group. The present study aims to evaluate the effectiveness of autogenic relaxation on depression among old age people residing in old age homes. The study was conducted by using pre experimental one group pre test post test research design. Kheda district was selected for conducting the study. The sample size was 60 old age people by using purposive sampling technique.

Conflict of Interest :- No any conflict of interest in this study

Drug Utilization of Antibiotics in Medicine ward of Tertiary Care Teaching Hospital

Mayank, Saini[1], Sourav[1], Abhimanyu Prashar[1], Manish Kumar[1], A. Pandurangan[1], Vipin Saini[3], Amit Mitttal[4]

[1]Student, [2]Professor, M. M. College of Pharmacy, Maharishi Markandeshwar (Deemed to be University) Mullana-Ambala, [3]Vice-Chancellor, M. M. University, Solan, Himachal Pradesh, [4]Professor, M. M. Institute of Medical Sciences and Research, Maharishi Markandeshwar (Deemed to be University) Mullana-Ambala

Abstract

Background: Drug utilization study are used to foster more efficient use of scarce resources to improving the standards of medical treatment at all levels in health system. It also helps in the identification of problems created with drug use. The aim of study was to evaluate the pattern of drug utilization of antibiotics in patients.

Methods: This was a prospective observational study which was done in six months from August 2018 – February 2019. 100 patients were enrolled in the study. Which were taking antibiotics from in-patient department of medicine ward of tertiary care teaching hospital. **Results:** It was observed that out of 100 patients, 52 were female and 48 were males. Majority of the patient lies in the age group of 20-40 years. It was observed that total 623 drugs were prescribed out of which 146 were antibiotics (23.43%). The use of these antibiotics was in intravenous (87) and oral (59). There were 78 conditions in which antibiotic were prescribed empirically and in 22 conditions prophylactically. The maximum antibiotic prescribed was observed in Urinary Tract Infection (20.51%). Major cost was rendered by Cephalosporin class (36.98%) and the least was of tetracyclines (2.05%). The ratio of cost of total drugs to the antibiotics was found to be 49.37%.

Conclusion: Thus the study conclude that the Drug Utilization Study can help to understand the usage pattern and extra cost rendered by the patient due to intravenous antibiotic and thus providing a helping hand in the designing of antibiotic policies.

Keywords: *Antibiotic, Drug utilization study, Antibiotic usage pattern.*

Introduction

In contrast to the public health, resistance of antibiotic becomes a major threat as the consumption of antibiotic increases [(1)]. Antibiotics-resistant pathogens have become evident and spread among human and animal populations worldwide [(2, 3, 4)]. Pathogens such as methicillin-resistance staphylococcus aureus (MRSA) [(5)] and carbapenem-resistant *Enterobacteriaceae* (CRE) [(6, 7)] have become a worldwide problem. The loss of efficacy against common pathogens has not only led to a shift towards extortionate antibiotic drugs in high-income countries, but also to increased morbidity and mortality in low-income and middle-income countries, where it restricts their use due to affordability of second line drugs [(8)]. An inappropriate prescription increases the cost of the medical treatment and it also increases the morbidity and mortality. The impact of the irrational prescription of drugs also leads to an increase in the incidence of adverse drug events. To control the worldwide ascendancy of bacterial resistance, to minimize the side effects and to reduce the cost of

the treatment, the rational use of antibiotics is being increasingly recognized as an important contributor [9].

In recent years, issues of quality assurance and cost control have often focused on the use of antibiotics [10, 11]. This has led to the broadcasting of antibiotic utilization review which is an authorized, structured, ongoing review of prescribing, dispensing and use of medication. Antibiotic utilization review results are used to foster more efficient use of scarce health care resources. It provides opportunity to identify trends in prescribing within groups of patients whether by disease-state or drug-specific criteria [12, 13, 14, 15].

So this study was undertaken in an active inpatient environment of tertiary care teaching hospital to evaluate the usage pattern of intravenous and oral antibiotics, to assess the additional cost rendered by the patients due to over utilization of antibiotic and drug related problems evaluation associated with the antibiotic.

Study Design

A prospective observational study on antibiotic utilization pattern was conducted by the department of pharmacy practice in collaboration with M.M. Hospital, mullana-ambala (India) with a sample size of 100 patients. The study was conducted for a period of six months from August 2018 to February 2019. A total of 100 patients were analyzed on the basis of inclusion and exclusion criteria. All the prescription had complete documentation of information including, patient demographic characteristics, date of admission and discharge, clinical diagnosis, drug name, dose and route of administration, investigations, rationality and outcome of health status. The data of the patients who received antibiotic was recorded and analyzed further for drug utilization studies. The study protocol and all the other documents which were related to the study were approved by the Institutional Ethics Committee.

Inclusion Criteria

All the patient of either gender with any kind of diseased condition admitted in medicine ward of M.M. hospital during the study period were included in the study.

Exclusion Criteria

We excluded the inpatients who discharged on the day of admission, outpatient and patients admitted to ICU. All the pediatrics, geriatrics, pregnant/lactating mothers were also excluded in the study.

Method of Data Collection

During our study, we reviewed the case record sheets of all patients who met the inclusion criteria. Data was collected using a well-structured case record form (CRF) which includes patient's demographics, drug allergies, patient's disease history, medication chart, culture reports and laboratory parameters. The culture and sensitivity reports were analyzed to assess the appropriateness of the antibiotic selection. Any medication error and drug related problems that were found in our cases were also recorded. All the discrepancies observed have been documented appropriately in the CRF designed for our study.

Results

A total of 100 patients were enrolled in the study from August 2018 to February 2019. The subjects were segregated into 5 major groups as discussed in table 2. The mean age of the subjects was found to be 38.97 ± 19.70 years. It implies that the maximum patients were in the age group of 20 – 40 years with standard deviation of 19.70 years. Moreover, it was observed that male-female ratio almost equal, contributing to 1:1.1(48; 52). The mean age of male population was observed as 39.09 ± 19.67 years whereas; in female population it was found to be 38.98 ± 19.70 years. This implies that the majority of male and female patients were from the age group of 20 – 40 years.

It was observed that, majority of the subjects are from the age group of 20-40 years with 17 males and 21 females patients, followed by the patients under 41-60 years (29 Females; 11 male) shown in figure 1.

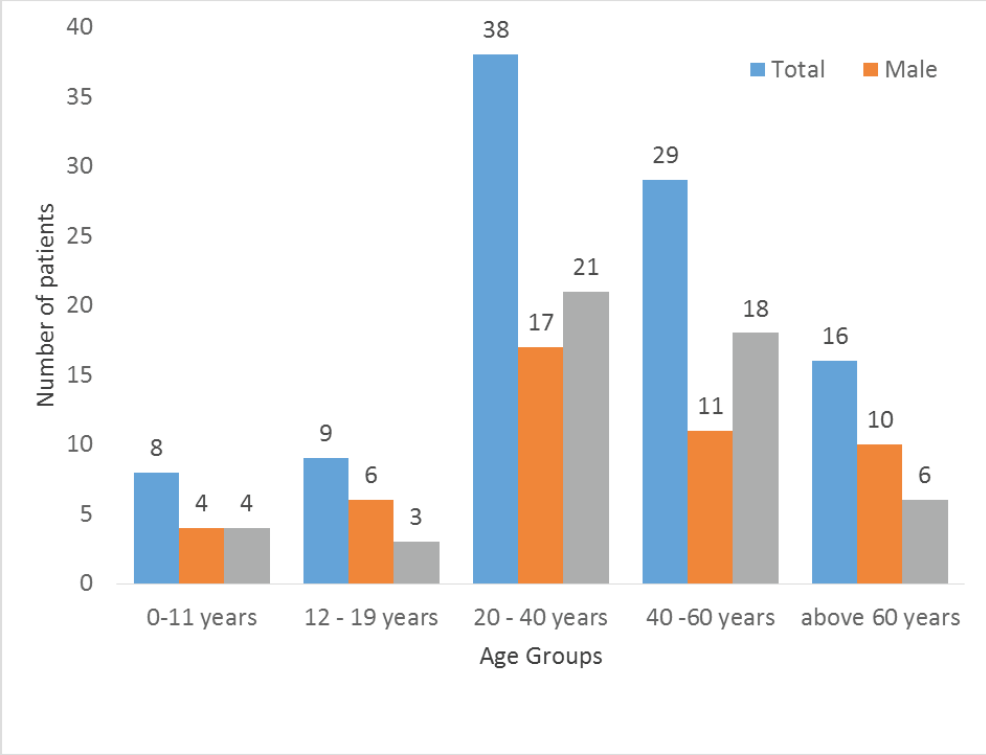

Figure 1: Gender wise age-distribution

Antibiotics were the most used drug along with anti-tubercular drugs and anti-malarial drugs (n=146; 23.43%), followed by antacids (n=100; 16%), utilization of multivitamin and supplements was less (n=78; 12.52%), followed by NSAIDS (Non-steroidal Anti-inflammatory drugs) (n=70; 11.23%). (Table 2).

Table 1 Antibiotic usage pattern

Medication class	Total number(n)	Percentage
Antacid	107	17.17%
Anti-allergic	13	2.09%
Anti-anemic	7	1.12%
Antibiotic	146	23.43%
Anti-emetics	47	7.54%
Anti-epileptic	20	3.21%
Anti-hypertensive	27	4.33%
Anti-thyroid	5	0.8%
Anti-viral	1	0.16%
Hypoglycemic	8	1.28%
Hypolipidemic	3	0.48%
Laxatives	21	3.37%
Multivitamins & supplements	78	12.52%
NSAIDS	70	11.23%
Others	45	7.22%
Probiotics	8	1.28%
Steroids	15	2.4%
Vaccine	2	0.32%

The comorbid conditions of the subjects (n=100) were classified into three types. Patients with one morbidity was the highest (n=49), followed by the patients with two comorbid conditions (n=31) and the patients with more than two comorbidities was the least (n=20) (Table 1).

Systemic conditions	Total drugs (n1)	Antibiotic (n2)	Percentage (n2/n1)
Infectious	263	62	23.57
Gastro intestinal	147	37	25.17
Renal	56	11	19.6
CNS	47	10	21.27
Reproductive	41	11	26.82
Respiratory	37	10	27.25
CVS	14	2	14.28
Hematologic	10	1	10
Musco-skeletal	5	2	40

Table 2: Pattern of antibiotic usage in various systemic conditions

There were total 78 conditions in which antibiotics were prescribed empirically and 22 conditions in which antibiotics were prescribed prophylactically. The antibiotic count was maximum in Urinary tract infection (UTI) (n=16, 20.51%) following hepatitis (n=14; 17.94%), fever (n=12; 15.38%), dengue (n=7; 8.97%), pneumonia (n=6; 7.69%), cystitis (n=5; 6.41%), psoriasis (n=4; 5.12%), sinusitis (n=3; 3.84%), malaria (n=3.84%) and scabies (n=2; 2.56%). (Table 2).

Table 3 Various infection conditions

Infection condition	Total number (n)	Percentage
UTI	16	20.51
Hepatitis	14	17.94
Fever	12	15.38
Dengue	7	8.97
TB	6	7.69
Pneumonia	6	7.69
Cystitis	5	6.41
Psoriasis	4	5.12
Sinusitis	3	3.84
Malaria	3	3.84
Scabies	2	2.56

It was observed that, a total of 11 different antibiotic classes were used during the study. A major proportion of the antibiotics involved the usage of cephalosporin (n=54; 36.98%) (Table 3).

Table 4 Various classes of antibiotic used

Antibiotic	Total number (n)	Percentage	Cost (INR)
Cephalosporin	54	36.98	8894
Fluroquinolones	22	15.01	4403
Penicillin	16	10.95	3329
Beta-lactams	10	6.84	3304
Aminoglycosides	9	6.16	2250
Macrolides	9	6.16	1376
Nitroimidazoles	8	5.47	1260
Nitrofurantoin	7	4.79	451
Tetracycline	3	2.05	438
rifaximin	3	2.05	2347

The cumulative cost of 623 drugs was found to be INR 64,573. The average cost of total drugs was found to be INR 443 with a quartile range of 322.5-601 INR. The cumulative cost of 146 antibiotics was observed as INR 25,705. The average cost of antibiotic was found to be INR 224 with the quartile range of 144-288 INR .The ratio of cost of total drugs to the antibiotics was found to be 49.37% of total cost of the medication of a single patient was spent on antibiotic itself. Thus it was clearly evident that, a major portion of the medication cost comprises of antibiotics (Table 4).

Discussion

As India, the most populous country in the world, with over 1.21 billion people (2011 census), India houses more than a sixth of world's population. Already containing 17.5 % of the world's population, India is projected to be the world's most populous country by 2025, surpassing China, with its population reaching 1.6 billion by 2050. India has more than 50% of its population below the age of 25 and more than 65% below age of 35. The life expectancy level has been improving over these decades for both male and female population[16]. The improvement among female is better than male population [17, 18]. Sex ratio has improved from 930 in 1961 to 940 in 2011 which is an appreciable improvement but still below the international levels. The country has a long way to go before attaining the levels achieved by developed countries and many developing countries [19, 20].

A majority of the study subjects were housewives (n= 44), followed by students (n= 27), workers (n=11), businessmen (n=8) and farmers (n=8).

The WHO prescribing indicators provided earlier, gives a comprehensive idea regarding the pattern of antibiotic use in this institution. The overall antibiotic encounter rate as per our study was 23.43%, which is not much different from the WHO standard of 20-26.8%. This is certainly a welcome attitude, and could reflect the concern of the practicing doctors for the rapidly spreading bacterial resistance. This is significantly less

than the values reported from many other parts of India – (47.6%, 73>1% and 81.8% from T.puram, Chennai, Vellore and Lucknow) respectively [21, 22, 24]. In another study from South India, the percentage of injections was as low as 1.6%. It is a well-accepted fact that parenteral therapy is significantly costlier, because of the higher price for the formulations, the cost of the syringes as well as nursing charges. The significant use of injectable in this institution requires pointed focus for the reduction of use of injectable to deserve appreciation [24].

The selection of individual agents in most instances raises a big question mark on their scientific basis. In our study, there were 78 conditions in which antibiotic were prescribed empirically and 22 conditions in which antibiotic were prescribed prophylactically. Lab reports from microbiology had not been given due to definitive line of management in majority of infections. This also appears to be the situation in many developing countries [25, 26].

The use of tetracyclines, however, was high in the rural hospital setup in the Vellore study.[27,28] Among the newer agents, meropenem, linezolid and tigecycline found only very little usefulness probably due to their high cost and because of exclusion of ICU patients from this study.

Management of infections like Urinary Tract Infection, Upper Respiratory Tract Infection as well as Skin Infection with a single antimicrobial could be appreciated, though this was probably feasible as the involved pathogen could be correctly guessed/ identified[29,30]. In management of Urinary Tract Infection, especially as an empirical therapy, use of flouroquinolones (15.01%) goes certainly against the currently accepted policy. Nitrofurantoin is now considered as the first line agent for treatment and prophylaxis of lower Urinary Tract Infection, based on its proved effectiveness and established safety accrued from its long term use[31, 32, 33]

Conclusion

The study highlighted the usage pattern of antibiotics. The average antibiotics prescribed was found to be low but there was an overuse of intravenous dosage form that had increased the cost of treatment. Also more antibiotic was prescribed based on the empirical therapy followed by the prophylactic therapy. Thus the study conclude that the Drug Utilization Study can help to understand the usage pattern and extra cost rendered by the patient due to antibiotic and thus providing a helping hand in the designing of antibiotic policies.

Effect of Postnatal Exercises and Education on Lowback Pain in Early Postnatal Mothers

Meena Sekar[1], B. Sathyaprabha[2], N.Venkatesh[3], R.Siva Kumar[4]

[1]Post graduate, [2]Associate Professor, [3]Chairman and Professor, [4]Principal and Professor, Faculty of Physiotherapy, Sri Ramachandra Institute of Higher Education and Research (Deemed to be University), Porur, Chennai

Abstract

Background: Back pain is one of the most common problems during postpartum period. The physical and mental changes and demands in postpartum period challenge the quality of life of postnatal mothers. Approximately 70% of women report back pain at some point in their postnatal period. This study aimed to analyze the effect of postnatal exercises and education on functional outcomes of low back pain in early postnatal mothers. **Methodology**: Experimental group was treated with core stabilization exercises along with education on postural care and back care while control group were on conventional postnatal exercises and education. Follow up sessions were conducted once in two weeks for experimental group and both the groups were followed up by phone calls. **Results**: There is a significant reduction in disability from baseline ($p<0.05$*) in the study group and both the group had shown significant reduction in VAS from baseline ($p<0.05$*). **Conclusion**: Core stability exercises along with postural care and education will increase the strength of lumbo-pelvic muscles, improve posture, physical activity level, decrease the pain intensity, and improve the functional disability in postpartum period.

***Keywords**: postnatal, low back pain, stabilization exercises, core muscle exercises and postnatal back care.*

Introduction

The postnatal period is the duration after the birth of a child and extending for about six weeks. Majority of (72%) women regaining their physical energy level within 6 weeks after normal vaginal delivery [1]. During postnatal period hormone levels and uterus size returns to a non–pregnant state, fluctuating hormone levels results supporting ligaments in the body to soften and become lax or stretch. This could lead to various musculoskeletal problems such as excessive joint mobility, weakness of core stabilizers in postpartum period. The common musculoskeletal postpartum complications are low back pain, upper back pain, pubic pain, coccyx pain, pelvic girdle pain, general fatigue and tiredness[2].

Approximately 70% of women have reported low back pain (LBP) at some point in their lives and majority of them were affected in their first pregnancy. LBP during pregnancy is considered to be the most important risk factor for postpartum LBP which could have impact on daily routine and quality of life[3]. Greater BMI, younger age, a history of low back pain during pregnancy, before pregnancy, multiparty and joint hyper mobility have been found to be predisposing factors of low back pain in women after childbirth [4].

The classical hypothesis of low back pain postulates that weight gain experienced during pregnancy results in postural changes that produce pain and weak abdominal muscles may also have a role in pathology of low back pain during postpartum period. Due to the anterior displacement of the center of gravity of the trunk and abdomen, women may unconsciously shift their head and upper body posteriorly over their pelvis, inducing hyperlordosis of the lumbar spine. This shift generates stress on intervertebral disks facet joints, ligaments, and inflammation of the joint capsule creates pain and increase sensitivity to movement [5].

The control and activation of the deep spinal muscles are impaired during postpartum period. Lumbar stabilizing muscles are local and global muscles .The multifidus, transverse abdominis, internal oblique, medial fibers of external oblique, quadratus lumborum, diaphragm, and pelvic floor muscles constitute the local

stabilizer muscles. The global stabilizing muscles are rectus abdominus, lateral fibers of external oblique, psoas major and erector spinae [6].

The duration of the postpartum recovery is affected by many physiological and social factors such as lack of sleep, new born care, family support, upper back pain and low back pain [7]. Mild to moderate intensity postpartum exercises helps to improve their quality of life. Postpartum exercises results in improved cardiovascular fitness, facilitated weight loss, increased positive mood , lactation, decreased anxiety and depression [8].

There are several guidelines such as ACOG (American College of Obstetrics and Gynecology and NICE (National Institute for Health and Care Excellence) which mentioned about postpartum exercises for low back pain and pelvic pain [9]. The Canadian guidelines suggested that if pregnancy and delivery are uncomplicated, a mild exercise programme consisting of walking, pelvic floor exercises and stretching of all muscle groups can be started immediately [5]. Earlier studies stated that the pelvic stabilization exercises are important to reduce the incidence of low back pain. This study aimed to analyze the effectiveness of early postnatal exercises and education on low back pain and functional outcomes in postnatal mothers.

Methodology

This Study was approved by the Ethics committee for Students proposals (CSP/17/OCT/61/280). This Quasi experimental study was conducted during December 2017-April 2018.The estimated sample size was calculated using comparison of two means (Power -80 %) (CI – 95%), sample size was rounded to 50 subjects in each group. The subjects were recruited by purposive sampling from the family welfare outpatient clinic and pediatrics outpatient department from G-block of Sri Ramachandra Medical Center and Hospital. Women between the age group of 20-35, assisted vaginal delivery or spontaneous vaginal delivery, postpartum mothers up to 4 weeks after delivery were included. Caesarian delivery, Diastasis recti, previous musculoskeletal problems, pubic pain, severe anemia, respiratory and cardiac conditions , poorly controlled diabetes and hypertension were the exclusion criteria.

Mothers who met the inclusion criteria will be allotted to interventional (27) and control group (25) by purposive sampling. Written informed consent obtained in accordance with the guidelines of the ethics committee.

Base line assessment was done using performa which include demographic data, maternal history, labour history, gynaecological history, occupation, Numerical Rating Scale, BMI, mode of delivery, body chart, Schober's test, and special test. Experimental group participated 20 minutes supervised post natal programme, once in two weeks from 4th week to 10th week. The postnatal exercises sessions include the following- greeting and warm-up, diaphragmatic breathing exercises, general stretches, postural care, basic core stability exercises. Borg scale-(13-14)) and Audio visual aids were used for conducting postnatal supervised sessions.

Control group received conventional postnatal exercises at 4th week and they continued home exercises programme up to 10 weeks. Both the groups will be receiving the exercise information sheet and the follow up ensured with exercise follow up diary and by phone calls. The primary outcomes were pain and functional status. At 4th week and 10th week, both the group mothers will be evaluated by using visual analog scale for pain severity and the Oswestry disability index questionnaire will be used to measure the severity of functional disability[10].

Significant at *p<0.05, Mann Whitney 'U'test

Results

Statistical analysis was performed by using SPSS software version 20.0.Wilcoxon signed rank test is used to determine the difference in ODI and VAS within the groups. Mann Whitney "U" test is used to determine the difference in ODI and VAS in between the groups. Significance level of ($p \leq 0.05$) was used throughout all statistical tests. Similarly interventional group had shown better improvement in ODI score (Fig-1). Both the groups had a significant difference in VAS but interventional group had shown better improvement than the control group (Fig-2). There was a significant reduction in the low back pain in the subjects of the experimental group after the intervention (Table-2). The between group analysis showed improvement in ODI at 10^{th} week ($P \leq 0.05$*).The functional disability level is more improved in experimental group than the control group.

Discussion

Postpartum lumbo-pelvic pain is the discomfort experienced by the women, as it has an impact on their activities of daily living which may influence on their family, social, economic characteristics and physical health. More than 50% of women complain postpartum low back pain which may persist up to one year.

In similar to this study, (Britt stuge *et al,* 2004) stated that the ODI scores revealed minimal disability in 85 % of the SSEG (spinal stabilization) as compared to 47% in the CG ($p<0.001$*) [11]. There was a significant reduction in VAS from baseline ($p<0.05$*) in both the groups but the results showed that significant improvement seen in experimental group than the control group.

Turgut F *et al*, (1998) observed that multigravida women who experience recurrent low back pain relate their first episode of pain to pregnancy [3]. Thus, pregnancy seems to represent a risk for long term lumbopelvic pain which could be managed efficiently through the core stabilizing exercise[12]. Hence, specific stabilization exercises focusing on multifidus and transverse abdominis muscles will provide support for the lumbar spine thereby preventing muscle imbalance in chronic low back pain patients[13].

Stuge *et al*(2004) & (Bennett, 2014) concluded that specific stabilization exercises programme showed a significant reduction in pain intensity, lowering disability, and increased the quality of life in women with post partum pelvic pain. In this study, the mothers received stabilization exercises showed a statistically significant reduction in pain severity. This result is in concordance with the study conducted by Hides et al. 1996, compared lumbar stabilization exercises and medical treatment in acute low back pain patients and reported a significant decrease in pain severity in both the lumbar stabilization exercise program group and control group. These study findings suggested that the experimental group which received a core stabilization exercises programme mainly focused on activation of local muscles and global muscles along with basic post natal care and education with three follow ups showed a significant improvement than the control group. Pain related fear and avoidance appears to be an essential feature in development of the low back pain. Patients who were in the early stage of treatment experienced that stabilizing exercises did not provoke their pain and the functional disability level is more improved in experimental group than the control group [14].

National Health Service -UK (2011) reported that exercise programmes are most effective if performed regularly over prolonged periods and the national institute for health and clinical excellence (NICE 2009) guidelines on chronic low back pain recommended the exercise sessions for several weeks 3-5 times per week with 20-30 minutes of duration[15,16]. Early postnatal exercise sessions from 4^{th} week to 10^{th} week could bring about better outcomes on postnatal low back pain and disability.

Limitations

- Small sample size.
- Limited follow-up period.

Conclusion

The post natal exercises and education improve the pain and functional disability in early postpartum mothers.

Time management skills among medical students

Meenal Kulkarni

[1]*Associate Professor, Community Medicine, NKP Salve Institute of Medical Sciences and Research Centre, Digdoh Hills, Hingna, Nagpur, Maharashtra*

Abstract

Background: Time management is the art of arranging, organizing, scheduling and budgeting one's time for generating more effectiveness work and productivity. Effective time management techniques help us to judiciously organise and plan time which we spend on various activities with the aim to increase productivity and quality of life. Students' time is a limited resource. Time management plays a vital role in improving student's academic performance. So the present study was conducted to assess the time management skills among medical students and to find out correlation between time management and academic performance. **Material and Methods:** After taking informed consent, cross sectional study was conducted from July 2018 to September 2018 among second year medical students. All medical students from second year willing to participate were included in the study (n= 115 students). The data was collected by using self administered close ended questionnaire. The questionnaire consisted of Time Management Questionnaire (TMQ) developed by Britton and Tesser (5 point Likert scale) with 18 questions. The data was analysed by percentage, mean and Pearson's correlation test. **Results and conclusions:** Mean score of time management was found to be 56.29±8.65 with maximum score of 81 and minimum score 36. A weak positive correlation (γ=0.21) was found between time management score and academic performance. Sessions regarding time management skills should be conducted for students.

Keywords- *time management skills , academic performance, medical students*

Introduction

The concept of time has been widely discussed throughout history, and it has been expressed in different ways that time is of vital importance for all beings in the universe. Although, time is the same for everybody, actually, time cannot be borrowed or lent; time cannot be saved or changed and it can only be used[(1).] Time management has been referred to as set of principles, practices and skills which enable a person to get things done by working smarter but not harder[(2)]. A lot of university students complain about shortage of time when asked them to do a certain task, they get frustrated because they are not able to make it before the deadline. On the other hand, others find enough time to meet their friends and complete their assignments with no struggle [(3)].

Time management is the art of arranging, organizing, scheduling and budgeting one's time for generating more effectiveness work and productivity [(3)]. Effective time management techniques help us to judiciously organise and plan time which we spend on various activities with the aim to increase productivity and quality of life [(2)]. Students' time is a limited resource. Like other limited resources, time can be more or less effectively managed [(4)].

Academic performance is the outcome of education, that is, the extent to which a student, teacher or institution has achieved their educational goals. Medical students have vast curriculum. It may be difficult for some of them to manage their study . Time management plays a vital role in improving student's academic performance [(5)]. Academic performance seems to increase when time

management skills are well-handled. Time management is a skill that perhaps impacts the student's academic performance. Prioritization of tasks may make studying and work less overwhelming and more enjoyable[6].

So the present study was conducted to assess the time management skills among medical students and to find out correlation between time management scores and academic performance.

Aims and Objectives

1) To assess the time management skills among medical students

2) To find out correlation between time management scores and academic performance

Material and methods

- Study design-cross sectional study
- Study population-second year medical college students.
- Study area-Medical college attached to a tertiary care hospital.
- Study duration -August 2018 to November 2018(four months)
- Sample size-All medical students from second year willing to participate were included in the study (n=115).
- Sampling method-convenient sampling
- Statistical analysis- Pearson's correlation test by using EPI info statistical software

After taking informed consent the cross sectional study was conducted among second year medical students. All medical students willing to participate were included in the study (n=115). After finishing of classes, the students were contacted. The data was collected by using self administered close ended questionnaire. The questionnaire included demographic information of students, Time Management Questionnaire (TMQ) and percentage of marks obtained in the last examination.

The time management questionnaire (TMQ) developed by Britton and Tesser (4)was used. It includes 18 questions .All the questions were value based on the Likert scale of five value scores: Always (5), frequently (4), sometimes (3), infrequently (2), Never (1). Except for question number 8, 10, 12 and 15, here the responses were reverse. The range of possible scores was 18-90. Higher values on the scale correspond to better time management practices. The data was analysed in percentages. Pearson's correlation test was used to find out co-relation between time management scores and academic performance.

Findings

Total 115 students were included in the study. Mean Age of student was found to be 20.37±1.16 years. Proportion of Female and a male student was found to be 60.87%and 39.13% respectively.

Time management score of students

Overall Mean score of time management was found to be 56.29±8.65 with maximum score of 81 and minimum score 36. Very few students (4.35%) make a list of things to do each day.11%students make schedule of the activities to do on work days and plan the day before start. More than 50% students never or rarely spend time for each day planning. Approximately half of the students believe that there is room for improvement in time management. More than half of the students complete the assignment on time. One fourth of the students keep the desk clear of everything other than what they currently working on. (Table no. 1).

Mean scores were better for the response number 7,9,11,12 and 16 i.e. I set and honour priorities, I believe that there is room for improvement in the way I manage my time , I feel I am in charge of my own time by and large, On an average class day I spend more time in personal grooming than doing college work, I keep my desk clear of everything other than what I am currently working on. Mean scores were poor for the response number 4,6,10,14 i.e. I write a set of goals for myself for each day, I spend time each day planning, I find myself doing things which interfere with my college work simply because I hate to say-No to people, The night before the major assignment is due, I still working on it.

Correlation between time management and academic performance

A weak positive correlation (γ=0.21) was found between time management score and academic performance. This may be due to small sample size.

Table no. 1: Responses on items of time management skills by students (n=115)

Factors/items	Responses No.(%)				
	Always 5	**Often 4**	**Some Times 3**	**Rarely 2**	**Never 1**
1.I make a list of things that I have to do each day	5(4.35)	18(15.65)	46(40)	29(25.22)	17(14.78)
2.I make a schedule of the activities that I have to do on work days	13(11.30)	20(17.39)	49(42.61)	19(16.52)	14(12.17)
3.I plan the day before I start it	12(10.43)	32(27.83)	38(33.04)	23(20)	10(8.70)
4.I write a set of goals for myself for each day	9(7.82)	22(19.13)	27(23.89)	42(37.17)	15(13.27)
5.I have a clear idea of what I want to accomplish during the next week	7(6.09)	23(20)	41(35.65)	32(27.83)	12(10.43)
6.I spend time each day planning	7(6.09)	17(14.78)	33(28.69(	40(34.78)	18(15.66)
7.I set and honor priorities	30(26.09)	40(34.78)	27(23.48)	13(11.30)	5(4.35)
8.I continue unprofitable routines and activities	13(11.30)	26(22.61)	39(33.91)	28(24.35)	9(7.83)
9.I believe that there is room for improvement in the way I manage my time	54(46.96)	34(29.57)	22(19.12)	00	5(4.35)
10.I find myself doing things which interfere with my college work simply because I hate to say-No to people	11(9.57)	27(23.48)	29(25.22)	32(27.83)	16(13.91)
11.I feel I am in charge of my own time , by and large	41(35.65)	37(32.18)	23(20)	9(7.82)	5(4.35)
12.On an average class day I spend more time in personal grooming than doing college work	18(15.65)	47(40.87)	27(23.48)	14(12.17)	9(7.83)
13.I make constructive use of time	7(6.09)	41(35.65)	50(43.48)	12(10.44)	5(4.34)
14.The night before the major assignment is due, I still working on it.	9(7.83)	12(10.44)	33(28.69)	38(33.04)	23(20)
15.I have a set of goals for entire quarter	8(6.96)	33(28.70)	42(36.52)	20(17.39)	12(10.44)
16.I keep my desk clear of everything other than what I am currently working on	29(25.22)	32(27.83)	22(19.13)	19(16.52)	13(11.30)
17.When I have several things to do, I think it is best to do a little bit of work on each one.	24(20.87)	35(30.43)	37(32.17)	14(12.17)	5(4.35)
18.I review my class notes ,even when a test is not imminent	10(8.7)	26(22.61)	39(33.91)	28(24.35)	12(10.43)

Table no.2 : Mean score of time management skills among medical students.

Items	Mean ±SD	mode
1.I make a list of things that I have to do each day	2.69 ± 1.044	3
2.I make a schedule of the activities that I have to do on work days	2.99 ± 1.13	3
3.I plan the day before I start it	3.11 ± 1.11	3
4.I write a set of goals for myself for each day	2.69±1.13	2
5.I have a clear idea of what I want to accomplish during the next week	2.81±1.04	3

7.I set and honor priorities	3.71±1.08	4
8.I continue unprofitable routines and activities	3.05±1.11	3
9.I believe that there is room for improvement in the way I manage my time	4.14±1.09	5
10.I find myself doing things which interfere with my college work simply because I hate to say-No to people	2.86±1.44	2
11.I feel I am in charge of my own time , by and large	3.91±1.08	5
12.On an average class day I spend more time in personal grooming than doing college work	3.46±1.11	4
13.I make constructive use of time	3.31±0.8	3
14.The night before the major assignment is due, I still working on it.	2.49±1.13	2
15.I have a set of goals for entire quarter	3.01± 1.07	3
16.I keep my desk clear of everything other than what I am currently working on	3.39±1.32	4
17.When I have several things to do, I think it is best to do a little bit of work on each one.	3.51±1.08	3
18.I review my class notes ,even when a test is not imminent	2.94±1.11	3

Discussion

Rai A [7] conducted among school students and found that school performance is better among students who manage work according to the time. A direct positive relationship was found between academic performance and time management.In a study [8]conducted among engineering students, a positive correlation was found between time management and grades of students. A study was conducted among nursing students in Tehran [9]found a positive correlation between time management and academic satisfaction. It was found that 49% of students had moderate level of time management skills. a study [10] was conducted in Saudi Arabia among 89 medical students, it was found that more than half participants had inadequate time management. Positive correlation was found between time management and academic performance. A study was conducted in Egypt [11]found positive correlation between time management and GPA. In a study[12] conducted to find out the relationship between the time management and academic achievement of the university students found out that time management is highly related to the academic performance of the university students. The findings are similar to the present study findings.

Abraham et al [13]conducted a study among first year undergraduate medical students in Manipal and found time management skills among the students were moderate.

In a study conducted by Khanam N et al.[3] Showed that 51.90% of the participants possessed moderate to low level time management score. Participants who obtained higher percentages of mark (70-80%) also had high mean score on general time management.24.1% of the participants never write a set of goals for their self for each day and 21.5% never spend time for each day planning which was poor as compared to the present study(13.27% and 15.66% respectively). 48% always keep their desk clear of everything other than what they are working on it, 40.5% sometimes review their class notes, even when a test is not imminent which was better than the present study(25.22.% and 24.35 % respectively), 37.9% sometimes make a schedule of the activities that they have to do on work days and 37.9% sometimes make constructive use of their time. Approximately only ten percent of the students always have a set of goals for the entire quarter which is comparable with present study findings (7%).

Conclusions

Educational sessions should be conducted for medical students to improve time management skills.

Limitations of the study: As the study was conducted in a single institute, the results cannot be generalised.

Conflicts of Interest-Nil

Funding Source- Self

Ethical Clearance –permission of IEC was obtained before the study was started.

Radhikabai Meghe Memorial College of Nursing, Sawangi (Meghe), Wardha, Maharashtra, India. Datta Meghe Institute of Medical Sciences (Deemed University), Sawangi (Meghe), Wardha, (M.S.)

Abstract

Abstract: Metabolic syndrome is a grouping of cardiac risk factors that result from insulin resistance. A person with metabolic syndrome has a greatly increased risk of cardiovascular disease and premature death. While the mortality and morbidity from coronary artery disease has been falling in the western world, it has been climbing to epidemic proportion among the Indian population. **Objectives:** 1) To assess the existence knowledge regarding the risk of metabolic syndrome among general population. 2) To evaluate the effectiveness of planned teaching on knowledge regarding the risk of metabolic syndrome among general population. 3) To associate the post-test knowledge score with selected demographic variable. **Material and Methods**: Non experimental design **Research approach**: Interventional evaluatory approach **Sampling techniques**: Non probability convenience sampling and **Sample size**: 60 people. **Result:** The study shows that 8(13.33%) had good level of knowledge score, 34(56.67%) have very good level of knowledge 18(30%) had excellent level of knowledge score. Hence planned teaching was effective, calculated 't' value is more than tabulated value and calculated 'p' value was less than accepted level of P=0.05 thus H_1 is statistically accepted. There is significant association of knowledge score associated with family history of hypertension and diabetic. **Conclusion:** The study showed that the planned teaching on the risk of metabolic syndrome among general population was effective in improving the knowledge of general population and thus helps them to understand the meaning.

Keywords*: Metabolic syndrome, knowledge, effectiveness and planned teaching.*

Introduction

Metabolic syndrome is a metabolic disorder that involves not one, but a combination of three or more of the following health issues: abdominal obesity, high blood sugar, high triglyceride levels, high blood pressure or low HDL ("good") cholesterol.[1]

Metabolic syndrome is a grouping of cardiac risk factors that result from insulin resistance. A person with metabolic syndrome has a greatly increased risk of cardiovascular disease and premature death. While the mortality and morbidity from coronary artery disease has been falling in the western world, it has been climbing to epidemic proportion among the Indian population.[2]

Metabolic syndrome is a complex web of metabolic factors that are associated with a 2-fold risk of cardiovascular diseases and a 5-fold risk of diabetes. Metabolic syndrome is a constellation of multiple cardiometabolic abnormalities including truncal (central) obesity, borderline and high blood pressure, high fasting glucose, high triglycerides, and low high-density lipoprotein cholesterol. Studies performed

in India have reported the prevalence of metabolic syndrome among adults as to be from 11% to 56%, depending on the definition used. NCEP, ATP-III defines it with the presence of three out of five clinical and/or biochemical abnormalities also the International Diabetes Federation recommends abdominal obesity as an obligatory criterion and the presence of at least two other abnormal criteria.[3]

Worldwide prevalence of metabolic syndrome ranges from <10% to as much as 84%, depending on the region, urban-rural environment, composition (sex, age, race, and ethnicity) of the patient, and the definition used. The prevalence of metabolic syndrome in India has been documented to be from 11% to 41% across this vast country with numerous socio-cultural varieties. The present study was undertaken to find out the demographic profile of the metabolic syndrome in Kanpur region of northern India. The prevalence of Metabolic syndrome was more than 40% and its prevalence in <40 years age group is rapidly increasing. It's high time to be more active physically, before fatal cardiovascular events.[4]

The aim of study was to determine the prevalence of metabolic syndrome (MetS) in people with type 2 diabetes mellitus. National Cholesterol Education Program (NCEP) ATPIII Criteria, International Diabetes Federation (IDF) and the World Health Organization (WHO) definitions were used in quantifying the metabolic syndrome and also the concordance between these three criteria's used for identifying metabolic syndrome. The Prevalence of metabolic syndrome was found to be 45.8%, 57.7% and 28% following NCEP-ATPIII Criteria, IDF and WHO definitions, respectively.[5]

Problem statement

To assess the effectiveness of planned teaching on knowledge regarding the risk of metabolic syndrome among general population.

Objective

1. To assess the existence knowledge regarding the risk of metabolic syndrome among general population.

2. To evaluate the effectiveness of planned teaching on knowledge regarding the risk of metabolic syndrome among general population

3. To associate the post- test knowledge score with demographic variable

Assumption

1. General population may have some knowledge regarding the risk of metabolic syndrome.

2. Knowledge may vary from one another.

Hypothesis:

H_1:- There is significant increase in post-test knowledge score.

Methodology

Research approach: Interventional Evaluatory approach.

Research design: Non experimental one group pre test post test design

Setting of the study: This study was conducted in Wardha

Sample: General population

Sample size: The sample of the study consists of 60.

Sampling technique: Non probability convenient sampling

Tool- structured knowledge questionnaire including demographic variables will be used for the study.

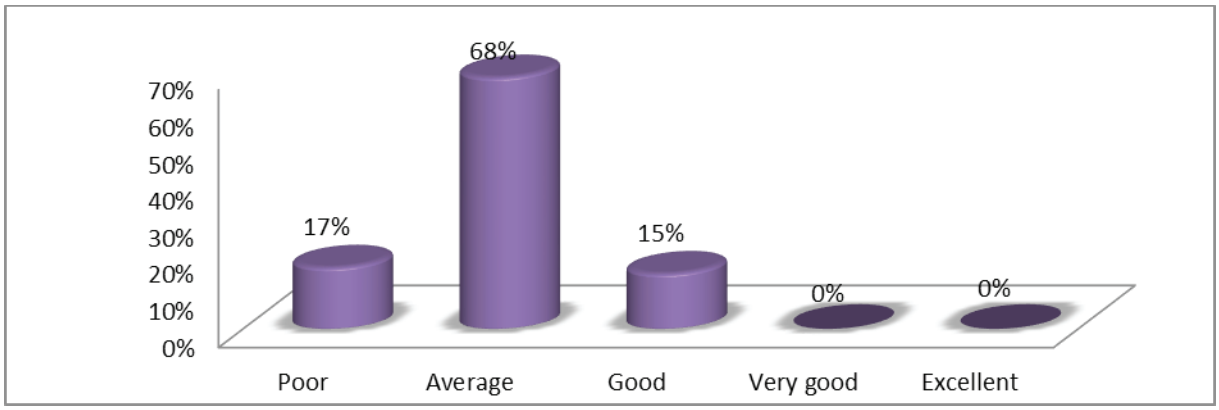
Independent variable: planned teaching regarding the risk of metabolic syndrome.

Dependent variable: knowledge of people regarding the risk of metabolic syndrome.

Result

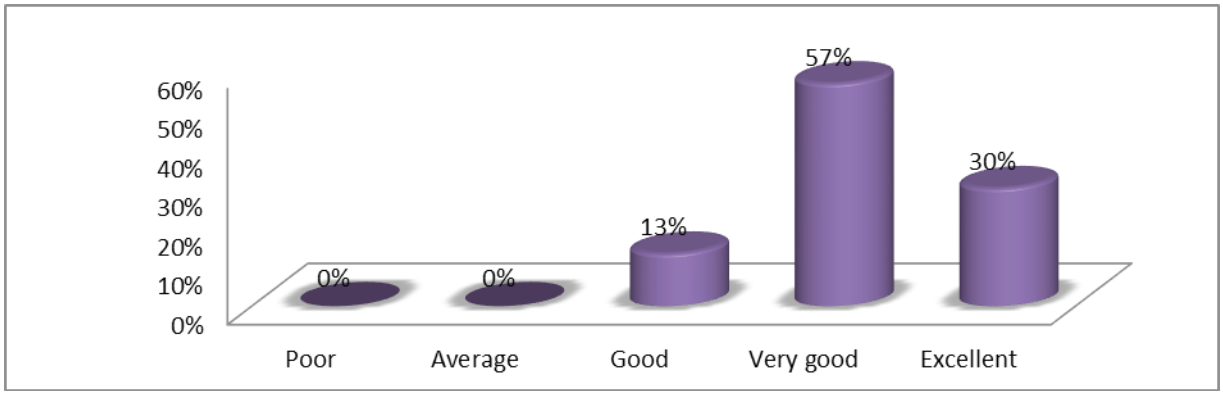
Graph No.1 Assessment of existing knowledge score regarding the risk of metabolic syndrome among general population.

The finding of the study shows that pretest 41(68.33%) having average level of knowledge, 10(16.67%) having poor level of knowledge, 9(15%) having good level of knowledge.



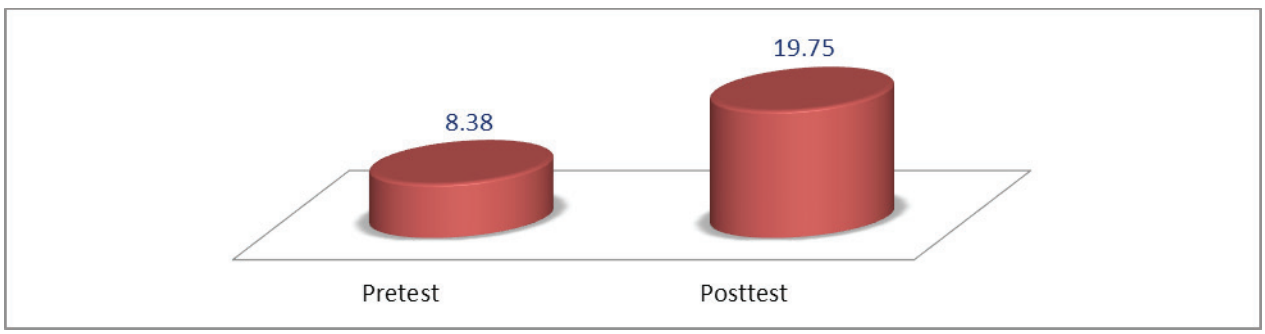
Graph No.2 Assessment of posttest knowledge grading the risk of metabolic syndrome among general population

The finding of the study show that post test 34(56.67%) having very good level of knowledge, 18(30%) having excellent level of knowledge. 8(13.33%) having good level of knowledge.



Graph No.3 Percentage wise distribution of Effectiveness of planned teaching on knowledge regarding the risk of metabolic syndrome among general population.

The overall mean knowledge scores of pre test and post test of general population which reveals that post test mean knowledge score was higher 19.75% with SD of ± 2.678 when compared with pre test mean knowledge score value which was 8.38% with SD of ±2.552. The statistical Student's paired t test implies that the difference in the pre test and post test knowledge score found to be 30.067 which is statistically significant at 5% level of significance($p<0.05$). Hence it is statistically interpreted that planned teaching on knowledge regarding the risk of metabolic syndrome among general population was effective. Thus H_1 is accepted.



Association of knowledge score with selected demographic variables

There is significant association of knowledge score associated with family history of hypertension and diabetic.

Analysis of data showed that there was significant difference between pre test and post test knowledge scores. Hence it is concluded that the planned teaching significantly brought improvement in the knowledge regarding the risk of metabolic syndrome among general population.

Discussion

In this study it is indicated that post test show that 34(56.67%) very good level of knowledge, 18 (30%) having excellent level of knowledge and 8(13.33%) having good level of knowledge. The overall mean knowledge scores of pre test and post test of general population which reveals that post test mean knowledge score was higher 19.75 % with SD of ± 2.678 when compared with pre test mean knowledge score value which was 8.38 % with SD of ± 2.552. the calculated t-value is 30.067 and tabulated t-value is 2.02, which is statistically significant at 5% level of significance($p<0.05$). Hence it is statistically interpreted that planned teaching on knowledge regarding the risk of metabolic syndrome was effective. There is significant association of knowledge score associated with family history of hypertension and diabetic.

Yadav D et al in their study the Prevalence of metabolic syndrome was found to be 45.8%, 57.7% and 28% following NCEP-ATPIII Criteria, IDF and WHO definitions, respectively. Using all the three definitions the prevalence was higher in women in all age groups. ATP III and IDF criteria showed good agreement (k 0.68) compared to ATP III with WHO (k 0.54) and IDF with WHO (k 0.34) criteria. Highest prevalence was observed following IDF definition.[6]

KwabenaNsiah et al in their study the prevalence of Metabolic syndrome was 58% in the studied Ghanaian population. Hypertension was the commonest risk factor (60%), followed by central obesity (48.67%) and dyslipidemia (37%). Female type 2 diabetics had a higher prevalence of metabolic syndrome, and carried more components than their male counterparts. Regression analysis showed three factors; femininity, high body mass index and low educational status were the most critical predictive risk factors of metabolic syndrome, according to this study.[7]

Puepet FH et al in there study the prevalence of Metabolic syndrome was 63.6% (74.5% in males and 54.9% in females, $p<0.05$). The mean (SD) age of patients with was Metabolic syndrome 54.7(9.5) years. About 80% of the patients were centrally obese, 63% had hypertension, 62% had high triglycerides and 70% with low high density lipoprotein cholesterol. Among patients with, 79% had metabolic syndrome dyslipidemia, 41% had body mass index 30, and 36% had microalbuminuria.[8]

Conclusion

The researcher as a part of her post graduate programmed, conducted an intervention research on the topic "To assess the effectiveness of planned teaching on knowledge regarding the risk of metabolic syndrome among general population".

The researcher aimed to improve the level of knowledge of risk of metabolic syndrome. She predetermined certain objectives, to precede the study. The objectives were adequate to reach into the findings. A particular time period has been allocated for each step. Investigator had presented her hypothetical views about the study in its beginning. The study had done by separating the topic into 5 chapters. And finally the researcher reached into her findings. The result of this study shows that 34(56.67%) having very good level of knowledge, 18(30%) having excellent level of knowledge 8(13.33%) having good level of knowledge, to find the effectiveness of planned teaching's' test was applied and t value was calculated, post test score was significantly higher at 0.05 level than that of pre test score. Thus it was concluded that planned teaching on the risk of metabolic syndrome was found effective as a teaching strategy.

Ethical Clearance- It has been Obtained by Datta Meghe Ethical Committee, Dmims, Sawangi Meghe Wardha.

Use of L-Arginine for inhaled Nitric Oxide (iNO) dependent hepatopulmonary syndrome (HPS) Post-Liver Transplant

Mohnish Kataria[1], Abhinav Rastogi[2], Sajaad Manzoor[3], Himanshu Tanwar[2], Sivaji Patibandla[2], Vishal V Singh[4]

[1]Assistant Professor, Gastroenterology, [2]DM Cardiology Resident, [3]Director, Interventional Cardiology, [6]Assistant Professor Cardiology, Affiliation: Department of Cardiology, MM Institute of Medical Sciences (Deemed to be University), Mullana, Ambala (INDIA)

Abstract

Hepatopulmonary syndrome (HPS) is one of the recognised complications of liver cirrhosis which warrants urgent liver transplantation. We report a case of 7 year old girl who underwent orthotopic liver transplantation (OLT) for severe HPS. Post transplantation the patient had a stormy respiratory course and became severely hypoxemic. She was started on inhaled NO and showed a good response. However, the patient then became NO dependent and multiple attempts to wean iNO failed albeit minimal ventilatory requirements. Following IV L-Arginine infusion, iNO could be weaned within 6 hours without recurrence of hypoxemia. L-Arginine infusion should be considered as a treatment option when facing difficulties to wean iNO in an otherwise well responding patient.

Keywords*: Hepatopulmonary syndrome, liver transplantation, L-Arginine.*

Introduction

Hepatopulmonary syndrome (HPS) is one of the recognised complications of liver cirrhosis which warrants urgent liver transplantation. The symptoms usually improve post transplantation but might take 6-12 months to resolve completely. Severe hypoxemia post liver transplantation, especially when done for hepatopulmonary syndrome has been reported. iNO use for the same has been reported in literature with good response. However it is practically very difficult to continue iNO in a stable child on a portable ventilator due to problems of scavenging. We report a case of 7 year old girl who underwent orthotopic liver transplantation (OLT) for severe HPS.

Case:

A 7 year old girl was referred to our centre for liver transplantation for hepatopulmonary syndrome secondary to cryptogenic liver cirrhosis. On admission she was centrally cyanosed with oxygen saturations of 75-80%. She was otherwise well and comfortable. She had bilateral grade III digital clubbing. She was noted to have hepatosplenomegaly. The contrast enhanced echocardiography prior to transplant showed a structurally normal heart with multiple aortopulmonary collaterals secondary to pulmonary arteriovenous malformations (AVMs) as concluded by the appearance of microbubbles as contrast in the left atrium within 3 cardiac cycles; there was no evidence of pulmonary hypertension. Liver MRI prior to transplant showed patent portal venous structures and no features of portal hypertension. No other vascular shunts were identified.

The patient was urgently listed for liver transplantation, and underwent cadaveric liver transplant. The procedure itself was uneventful. Her ventilation was gradually weaned aiming to keep oxygen saturations > 75%.

She was extubated on **day 3** post OLT to high flow nasal cannula device. She had a postoperative transthoracic echocardiogram which showed good cardiac function with no evidence of significant pulmonary hypertension. On **day 4** post OLT she developed a significant pleural effusion on right side

Corresponding Author:
Dr. Abhinav Rastogi,
Department of Cardiology, MMIMSR, Mullana, Ambala, Email id: dr.abhinav2017@gmail.com

which was drained. **Day 6** post OLT the patient was changed over to Continuous Positive Airway Pressure Ventilation (Non-invasive CPAP) in view of increased work of breathing, falling oxygen saturations, and persistent right lower lobe atelectasis. Her mixed venous saturations then were 35-50%.**On the 7th** post transplant day, she had to be intubated and ventilated because of respiratory failure. She was extremely difficult to oxygenate, she required moderate ventilator pressures to achieve acceptable tidal volume . She remained in 100% oxygen with arterial saturations of 50%. The patient was started on inhaled nitric oxide (iNO) at 5ppm which improved oxygenation to 70-80%. No difference was noted in oxygenation on high dose inhaled nitric oxide (iNO) of 20ppm. Oxygenation index remained borderline around 40.

Her ventilation remained stable but multiple attempts to wean iNO were unsuccessful. She eventually underwent tracheostomy to facilitate long term ventilation on **day 30** post OLT. She was started on Sildenafil (Dose range 0.5 mg/kg to 1 mg/kg every 4-6 hourly was tried) to wean iNO (from 5ppm to 1 ppm). However, by Day-60, the patient was still dependent on iNO though the ventilator requirements were minimal. Patient was completely interactive but would rapidly desaturate and become cyanosed on stopping iNO(1 ppm). Due to problems in scavenging of iNO with portable ventilators and practicalities in discharging a patient home on iNO, we were desperately looking for an alternative to iNO. On **day 68** post surgery after discussion with regional pulmonary hypertension team patient was started on L Arginine infusion to be able to wean off iNO, (details in the table). Her L-Arginine levels were 32 umol/L (normal range 26 – 180) prior to commencing L-Arginine.

Weaning regimen:
Acute: Intravenous L-Arginine infusion 15 mg/kg/min given over 20 minutes. Sildenafil in the dose of 0.3 mg/kg was administered after 2 hours of starting infusion. We weaned FiO2 to 0.3 after 90 minutes of Sildenafil administration. We then increased FiO2 to 0.6 & stopped inhaled Nitric Oxide after 24 hours of starting L Arginine infusion.
Same dose L-Arginine (15 mg/kg) was given daily intravenously for 1 month
Long term: Arginine was weaned to half the dose every alternate day for 1 month and then dose was gradually tapered over 1 month and stopped.

Patient was discharged to local hospital on **day 94** post OLT (1 month after starting L-Arginine and stopping iNO)on BIPAP through tracheostomy with a plan to wean Sildenafil and L Arginine over 2 months. Her Oxygen saturations were 75-80%. She was in 40% Oxygen. Patient's blood Arginine level was within normal limits [69 umol/L (Range 26 - 180)] prior to discharge.

Follow-up of this patient 6 months after transplantation revealed that she was discharged home on 0.5 litres/minute of nasal cannula oxygen, tracheostomy has been successfully decannulated and L-Arginine and sildenafil were stopped as planned. She was reviewed after 2 years for elective abdominal closure. She was noticed to be saturating more than 95% in room air.

Discussion

Hypoxemia in patients with liver cirrhosis may occur in the context of hepatopulmonary syndrome (HPS) together with portopulmonary hypertension (PPH). Although portopulmonary hypertension and the hepatopulmonary syndrome are associated with the same underlying diseases, they have contrasting pathophysiological backgrounds, and hence their management is different.

HPS is triad of Hypoxemia, underlying chronic liver disease and intrapulmonary vascular dilations (IPVD) [1]. In the paediatric population the prevalence of HPS is described as 8-20% in children with liver cirrhosis[2] . From a radiological standpoint, HPS is characterized by diffuse dilatation of the peripheral pulmonary vasculature. In this case, the diagnosis of HPS was discussed following contrast-enhanced transthoracic

echocardiography with agitated saline in detecting the presence of pulmonary arteriovenous malformations (AVMs). During this procedure, saline is shaken to produce microbubbles greater than 10μm in diameter and administered through a peripheral vein in the arm. The presence of microbubble opacification in the left atrium within 3 to 6 cardiac cycles following opacification of the right atrium is considered a positive test for the presence of intrapulmonary vascular shunting. In consequence, contrast echocardiography is the recommended study for the evaluation of IPVD in diagnosing HPS, as it is more sensitive than the lung perfusion scan with technetium and has no radiation exposure. CT angiogram showed the findings of dilated pulmonary vasculature (**Figure 1**). Thus, CT angiogram can be helpful in a patient with liver disease and unexplained hypoxemia.

Mortality of HPS has been reported to be around 25% to 46 % [3] .This syndrome is due to abnormal intrapulmonary vascular dilatation, which results in an excess perfusion for a given state of ventilation. This complication is characterised by anatomical shunting and a diffusion-perfusion abnormality[4] . Evidence is growing rapidly that excess production of Nitric Oxide plays a central part in pathogenesis of HPS[5] . Excess production of Nitric oxide is secondary to altered bowel perfusion and an increased rate of enteral translocation of gram-negative bacteria and endotoxin, due to altered bowel perfusion[6] .Diets containing low amount of Arginine (Substrate for nitric oxide),IV Methylene blue have been tried without much success. Complete resolution of condition post transplant is well documented.

In the literature, cases of transient or fatal deterioration of intrapulmonary shunting post OLT with dramatically worsening hypoxia had been described. Schiller et al reported a case of 10 year old patient who was treated with inhaled Nitric oxide for post OLT hypoxemia. iNO was stopped successfully on day 14 post OLT in their patient[7] . In another case report by PH Durand at al, patient responded very well to NO and they were able to wean NO by day 10 post OLT[8] .

In our patients multiple attempts to wean and stop NO were unsuccessful and patient would become clinically cyanotic with oxygen saturations <60% if iNO was dropped to less than <1ppm. Patient was essentially iNO dependent for 8 weeks post OLT. Clearly the respiratory process in our patients was iNO responsive. The alternative therapies to iNO include IV L Arginine infusion, IV Citruline infusion.

L-Arginine is the nitrogen donor for synthesis of nitric oxide. Hence in theory administration of L Arginine would increase endogenous production of Nitric oxide which is a potent pulmonary arterial vasodilator. Several studies have demonstrated therapeutic benefits of L-Arginine therapy for pulmonary hypertension[9]. L-Arginine infusion has decreased pulmonary vascular resistance and improved oxygenation in infants with persistent pulmonary hypertension[10] . L-Arginine supplementation has been shown to improve pulmonary artery pressures and hemodynamics in patients with primary and secondary pulmonary hypertension[9] . Claudia et la, demonstrated that Oral Arginine produced a 15.2% mean reduction in estimated pulmonary artery systolic pressure after 5 days of therapy in 10 patients with sickle cell disease. Due to problems in using iNO on a portable ventilator associated with problems in use of iNO at home, we were desperate to find an alternative to iNO which in our case was L-Arginine. The protocol we followed was based on a study protocol used by Schulze-Neick at al. in their study on children with cardiac disease[11] . It was modified to suit our patient's needs.

In all previous case reports of hypoxemia post OLT, response to iNO was good and weaning of iNO was possible within 2 weeks post OLT without recurrence of hypoxemia. To the best of our knowledge this is a first case reported in literature where in patient who underwent OLT for HPS became hypoxic post surgery and remained iNO dependent, but responded well to L Arginine infusion. We therefore recommend use of L-Arginine and low dose Sildenafil in case of iNO dependent patient with HPS.

Prevalence of Extended Spectrum β- Lactamase Genes among the Oral Gram Negative Rods Isolated from HIV Infected Patients

Monica Singh[1], Arindam Chakraborty[2]

[1]Assistant Professor, [2]Associate Professor, Department of Microbiology, Motilal Nehru Medical College, Prayagraj Uttar Pradesh. India

Abstract

Objective: We investigated the incidence of gram negative rods from the oral flora of HIV infected patients, possession of ESBL genes and their sensitivity pattern.

Methods: A total of 100 HIV infected patients were included in the study. Their oral swabs were cultured on blood agar and Mac-conkey agar. Organisms were identified based on standard technique. Antibiotic sensitivity was done by the Kirby Bauer disc diffusion method. Detection of ESBL gens (TEM, SHV, CTXM) were performed by multiplex PCR methods.

Result: A total of 57 gram negative rods were isolated from oral swab of 100 HIV positive patients. Out of 57 isolates Pseudomonas *spp* (21 isolates) followed by *Klebsiella* (17 isolates), *E.coli* (10 isolates) and *Acinetobacter* (9 isolates) respectively. Thirty four (60 %) isolates were ESBL producer by phenotypic methods and 35 isolates carried ESBL genes detected by PCR methods. By Kirby Bauer disk diffusion methods 14 (25%) isolates were resistance to three or more antibiotics were reflected as multidrug – resistance (MDR) organism.

Conclusion: All the HIV positive patients respiratory sample should be include in routine screening for the MDR isolation. This will help the physician to choses the appropriate antibiotic when needed and to prevent the morbidity and mortality of the HIV patients due to the MDR gram negative isolates.

Key word: *HIV, Oral flora, Gram negative bacilli. ESBL, MDR.*

Introduction

According to estimates by WHO and UNAIDS, 36.7 million people were living with HIV globally at the end of 2016. That same year, some 1.8 million people became newly infected, and 01 million died of HIV-related causes. [1] The infection is alarming due to the unique pathogenesis of the virus that mainly affect the CD4 cells count, due to this there is the emergence of opportunistic infections in the host, the infection become worse with low CD4+ T cell counts.[2] Among the various opportunistic infections, respiratory infections account for up to 70% of AIDS defining illness. Studies have found an incidence of 5-10% of the HIV-infected patients had colonization with different species of *Enterobacteriaceae.* [3]

It was well known fact that unselective use of antibiotics may cause a shift of upper respiratory tract microbiota and favour colonization with gram negative bacteria. [4] In recent year high level of drug resistance among the gram negative rods are a serious issue, such extended-spectrum-β–lactamase (ESBL) producers have widely spread, and at present, they lead to a serious threat to human.[5] Aim of the present study was to find out the incidence of ESBL genes in commensal isolates and to establish any upsurge in resistance against the commonly use antimicrobial agents and also to find out the incidence of gram negative rods as commensals in oropharyngeal isolates.

Material and Method

The study was conducted during the period from

June 2017 to August 2018 in a multispecialty tertiary care teaching hospital at Prayagraj UP India. A total of 100 HIV positive patients who satisfied the following inclusion/exclusion criteria, were included in the study.

Inclusion criteria:

Subjects who were positive with HIV and no respiratory complication were included in the study.

Exclusion criteria:

I. Subjects who received antibiotic during the past one month.

II. Upper respiratory tract infection.

III. HIV infected patients who were under antiretroviral drugs.

Method

After obtaining the institutional ethics committee's clearance, the patient related data were collected in a structured proforma. The data included the demographic details, CD4 count and complete blood count of the patients.

Specimen collection:

Normal saline mouth gargles or oral washings were collected in a sterile containers from the study population. [6]

Isolation and identification of the organism:

The samples were culture in 5% sheep Blood agar and MacConkey's Agar using standard procedures. Isolates were identified based on colony morphology on blood agar, MacConkey's agar, Two to three suspected colonies from each bacterial plate were picked, cultured and then identified by the various biochemical tests. Biochemical tests were performed to confirm different gram negative organism using gram stain, catalase test, indole, methyl red, Voges-proskauer test, nitrate reduction , urease production, simmon citrate agar, oxidase test and various sugar fermentation tests. [7] LF and NLF isolates were catagorized based on lactose fermentation on MacConkey's agar.

Antimicrobial susceptibility testing:

Antibiotic susceptibility testing was done by Kirby–Bauer disk diffusion method as per Clinical and Laboratory Standards Institute guidelines [8] . The antibiotic disks (Hi-Media,India) used were ampicillin (10 µg), piperacillin (10 µg), piperacillin/tazobactam (100/10 µg), ceftriaxone (30 µg), cefotaxime (30 µg), ciprofloxacin (5 µg), norfloxacin (10 µg), amikacin (30 µg), gentamicin (10 µg), cotrimoxazole (1.25/23.75 µg), cefoperazone + sulbactam (75/30 µg), imipenem (IPM; 10 µg), meropenem (MRP; 10 µg), and ertapenem (ETP; 10 µg).

Screening for ESBL Production:

Gram negative rods which were resistance to third generation cephalosporines were tested for ESBL production by combination disk method using cefotaxime (30 µg), cefotaxime/ clavulanic acid (10 µg), ceftazidime (30 µg) and ceftazidime/ clavulanic acid (10 µg). A ≥5 mm increase in diameter of inhibition zone of cephalosporin + clavulanate disc when compared to cephalosporin disc alone was interpreted as evidence of ESBL production. [8]

Preparation of template DNA:

To 500 µl sterile distilled water taken in a micro centrifuge tube was added 2-3 identical colonies of the isolate. This suspension was heated in a water bath at 95 ° C for 10 min and then centrifuged at 10,000 rpm for 10 min. the supernatant were collected which contain the bacterial DNA was used as template for polymerase chain reaction (PCR). [9]

Genotypic detection of ESBL encoding genes:

A multiplex PCR assay was performed to detect bla $_{TEM}$, bla $_{SHV}$ and bla $_{CTX-M}$ genes as per the primers and conditions previously described, with minor changes [10, 11] . To summarize, PCR was done in a final reaction volume of 50 µl containing 750 Mm Tris HCl, 200Mm $(NH4)_2SO4$, 2.5mM $MgCl_2$, 0.2 mM each of dNTP, 0.5 µl of each primer, 1.5U of Taq DNA polymerase And 5µl of template DNA. The program for amplification included a step of initial denaturation at 95 ^{0}C for 3 min followed by 30 cycles of 95 ° C for 1 min, 58 ° C for 1 min and 72 ° C for 1 min and final extension step at 72 ° C for 7 min. The PCR products were loaded in 2% (w/v) agarose gel prepared in tris borate EDTA buffer at 120 V for 1h and detected using ethidium bromide staining after electrophoresis.

Statistical Analysis

Statistical analysis was performed by using SPSS, version 17.0. Correlation of numerical data with drug

resistance and virulence was done using Pearson's correlation coefficient and all categorical data were correlated by chi-square test. A value of $P < 0.05$ was considered statistically significant.

Results

A total of one hundred respiratory samples from HIV infected patient were included in the study. Out of 100 patients 78 were males and 22 were females. Of the total of 100 patients oral sample 57 sample contain gram negative rods. Of the total of 57 isolates maximum number of the isolates were *Pseudomonas spp* (21 isolates) followed by *Klebsiella spp* (17 isolates), *E. coli* (10 isolates) and *Acinetobacter* (9 isolates) respectively. The most common age group colonised by gram negative rods were 41-60 years followed by 17-40 years. (Table1). Maximum numbers (47.50%) of gram negative rods were isolated from the patients with the CD4+T cell count of 200-600 cells/µl (Table1). Prevalence of different gram negative rods with different CD4 cell count groups is summarized in Table 2.

Of the total of 57 gram negative isolates 34 (60 %) isolates were ESBL producer by phenotypic methods and 35 isolates harbouring ESBL genes which code for single or multiple enzymes**.** A total of 32 (91%) strains out of 35 isolates were positive for bla $_{CTX-M}$ gene, 6 (17%) isolates were positive for bla $_{TEM}$ and only 2 organism were positive for bla $_{SHV}$. Two organism were positive for both bla $_{TEM}$ and bla $_{CTX-M}$, However , non of the isolate was positive for all ESBL genes. When the isolates –wise distribution of ESBL genes was considered, 52% *Pseudomonas* isolates were harbouring bla $_{CTXM}$ genes (Table 3). The results obtained from the Kirby Bauer disk diffusion methodes indicated that, of the 57 gram negative bacilli all of them were fully susceptible to Ertapenem , Meropenem and Imipenem respectively. Around 25% isolates were resistance to three or more antibiotics and thus were considered as multidrug – resistance (MDR) strains. Around 95% of the all isolates were resistant to ampicillin and around 75% of the isolates were resistant to fluroquinolones group of drugs. In addition, the resistance profiles of the drugs among the isolates are summarized in figure 2.

Table 1: demographic details and CD4 cell count of the patients:

		HIV infected patients respiratory sample contain no GNB	**HIV infected patients respiratory sample contain GNB**	**Total**
Sex (N=100)	Male	40	38	78
	Female	3	19	22
Age (N=100)	0-16	3	4	7
	17-40	34	20	54
	41-60	9	26	35
	>60	1	3	4
CD4 Cell count (N=100)	<200	8	15	15
	200-600	11	27	29
	>600	24	15	15

Table 2: Prevalence of Gram negative rods with different CD4 cell count group:

Bacteria isolated n=57	**CD4 <200**	**CD4 200-600**	**CD4 >600**
Pseudomonas (21)	12.2%(7)	19.2%(11)	5.2 %(3)
Klebsiella (17)	5.2%(3)	52 % (9)	23.8% (5)
E.coli (10)	3.5%(2)	7%(4)	10.52%(6)
Acinetobacter(9)	5.26 % (3)	8.7% (5)	1.7% (1)
Total	15	29	15

Table 3: Phenotypic and Genotypic distribution of ESBL producing organism.

Organism		**Phenotypic n=34**	**Genotypic n=35**		
			TEM n=6	**SHV n=2**	**CTXM n=32**
1.	Pseudomonas n=21	13	1	1	11
2.	Klebsiella n=17	8	1	1	6
3.	E.coli n=10	6	2	0	7
4.	Acinetobacter n=9	7	2	0	7

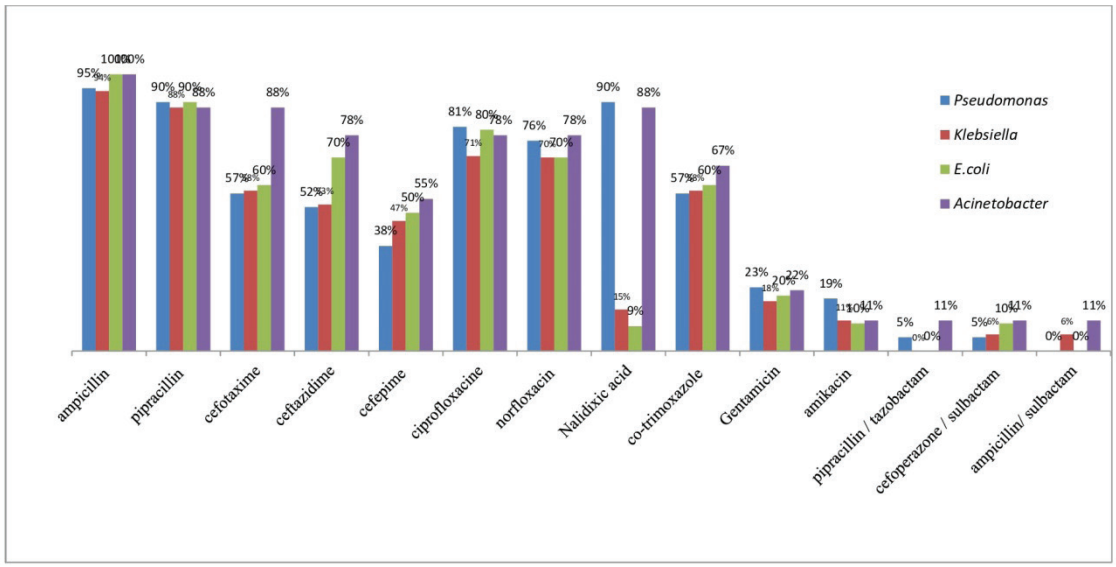

Figure 1: Antimicrobial resistance pattern of commonly used antibiotic among the isolates.

Discussion:

In the present study, we observed a high rate of colonization of gram negative rods (57%) among the HIV positive patients respiratory sample which is similar to the study done by Hegde et al. [6] where they have found around half of their isolates were gram negative rods.

We are not the first to observed that male were mostly effected by HIV in compare to female several other investigator also reported the same. We also witnessed that the incidence of colonization of gram negative bacilli were significantly higher in male patients. The age group mostly affected was the 41-60 years; this is consistent with the findings of *Hedge et al* [6] and Leynaert et al.[12] . Who reported the highest incidence of HIV in the late thirties.

In the study, we also observed that , the incidence of gram negative rods were significantly higher in patients who have lower CD4 cell count, which is similar to studies done by Sarkar K et al. [13] and Hegde et al. [6]

In our study population we found that around half of the HIV infected patients oral sample contain gram negative isolates, Among these isolates the most common were *Pseudomonas spp* (37%) followed by *Klebsiella spp* (30%). However a study done by Schmidt- *Westhausen et al*. [14] found that 5% of the HIV infected individuals oral cavity contain different species of *Enterobacteriaceae*. Yet in another study from India have reported 32% of their isolates were gram negative rods. [6]

On analysis of the antibiotic sensitivity testing by phenotypic methods of the isolates we observe a significantly high degree of resistance to first line of antibiotics which is in accordance to study done by Manfredi et al. [15] and Molyneux .[16] Many retrospective studies on commensal isolates from HIV positive patients reported a high degree of resistance among the commonly used antibiotics.

Regarding the possession of ESBL genes such as CTXM, TEM & SHV, our finding indicate that one in three HIV positive individual were harbouring gram negative rods with ESBL genes (100/35). However the incidence of ESBL producing isolates were significantly higher among the total gram negative rods isolated (57/35) from HIV positive individual. There are several study on *E.coli* phylogenetic groups indicates that commensal groups such as A & B1 were harbouring drug resistance genes and causing life threating infection. [17, 18]

In our study we also observed that CTXM is the most common ESBL gene harbouring by the isolates, the presence CTXM gene among the commensal isolates may act as a reservoir of antibiotic resistance genes.

It is well know that opportunistic infections are the most common causes of death in HIV infected patients and most of them are caused by commensal bacteria which are otherwise harmless in a normal individual. In our study we have reported that those commensal gram negative rods were harbouring ESBL genes, a finding that is of a major worry to attending clinicians and present day treatment modalities. Based on our finding we can suggest that the HIV positive individuals respiratory sample should be routinely scan for the pathogens and if there are any gram negative rods grown they should treated with the appropriate antibiotic. This will help in the fight against multidrug resistance organism and if corrective actions are not taken, in the absence of novel agents in the near future, the spread of MDR isolates and infection cause by those isolates in HIV infected individual may lead to therapeutic dead ends.

Acknowledgment: We would like to thanks Motilal Nehru Medical College, Prayagraj for providing us the infrastructure and financial support for the study.

Knowledge of students about rabies and its post exposure prophylaxis and health seeking behaviour in University of Western UP.

Monika Gupta[1] Chhavi Kiran Gupta[2] Sartaj Ahmad[3] Bhawana Pant[4] Kaynat Nasser [5] Deepak Kumar[2]

[1]Associate Professor, [2] Assistant Professor, Department of Community Medicine, Subharti Medical College Meerut, [3] Associate Professor, Medical Sociology, Swami Vivekananda Subharti University Meerut , [4]Professor, Department of Community Medicine ,Subharti Medical College Meerut, [5]Assistant Professor(Biostatistics), Department of Community Medicine, Subharti Medical College Meerut

Abstract

Introduction: Rabies is a major public health problem in Asia. Of the estimated 55,000 human cases that occur annually worldwide, more than half occur in Asian countries. Rabies is exceptionally fatal encephalitis but can be prevented by appropriate post exposure prophylaxis. **Objectives:** To assess the knowledge of students about rabies and its causes, reservoir , mode of transmission , symptoms, wound management , post exposure prophylaxis , seeking behaviour, site for anti rabies vaccine administration after dog bite. **Methodology:** This cross-sectional study was conducted among 375 college students in various colleges under Swami Vivekananda Subharti University Meerut UP. **Results:** (55%) of students knew that rabies is caused by a virus. 18.66% students knew correct first aid measures such as wash with soap and water. **Conclusion:** The findings of the study indicated lack of knowledge on various aspects of the rabies & its prevention. There are many misconceptions and lack of awareness about rabies. There is strong need to organize awareness programme using educational session.

Key words: *Students, Rabies, Misconception, Health seeking behaviour*

Introduction

Rabies is an enzootic and epizootic disease of worldwide importance. Rabies is a major public health problem in Asia. Of the estimated 55,000 human cases that occur annually worldwide, more than half occur in Asian countries [1] In India, rabies is a zoonotic problem of considerable magnitude. Annual mortality more than 30,000 reported by national authorities may not be a complete picture because, since 1985 India continues to report the same every year.[2] Every year approximately 1.1 to 1.5 million people are receiving post exposure prophylactic treatment. Although two million bites occur each year in India and more than 95% of these cases are bitten by dogs [3]

Corresponding author:
Dr Chhavi Kiran Gupta
Email:chhavikirangupta@gmail.com

The most well-known and ubiquitous lyssavirus is the rabies virus (RABV), which circulates in New World bats and both Old and New World terrestrial mammals. The vast majority of human rabies cases worldwide are transmitted by dogs infected with RABV. [4] In recent decades, initiatives aimed at raising rabies awareness (e.g. the World Rabies Day campaign) and lowering human exposure risk through mass vaccination of leading reservoir species have been implemented globally, coinciding with the development of highly potent human rabies vaccines.[5]

This study was undertaken to find out the knowledge, attitude, and practice regarding rabies and its prevention among the college going students.

Objectives of the present study were:

1) To assess the knowledge and awareness of students about rabies.

2) To ascertain the management of wound practiced

by students after dog bite.

3) To assess the awareness of students regarding anti rabies vaccine & their health seeking behaviour.

Material and Method

This cross-sectional study was conducted among 375 college students in various colleges under Swami Vivekananda Subharti University Meerut UP. A Total of *375* first year students of three colleges were interviewed. Out of them, Law (185), Pharmacy (142) and Mass communication (48) students were randomly selected for interview. A predesigned semi structured, pre-tested questionnaire was used after taking consent of the students. Permission from the institutional ethics committee of Subharti medical college, SVSU, Meerut was taken. A data collection for the study was carried out during from October to December 2019. The data was entered and analyzed by using Micro soft Excel software and the results were expressed in percentages and chi square test.

Results

Table 1: Distribution of study participants according to Knowledge of cause and reservoir of rabies.

Knowledge about cause of rabies	Law students (N=185)	Pharmacy students (N=142)	Mass Communication students (N=48)	Total (N=375)
Virus	105 (56.75)	82 (57.74)	20 (41.66)	207 (55.2)
Others	48 (25.94)	25 (17.60)	15 (31.25)	88 (27.46)
P value= 0.00 (Significant differences) Knowledge about reservoir of rabies				
Dog	160 (86.48)	125 (88.02)	32 (66.66)	317 (84.53)
Monkey	42 (22.70)	35 (24.64)	13 (27.08)	90 (24.0)
Cattles	18 (09.72)	13 (09.15)	04 (08.33)	35 (09.33)
Cat	15 (08.09)	14 (09.05)	08 (10.41)	37 (09.06)
Rat/others	10 (05.40)	03 (02.11)	07 (31.26)	21 (05.32)

P value= 0.04 (Significant differences)

Table 2: Distribution of study participants according to Knowledge regarding Mode of Transmission & symptoms of rabies:

Mode of Transmission	Law students (N=185)	Pharmacy students (N=142)	Mass Communication students (N=48)	Total (N=375)
Animal bite	180 (97.29)	135 (95.07)	40 (83.33)	355 (94.66)
Scratch by animal	28 (15.35)	25 (17.60)	12 (25.00)	65 (17.33)
Lick on broken skin	22 (11.89)	13 (09.15)	09 (18.75)	44 (11.73)

Cont... **Table 2: Distribution of study participants according to Knowledge regarding Mode of Transmission & symptoms of rabies:**

Touching secretions of rabid animal/person	47 (25.39)	32 (22.5)	20 (41.60)	99 (25.59)
Drinking unboiled milk of rabid animal	18 (09.72)	23 (16.19)	15 (31.39)	56 (14.93)
P value =0.05 (No Significant differences) **Knowledge about Symptoms**				
Hydrophobia	48 (25.94)	25 (17.60)	15 (31.25)	88 (27.46)
Convulsions	18 (09.72)	13 (09.15)	04 (08.33)	35 (09.33)

P value=0.92 (No Significant differences)

Table 3: Distribution of study participants according to the knowledge regarding wound management:

Wound management	**Law students (N=185)**	**Pharmacy students (N=142)**	**Mass Communication students (N=48)**	**Total (N=375)**
Wash with soap & water	48 (24.94)	14 (9.85)	08 (16.66)	70 (18.66)
Apply Chilly Powder	66(35.68)	80 (56.33)	30 (62.05)	176 (46.93)
Used herbal Paste	12 (6.48)	13 (9.15)	05 (10.41)	30 (8.0)
Apply oil etc	05 (2.70)	03 (2.11)	03 (6.25)	11 (2.93)

P value=0.00 (Highly significant association)

Table 4 : Distribution of study participants according to Knowledge regarding post exposure prophylaxis & health seeking behaviour

Knowledge about Number of doses of ARV	**Legal Education (N=185)**	**Pharmacy (N=142)**	**Mass Communication (N=48)**	**Total (N=375)**
05 Dose	20 (10.81)	35 (24.62)	13 (27.08)	113 (30.13)
14 Dose	115 (62.16)	80 (56.33)	25 (52.08)	175 (46.66)

P value= 0.00 (Highly significant association) Knowledge about Site for Anti Rabies Vaccine administration				
Upper arm / Anterolateral thigh	05 (2.70)	18 (12.67)	13 (27.08)	36 (9.06)
Buttock/ abdomen	120 (64.86)	95 (66.89)	33 (66.66)	247 (57.68)

Cont... **Table 4 : Distribution of study participants according to Knowledge regarding post exposure prophylaxis & health seeking behaviour**

P value =0.00 (Highly significant association) Health seeking behaviour				
Private Practitioners	126 (68.10)	97 (68.30)	23 (47.9)	246 (65.6)
Government Health centers	32 (17.29)	18 (12.67)	12 (25.00)	62 (16.53)
Quacks/ Traditional healers	27 (14.57)	27 (18.20)	13 (27.07)	67 (17.86)

P value= 0.04 (Significant association)

In this study, 61% of the study subjects were males and 39% were females. Majority of the students (67%) were in the age group of 17 > years. Only about half of the subjects (55.2 %) knew that rabies was caused by a virus. There was significant difference in knowledge about causes of rabies.

(84.53 %) respondents thought that the reservoir of rabies was dog. Knowledge regarding other animal reservoir was monkey (24.0 %), cattle's (9.33%), cat (9.06%), and rest to rat and other animals (05.32%). There was significant difference in knowledge about reservoir of rabies.

(94.66%) students knew that rabies could be transmitted by animal bite. Besides animal bite students knew that rabies could also be transmitted by scratch by animals (17.33%), lick on broken skin or mucous membrane (11.73%), touching secretions of rabid person/animals (25.59%), and drinking unboiled milk of rabid animal (14.93%). There was not significant difference in knowledge about mode of transmission of rabies.

Symptoms of rabies were found hydrophobia (27.46 %) and convulsion (9.33%). There was not significant difference in knowledge about symptoms of rabies.

Application of chilly powder (46.93%) and herbal paste (08. %) was found management of wound. Only (18.66%) students knew that wash with soap and water was better management of wound after animal bite. There was highly significant association in knowledge about management of wound after dog bite.

Only (30.13%) knew of 05 doses of anti rabies vaccines (ARV) for prevention against rabies and majority (46.6%) still opined that 14 injections (ARV) had to be taken. There was highly significant association in knowledge about doses of anti rabies vaccines (ARV) for prevention against rabies.

In our study, very few (9.06%) students knew that anti rabies vaccines (ARV) should be given over arm/ anterolateral part of thigh. (57.68%) students believed that anti rabies vaccines were given around the umbilicus or intra abdominal. There was highly significant association with knowledge about site for ARV doses.

In case of visit for health services after animal bite, private practitioners (65.6%) were first choice of students. (16.53%) students wanted to go to the government health centers, and (17.86%) prefer to quacks and others traditional healers. There was significant in knowledge association with health seeking behavior.

Discussion

In this study, 61% of the study subjects were males and 31% were females, maximum students were in age group 17-20 years (67%). Only about half of the subjects (55.2%) knew that rabies is caused by a virus. There was significant difference in knowledge about causes of rabies.

(94.66%) students knew that rabies could be transmitted by animal bite. Besides animal bite students knew that rabies could also be transmitted by scratch by animals (17.33%), lick on broken skin or mucous membrane (11.73%), touching secretions of rabid person/animals (25.59%), and drinking unboiled milk of rabid animal (14.93%). There is no significant difference in knowledge about mode of transmission of rabies. Similar results were reported in a survey of knowledge, attitudes, and practices of dog and cat owners in Ottawa.

Carleton stated that 95% of respondents were aware that they were likely to get rabies from a bite or 77% from a scratch of a rabid animal. [6]

In our study, only (18.66%) students knew that wash with soap and water was better management of wound after animal bite. There are many myths and false beliefs associated with wound management such as application of oils, herbs, and red chilies on the wounds inflicted by rabid animals. In this study , 46.93% students told that chilly powder should be applied after dog bite where as 8% students told that herbal paste should be applied after dog bite. A study done by Sekhon AS et al (2002) also revealed many myths and false beliefs associated with wound management such as application of oils, herbs, and red chilies on the wounds inflicted by rabid animals. [7]

A study done by S. Sehgal, D. Bhattacharya et al. (1994) in Delhi on the victims of dog bite reported that by the incidence of mortality from dog bite could be prevented by proper wound toilet with soap and water and prophylactic tetanus toxoid injection.[8] A study conducted by Sekhon AS et al(2002) revealed that only 21.2% students practiced washing wound with soap and water. [7] Rabies expert suggested that a detergent or carbolic soap should be available to the patient for wound washing , although plain water could be used, in case of non-availability of a soap. If the wound was large or deep, it should be cleaned by a dresser or health staff using antiseptic cream or solution. It was important to remove the saliva. Simply washing the wound and application of antiseptic lotion could reduce the risk of rabies by about 50%.

In the present study, only 30.13% students had knowledge that number of ARV doses required were 5 whereas 46.66% students still thought that 14 doses of ARV were required for management of dog bite. It was comparable to the findings of report by CDS of Rabies: Introduction . [9] A study conducted by Sehgal S. et al. (1994) suggested that people had very basic knowledge about anti-rabies treatment getting 14 injection after dog bite, as per the old concept, but not aware of the disease which could occur if they do not manage dog bites properly. About 0.40 million people continue to receive the sheep brain vaccine despite the fact WHO has recommended for its discontinuation.

In our study, very few (9.06%) students knew that anti rabies vaccines (ARV) should be given over arm/ anterolateral part of thigh. (57.68%) students wrongly believed that anti rabies vaccines are given around the umbilicus or intra abdominal. It indicated the need of increase in awareness among students regarding management of rabies among university students. There was highly significant association with knowledge about site for ARV doses. The most widely used WHO Essen regime calls for a 1 ml dose intramuscular, administered in upper deltoid region or anterolateral area of thigh for children on day 0, 3,7,14 & 28 regularly.[10] Study conducted by Singh US [11] , 79% of study subjects told 14 injections and 5.7% told that the site of administration of rabies vaccine was over abdomen. An another study conducted by Bhatia R et al. (1994) revealed that gluteus region is not recommended as it has high fat content that slow the absorption of the vaccine.[12] It implied that the private practitioners should be made aware about correct techniques of rabies vaccines administration.

In case of visit for health services after animal bite, private practitioners (65.6%) was first choice of students. (16.53%) students wanted to go to the government health centers, and (17.86%) preferred to quacks and others traditional healers. It might be due to poor availability of rabies vaccine at governmental health centers. A study conducted by Bhalla S et al. (2005) suggested that 56% of the general practitioners preferred to give the anti rabies vaccine in gluteus region.[13]

Conclusion

It was observed that knowledge on various aspects of the rabies was poor among college students. It was also observed that there are many myths and misconceptions associated with wound management. The modern treatment is available but not properly utilized by the students because they have poor knowledge about current anti-rabies treatment .Awareness is the most effective tool for the prevention of rabies. So, there is strong need to organize awareness activities about rabies prevention using educational session. It may include various interventional activities for health education, distribution of IEC materials and role play activities in colleges to promote prevention through appropriate health-care practices.

Awareness about Periodontal Diseases and Its Management among Medical Students- A Questionnaire Study

Mounika. S[1], Arvina Rajasekar[2]

[1]Intern, Saveetha Dental College and Hospitals, Chennai, Tamil Nadu, India, [2]Senior Lecturer, Department of Periodontology, Saveetha Dental College and Hospitals, Chennai, Tamil Nadu, India

Abstract

Aim: To assess the awareness about periodontal diseases and its management among medical students.

Materials and Method: A web based questionnaire consisting of 11 questions was formulated and circulated among 100 medical students. The responses were then subjected to statistical analysis.

Results and Conclusion: The present study depicts that the level of awareness among medical students is not very encouraging. This emphasizes the urgent need for educating the budding medical students about the periodontal diseases, its association with systemic diseases and its management.

Keywords: *Gingivitis, Periodontitis, Oral health.*

Introduction

Periodontitis is a chronic inflammatory disease which causes destruction of supporting structures of teeth resulting in formation of pathological pocket around the diseased tooth, loss of connective tissue attachment and alveolar bone loss. Eventhough bacterial plaque is the primary etiology of the disease, there are variety of predisposing factors like systemic diseases, genetic background, environmental factors like smoking and stress.[1,2,3] Microorganisms specifically gram negative anaerobic bacteria play a major role with development and progression of periodontal disease.[4,5,6]

The treatment for periodontal disease depends on the factors such as oral hygiene status,[7] gingival condition,[8] pocket depth, attachment level,[9] alveolar bone height. [10] Treatment for a periodontal compromised patient ranges from oral prophylaxis, curettage, flap surgery, osseous surgery, LASERs, extraction of the involved teeth that has poor prognosis, its replacement by means of implants, crowns and bridges etc. The prognosis of any periodontal therapy includes the following factors such as patient's compliance, patient's ability to maintain good plaque control and regular dental visits.

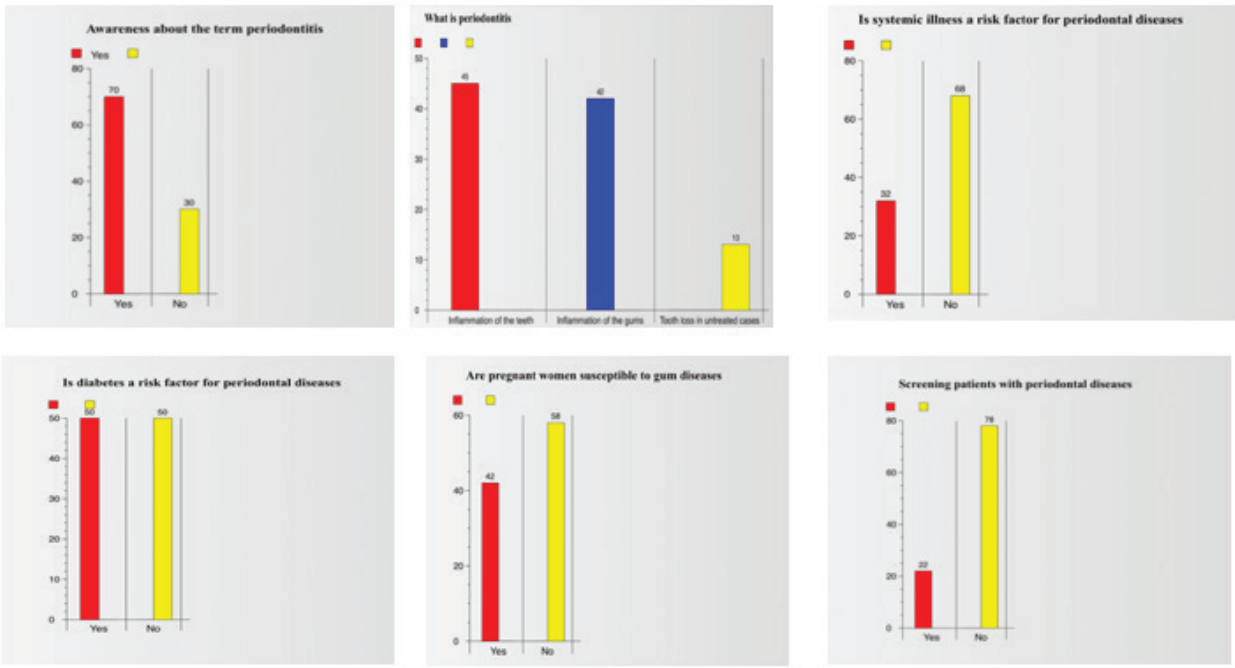
In case of advanced periodontal diseases, the destruction of attachment apparatus calls for extraction of several teeth. In such cases only a few teeth will remain which would be in reduced periodontal tissue support that would eventually result in continuous progression of the disease.[11] It thus becomes difficult to restore the function. Hence, early identification and intervention is very important for better prognosis.

Medical and dental field goes hand in hand towards providing betterment in patient's life. This study pertains to the contribution of the medical students in identifying, referring and suggesting treatment for patients with periodontal diseases. Therefore the present study was conducted to assess the awareness about periodontal diseases and its management among medical students.

Materials and Method

The study was conducted among 100 medical students in Tamil Nadu during the month of January 2019. A web based questionnaire comprising of 11 questions with 7 questions relating to awareness about periodontal diseases and 4 questions relating to periodontal disease management was formulated and circulated. The responses were then subjected to statistical analysis. The study protocol was reviewed and approved by the Institutional Ethical Committee of Saveetha Dental College and Hospitals, Chennai.

Results



Graph 1 shows that among 100 students 70% of the students were aware with the term periodontitis. Graph 2 shows that only 42% was aware that periodontitis is the inflammation of gums. Graph 3 shows that 32% of the students considered systemic illness to be the risk factor for periodontitis. Graph 4 shows that 50% of them considered diabetes as a risk factor for periodontal diseases. Graph 5 indicates 42% of the students were aware that pregnant women are susceptible to gum diseases. Graph 6 indicates only 22% of the students screen patients for periodontal diseases. Study shows only 5% of them very often refer patients with gum diseases to the dentist.Study show shows 42% of the students insisting pregnant women for dental checkup. Study shows that 29% of the students are aware about the interdental cleaning aids.

Study shows 49% were aware that LASERs are used to treat periodontal diseases. Study shows 82% were aware that implants are used to replace the missing teeth.

Discussion

The present study assessed the awareness about periodontal diseases and its management among medical students.

Literature search reveals positive association between periodontal disease and systemic illness. This association is a matter of debate for past fifty years. This is due to the fact that periodontal infection may act as a focus of infection for systemic diseases. In periodontitis, due to increased microbial load, the epithelial barrier is breached and thus microorganisms get an access to the underlying blood vessels thereby entering systemic blood circulation. This is the primary mechanism of periodontitis related systemic diseases.[12-15]

Several studies have revealed positive link between periodontal diseases and other systemic illness like coronary heart disease,[16-18] coronary heart disease-related events such as angina, myocardial infarction and atherosclerosis,[19] stroke,[20] diabetes mellitus,[21,22] preterm low birth-weight infants,[23] chronic obstructive pulmonary diseases and hospital-acquired pneumonia.[24] The agenda behind the present study is to assess the awareness about the periodontal diseases and its management among the young medical students who would be future medical professionals.

A study conducted among final year medical students and interns demonstrated that most of them were not aware about the association between periodontitis and systemic diseases.[25] Our results were in accordance with the above mentioned study, as only 32% of the students considered systemic illness to be a risk factor for periodontitis and 50% of them considered diabetes

as a risk factor for periodontal diseases.

Also, another study by Kalburgi V et al[26] demonstrated that awareness about treatment modalities of periodontal diseases was poor among medical interns and postgraduates. Similarly in our study, only 29% of the students were aware about the interdental cleansing aids, 49% were aware that LASERs are used to treat periodontal diseases.

However, it is important to note that the findings described above cannot be generalized because the study was conducted among a small population. Hence a correspondent study on a large scale is required to give more appropriate results.

Conclusion

The present study depicts that the level of awareness among medical students is not very encouraging. This emphasizes the urgent need for educating the budding medical students about the periodontal diseases, its association with systemic diseases and its management.

Outcome of Transscleral Cyclophotocoagulation in Refractory Glaucoma at a Tertiary Eye Hospital in India

Neetha I R Kuzhuppilly[1], Shibi Dev[2], Shilpa N Patil[3], Aditya Deo[4]

[1]Assistant Professor, Department of Ophthalmology, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, Karnataka, [2]Glaucoma Fellow, Nethradhama Superspeciality Eye Hospital, Kanakapura Main Road, 7th Block, Jayanagar, Bangalore, [3]Glaucoma Consultant, [4]Glaucoma Fellow, Nethradhama Superspeciality Eye Hospital, Kanakapura Main Road,, 7th Block, Jayanagar, Bangalore

Abstract

Background: Transscleral cyclophotocoagulation (TSCPC) is a cyclodestructive procedure used to control elevated intra ocular pressure(IOP) in refractory glaucoma. We studied the efficacy and safety of TSCPC in refractory glaucoma at our hospital.

Method: Data was collected retrospectively from patients who underwent TSCPC over a two year period. Primary outcome measure was success in terms of IOP reduction and the secondary outcome measures were relief of symptoms and incidence of complications.

Results: 27 of 42 patients who underwent TSCPC were included for analysis which included 16 men and 11 women with mean age 61.8±13years and visual acuity ranging from 6/24 to no perception of light.

Mean IOP decreased from 46.0±8.6 mmHg(range: 26-58 mmHg) pre-procedure to 16.7±13.4 mmHg($p<0.001$) at last follow-up. Complete success was achieved in 22.2%, qualified success in 18.5%, 29.6% eyes had hypotony and 29.6% failed. Mean glaucoma medications decreased from 3.2±1.3 to 0.9±1.2($p<0.001$). Patients were asymptomatic; complications were phthisis and vitreous hemorrhage which resolved (one case each).

Conclusion: TSCPC is a safe and effective method of controlling IOP in refractory glaucoma. It may not be restricted to eyes with poor vision potential and a pain-free patient is often the end result.

Key Words: *Glaucoma, Cyclophotocoagulation, Lasers in glaucoma, Pain*

Introduction

Cyclodestructive procedures are used to manage glaucoma in refractory cases where conventional medical and surgical treatments are ineffective in controlling elevated intra ocular pressure(IOP).[1] It can be performed using β-irradiation, electrolysis, photocoagulation, cryotherapy, ultrasound or microwave cyclodestruction. Transscleral Cyclophotocoagulation(TSCPC) is one of the common cyclodestructive procedures in use today. It reduces the aqueous production by damaging the pars plicata, either by destruction of the ciliary epithelium or by reduced vascular perfusion. It may also increase the outflow through an effect on the pars plana.[2]

Many studies have shown that it is an effective method to control IOP in advanced, refractory glaucoma.[3,4,5,6,7,8,9] It has also been reported to have a role in glaucoma management in patients with good vision, with comparable visual outcomes to trabeculectomy or tube shunt surgery.[10] Recent literature suggests that

ORCID: 0000-0002-7297-829X

cyclophotocoagulation is being performed increasingly as the primary surgery for various types and stages of glaucoma.[11,12] Nevertheless, cyclodestructive procedures carry the risk of serious complications like hypotony and visual loss.[13] Literature from the Indian subcontinent regarding TSCPC is limited and hence we studied the efficacy and safety of TSCPC in refractory glaucoma managed over a two year period at our hospital.[14,15,16]

Materials and Method

The retrospective, observational study was conducted at a tertiary eye hospital and included all patients who underwent TSCPC from January 2013 to August 2015. The Institutional Ethics Committee reviewed and approved the protocol prior to conducting the study.

All patients underwent a comprehensive eye examination and the decision to treat was based on presence of pain/symptoms, visual potential, elevated IOP on maximal tolerated medical therapy. Under peribulbar anaesthesia TSCPC(Oculight SLx, Iridex Corporation, Mountain View, CA) was performed using a G-probe(Iris Medical Instruments, Mountain View, CA, USA). The probe was placed adjacent to the corneoscleral limbus, power set at 1750mW for 2000ms and increased until a 'pop' was heard and adjusted to a sub-threshold level. 6-9 spots of laser were applied in each quadrant, with total spots ranging from 24-35.

Patients were examined on the next day, at one week, one month, three months and six monthly after that. At each follow-up, symptoms, vision, the anterior segment, IOP and posterior segment details were documented along with any change in treatment. Patients were excluded from analysis if the follow-up period was less than 3 months. All data was collected from the electronic medical records of the patients at the hospital.

Efficacy was evaluated in terms of IOP reduction, symptom relief and reduction in anti-glaucoma medication(AGM). Complete success was defined as IOP ≤21mmHg and ≥6mmHg without medication or additional treatment. Qualified success was defined as an IOP between 6-21mmHg with additional treatment. Hypotony was defined as IOP <6mmHg and failure as IOP>21mmHg. The safety was assessed in terms of complications that occurred during/after procedure.

Statistical analyses were done with Statistical Package for Social Sciences(SPSS 22) (IBM Corp. IBM NY, USA). Paired t-test was used for comparison of before and post-procedure IOP and AGM. p value <0.05 was taken as statistically significant. Numerical data was expressed in the form of mean±standard deviation when distribution of outcome variable was normal.

Table 1: Vision in the eyes that have undergone TSCPC

Pre-treatment Vision	Vision at last follow-up	Number of eyes
No PL	No PL	13
PL Present	No PL	3
	HM	1
HM	HM	2
	CFCF	1
CFCF	No PL	1
	CFCF	1
	Counting fingers at 3m	2
6/24	6/24	1
6/36	6/60	1
6/60	6/60	1

PL: Perception of light, HM: Hand movements, CFCF: Counting fingers close to face

Table 2: Reduction of IOP post TSCPC

Paired t-test comparing Pre procedure IOP with IOP on follow up	Mean reduction in IOP(mmHg)	Std.Deviation	95% Confidence Interval of the Difference		P value
			Lower	Upper	
First day	24.00	14.68	14.14	33.86	<0.001
First week	28.44	11.44	23.72	33.16	<0.001
First month	24.09	12.19	18.69	29.50	<0.001
Third month	20.55	14.29	13.86	27.23	<0.001
Sixth month	23.64	14.05	17.41	29.86	<0.001
One year	26.61	13.35	19.97	33.25	<0.001
Last visit	29.33	15.05	23.38	35.29	<0.001

Results

A total of 42 patients underwent TSCPC from January 2013 to August 2015. 27 eyes of 27 patients were included in this retrospective analysis of which 16 were men and 11 women. The remaining 15 were referred cases who followed up with their referring doctors. The mean age of patients was 61.81±12.98 years(range:18-74yrs). Visual acuity in the eyes undergoing TSCPC ranged from 6/24 to no perception of light. Ten eyes had vision better than or equal to Hand Movements(HM) and 17 had vision poorer than HM.(Table 1)

The indications for TSCPC included neovascular glaucoma(NVG) (18eyes), post vitreo-retinal surgeries(4), trauma(2), primary angle closure glaucoma(1), primary open angle glaucoma(POAG) (1) and uveitis(1). The median follow-up period was 16months(Q1= 10 months)

The mean IOP reduced from 46.0±8.6 mmHg(range:26-58 mmHg) to 16.7±13.4 mmHg (range:1-46 mmHg). This difference was significant statistically($P<0.001$) in all postoperative intervals accounted for.(Table.2)

Complete success was achieved in six eyes(22.2%), qualified success in five eyes(18.5%), eight eyes had hypotony(29.6%), and eight failed to achieve IOP ≤21mmHg(29.6%). The mean IOP reduction from baseline was 63.7%. In 24 eyes(88.9%) IOP reduction was more than 30% of baseline IOP. Three eyes(11.1%) failed to get an IOP reduction of at least 30% from baseline.

The mean number of preoperative AGM was 3.2±1.3 which decreased to 0.9±1.2($p<0.001$). Four eyes underwent a single repeat TSCPC. Pain was the most prominent symptom, others included redness, watering and diminution of vision. At last follow-up, all 27 patients were pain-free.

There was no statistically significant change in vision after TSCPC. In 66.7% the visual status remained stable, in 14.8% there was improvement and in 18.5% there was worsening of vision.(Table 1) The complications included phthisis of one eye and vitreous hemorrhage in one eye which resolved spontaneously.

Discussion

Management of refractory glaucoma can be challenging. The response to medications is poor, traditional surgery like trabeculectomy can fail and often the patients have intolerable symptoms. In our study we found that TSCPC reduced IOP significantly, with modest success, good reduction of AGM and pain relief.

Previous studies have noted effective IOP reduction by TSCPC in refractory glaucomas.[3,4,5,6,7] Osman and Frezzotti reported a success rates of 82.8% and 63.0% and Schlote described success of 44% in traumatic and aphakic glaucomas.[3,4,7] Our study too confirms this efficacy with mean reduction of IOP of 63.7%, but lower success rate due to larger number of eyes developing hypotony. Hypotony was most common in NVG, similar to report by Iliev.[8] Kaushik hypothesized that Asian eyes needed lower energy levels to reduce IOP, and even with a limited 180 degrees TSCPC, Bezci-Aygün found the procedure reasonably successful.[16,17] The large variation in the success rates among studies is explained by the variation in the etiologies and in the laser parameters. By tailoring the parameters to patient response, the results may be optimized.[18]

Even with a poor visual potential, intolerable pain compels the patients to undergo TSCPC.[5,6] In our study, all patients were pain-free on follow-up, even those in whom TSCPC failed. Pain relief could be because of damage to the sensory nerve supply of the anterior segment in addition to lower IOP.[4] Mistlberger and Schlote have taken pain relief as one of the indicators of success when vision was poorer than HM.[5,6] In our study, among the 16 unsuccessful eyes, 11 had pre-procedure vision poorer than HM. By redefining success in terms of pain relief, the success rate becomes 81.48%.

In the Indian subcontinent, Kaushik reported a reduction of AGM following TSCPC from 2.6±0.9 to 1.8±1.2, similar to our study.[16] Other reports around the world also show significant reduction of AGM.[8,11,23]

There was only one case of phthisis in our study and vision was stable in the majority, unlike earlier reports.[13,19] TSCPC is increasingly tried in patients with good vision potential and as primary treatment in glaucoma.[10,13] Shah found TSCPC effective in eyes with good visual potential, but 33% had a vision drop of ≥2lines due to iritis and cystoid macular oedema.[20] In a study by Ghosh, ≥2lines reduction in vision was seen in 23.9% cases but with a success rate of 84.8% and good safety.[10] Contrary to this, Bleisch found that the visual fields continued to worsen after cyclophotocoagulation and Hasan reported cyclophotocoagulation is less effective that trabeculectomy in POAG.[21,22] Abdull found TSCPC to be safe and effective in cases of primary glaucoma where regular follow-up is not critical.[12] Stanca described a 'slow-burn' technique which can be used in eyes with better vision.[23] These reports are not conclusive about suitability of TSCPC in eyes with good vision or POAG. In secondary glaucomas TSCPC still continues to play a significant role. In fact, Choy and colleagues have found that TSCPC fared better that tube surgery in NVG cases.[24]

High intensity focused ultrasound(HIFU), endocyclophotocoagulation(ECP) and micropulse TSCPC(MP-TSCPC) are newer cyclodestructive procedures.[25,26,27,28] Graber and colleagues have found HIFU to be safer but less effective than TSCPC(25% success versus 52%).[25] ECP is reported to be comparable to other treatments, in refractory glaucoma and pediatric glaucomas.[29,30] One disadvantage of ECP is that it is an invasive procedure.

Zaarour reported a success of 73.3% with MP-TSCPC and Subramaniam found it to be effective and repeatable in keratoplasty eyes with good graft survival.[31,32] Abdelrahman found MP-TSCPC to be better than TSCPC in pediatric refractory glaucomas.[33] MP-TSCPC is not devoid of complications; vision change, pain, corneal edema, hyphema, persistent hypotony, choroidal detachment and phthisis have all been reported.[34] The IOP reduction in MP-TSCPC is partly due to inflammation of the ciliary body and once it settles, IOP can potentially build up again.

In the era of emerging MP-TSCPC, the distinct advantage TSCPC has is that the G probe can be reused after ethylene oxide sterilization, even up to 30 sessions.[35,36] Rootman has devised a sterile disposable cover for G probes eliminating risk of contamination on reuse.[37] In contrast, the MP-TSCPC probe is not reusable making it a more expensive procedure. This advantage of TSCPC makes it indispensable in developing nations around the world.

A few patients who underwent TSCPC at our centre could not be included in the study due to inadequate follow-up. These patients had been referred to our institute for TSCPC and would follow-up elsewhere. Our study is limited by its retrospective nature and unequal

follow-up periods among the patients.

Future studies can be conducted with grading of pain before and after. Studies where the laser is tailored to the patient or disease condition are necessary, to avoid hypotony complications. Further randomized controlled trials would be needed to establish the role of TSCPC in eyes with good visual potential or in cases of primary glaucomas.

Transscleral cyclophotocoagulation is an effective and safe method of controlling intra ocular pressure in refractory glaucoma. It is repeatable, may not be restricted to eyes with poor vision potential and a symptom-free patient is often the end result. It continues to have a role even with the advent of newer cyclodestructive procedures.

A Descriptive Study to Identify the High-Risk Factors of Pregnancy among Married Women in Selected Areas of Derabassidistrict Mohali Punjab

Neha Brari[1], Nikhil Raj[2], Imran Khan[3]

[1]Assistant Professor, [2]Associate Professor, in the mental health nursing department, School of Nursing Science and Research-Sharda University, [3]Assistant Professor in the Medical-Surgical Nursing Department, Prakash Institute of Physiotherapy, Rehabilitation and Allied Medical Sciences, Greater Noida, Uttar Pradesh

Abstract

Background Pregnancy is the concept of the reproductive process through which a baby conceived, incubated and ultimately born into the world.Pregnancy, also known as gestation, is the time during which one or more offspring develops inside a woman.The risk of early loss of fertility is mainly due to low levels of HCG, infections, medical conditions, immune system responses, uterine abnormalities etc.… Identifying a pregnancy as high risk ensures that it receives extra attention and proper care and prenatal care can help to prevent complications. The researcher in the view of facts and figures analysed the present research under various **Objectives** they are to identify the high-risk factors of pregnancy among married women, to find the association between the high-risk factors of pregnancy among married women with selected demographic variables. **Methodology** a non-experimental descriptive research design conducted to find the various high-risk factors of pregnancy. A total of 100 subjects selected via purposive sampling technique. The **results** showed that the mean and standard deviation of high-risk factors of pregnancy were 6.91± 4.50.Among the 100 samples selected, 93% of the married women had low-risk factors of pregnancy, 7% had no risk, and none of them had high and very high-risk factors of pregnancy.Hence, the obstetric results suggested that reducing high-risk cases to be identified as early as possible.The **conclusion** shows that most of the married women had low-risk factors of pregnancy. The study results show a significant association between high-risk factors of pregnancy and the number of pregnancieswas seen to be significant($F=3.22$ at $p<0.05$).

Keywords: *High-risk factors, Pregnancy and married women.*

Introduction Or Background

Being a mother is the most blessed and the most challenging job in the world.(1)The woman's incredibly creative and nurturing powers highlighted during the process of pregnancy.(2)A healthy lifestyle during the pre-natal period of pregnancy is a start to a healthy outcome for infants.(3)A high-risk pregnancy is one that threatens the health or life of the mother or her fetus, while some women are at increased risk for complications even before they get pregnant for a variety of reasons.(4) The risk factors which may lead to complications during pregnancy are maternal age, medical conditions that are pre-existing to pregnancy, medical conditions that occur during pregnancy, lifestyle choices, surgical history, etc. (5)(6).

The preventive measures such as scheduled prenatal visits and check-ups, counselling, attentive lifestyle practices, avoid substances and medications without doctors supervision, regular screening via bio-physiological profiles, treat the pre-existing conditions, test for birth defects and genetic diseases, prevent complications that mothers have had before.(7)(8)

In the present study,the risk factors which put mothers under high-risk pregnancy classified into high-risk physical factors, high-risk medical factors, high-risk gynaecological factors, high-risk obstetrical factors and high-risk family factors. The researcher then identified many indicators representing the broader classifications of high-risk factors. The significant findings of the present study indicated that married women had the highest risk factors of pregnancy in the area of physical

factors and least in the area of gynaecological factors.

Materials and Method

Research Approach

In this research,a quantitative research approach was used.

Research design

Non-experimental descriptive research design were used.

Demographic Variables

The attributes in this study are age, type of family, educational status, occupation, educational status of the husband, occupation of husband,total family income, residence, religion and number of pregnancy.

Settings of the study

The present study was conducted in selected areas of District Mohali, Punjab.

Sample

In this study, the sample comprised of married women.

Sample size

In this study, the sample size was 100

Sampling technique

Purposive sampling was used to select the samples.

Criteria for sample selection

Inclusion criteria

Married women who were:

- Willing to participate in the study
- Available at the time of data collection.

Married women who have one or more children in a previous pregnancy.

Exclusion criteria

- Currently pregnant married women.
- Married women who were never pregnant.

Description of the tool

The instrument consists of the following

- Section A:-Frequency, percentage, mean, standard deviation and association of demographic variables.

o Demographic variables included age, type of family, educational status, occupation, educational status of the husband, occupation of husband, total family income, residence, religion and number of pregnancy.

- Section B:-anthropometric and bio-physiologicalmeasurementto identify

o The physicalhigh-risk factors of pregnancy which consisted of 5 items.

- Section C:-structured interview schedule to assess:

o Medical high-risk factors

o Obstetrical high-risk factors

o Gynaecological high-risk factors

o Familyhistory high-risk factors

Analysis and Findings

The data were analysed using descriptive statistics which included the organisation of data in master sheet, frequency and percentage for analysis of demographic data, mean/standard, the association between high-risk factors of pregnancy and selected demographics carried out by chi-square test.

Section A

Frequency, percentage, mean, standard deviation and association of demographic variables analysed for 100married women who fulfilled the inclusion criteria, and the findings showed in the age the df=3.96, P=0.20 and F=1.53, among age groups 20-25 (n=51, 5.98±4.45), 26-30 (n=39, 7.84±4.41), 31-35 (n=7, 7.71±4.95), 36-40 (n=3, 8.66±4.50). The type of family df=2.97, P=0.03 and F=2.03, among nuclear family (n=64, 6.45±3.95), joint family (n=30, 8.46±5.41), extended family (n=3, 4.00±2.68). The educational status df=4.95, P=0.72 and F=0.52, the married women were illiterate (n=4, 9.00±3.74), primary education (n=13, 6.07±4.44), secondary education (n=33, 6.39±4.32), senior secondary (n=29, 7.24±4.81), graduates and above

(n=21, 7.38±4.70). The occupation df=2.97, P=0.26 NS F=1.34, married women with government jobs were (n=7, 4.57±4.46), private jobs (n=17, 7.88±4.12), home maker (n=76, 6.90±4.57). The educational status of husband df=2.97, P=0.47 and F=0.733, husbands had secondary education (n=31, 7.48±4.92), senior secondary (n=35, 7.11±4.12), graduate and above (n=34, 6.17±4.52). The occupation of husband df=3.96, P=0.01 and F=2.10, the husbands had occupation in government job (n=20, 5.95±4.66), private jobs (n=41, 7.43±4.22), self employed (n=35, 6.14±4.49), unemployed (n=4, 13.00±0.00). The total family income df=2.97, P=0.59 and F=052, under 5001-10000 (n=19, 7.42±3.80), 10001-15000 (n=41, 7.21±5.14), above 15000 (n=40, 6.35±4.15). The residence of married women df=2.97, P=0.92, and F=0.08, residence of urban area (n=23, 7.04±4.59), semi-urban (n=57, 6.75±4.40), rural (n=20, 7.20±4.89). The religion df=9.8, P=0.33 and F=0.97, hindus (n=40, 7.45±4.40), sikh (n=60, 6.55±4.57). The number of pregnencies df=2.97, P=0.04 and F=3.22, women with one pregnency (n=46, 5.89±4.24), Two pregnencies (n=51, 5.98±4.45), three and above (n=20, 6.7±4.74). The obtained F value of the demographic variable number of pregnancy (F=3.22) at $p<0.05$ level were higher than the table value indicating significant association between the high-risk factors of pregnancy and the above variable.

Section B

Anthropometric and bio-physiological measurement represented by frequency and percentage distribution of high-risk physical factors of pregnancy among married women consisted of the respondents, i.e. 100 married women, analysed for having high-risk physical factors of pregnancy. The results showedn=4 (4%) respondents had a height less than 145cm, n=11 (11%) had a BMI more than 29, and n=16 (16%) had a BMI less than 29.n=48 (48%) married women had Hb level less than 10 gm%, none of them had Rh incompatibility and age less than 17 years, and n=5 (5%) respondents had aged more than 35 years.

Section C

Structured interview scheduled results of medical risk factors, Gynaecological high-risk factors, Obstetrical high-risk factors and family history high-risk factors

a. Frequency and percentage distribution of high-risk medical factors of pregnancy among 100 married women, reveals that among the married women having high-risk medical factors of pregnancy, n=11 (11%) of the married women had high blood pressure, n=7 (7%) in each had diabetes mellitus and kidney diseases, n=0 (0%), i.e. none of them had Convulsions, Tuberculosis, HIV/AIDS, Endocrinal disorder and took drugs like phenobarbital, streptomycin and folic acid antagonists etc., n=4 (4%) had lung diseases, n=2 (2%) in each had thyroid disease and cardiopulmonary diseases, only 1% had hepatitis and 32% of the married women took excessive amount of caffeine.

b. Frequency and percentage distribution of obstetrical history high-risk factors of pregnancy among 100 married women, obstetrical history high-risk factors of pregnancy, 30% of the respondents had history of abortions, 8% in each had history of high blood pressure and history of amniotic sac rupture before completing 37weeks, 2% in each had history of convulsions and history of pregnancy outside the normal uterine cavity (fallopian tubes, ovary, abdomen, cervical canal etc., 24% had history of anaemia, 6% in each had history of excessive bleeding immediately after delivery, history of abnormal fetal presentation (breech, face, brow, compound etc.) and history of puerperal fever and sepsis, none of them had history of excessive bleeding within 6 weeks after delivery, history of excessive bleeding (from 24h week to term), delivered more than five times, excess amount of amniotic fluid, delivered a baby with birth defects (clef lip, palate, anencephaly, spina bifida etc. and history of cord prolapsed), 3% in each had history of more than one foetuses develop simultaneously in the womb and less amount of amniotic fluid, 4% had history if instrumental delivery (forceps and vacuum), 18% had history of delivery of large baby (weight 3.5kg or more), 5% had history of delivery of dead fetus, only 1% had history of neonatal death (within 28 das), 7% had history of delivery of baby before term (before 37weeks of gestation), 11% had history of delivery of baby after term (beyond 42 weeks of gestation) 14% had previous delivery by untrained dais and 10% had history of caesarean section.

c. Frequency and percentage distribution of high-risk gynaecological factors of pregnancy among 100 married women, high-risk gynaecological factors of pregnancy: in this study, it was found that 1% of women had incompetent cervix,none of them had contracted pelvis, pelvic inflammatory diseases, uterine malformations and syphilis. 2% of women had polycystic ovarian disease and uterine prolapse, respectively. Around 12% of women had a bladder infection, and 3%

of women had fibroid uterus.

d. Frequency and percentage distribution of family history with high-risk factors of pregnancy among 100 married women; in this study, 20% of the women had family history of diabetes. 29% had family history of high blood pressure. 2% of family history of more than one fetus developed simultaneously in the womb in previous pregnancy/pregnancies, and 11% of married women had a family history of abortion (maternal side)

Note: The findings of the study in relation to percentage distributions of married women according to their level of high-risk factors of pregnancyshows that out of 100 married women, 7% of the married women had no risk, 93% married women had low risk, and none of the married women was having high risk and very high-risk factors of pregnancy.

Conclusion

The descriptive study showed that the mean and SD of high-risk factors of pregnancy was 6.91 and ± 4.50 and these results were interpreted with 100 married women assessed underhigh-risk medical factors, high-risk obstetrical factors, high-risk factors gynaecological, family history high-risk factors. The overall risk stood at low risk among married women. The study also showed a path to assess various risk factors affecting married women.

Discussion

Frequency, percentage, mean, standard deviation and association of demographic variables depict that the obtained F value of the demographic variable,i.e. a number of pregnancy ($F=3.22$) at $p<0.05$ level were higher than the table value indicating a significant association between the high-risk factors of pregnancy.

Anthropometric and bio-physiological measurement represented by frequency and percentage distribution of high-risk physical factors of pregnancy among married women depicts that among all he married women having high-risk physical factors of pregnancy, 4% respondents had height less than 145cm, 11% had BMI more than 29, 48% married women had Hb level less than 10 gm%, none of them had Rh incompatibility and age less than 17 ear and 5% respondents had aged more than 35 years.

Structured interview scheduled results of medical risk factors:reveals that among the married women having medical high-risk factors of pregnancy, 11% of the married women had high blood pressure, 7% in each had diabetes mellitus and kidney diseases, none of them had Convulsions, Tuberculosis, HIV/AIDS, Endocrinal disorder and took drugs like phenobarbital, streptomycin and folic acid antagonists etc., 4% had lung diseases, 2% in each had Thyroid disease and Cardiopulmonary diseases, only 1% had Hepatitis and 32% of the married women took excessive amount of caffeine.

Structured interview scheduled results ofobstetrical high risk factors: reveals that among he married women having obstetrical history high risk factors of pregnancy, 30% of the respondents had history of abortions, 8% in each had history of high blood pressure and history of amniotic sac rupture before completing 37weeks, 2% in each had history of convulsions and history of pregnancy outside the normal uterine cavity (fallopian tubes, ovary, abdomen, cervical canal etc., 24% had history of anaemia, 6% in each had history of excessive bleeding immediately after delivery, history of abnormal fetal presentation (breech, face, brow, compound etc.) and history of puerperal fever and sepsis, none of them had history of excessive bleeding within 6 weeks after delivery, history of excessive bleeding (from 24h week to term), delivered more than five times, excess amount of amniotic fluid, delivered a baby with birth defects (clef lip, palate, anencephaly, spina bifida etc. and history of cord prolapsed), 3% in each had history of more than one foetuses develop simultaneously in the womb and less amount of amniotic fluid, 4% had history if instrumental delivery (forceps and vacuum), 18% had history of delivery of large baby (weight 3.5kg or more), 5% had history of delivery of dead fetus, only 1% had history of neonatal death (within 28 das), 7% had history of delivery of baby before term (before 37weeks of gestation), 11% had history of delivery of baby after term (beyond 42 weeks of gestation) 14% had previous delivery by untrained dais and 10% had history of caesarean section.

Structured interview scheduled results ofGynaecological high-risk factorsdepicts that among the married women who have gynaecological high-risk factors of pregnancy: in this study, it was found that 1% of women had incompetent cervix. None of them had contracted pelvis, pelvic inflammatory diseases, uterine malformations and syphilis. 2% of women had polycystic ovarian disease and uterine prolapse, respectively. Around 12% of women had a bladder infection, and 3% of women had fibroid uterus.

Structured interview scheduled results offamily history high-risk factors:depicts that among the married women who have a family history of high-risk factors of pregnancy: in this study 20% of the women had a family history of diabetes. 29% had a family history of high blood pressure. 2% of a family history of more than one fetus developed simultaneously in the womb in previous pregnancy/pregnancies, and 11% of married women had a family history of abortion (maternal side)

Effect of Plyometric Training on Jumping Performance and Agility in Badminton Players

Neha Bhosale [1], Ujwal Yeole[2], Manasi Chavarkar[3]

[1]Assistant Professor, [2]Principal, [3]Student, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth Pune

Abstract

Background: Badminton is a popular worldwide sport that requires fast and powerful shots and agile footwork. It is one of the fastest racket sports in the world. [1]The agility and vertical jump are important motor skills to hit a shuttlecock at different positions around the court. **Objectives:** To see the effect of plyometric training on jumping performance and agilityin badminton players.**Methodology:** 30 participants, both male and female were included in this study. All participants were tested for agility and vertical jump before and after 6-weeks plyometric training period. Agility performance was assessed using Agility T-Test and vertical jump height was assessed using vertical jump test. The participants performed plyometric training thrice a week, for 6 weeks.**Results:**The data was collected and statistically analysed using paired t test.The study concluded that there was an increase in vertical jump height(40.37±7.690cm) and agility (11.74±1.366sec) post plyometric training with significant p value (<0.0001).**Conclusion:**Our results show that six weeks plyometric training improved jumping performance and agility in badminton players.

Key words:*Agility, vertical jump height, plyometric training, badminton players, sports physiotherapy.*

Introduction

Badminton is a worldwide popular sport that requires fast and powerful shots and agile footwork. In the world it is considered asone of the fastest racket sports; the speed of badminton smashes can be as high as 30m/s.[1]

Badminton is a racket sport in which two or four people can participate, with a temporal structure characterized by actions of short duration and high intensity.Players require their maximum limits of speed, agility, flexibility, endurance and strength.The game consists of combination of high-intensity short rallies (anaerobic system) and longer, moderate or high-intensity rallies (aerobic system). [2]The game involves most of the body parts and majority of large muscle groups.[3]

Badminton players have toreact to the moving shuttlecock and adjust their body position rapidly and continuously throughout the game. Players have to maintain their centre of gravity within the base of support while performing very rapid and asymmetrical upper limb movements[1] and it also requires extremely volatile movements to be carried out over a small court area. Changes in direction are necessary after each shot and all movements must be completed quickly with high-quality technique and good control. Vertical and lateral jumps are more common in all aspects of the game. [4]

Few authors reported that acute injuries are common during training and badminton game. Lower limb injuries were commonly reported. It is assumed that repeated jumping and the deviations in jumping and landing technique during the games are the primary causes of injury in lower limbs.[5]

The higher the player hits the shuttlecock the higher the height of the jump – the steeper the trajectory and the shorter the path of the shuttlecock.The height of the hitting point depends on jump ability, spatiotemporal perception, flight behaviour of the incoming shuttlecock, as well as the temporal interconnection of sub-segments. [6]

The vertical jump test is a physical fitness test. The main goal of this test is to measure how high an athlete can jump which is based on their explosive lower body power. Hence this was taken as outcome measure to assess vertical jump height in badminton players in current study.[7]

Second outcome measure of this study was Agility T test which is described as a 4-directional agility and body control that evaluates the ability to change directions quickly while maintaining balance without loss of speed. The test is relatively simple to manage, because it requires minimal equipment and preparation. The T-test is a reliable and valid measure of agility, leg power and leg speed to test the performance. [8]

Agility was related to physical performance during a badminton match. Defined as a rapid whole-body movement with change of direction and/or velocity in response to a stimulus. Agility is one of the most important aspects that should be developed and usually implemented in strength and conditioning programs for team sports athletes. [9]

Plyometrics is a known form of 'ballistic training', designed to improve jumping performance capabilities. Plyometrics are used to improve power output and increase explosiveness by training the muscles to work more in a shorter amount of time, it also helps to improve landing mechanics (reduce valgus stress and strain), eccentric muscle control, and increase knee flexion and hamstrings activity, which in turn reduce landing forces and reduces the risk of non-contact injuries.It has been shown to be an effective method for improving strength, running economy, agility and sprint ability.[10]

To our knowledge, there are limited number of studies investigating the effects of plyometric training on athletic performance in badminton players hence the aim of this study was to find out the effects of plyometric training on jumping performance and agility in badminton players.

Method

Study Design: Experimental

Selection of subjects: The participants selected for the study were 30 badminton players with age group 18-25 years and year of experience more than 1 year in sports club. The players were selected according to the inclusion criteria exclusion criteria. Inclusion criteria were both males and females, and the players willing to participate. Exclusion criteria were any recent fracture or musculoskeletal injuries to lower limb.

Materials used are measuring tape, cones, stopwatch, measuring tape, chalk, data collection sheet, consent form pen, pencil.

Procedure:

Ethical clearance was taken from the Institutional Ethical Committee and informed consents were taken from each participant. Participations were selected according to inclusion and exclusion criteria. The aim, objectives and method of study was explained to the participants. Consent was taken on the consent form. The Vertical jump test and Agility T test was conducted using standardized procedure. The participants performed plyometric exercises thrice a week for 6 weeks period. The plyometric training program included progressive exercises similar to the protocol of miller et al, with few modification.[11]

Plyometric training program:

Week	Exercise	Sets X rep
1	Side to side ankle hops Standing jump and reach Front cones hops Push up plus	2X15 2X15 5X6 2X15
2	Side to side ankle hops Standing long jump Lateral jump over barrier Double leg hops Scapular squeeze	2X15 5X6 2X15 5X6

Cont ... **Plyometric training program:**

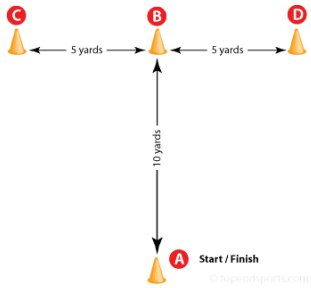
3	Side to side ankle hops Standing long jump Lateral jump over barrier Double leg hops Hand walk for 1min	2X15 5X6 2X15 5X6 2X20
4	Lateral jump over barrier Single leg bounding Lateral jump single leg Diagonal cone hops Cone hops with 180 degree turn Push up	2X15 4X7 4X6 4X8 4X5 2X20
5	Lateral jump over barrier Single leg bounding Lateral jump single leg Diagonal cone hops Cone hops with 180 degree turn Wall scapular push ups	2X15 4X7 4X6 4X8 4X5 3 X10
6	Diagonal cone hops Hexagon drills Cone hops with 180 degree turn Double leg hops Lateral jump single leg Ceiling punches	2X15 2X12 4X6 4X8 4X6 2X15

Procedure of Vertical jump test:

The athletes have to stand side on to a wall and reaches up with the hand closest to the wall. Keeping the feet flat on the ground, the point of the fingertips is marked with the chalk. This is called the standing reach height. The athlete then stands one step away from the wall, and jump vertically as high as possible using both arms and legs, attempting to touch the wall at the highest point of the jump. The difference in distance between the standing reach height and the jump height is recorded.[7]

Procedure of Agility T test: 3 cones were placed at each corner (B, C, and D) in an attempt to monitor accuracy of test. Subjects began with both feet behind the starting point A. At their own discretion, each subject sprinted forward 9.14 m (10 yd) to point B touches at the

base of a cone with the right hand. They then shuffled to the left 4.57 m (5 yd) and touched the base of a cone (C) with the left hand. Subjects then shuffled to the right 9.14 m and touched at the base of a cone (D) with the right hand. They then shuffled to the left 4.57 m back to point B and touched with the left hand. Subjects then ran backward; passing the finishing line at point A. Time is measured using stop watch. [8]

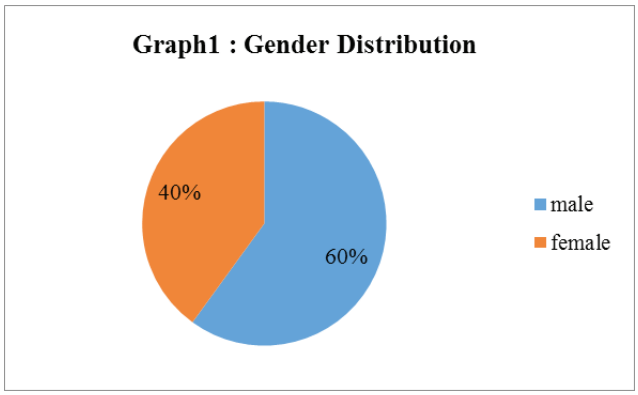


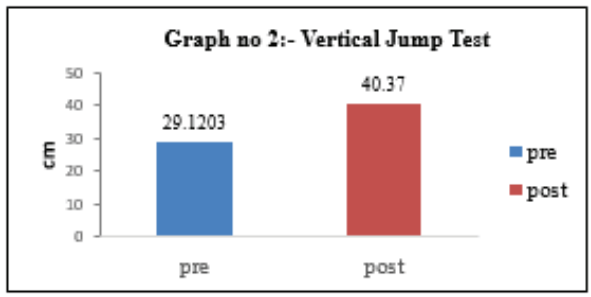
Statistical Analysis

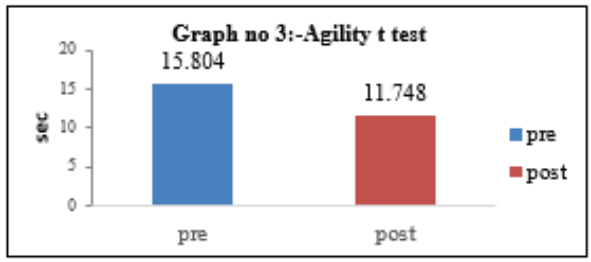
The data was statistically analyzed and passed all the Normality tests. Results of the pre- and post-tests were compared using the two tailed Paired t test. Statistical significance was set at $p \leq 0.05$.

Results

As shown in graph no 1, out of 30 samples 18(60%) were males and 12(40%) were females. Graph 2 shows mean values of pre and post intervention of vertical jump test. Mean values of pre intervention were 29.12±7.104 cm and post intervention were40.37±7.690with extremely significant p value (<0.0001).Graph 3 shows mean value of pre intervention were 15.804±2.410 and post intervention were 11.74±1.366 with significant p value (<0.0001).







Discussion

Besides table tennis and tennis, badminton is one of the fastest Olympic racket and net sports in the world. Included continuous change between accelerated and decelerated movements, Badminton-specific running paths, jumps, and lunges[4]

It is appropriate for all ages, women and men and even disabled persons. Beginners can start playing badminton early since the basics are learned quickly.[6]

The aim of this study was to find the effect of plyometric training on jumping performance and agility in badminton players. The sample size was taken from sports academies. Every individual's consent was taken by filling up the consent form. Men and women both were included for the study. 30 samples were taken according to the inclusion and exclusion criteria out of which 18(60%) were males and 12(40%) were females as shown in table no 1 and graph no 1.Participants with any musculoskeletal injury were excluded from study.

In current study there was increase in post intervention of vertical jump height with mean value of post intervention 40.37±7.690 as compared to mean value of pre intervention 29.12±7.104 with significant p value (<0.0001) . This may be result of production of muscle force and power coupled with smaller increase in isometric contraction which activates the stretch shortening cycle of the muscle. These physiological adaptations facilitated increases in vertical jump height.[12]Systematic review and meta-analysis done

by EmilijaStojanovicet al, confirms longer plyometric training durations (≥10 weeks) provide larger improvements in vertical jump performance in female athletes.[9]Paul E. Luebbers et al included2 equal volume plyometric training programs of both 4-week and 7-week durations, resulted in significantly increases in vertical jump height, vertical jump power and anaerobic power in physically active young men.[13]

Another result of the present study as shown in table no 3 and graph no 3 was that 6 weeks of plyometric training improves agility time with post intervention 11.74±1.366sec as compared to pre intervention 15.804±2.410sec with significant p value (<0.0001). Agility training is re-enforcement of motor programming through neuromuscular conditioning and neural adaptation of muscle spindles, golgi-tendon organs, and joint proprioceptors by enhancing balance and control of body positions during movement.[11]

Previous studies have been reported that plyometric training was effective in improving muscle strength, vertical jump, speed, and agility in all types of sports. Plyometric drills typically involve stopping, starting, and changing directions in an explosive manner. These movements are important components that can assist in developing agility.[13]TarikOzmen et al, observed that 6 weeks plyometric training improved agility and vertical jump in adolescent badminton players.[14] Kevin Thomas et al, compared the effects of two plyometric training methods on power and agility in youth soccer players. After six weeks, they found significant decrease in agility times and improvement in sports performance. [12]

Plyometric exercises involve explosive lower extremity movements and fast muscle contractions [12] when the active muscle switches from a rapid eccentric muscle action (deceleration) to a rapid concentric muscle action (acceleration, it creates a stretch reflex that produces a more forceful concentric muscle action. The faster the muscle is stretched, the greater the force produced, and the more powerful muscle movement [13] it also facilitate peripheral and central neural adaptations that increase joint proprioception and kinesthetic awareness.

Overall our study shows improvement in both jumping performance and agility. However, this study was pre-post experimental design, so it cannot be concluded that improvement showed was only because of our training programme hence further study can be done.

Conclusion

Study concluded that 6 weeks of plyometric training showed improvement in jumping performance and agility in badminton Players.

Effect of Physiotherapeutic Exercises on Fatigue and Quality of Life in Cancer Patients

Nilesh Maharudra Andhare[1], Ujwal Laxman Yeole[2], Forum Varde[3]

[1]Assistant Professor, [2]Associate Professor and Principal, [3]Intern BPT, Department of Physiotherapy, Tilak Maharashtra Vidyapeeth, Pune

Abstract

Background: Cancer patients undergone chemotherapy or radiotherapy reports cancer-related fatigue(CRF), which impairs their aerobic capacity and quality of life (QOL). **Aim**: To study the effect of physiotherapeutic exercises on fatigue and quality of life in cancer patients. **Setting and Design**: Ethical approval was obtained from Institutional ethical committee. The cancer patients visiting affiliated cancer rehabilitation centers at Alandi were assessed by oncologist and referred for physiotherapy. The patients were evaluated for fatigue and quality of life (Total 64 patients). Patient satisfying inclusion criteria and who willing to participate in study were recruited and further randomly allotted in two groups using Random sampling method. **Methods and Material**: Experimental group (Group A, n=25) received home based aerobic exercise program for 3 days/week for 4 weeks whereas control group (Group B, n=25) received the individually tailored walking program. Pre and post treatment analysis was recorded using Modified Fatigue Impact Scale and SF-36 Questionnaire. **Statistical Analysis**: The Analysed Data showed normal distribution using Shapro-Wilk test, hence parametric Whitney Rank Sum Test was performed to analyse the data within the groups. **Result**: Total 50 patients participated in study. Between group comparisons; group A (n=25, mean age= 44.40±9.92) showed extremely significant ($p<0.0001$), improvement in Modified Fatigue Impact Scale (MFIS) in pre (44.56 ± 9.36) to post intervention (35.16±7.526) than group B(n=25, mean age=51.76±13.47) in pre (44.24 ±8.57) to post intervention (50.68±7.034).As well Quality of life of cancer patients underwent treatment has been significantly improved ($p<0.0001$) in group A (pre= 62 to post=67.52) than group B (pre=.63.94 to post=63.08). **Conclusion**: It is concluded that aerobic training showed greater impact on fatigue and quality of life in cancer patients.

Keywords*: Aerobic Exercises, Cancer, Fatigue, Quality of Life.*

Introduction

Cancer is a term used to describe more than 100 different diseases with the common characteristic of uncontrolled malignant cell growth[1]. The word 'cancer' means crab, thus reflecting true character since 'it sticks to the part stubbornly like a crab'[1]. New growth is termed as 'neoplasia' and is called as 'neoplasm' or 'tumour'[1].

Chemotherapy is a type of cancer treatment that uses one or more anti-cancer drugs (chemotherapeutic agents) as part of a standardized chemotherapy regimen. Chemotherapy may be given with a curative intent (which almost always involves combinations of drugs), or it may aim to prolong life or to reduce symptoms (palliative chemotherapy).[2]

Chemotherapy is a well organised toxicity of taxanes, usually resulting to modification of dose and change in treatment plan. A mass of tissue formed because of excessive, uncoordinated, autonomous, abnormal and purposeless proliferation of cells even after cessation of stimulus for growth which caused it.[2]

Chemotherapy may be given with a curative intent which almost always involves combinations of drugs, or

it may aim to prolong life or to reduce symptoms[2]. During radiation therapy, cancer patients may report cancer-related fatigue, which impairs aerobic capacity, strength, muscle mass, and ultimately, quality of life[2]. Cancer related fatigue can be a significant disability following the treatment of many types of cancer, including breast, colorectal, haematological malignancies and testicular, and have an impact on quality of life. There is a critical need to understand pathophysiological mechanisms, optimize clinical assessment, and develop neuroprotective strategies to prevent neuropathy.[2]

Cancer Related Fatigue on patient's quality of life particularly in relation to perform daily activities and in relation to patient's quality of life is profound and pervasive. Cancer related Fatigue is also associated with considerable psychological distress and can impose a significant financial burden by limiting a patient's ability to work. These effects can extend to caregivers and family members, who may also have to reduce their working capacity in order to provide additional care to the patient having other problems too[4].

Hence there is need to study about impact of physiotherapeutic exercises over cancer related fatigue and quality of life.

Method:

Permission was obtained from the institutional ethical committee. Different cancer rehabilitation centers were approached and permission was obtained prior to the study. 64 patients were evaluated for symptoms using Modified fatigue impact scale and SF 36 Questionnaire. Patients satisfying inclusion and exclusion criteria and who are willing to participate in study were recruited (total 50 patients) and were further randomly allotted in two groups using Random sample technique. Patients with Stage III and IV cancer, critically ill patients, and patients with neurological deficite were excluded from the study. The patients were divided into 2 groups (A and B). Group A (n=25) was given aerobic exercises and Group B (n=25) was given individual tailored walking at home. The Group A patients performed Aerobic exercises for 30 minutes, and Group B performed individual tailored walking for 30 minutes thrice in a week for 4 week.

Protocol: The patients were given 10 minutes of warm up exercises in sitting and standing position which included upper limb and lower limb mobility exercises. For aerobic training the group A was given mild to moderate intensity aerobic activities like Forward Walk, Backward Walk, Side Walk, Step Up and Down, Marching, Lunges while group B was given individually tailored walking. Cool down involved deep breathing and stretching for both groups.

Statistical Analysis: The Analysed Data showed normal distribution using Shapro-Wilk test, hence parametric Whitney Rank Sum Test was performed to analyse the data within the groups.

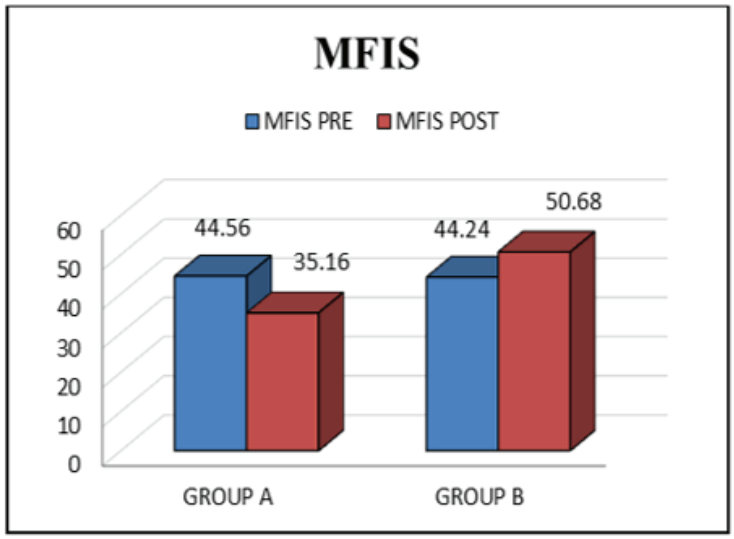
Result

Parameters		Experimental group (n=25)	Control group (n=25)
Age		44.40±9.92	51.76±13.47
Gender	Male	12	7
	Female	13	18
MFIS	Pre	44.56 ± 9.36	44.24 ±8.57
	Post	35.16 ± 7.52	50.68 ± 7.03
	p value	<0.0001	<0.0001
SF36	Pre	62	63.94
	Post	67.52	63.08
	p value	<0.0001	<0.032

*MFIS – Modified fatigue impact scale

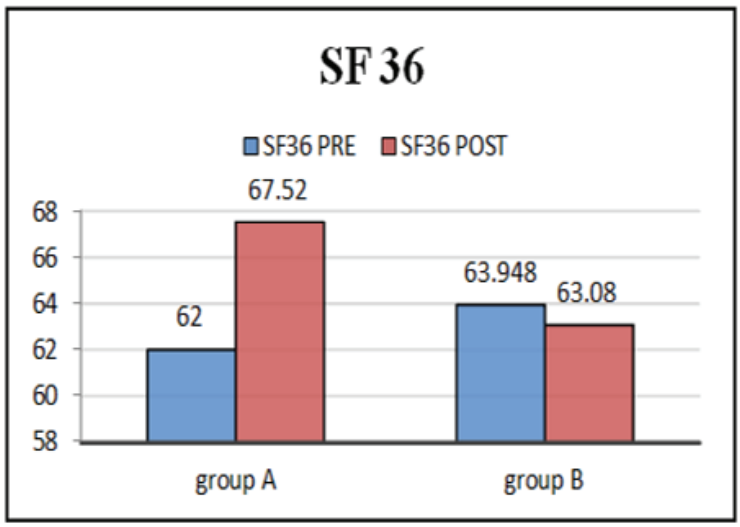
* SF36 – Short form 36

Graph 1: Distribution of patients according to Modified fatigue impact scale



Interpretation: Modified Fatigue Impact Scale shown significant improvements ($p<0.0001$) in fatigue resistance in experimental group (pre- 44.56 ± 9.36 to post- 35.16 ± 7.52) than control group
(Pre-44.24 ±8.57 to post- 50.68 ± 7.03).

Graph 2: Distribution of patients according to Short form 36



Interpretation: Short form 36 questionnaire shown significant improvements ($p<0.0001$) in quality of life in experimental group (pre- 62 to post- 67.52) than control group
(Pre-63.94 to post- 63.08).

Discussion

Cancer related fatigue(CRF) is a physiologic state and a multifaceted subject characterized by persistent, overwhelming exhaustion and a decreased capacity of physical and mental work which does not go with rest.[2]This clinical study provide preliminary support suggesting the combination of home based aerobic training and walking. The present study focusing on effect of programmed aerobic versus individually trailered walking on fatigue and quality of life in cancer patients after 4 weeks of training.

In 2018, Sunil Rajpal and colleague; were mentioned in their study about economic burden of cancer in India is estimated about 83 per 100,000 persons in which more prevalence is observed in females than male[8]. As present study also mentioned about increased incidence of cancer in females than males.

Karen M. et al studied 'A 4week home based aerobic and resistance exercise program during radiation therapy' which provided positive evidence that exercise during radiation therapy may be beneficial for cancer patients[4]. The importance of combing aerobic and resistance exercise was for health related benefits which was well documented in healthy individuals and chronically ill populations, and this combination of exercise modes possessed great potential as an intervention for optimizing recovery during radiation therapy for prostate and breast cancers.Similarly; in present study aerobic training improved fatigue resistance and quality of life in patients who diagnosed with cancer. In 1999, Portenoy Rk and colleague stated that Physical fatigue frequently results from alterations in the muscular energetic systems caused by cancer treatment. The muscle cells obtain energy for work via two metabolic pathways. In the first one, carbohydrates and fats are completely oxidated to water and carbon dioxide in the mitochondria; the energy obtained is stored in the cells as adenosine triphosphate (ATP). This process can only be carried out in the presence of oxygen and is therefore called aerobic. When the oxygen supply is reduced, the cells produce energy through the second metabolic pathway, called anaerobic glycolysis. In this process, glucose is incompletely metabolized, resulting in the production of ATP and lactic acid[8]. Roanne J. et.al studied 'Randomized controlled trial of resistance or aerobic exercise in men receiving radiation therapy for prostate cancer concluded that resistance and aerobic exercises mitigated fatigue and improved the quality of life in cancer patients[5].

Conclusions

The study concludes that physiotherapeutic aerobic training affects fatigue and quality of life in cancer patients.

Acknowledgment: It is a great pleasure in sharing this project. Also I wish to express my sincere gratitude towards oncologist from affiliated hospitals to help me with the study.

A Study to Find Out the Effect of Upright Sitting and Forward Lean Sitting Position on Lung Functions in Stable COPD Patients A Comparative Study

Nitin Ishwarchandra Agrawal[1], Divya Khare[2]

[1]Mpt (cardio-thoracic), Rajkot, Gujarat, India, [2]Mpt Guide, Ayushman College, Barakatullah University, Bhopal, India

Abstract

Back Ground: Chronic Obstructive Pulmonary Disease (COPD) is a major cause of health care burden worldwide and the only leading cause of death that is increasing in prevalence. Patients with Chronic obstructive pulmonary disease (COPD) are severely limited in the ability to carry out activities of daily living due to dyspnoea and breathlessness, this is due to reduction in lung functions. The purpose of the study was to find out the effect on lung functions in forward lean sitting position and upright sitting position in COPD patient.

Aim/Purpose: To find out the effects of Upright sitting position on pulmonary functions in patients with stable COPD.

To find out the effects of forward lean sitting position on pulmonary functions in patients with stable COPD.

Objectives: To compare the change in FEV1, FVC, FEV1/FVC in patient with COPD in the Upright sitting and Forward lean sitting positions.

Methodology: 60 COPD patients were participated in the study. All subjects had undergone spirometry in 2 different positions i.e. position A: Upright sitting position and position B: Forward lean sitting position. FEV1, FVC, FEV1/FVC of subjects were recorded. Same measures were taken for 7 consecutive days. Mean of all 7 days was taken for all measures and used for statistical analysis.

Outcome Measure: FEV, FVC, FEV1/FVC

Results: The results of the above study shows that there are Significant Improvements of Forward Lean Sitting on FEV1, FVC, FEV1/FVC compared to Upright Sitting.

Keywords: *COPD - Chronic obstructive pulmonary disease, FEV1 - Forced Expired Volume in One second, FVC - Forced Vital Capacity, PFTs - Pulmonary Function Tests, Upright Sitting & Forward Lean Sitting*

Introduction

- According to WHO chronic obstructive pulmonary disease (COPD) is a lung disease characterized by chronic obstruction of lung airflow that interferes with normal breathing and is not fully reversible.[1]
- Chronic obstructive pulmonary disease (COPD) is a major cause of health care burden worldwide and the only leading cause of death that is increasing in prevalence.[2]
- COPD is predominately a disease of men and only 40% of cases in India occur in women.

Corresponding author:
Nitin Ishwarchandra Agrawal

Email address: nitinphysio14@gmail.com

Prevalence rate of COPD in India is 5% in males and 3.5% in females. [11] Its prevalence is more in cigarette smoking and bidi. [12]

- In COPD there is increased use of expiratory muscle during normal expiration due to reduced elastic recoiling of the lung tissue, and dynamic hyperinflation.[3]
- There is considerable variability in the relationship between the FEV_1 and other physiologic abnormalities in COPD.
- Studies have confirmed that various postures affect pulmonary function.[4,5]
- However, studies done on specific sitting positions, mainly slumped and upright, to determine a change in pulmonary function.[6]
- The position did not affect forced vital capacity (FVC), respiratory rate (RR), or forced expiratory volume in 1 second (FEV_1).
- Previous research to this point has not examined the relationship between an upright sitting and forward lean sitting posture in a population of patients diagnosed with COPD
- Therefore, the purpose of the present study was to explore population of adults with COPD to investigate whether a forward lean sitting posture, relative to an upright sitting posture, would result in increased respiratory function in patients diagnosed with COPD.

Method

Study Design : A Comparative Study

Duration Of Study 1 Month

Sample Size: 60

Study Sampling : Purposive Sampling

Inclusion Criteria:

1. Age 30-80 years.
2. Both sexes.
3. Physician Diagnosed COPD patients as per GOLD classification
4. No acute exacerbation in past 3 months.
5. Willing to participate in study

EXCLUSION CRITERIA:

1. People with severe cardio vascular, vestibular, musculo-skeletal disease major psychiatric illness, acute metabolic diseases, neurological diseases, tumour.
2. People unable to sit, walk and change the position. And dependent on every ADL activity
3. Patient younger than 30 years and older than 80 years.
4. Unconscious patient
5. Patient with Diabetes and Hyper tension
6. Pregnant women
7. Patient with recent thoracic or abdominal surgeries
8. Uncooperative patients.

MATERIALS USED:

- Examination table and stool, plinth
- Consent form and assessment chart
- Pencil, papers and recording sheet
- Weighing machine, measure tape,
- Spirometer Figure 3: Spirometer

OUTCOME MEASURES:

FEV1:

FEV1 is defined as forced expiratory volume in 1st second during forceful expiration.

It is very helpful measure in assessing COPD its value mostly decrease in COPD and correlate with progression of the diseases.

FEV1 that is reproducible, objective and allows a measurement of the severity of the disease to be categorised. COPD is classified as mild, moderate or severe.

FVC:

FVC is defined as a forced vital capacity. It is the amount of air coming out of the lung forcefully after deep inspiration.

FEV1/FVC:

It is the ratio of FEV1 and FVC expressed in percentage.

FEV1/FVC*100= FEV1/FVC ratio.

Methodology:

Those who fulfilled the inclusion criteria were taken up for the study. The procedure of the study was explained to the subjects. A written informed consent of the subject was taken prior to the study. All subjects were assessed as per assessment form.

60 COPD patients were recruited. All the patients were underwent spirometric measurement in 2 different positions. ***Upright sitting position, forward lean sitting position.***

Assessment:

On the first visit patient was explained about the study measures. Patient who is willing to participate in the study were included in the study. Exclusion criteria and contraindication were checked.

Preparation of the Patient:

Prior to the test, patient was instructed about spirometry and all the procedure.

Patient is instructed to avoid following things before test.

- Smoking for 24 hours
- Drinking alcohol for at least 4 hours
- Eating a large meal at least 2 hours before the test
- Taking short-acting bronchodilators for 6 hours
- Taking long-acting beta-2-agonist inhalers for 12 hours
- Taking any slow-release medications that affect respiratory function and
- Theophylline-based drugs for 24 hours
- Vigorous exercise for at least 30 minutes
- Wearing any tight clothing
- Patient is instructed to empty the bladder prior to test.

PROCEDURE:

After obtaining informed consent, subjects were placed in either a forward lean or upright seated posture, which was determined by the flip of a coin.

Postural position was then counter balanced for the remaining subjects so that an equal number of subjects started with each position.

Position A (FIGURE 1) was defined as an **UPRIGHT SEATED** posture.

Instructions for assuming this posture included the following:

1. Sitting on stool or chair without arm support
2. Head in position assumed normally by the patient
3. Rib cage lifted upward to elongate the spine comfortably with support (a standard lumbar role was placed in the small of the back and the patient was instructed to maintain contact with it.)
4. Scapula retracted to decrease kyphosis of the thoracic spine
5. Ankles and knees at 90

Position B (FIGURE 2) was defined as a **FORWARD LEAN SITTING** posture.

Instructions for assuming this posture included the following:

1. Sitting on stool or chair
2. Head in position assumed normally by the patient.
3. Spine/upper body inclined forward.
4. Elbows and forearm supported on the plinth.
5. Ankles and knees at 90.

A person is allowed to spend as much time as he/she wants to become comfortable.

The patient should be instructed to take a full inspiration through the mouth and to place the mouthpiece in the mouth, ensuring the lips and teeth are securely around the mouthpiece to form a tight seal.

The patient is instructed to blow out, forcibly, as hard and as fast as possible, until there is nothing left to expel. Patients will require some encouragement to keep blowing to provide a complete blow.

Maximum 3 attempts were taken and best among them is chosen.

Same is repeated for 7 consecutive days. Then mean of all 7 days readings is taken for all 3 outcome measures.

Result

Statstics : Values of FEV1,FVC,FEV1/FVC (%pred) of position A and position B are analysed by Z test at 5% level of significance.

Summary of mean & SD of FVC, FEV1, FEV1/FVC (%Pred) values of position A & position B and the result of the Z-test.

Table 1: shows MEAN and SD of the all outcome measures in both groups, difference between two means and their p values, degree of freedom and comments which suggests that differences are significant or not.

Outcome Measures	Position "A" Mean±Sd	Position "B" Mean±Sd	Difference Between The Means	Z – Value	P - Value	Result
FEV1	55.63 ± 4.26	61.87 ± 4.99	6.233	10.886	<0.05	Significant
FVC	49.56 ± 9.01	52.40 ± 8.71	2.833	12.350	<0.05	Significant
FEV1/FVC	58.37 ± 4.46	63.98 ± 4.04	5.613	26.571	<0.05	Significant

FEV1/FVC: The ratio of FEV1 to FVC expressed as a percentage.

MV Minute Ventilation

RR	- Respiratory Rate
SaO2	- Oxygen Saturation
MIP	- Mean Inspiratory Pressure
MEP	- Mean Expiratory Pressure
PFTs	- Pulmonary Function Tests
FRC	- Functional Residual Capacity

Discussion

This study has found FEV_1, FVC, FEV_1/FVC are improved in forward lean sitting position than in upright sitting.

The forward-lean position for dyspnea relief has been reported as a posture that improves diaphragmatic function by reducing abdominal muscle tension.[7,8]

Kera and Maruyamamention that pectoralis major and minor and serratus anterior are easily activated when arms are supported.[9]

So study shows that Cephaled displacement of short flattened diaphragm in forward lean position could lead to stretching and greater tension generation and hence improve diaphragmatic function.[10]

Limitations

1. Sample size was small

2. We have compared only 2 positions i.e. Upright sitting and Forward lean sitting, so the effects of other positions were not signified.

3. We have compared effects on only 3 parameters i.e. FEV1, FVC, FEV1/FVC. Other parameters can also be considered.

Clinical Implication

As this study suggest significant improvement in the spirometric measures (FEV1, FVC and FEV1/FVC) in Forward lean sitting position, Forward lean sitting position will be the position of choice during breathlessness while exercises, and during exacerbation. And physiotherapist should encourage the forward lean sitting in patients with COPD.

Changes in Oral Mucosa during Pregnancy

Nivedha Srinivasan, Arvina Rajasekar

[1]Graduate Student, [2]Senior Lecturer, Department of Periodontics, Saveetha Dental College, SIMTS, Chennai, India

Abstract

The main aim of this review is to understand the changes in oral mucosa during pregnancy. This review highlights the major oral complication during pregnancy. Changes in the gingiva and physiological structure of the tooth take place in addition to hormonal, immunologic, dietary and behavioural changes. Characteristics of pregnancy gingivitis are that it gets swollen, smooth and tends to bleed easily. Enlargement of gingiva may occur but it tends to resolves within few months after delivery. Due to the increase in salivary microorganisms, there may be a decrease in salivary pH and impairment of buffer effect. This may also lead to dental caries or erosion during lactation period.

The dental management of pregnant patients requires special attention. Dentists, for example, may delay certain elective procedures so that they coincide with the periods of pregnancy which are devoted to maturation versus organogenesis. At other times, the dental care professionals need to alter their normal pharmacological armamentarium to address the patients' needs versus the foetal demands. Applying the basics of preventive dentistry at the primary level will broaden the scope of the prenatal care. Dentists should encourage all the patients of the childbearing ages to seek oral health counselling and examinations as soon as they learn that they are pregnant

Keywords: *Pregnancy, Oral mucosa, Gingivitis, Oral Cavity, Pregnancy Granuloma*

Introduction

During pregnancy, women may experience systemic disorders such as respiratory alterations: dyspnoea (in 60-70% of all the pregnant women), hyperventilation, snoring, an upper ribcage breathing pattern and chest widening and rhinitis; hemodynamic alterations: elevation of the coagulation factors V, VII, VIII, X and XII, and reduction of the factors XI and XIII, with an increased fibrinolytic activity to compensate for the increased clotting tendency; gastrointestinal alterations: an increased intragastric pressure and a reduction in the lower oesophageal sphincter tone which is secondary to inhibition of the production of the motilin peptide hormone due to a rise in progesterone concentrations which are observed in this period — which give rise to heartburn (acidity) in 30-70% of all the pregnant women and an almost two-fold prolongation of the gastric emptying time as compared to those in non-pregnant women [17,18]. Nausea and vomiting are experienced by 66% of all the pregnant women, starting approximately 5 weeks after the last menstrual period, and reaching a maximum prevalence after 8-12 weeks. In this context, the morning dental appointments are to be avoided by pregnant women with an increased vomiting tendency due to pregnancy; renal alterations: an increased renal perfusion, particularly during the second half of the pregnancy, which gives rise to an increased drug excretion in the urine.

Oral mucosa is known to be the mirror of the digestive system. During pregnancy changes in the oral mucosa are drastic.

Changes in hormonal levels, such as those that occur during pregnancy, puberty and menopause have varying effects on oral cavity [1]. Many researchers have proposed a direct link between changing hormonal status among female.

Some observations on the sex hormones have been made in the development of pathologic changes role of sex hormone in gingiva. It has been known that sex hormones contribute to the vascular changes in the gingiva during pregnancy. Evidence suggests that due to the alterations in the sex hormones, changes would be present in the normal sub gingival fossa and the

immune response in the oral cavity, resulting in intense (pregnancy granuloma) and frequent gingivitis in pregnant women[2].

If the stage of growth and the extent of dental trial are considered, then normal pregnancy does not essentially contraindicate dental treatment. The patient must be counselled about these transient changes, treatment plan, reassured accordingly. Nausea and vomiting are experienced by 66% of all the pregnant women, starting approximately 5 weeks after the last menstrual period, and reaching a maximum prevalence after 8-12 weeks. In this context, the morning dental appointments are to be avoided by pregnant women with an increased vomiting tendency due to pregnancy; renal alterations: an increased renal perfusion, particularly during the second half of the pregnancy, which gives rise to an increased drug excretion in the urine. Many oral conditions were reported to occur during pregnancy such as gingivitis and periodontal diseases [16].

Other problems that seem to appear in the oral cavity during pregnancy are discussed later. The special treatment and prevention needs dental patients during pregnancy are also discussed along with the discrete pathologic results that include periodontitis and dental caries. Hormonal changes in pregnancy combined with neglected oral hygiene tend to increase the incidence of oral diseases like gingivitis. Gingival bleeding on probing and visible dental plaque is usually seen at sites per tooth for all teeth. Patient with severe gingivitis may require professional cleaning and need to use mouth rinses such as chlorohexidine. Gingival inflammatory changes are generally observed in the second and third month of pregnancy, persist or increase during the second trimester, and then decrease in the last month of pregnancy [8]. Eventually regressing after parturition. To summarize the increased levels of sex hormones found in pregnancy help depress the immune response, compromise the local defence mechanism necessary for good health, and reduce the natural protection of the gingival environment. These changes, combined with a microbial shift favouring an anaerobic flora dominated by P intermedia, are partly responsible for the exaggerated response to bacterial plaque in pregnancy [9]. Moreover, periodontal therapy can be effective in reducing signs of periodontal disease and the level of periodontal pathogens. Thus, periodontal care is very important and should not be ignored o postponed.

Advances in technology have made dental X-rays much safer. Digital X-rays use much less radiation than older systems that use dental film. Studies have shown that using a lead apron will protect you and your foetus from radiation. X-rays are taken in the first trimester only if they are needed for diagnosis or treatment that cannot wait until after the baby is born. After the first trimester, there is even less chance of any negative results from an X-ray[3,16].

Physicians are responsible to address the maternal oral problems and prevent changes in the oral cavity without any further delay.

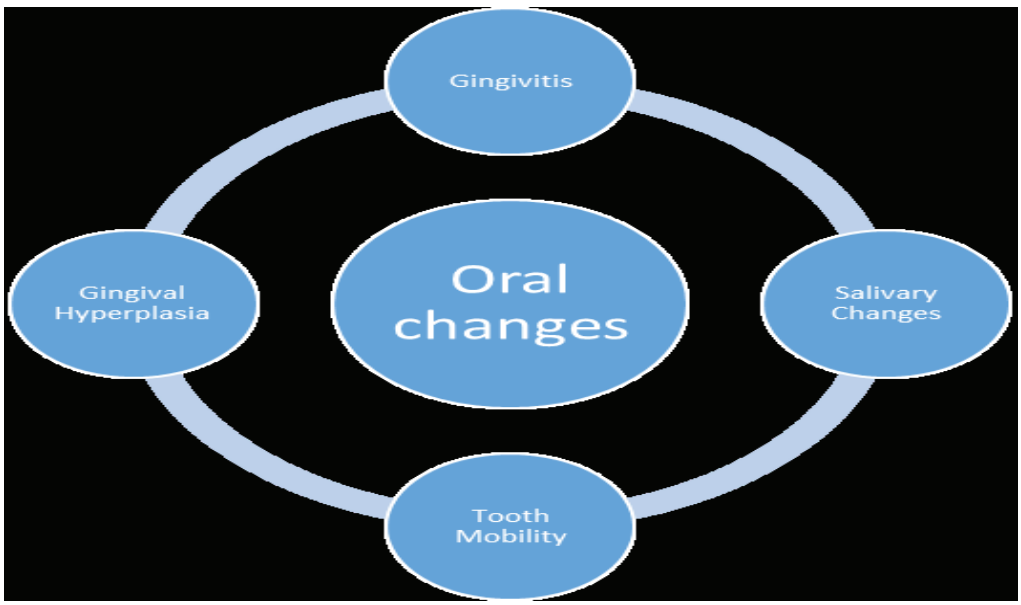

Fig 1 Key Features in the oral cavity during Pregnancy

Tooth mobility

Increased tooth mobility has been detected as it is mainly associated with the presence of relaxin that is released for preparation of the birth passage way [4, 16]. There is normally not any tooth loss unless other complication is present.

Oral tumour

Pregnancy oral tumour occurs in up to 5% of pregnancies. The tongue, palate, or buccal mucosa may also be involved. This is very rarely to be observed unless the tumours bleed, due to which it tends to interfere with mastication. This vascular lesion is caused due to progesterone [5]. The colour tends to vary from purplish red to deep blue, depending on the vascularity of the lesions. In some situations the lesion may need to be excised during pregnancy, such as when it causes discomfort for the patient, disturbs the alignment of the teeth, or bleeds easily on mastication. The patient should be advised, however, that a pregnancy granuloma excised before term may recur. In general, the pregnancy granuloma will regress postpartum; however, surgical excision may be required for complete resolution.

Caries

Pregnancy causes food cravings, and if cariogenic it causes excessive caries [6]. It is an infectious disease caused by bacteria. Prevention can be made by plaque removal, fluoride, and sealant application. Initially appears as white spots. These spots may progress until they result in cavity. Changes in salivary composition in late pregnancy and during lactation may temporarily predispose to erosion as well as dental caries [7]. There are no convincing data, however, to show that the incidence of dental caries increases during pregnancy or in the immediate postpartum period, although existing untreated caries will likely progress.

Gingivitis

Gingivitis is the most common oral disease in pregnancy. It is inflammation of the superficial gum tissue. During pregnancy, gingivitis is aggravated by fluctuations in estrogens and progesterone levels due to decreased immune response. Gingival inflammatory changes are generally observed in the second and third month of pregnancy, persist or increase during the second trimester, and then decrease in the last month of pregnancy [8]. Eventually regressing after parturition. To summarize the increased levels of sex hormones found in pregnancy help depress the immune response, compromise the local defence mechanism necessary for good health, and reduce the natural protection of the gingival environment. These changes, combined with a microbial shift favouring an anaerobic flora dominated by P intermedia, are partly responsible for the exaggerated response to bacterial plaque in pregnancy [9]. Moreover, periodontal therapy can be effective in reducing signs of periodontal disease and the level of periodontal pathogens. Thus, periodontal care is very important and should not be ignored o postponed.

Periodontitis

Periodontits is a destructive inflammation of the periodontium affect about 30% of pregnant women. Toxins produced by the bacteria stimulate a chronic inflammatory response, due to which periodontium is destroyed and hence creating pockets that becomes infected [11]. The symptoms involve red, swollen, or tender gums, bleeding while brushing, flossing or eating hard food, tooth sensitivity, receding gums, persistent bad breath etc. while research continuous into the patho-physiology of a cause and effect relation between oral health and pregnancy outcomes, it is prudent to keep pregnant patients periodontal system free of disease.[12]

Oral health Assessment

Pregnant women can be motivated to have a healthy behaviour. Dental and obstetric teams can be influential in helping women initiate and maintain oral health care during pregnancy to improve lifelong oral hygiene habits [13]. A simple approach can be done by asking questions such as;

1. When was your last dental visit?
2. Do you have swollen or bleeding gums?
3. Do you face any problem while eating or chewing food?
4. How long have you been facing this problem form?

Providing the patients with strict diet would help them. Patients usually require a reassurance that the prevention and treatment of oral conditions include dental x-rays (shielding abdomen and thyroid), are safe during pregnancy [14]. Conditions such as root canals,

restoration (amalgam or composite) or caries should be treated immediately if required. Delaying of such treatments may lead to further problems. A separate counselling session can be taken. It should include reinforcement of routine oral health maintenance, such as flossing daily, limiting carious food and drinks, brushing twice with fluoridated toothpaste, visiting the dentist twice a year.

Dental Management Guidelines during Pregnancy

For the first trimester (1-12 weeks)

During the first trimester, it is recommended that the patients be scheduled to assess their current dental health, to inform them of the changes that they should expect during their pregnancies, and to discuss on how to avoid maternal dental problems that may arise from these changes. It is not recommended that the procedures may be done at this time. The concern about doing procedures during the first trimester is twofold. First, the developing child is at a greatest risk which is posed by teratogens during organogenesis, and second, during the first trimester, it is known that as many as one in five pregnancies undergo spontaneous abortions. Dental procedures which are performed near the time of a spontaneous abortion may be assumed to be the cause, which lead to concerns for both the patient and the practitioner, as to whether this could have been avoided [16, 19].

For the second trimester (13-24 weeks)

By the second trimester, the organogenesis is complete, and the risk to the fetus is low. The mother has also had time to adjust to her pregnancy, and the fetus has not grown to a potentially uncomfortable size that would make it difficult for the mother to remain still for long periods. The positioning of the pregnant patients is important, especially during the third trimester. As the uterus expands with the growing fetus and the placenta, it comes to lie directly over the inferior vena cava, the femoral vessels, and the aorta. If the mother is positioned supine for the procedures, the weight of the gravid uterus could apply enough pressure to impede a blood flow through these major vessels and to cause a condition which is called supine hypotension. In this condition, the blood pressure drops secondary to the impeded blood flow, which causes an asyncopal or a near-syncopal episode. This situation is easily remedied by a proper positioning of the patient on her left side and elevating the head of the chair, to avoid compression of the major blood vessels. The dental practitioner should not hesitate to consult the patient's obstetrician, should any question arise about the safety of a procedure, particularly if there are special circumstances which are associated with the pregnancy [19, 20].

For the third trimester (25-40 weeks)

The fetal growth continues and the focus of the concern now is the risk to the upcoming birth process and the safety and comfort of the pregnant woman (e.g. the chair positioning and the avoidance of drugs that affect the bleeding time). It is safe to perform a routine dental treatment in the early part of the 3rd trimester, but from the middle of the 3rd trimester, routine dental treatments are avoided.

General Recommendations

§ For any women, treatment of oral disease during pregnancy is particularly important because health and dental health insurance may be available only during pregnancy or up to two months post pantrum.

§ Treatment for acute infection or sourced of sepsis should be provided at any stage of pregnancy. A number of antibiotics are safe foe use.

§ Scaling and root planning to periodontal disease can be undertaken safely. Avoid using metronidazole in the first trimester [15].

§ Advise women that oral health care improves a woman's general health through her life span and may also reduce the transmission of potentially caries-producing oral bacteria from mothers to infants [19].

§ Elective restorative and periodontal therapies during the second trimester may prevent any dental infections or other complications from occurring in third trimester [20].

Conclusion

Pregnancy is a condition involving complex physical and physiological changes. Oral care during pregnancy is very important. Pregnant patients should be educated about the importance of maintaining good oral health, expected changes in the oral cavity and routine dental visits. The changes seen during pregnancy are mainly attritubuted due to hormonal changes occurring during that period. Every pregnant woman should be advised to

seek medical and dental care. Failure to do both results in affecting the health of both mother and unborn child.

Research article

Effect of Radiotherapy on the Whole Mouth Salivary Flow Rate, Ph and Its Influence on Oral Hygiene Using Oral Hygiene Index

Nivedha Srinivasan[1], Arvina Rajasekar[2]

[1]Undergraduate Student, Saveetha Dental College, SIMTS, Chennai, India, [2]Senior Lecturer, Department of Periodontics, Saveetha Dental College, SIMTS, Chennai, India

Abstract

Aim: The aim is to understand the alteration in the salivary flow, pH, and oral hygiene in patients undergoing radiotherapy.

Objective: I) To compare the SFR in patient undergoing radiotherapy with normal controls

II) To determine the pH in the content of saliva

III) To assess oral hygiene using oral health index

Materials and Method: A cross-sectional study was conducted among patients undergoing radiotherapy in Dr.Raii Cancer Institute, Chennai, Tamil Nadu, India. A total convenience sample of 20 adults aged between 24 and 60 years were selected, out of which 10 adults were undergoing radiotherapy for head and neck cancer and 10 age and sex matched controls.

Conclusion: Hence this study evaluates the salivary flow rate, pH and oral hygiene of patients undergoing radiotherapy, which is important for dental professionals to familiarize with these complications of radiotherapy to treat patients effectively to improve their quality of life.

Key Words : *Oral hygiene index, salivary flow, xerostomia, radiotherapy, osteronecrosis*

Introduction

Saliva plays a major role in maintaining the oral health. This becomes apparent when the amount and the quality of the saliva is significantly reduced by medications, salivary gland neoplasm, disorders such as Sjogren's Syndrome, and especially ionizing radiation therapy for tumors of head and neck [1].

Saliva in the mouth is a biofluid produced by three pairs of major salivary glands--the submandibular, parotid and sublingual glands--along with secretions from many minor submucosal salivary glands. Salivary gland secretion is a nerve-mediated reflex and the volume of saliva secreted is dependent on the intensity and type of taste and on chemosensory, masticatory or tactile stimulation. Long periods of low (resting or unstimulated) flow are broken by short periods of high flow, which is stimulated by taste and mastication [2].

Radiotherapy is a treatment option for malign tumors whose therapeutic agent is ionizing radiation, which is said to be the type of radiation that promotes ionization in the area in which it is applied, making it electrically unstable. Ionizing radiations are divided into the corpuscular and electromagnetic ones. The corpuscular radiations are represented by electrons, neutrons and photons whereas the electromagnetic radiations are called photons, being represented by X rays and by gamma rays. In the clinical practice, most radiotherapy treatments are done through the use of photons [3].

Ionizing radiations act on the nuclear DNA due to which its reproducing ability is lost or destroyed. Due to the fact of being in a continuous multiplying process, malignant cells can suffer the radiation effects. However, the multiplying ability varies according to cell type. Thus, there is a radiosensitivity scale both for tumor and

normal cells. Embryonic malignancies and lymphomas are radiosensitive tumors, whereas carcinomas are moderately radiosensitive [4].

Radiation therapy for cancer of the head and neck can devastate the salivary glands and partially devitalize the mandible and maxilla. Tumors and elective nodal areas are often in close proximity to radiosensitive normal tissues, a factor due to which the success of radiotherapy is limited.

Acute radiation-induced adverse effects such as mucositis and skin reactions occur during the course of treatment. These effectes are reversible types and thus the patient tends to recover within 3-4 months. Late radiation reactions such as fibrosis and osteoradionecrosis occur more than 3 months after the treatment has been conducted. Such reactions are characterized by their gradual progression [5]. Xerostomia is the single most important factor leading to chronic loss of quality of life in head and neck cancer patients. As a result, the production of the saliva is drastically reduced and its quality is adversely affected.

Oral complication has hence been a common problem among patients undergoing radiotherapy for tumors of head and neck. Radiotherapy and Chemotherapy are known to slow or stop the growth of new cells. These therapies can cause changes in the epithelial lining of the mouth and the salivary glands. This can thus affect the salivary flow and the bacterial balance.

Adverse reactions to radiotherapy will depend on the volume and area being irradiated, on the total dose, on the fractioning, on the age, on the patient's clinical conditions and on the associated treatments. A small increase on tumor dosage is enough for a significant increase on the complications incidence. Acute reactions happen during the treatment and most of the time, they are reversible. Late complications are normally irreversible, leading to permanent incapability and to a worsening of quality of life [6], and they vary on intensity, being normally classified into mild, moderate and severe [7].

While radiation damage to salivary glands is well known in the clinic by its side effects, the mechanism of the ionizing radition causing destruction to the salivary glands is not known yet. Kowever, it is known that the serous acini are more radiosensitive than mucous acini [7]. The fibrous and glangular atrophy bein immediately after the treatment and they intensify until the treatment ends. There has been a debate regarding the complications associated with the radiation approximity. Some authors suggest that with only 20 Gy, 80% of the salivary function is lost but the complications remain reversible. And after 30 Gy the damage caused seems to be permanent [8].

On an average unstimulated salivary flow is 0.3-0.5mL/min and stimulated salivary flow is 1.1-3.0mL/min. This average rate tends to vary due to radiotherapy. The buffering capacity and microbial load of saliva is a very important for oral hygiene maintenance after radiotherapy.

This study aimed to explore the changes in salivary gland function in patients undergoing radiotherapy by performing individual functional performances and to plot the change tendency on every single patient examined.

Materials and Method

A cross-sectional study was conducted among patients undergoing radiotherapy in Dr.Raii Cancer Institute, Chennai, Tamil Nadu, India. A total convenience sample of 20 adults aged between 24 and 60 years were selected, out of which 10 adults were undergoing radiotherapy for head and neck cancer and 10 age and sex matched controls.

The study protocol was in compliance with the Helsinki Declaration and an approval was obtained from the institution's ethical committee. An oral informed consent was obtained from all participants prior to the study procedure. The intraoral examination was conducted by a single examiner under favorable lighting conditions using a sterile mouth mirror, diagnostic probe, and explorer. The clinical findings were recorded and the oral hygiene index was obtained to determine the prevalence of oral hygiene.

The saliva sample collection procedure was standardized prior to the study. The collection of unstimulated whole saliva was performed under resting conditions between 9.30 am and 11.30 am, 90 mins after their meal. The subjects were advised to rinse their mouth several times with (distilled) water and then relax for 5 min before the procedure. The subjects were asked to sit comfortably with head tilted slightly forward and expectorate the saliva accumulated in the floor of the mouth into disposable plastic containers for duration of 30 seconds. The salivary samples were quantified volumetrically using graduated measuring cylinder. The salivary flow

rate was expressed as ml/min. The collected fluid was also used to measure salivary pH using a pH strip. The oral hygiene index was taken into account after thorough examination of the oral cavity was done. The data obtained was subjected to statistical analysis using SPSS package.

Results

A total convenience sample of 20 adults aged between 24 and 60 years were selected, out of which 10 adults were undergoing radiotherapy for head and neck cancer and 10 age and sex matched controls. Their salivary flow, pH and oral hygiene index was examined. The collected results were as such;

Table 1- Comparison in the salivary flow, pH, OHI-S in patients undergoing radiotherapy and clinically healthy patients.

S.No.	AGE	SEX	CONTROL SAMPLES			UNCONTROLLED SAMPLES		
	(years)		SALIVARY FLOW	Ph	OHI-S index	SALIVARY FLOW	Ph	OHI-S index

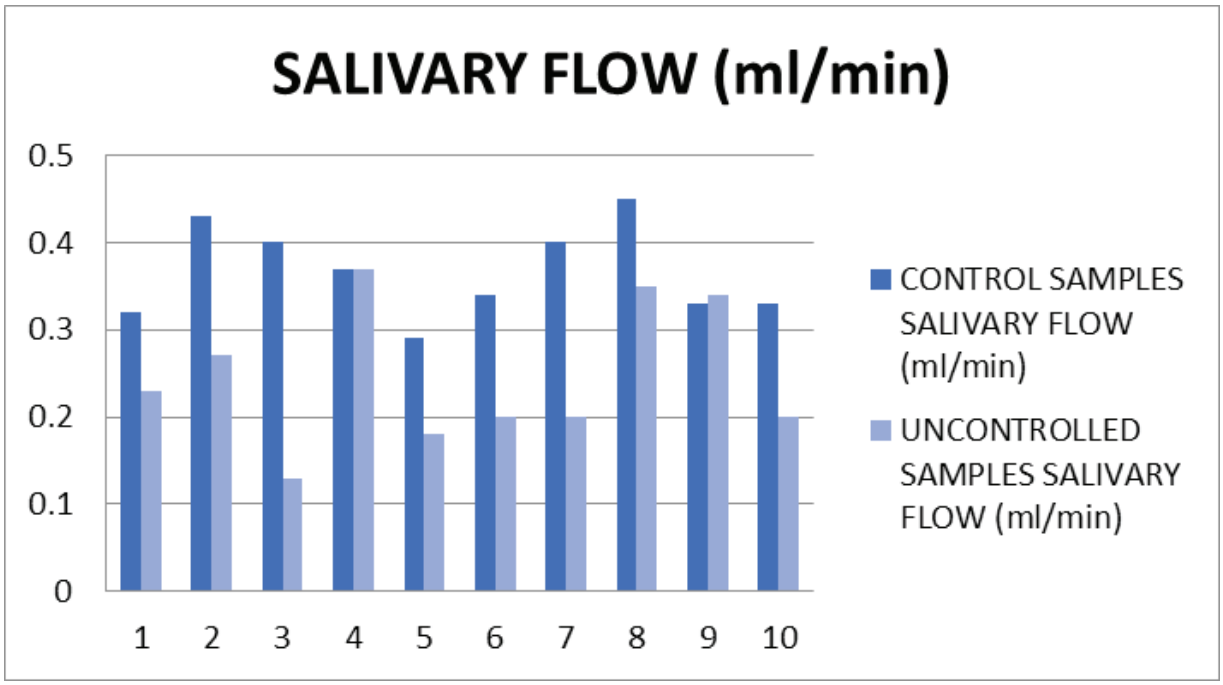
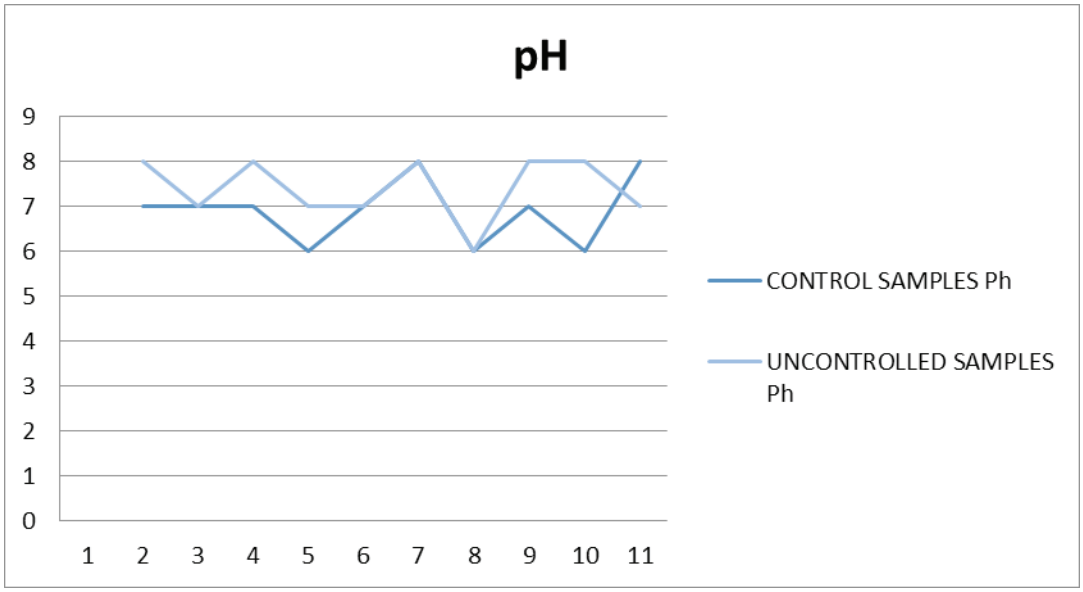
UNCONTROLLED SAMPLE		1.117	0.34535	0.1092

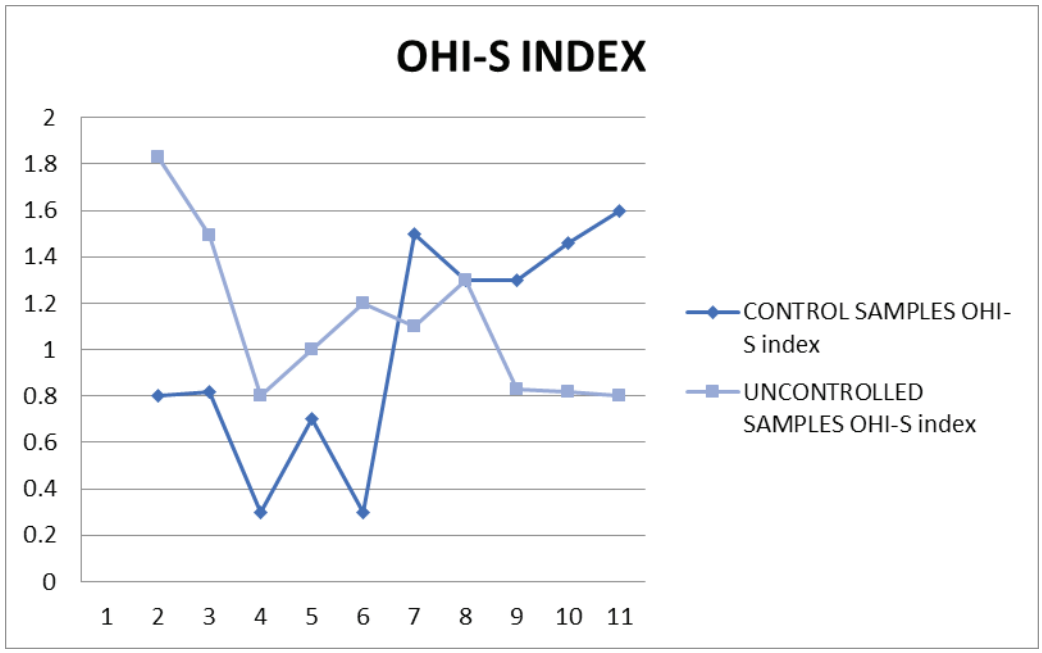
The alteration in the salivary flow seemed to have reduced in patients undergoing radiotherapy (0.279 ±0.11) (p=0.037). The ph had increased when compared with clinically healthy patients (7.4±0.699) (p=0.22). the oral hygiene index did not show any significant change (1.117±0.345) (p=0.109).



Graph 1: alteration in the salivary flow (ml/min).



Graph 2: Alteration in the pH.



Graph 3: Alteration in the OHI-S index.

Discussion

The salivary glands are externally found contrasted at most to the head and neck tumors, and therefore, the ionizing radiation needs to elapse through the salivary organs to viably treat the tumor [9]. Early radiation event to alter cell signal transduction and the late radiation exposure to damage acinar progenitor cells in stem cells niche [10]. Therefore we investigated salivary flow rate, ph and oral hygiene index changes of HCN patients in different age groups after radiotherapy.

One of the main problems resulting from tissue damage generated by radiotherapy is the reduction of salivary flow. The radiation level necessary to cause severe dysfunction to gland tissue is >52 Gy. Some articles [11] indicated that there were relatively large inter individual differences with respect to salivary flow changes. In our study the salivary flow rate reduced from 0.36 (ml/min) to 0.27 (ml/min) [table-2, graph-1]. It was also reported that salivary flow rate reduced 50-70% after radiotherapy.

The major reduction in salivation after radiotherapy is observed in the period from the onset of radiotherapy to 3 months after completion. Amid radiotherapy, the initial 10 days are the most noticeably awful ones as a massive decrease in salivary production takes place; particularly in the first week, it could decrease by 50%– 60% [12]. After this period, the flow rate is reduced by <10% of the initial conditions [13]. CHENG et coll. [14] It is found that when 100 per cent of the parotid glands' volume was irradiated, the parotid glands did not produce saliva at all, but when even a small portion (10 to 20 per cent) of the parotid gland was outside the radiation fields the glands could be stimulated to produce saliva. This fact should be kept in mind when radiation treatment is planned. . Besides, Moller et al [15] also reported that flow rate would slowly recover 4-months after radiotherapy but cannot return to the original level. From the results of the single measurement group, age, sex, and time-interval after radiotherapy were all not significant predictor factors for salivary flow rate. This outcome was similar in our study too. Most articles only reported the data of total saliva or stimulated parotid gland saliva [16]. Kwong et al [17] reported that the mean dose to the parotid glands could be as high as 32.0–46.1 Gy for early stage NPC patients treated with IMRT. Eneroth et al [18] found that radiation as low as 2 to 3 doses of 2 Gy could cause radiation-induced xerostomia.

To examine the salivary Ph, the acid base titrations, pH test strips, and handheld portable pH meters were mentioned.[19] whereas the Modified Ericsson method, Dentobuff method, and Strip method were mentioned for buffering capacity.[20] We used the pH test strips for its advantages of noninvasiveness, simplicity, and elegance. Chia-Yung Lin et al. demonstrated that the pH(P) was 6.60 before radiotherapy, and declined steadily to the lowest 6.00 (P Z 0.148) [21]. Thus it indicated that there was not considerable change in the pH, whereas in our study there was a significant increase in the pH when compared with clinically healthy patients (7.4±0.699) (p=0.22) [Table-2, Graph-2]. Mo¨ller et al indicated the buffering capacity and flow rate were irreversibly reduced after radiotherapy [22]. Edmond H. N. Pow et al. [23] came to a conclusion that eduction in stimulated saliva flow and salivary pH was accompanied by sustained changes in anionic composition. At 2 months following radiotherapy, there was a significant increase in chloride, sulphate, lactate and formate levels while significant reductions in nitrate and thiocyanate levels were found. No further changes in these anion levels were observed at 6 and 12 months. No significant changes were found in phosphate, acetate, or propionate levels throughout the study period.

Oral hygiene habits in patients undergoing radiotherapy and clinically healthy patients were evaluated by recording oral hygiene method, frequency, and the material used. Oral hygiene status of the patient was examined using OHIS index by Green and Vermillion. They were analyzed using paired t-test. The test showed a statistically insignificant correlation for OHIS controlled and uncontrolled samples. This may be due to hyposalivation and poor oral hygiene maintenance by patients during the course of radiotherapy.

Conclusion

The resulting salivary gland hypofunction and xerostomia arising from radiotherapy for HNC can cause a serious diseased condition [24].The stomatologic complications could depend on the type of cancer treatment and the cumulative radiation dose to the gland tissue. They can be reversible or irreversible, transient, or enduring. The best approach to manage the radiotherapeutic patient begins with a careful clinical assessment of the individual case, followed by preventive therapy aimed to reduce oral complications when possible. To minimize patient discomfort and morbidity, an understanding of the deleterious effects of radiotherapy is required. Introducing good oral home care and more frequent oral prophylaxis visits to the dentists before radiotherapy will allow for continuing care during and after therapy. Therefore, the clinician must keep this kind of patients under careful control in order to palliate the symptoms of xerostomia and improve their quality of life.

Sentiment analysis on Healthcare Tweets

P.Kamakshi[1]

[1]*Professor, Department of Information Technology, Kakatiya Institute of Technology and Science, Warangal, India*

Abstract

In today's world variety of posting on social media offer huge information about the health issues, remedies, food and medication. Twitter is an online social networking service in which users can post their opinions about various topics and also cooperate with each other with messages known as "tweets". Tweets are very helpful in sharing the health related issues, medicines, hospitals information. Twitter helps the people to know about the disease symptoms, services and details about the hospital before they go for consultation. *Sentiment* analysis is a metric commonly used to investigate the positive or negative opinion within these *messages*. *Sentiment* analysis methods can be used in *Twitter health* care research. The analysis will help the users to better understand the alternative available. Sentiment analysis can also facilitate the healthcare industry to use reliable data for their growth by taking necessary measures. Sentiment analysis applies software to analyze the patient's tweets regarding their healthcare experiences regarding medicine, doctor, hospitals..It helps users as well as many healthcare organizations to understand their customers opinion and to take necessary measure to rectify the gaps. Ultimately, as more attention is given to such opinion analysis the health standard in the society will improve. Main aim of this paper is to build an algorithm that can accurately classify Twitter messages as positive or negative.

Keywords : *Tweets, sentiment analysis Health care, Healthcare organiations*

Introduction

With more concern towards individual health, today everyone is using Internet to participate in medical forums to gather health-related information, to share experiences about drugs, treatments, diagnosis or to interact with other users with similar condition in communities. Monitoring social media platforms has recently fascinated medical natural language processing researchers to detect various medical abnormalities such as adverse drug reaction. In this paper, we present a benchmark setup for analyzing the sentiment with respect to users' medical condition considering the information, available in social medium called twitter. Twitter is an online social networking medium, where registered users share or post messages known as tweets. There are several unstructured, free-text tweets related to health care being shared on Twitter, which is becoming a popular area for health care research In this work we used this data to observe general users health Awareness towards sentiment analysis has been promising over the last few decades due to the huge popularity of social media. The extraordinary rise in sharing the information in social media is observed in health conscious people such as medical debates which are flooded by many users. Many of such users are likely to be patients who seek help for health-related information, want to share medical problems [4] and their experiences and also want to opt for informational support or opinions from the other users like patients, health-practitioners. These texts present a platform to glance into a user's opinions, sentiments and feelings in a very wide range.Sentiment is a metric normally used to explore the positive or negative judgment within these messages. Exploring the methods used for sentiment analysis in Twitter health care research may allow us to better understand the available options.

Sentiment Analysis estimate whether a part of text called tweet[2] is representing positive, negative or neutral. It is called as opinion mining as it derives the opinion or mind-set of a user who posted the tweet. The objective of this paper is to build an algorithm that can accurately classify Twitter messages as positive or negative, with respect to a query term. Our hypothesis is that we can

obtain high accuracy on classifying sentiment in Twitter messages using machine learning techniques.

Background

With advancement of Internet , its scope is becoming wider day by day. Social Media platforms like Twitter Facebook, plays a major role in disseminating the trendy topics , news at very fast speed. People give their opinion[1] and judgments in large and make the topic trendy. These topics in general are meant to bring consciousness or to promote movies, elections, celebrities. Many organizations take benefit from the people's feedback. They try to enhance their goods, services and also in improving promotion policies. Thus, there is a huge possibility to improve business driven applications by identifying and analyzing fascinating patterns from the huge data available in social media. In particular, the hypothesis try to categorize all the exchanged chat into the label of positive, negative or neutral. This sort of information develop a source for people to assess, rate about a particular movie, products etc.

Sentiment Analysis on Tweets

Twitter is a social networking service where users can send and read short 140-character messages called "tweets." One of the popular areas i.e. in healthcare several unstructured, free-text tweets relating to health care are shared on Twitter. It is becoming a popular area for health care research. Sentiment is a metric[6] commonly used to investigate the positive or negative opinion within these messages. Exploring the methods used for sentiment analysis in Twitter health care research may allow us to better understand the options available for future research in this growing field. Patients and citizens in general, are increasingly using the Internet for searching health information and support. Eurobarometer, which is a series of public opinion surveys reports that nearly 60% of European people had a glimpse on online health-related information and more 90% of them , reported that they will prefer to continue the use of Internet as a main resource in the future to access health-related information. It is found that nearly 80% of searches through search engine are related to health topics, symptoms, treatments. Some of the users show interest in reading others comments or experiences in Health communities and some of the users take online consultation for disease, drug or treatment. The use of online health communities is particularly popular among chronic patients. Surveys show that these patients significantly benefit from social interaction with peers and the sharing of knowledge, experiences and support. Information in online health forums and communities is also of great interest for researchers and professionals, as it allows for research in a very normal process and cannot be simulated in laboratory atmosphere. Some of the examples are the side effects of medicines, alternative treatments are some of the examples.

The health industry is one of the important stakeholders which monitor the people and patients[5] opinion regarding their products and services and the level of their satisfaction. However, the quantity of information is so gigantic that it is difficult for the users to find the information that is really needed. Opinion *mining* is the process which is used to classify a portion of text into positive, neutral or negative. Several unsupervised and supervised learning methods are[7] anticipated to achieve better result.

Process

The dataset about health care sentiment is expected to be from the peoples own opinion about the discussed matter. As the data collected form online resources don't follow any standard format. Such information or reviews are of little use to sentiment analysis and are therefore filtered off, in order to focus on the opinion rich content only. Subjective reviews may also contain some objective statements representing facts and figures which are filtered for the same purpose. Review documents produced by ordinary authors may contain all kind of inconsistencies like grammatical errors, spelling mistakes, over or under use of capitalization, word shortening, The order of tweets are also very important in such discussion as they lead towards common grounds. It not only express sentiment for healthcare problems but also support the opinion with strong reasons which make useful information to public.

Sentiment Analysis is the process of 'computationally' determining whether a piece of writing is positive, negative or neutral. It's also known as opinion mining, deriving the opinion or attitude of a speaker. In this module the sentiment analysis is done on the data i.e twitter tweets which is collected from the input given by the user and it will able to identify whether the given sentence is negative or positive by using natural language tool kit and able to produce whether it is positive or negative. The NLTK module is a massive tool kit, which performs everything from splitting sentences

from paragraphs, splitting up words, recognizing the part of speech of those words, highlighting the main subjects, and then even with helping user machine to understand what the text is all about. The live data coming in from the Twitter streaming API, can be represented by live graph that shows the sentiment trend. The Matplotlib. animation function helps in creating the live graph.

Result

The tweets in the form of texts are classified and sentiment analysis is done .The classified tweets in the form of negative and positive are shown on the screen by using the naïve bayes algorithm and the sentiment analysis modules in which the process of tokenizing, lemmatizing, chunking, tokenizing are done. The input given in the text formats i.e. either an word or sentence. After the sentiment analysis is done on the data which was generated by the twitter related to the input the data will be represented in the graphical form using matplotlib. The graph helps to know the accuracy percentages of individual classifiers[3] which helps in identifying the classifier which gives optimized solution.In the graph by matplotlib, the representation of the analysis of the tweets is in the form of the graph model. The X-axis represents the number of tweets which are generated directly and Y-axis represents the value of the sentiment analysis which is generated for each tweet .

After getting the output of the graph we checked the accuracy percentages of the Naïve Bayes Classifier and the other classifiers for 3000 tweets for the term cancer. The best classifier for 3000 tweets is SGDC Classifier with the accuracy percentage of 89.0.

Conclusion

One of the most popular application of Sentiment analysis which will be helpful for the user in better healthcare is to apply it on the information collected from social media. The workflow of analyzing healthcare content in the social media helps to overcome the limitations of large scale data analysis and manual analysis of user generated textual content in social media. This work can help the users to be updated with the effectiveness of the medicines and it can even suggest them with few better medications available. This project can provide feedback to the healthcare system organization and pharmaceutical companies for the available treatments and medicines. With the help of this project, pharmaceutical companies and healthcare providers can work on the feedback and try to come up with the improvised medicines and treatments. Users are provided with the resources of social media for the corresponding field of healthcare.

A Cross Sectional Study on Prevalence of Anemia in Children Below 5 Years, Kuthambakkam Village, Tamil Nadu

D.Jayashri[1], B.Charumathi[1], Yamini[1], Timsi Jain[2], Ruma Dutta[3], Gomathy Parasuraman[4].

Post Graduate[1], Professor and Head[2], Professor[3], Associate Professor[4], Department of Community Medicine, Saveetha Medical College Hospital,Thandalam, Kanchipuram District

Abstract

Background: Anemia deficiency is a significant public health problem that occurs worldwide in both developed and developing countries. Iron deficiency anaemia in children has been linked to increased childhood morbidity and impaired cognitive development and school performance. Children between 5 and 12 years of age are at a critical stage of intellectual development, and optimization of their cognitive performance during this period could have life-long benefits. **Objectives:**To estimate the prevalence of anaemia among children below five years of age in Kuthambakkam village and to find the factors associated with anemia among study participants. **Material and Methods:** A Cross sectional study conducted among Children below 5 years of age in kuthambakkam area.A pre-tested questionnaire, clinical examination was done to find out anemia among study subjects.The sample size calculated was150.Dataanalysis:Proportions and chi-square was used for analysis. **Results:** The prevalence of anemia was found to be 37(25.17%). **Conclusion**: Measures for treating anaemia should also be strengthened; doses should be modified according to the current anaemia status of the children.

***Key words**: Anemia, Prevalence, children.*

Introduction

Anemia deficiency is a significant public health problem that occurs worldwide in both developed and developing countries. Approximately 300 million children globally had anemia in 2011[1] and 50% of anemia cases are caused by iron deficiency.[2]Anemia is defined as a condition in which the number of red blood cells or their oxygen carrying capacity is insufficient to meet physiological needs which vary by age, sex, altitude, smoking and pregnancy status(WHO). It is a common blood disorder and is one of the major disease in India that exists in all age groups especially seen among preschool children and pregnant women.[3]

Low oxygenation of brain tissues, a consequence of anemia, may lead to impaired cognitive function, growth and psychomotor development, especially in children.[4]Infants, under 5-year-old children and pregnant women have greater susceptibility to anemia because of their increased iron requirements due to rapid body growth and expansion of red blood cells.[5]

National Anaemia Prophylaxis Programme (NAPP) has been set up in all states, the benefits have not yet been appreciated in the target population due to constraints like lack of operational feasibility to estimate the haemoglobin level, orientation of field workers and acceptance of the programme by the beneficiaries. According to National Family Health Survey (NFHS)-4 shows prevalence of anemia among children between 6-59 months age is 59.4% and Tamil Nadu data shows prevalence of anemia 52.3 in rural area.[6]

Anemia is associated with socio-economic, biological, environmental and nutritional factors.The prevalence of anemia within interior parts of India is unknown and due to this lack of information its necessary to conduct a study, which will be helpful in directing the resources to deficit areas,thereby to reduce prevalence of anemia by 3 percent per year among

Post Graduate, Department Of Community Medicine, Saveetha Medical College. Email id: jayashri49@gmail.com, Phone no: 9943080711

children,adolescents and women of reproductive age group (15-49 years) between 2018-2022.[7]

Objectives

1.To estimate the prevalence of anaemia among children below five years of age in Kuthambakkam village.

2.To find the factors associated with anemia among study participants.

Methodology

A cross sectional study was conducted in Kuthambakkam village on July 2017 – September 2017. Children between 1-5 years of age were selected by using Simple Random Sampling method. The sample size of 150 children was estimated from the family folder survey details of our rural field practice area of Saveetha medical college. Using a pre-tested questionnaire socio-demographic details, and factors leading to anemia were collected by interviewing the mothers of under 5 year children. Clinical examination was done by looking for pallor at palpebral conjunctiva, nails, oral cavity and tongue to assess the prevalence of anemia in children. Children who were not present in the field at the time of data collection and those who are not willing to participate were excluded from the study. Data was entered in MS Excel.

Results

Cross-sectional study was conducted among 147 children below 5years of age group of whom 37(25.17%) were found to be anaemic. Among 95 males ,20(21.1%) were found to be anemic and among 52 females 17(32.7%) were found to be anemic.

However no significant association was found with sex, socio-economic status, IFA consumption history and history of deworming. One third of the children are not taking or taking irregularly iron folic acid supplementation.

Table 1- Distribution of anemia among study subjects

S.no	Characteristics	Anemia Present (%)	Anemia absent (%)	Total	Chi square	P value
1.	AGE					
	1-3 years	19 (19.6)	78 (80.4)	97	4.719	0.030 (S)
	4-5 years	18 (36.0)	32 (64.0)	50		
2.	Gender					
	Male	20 (21.1)	75(78.9)	95	2.417	0.120
	Female	17 (32.7)	35(67.3)	52		
3.	Socioeconomic status					
	Upper Middle	10 (27.8)	26 (72.2)	36	1.970	0.579
	Lower Middle	20 (28.2)	51 (71.8)	71		
	Upper Lower	6 (19.4)	25 (80.6)	31		
	Lower	1 (11.1)	8 (88.9)	9		

Discussion

In this Cross-sectional study out of 147 children, 37(25.17%) were found to be anaemic. A study done by Sudhagandhi et al in Kancheepuram district ,results showed that 75.2% of toddlers were anaemic.[8]

A study done by Verma et al, they found that the Prevalence of anemia among male and female pre-schoolers residing in a slum of Delhi was 82.4% and 73.0% respectively.[9]

Conclusion

The Overall Prevalence was found to be lower than the national and state average. Both boys and girls were found to be anaemic. Measures for treating anaemia should also be strengthened; doses should be modified according to the current anaemia status of the children. Mothers should be informed regarding importance of IFA and iron rich food diet for the children.

Limitation: The Hemoglobin level was not estimated in this study.

Conflict of Interest: Nil

Source Of Funding: Nil

Ethical Clearance: Ethical approval was obtained from the Institutional Review Board (IRB) and Institutional Ethics committee. Written informed consent was obtained from the parents of the study participants and information sheet regarding the study was given to all the participants.

Status of Health Literacy among Rural Women to Community Health Center of Sagar Region: A Survey

Gulab Devi[1], Shilpi Verma[2]

[1]Research Scholar, [2]Head & Professore, DLIS, BBAU, Lucknow

Abstract

The present study investigated Health literacy among rural women and management of health services also investigated the functions of the 10 Community Health Center (CHCs) of Sagar region in India. This article is part of a larger study on improving health information among rural women for Community Health. The method for the study is user survey method and tool for the data collection is structured questionnaire. Total questionnaire distributed 300 among rural women to select 10 Community Health Center of Sagar regions. The purpose of this study is to determine the impact factors of health literacy target of rural women in rural areas. Health literacy was thought to impact women reproductive health; yet no inclusive systematic reviews have been conducted on the topic. Our objective was to systematically identify, investigate, and summarize research on the relationship between health literacy and women reproductive health knowledge, behaviors, and outcomes.

Keywords: *Health Literacy, contraception ,Community Health Center, PHCs, Rural Women, Sagar, MP.*

Introduction

Whereas many studies examined the relationship between health literacy and health outcomes,less awareness has been particularly focused on the effects of health literacy on reproductive health of women.[1] Health Literacy refers to the personal characteristics and social resources that people and community need to access, understand, evaluate and use information and services to make health decisions. Limited access to a variety of health care services has also been recognized by rural women. of Sagar region .[2] Although some general works on utilisation of health services in Sagar resion have been attempted, not much work has been done on the utilization of health services by women, especially by rural women. Rural women are fundamental to improvement in Indian country as they play diversified roles in growth. They contribute to the family and wage activities keep in marketing and the allocation of cooking, and like the wives and mothers to make certain the survival of the family and (as a group) the society.[3] Their household activities critically contribute to the maintenance of the local economy to improve sustainable development. Observation on some rural women in Sagar , all sub-district . Community Community Healthcare is a subdivision of the Health community that is categorized into Primary health, Secondary healthcare. Government and health professional organized these services.[4] The goal of community health services is to provide quality care and free mental health treatment for rural women' of Sagar District.

Profile of Sagar District

Madhya Pradesh, located in central India, has a total population of 7.2 crores in 52 districts and 342 blocks (Census, 2011). The district of Sagar is located 180 km from the state capital Bhopal and serves a population of 24 lakhs, 3.5 of whom live in Sagar city.5 The Sagar Health Community division is made up of five bundelkhand districts in M.P. One of which is the district of Sagar.

Sagar District

CHCs of Sub-district/ Blocks of Sagar

S. No	Name of CHCs/ Block/ Rural Population (2011)	CHC/ Beds	District/Nagar Panchayat	Population (In Lakh)
1.	Banda	30	Nagar Panchayat	30,923
2.	Gadakota	30	Municipality	32,726
3.	Devori	30	Municipality	25,632
4.	Jaisinagarnagarnagar	30	Nagar Panchayat	7,392
5.	Kesli	30	Tehsil	116686
6.	Khurai	100	Municipality	51,108
7.	Malthone	30	Tehsil	15,2631
8.	Rahatgarh	30	Nagar Panchayat	31,537
9.	Shahgarh	30	Nagar Panchayat	16,300
10.	Surkhi	30	Nagar Panchayat	1081

Objective of the study

1. To identify the health issue of rural women

2. To find out health information literacy level in different community members;

3. To know about health community center working condition of Sagar district;

4. To find the habits of the health rural area using community health resources;

5. to evaluate the availability and sufficiency of medical, para-medical and supportive staff in CHCs;

Challenges faced

1. Social and Cultural stereotype

2. Poor women participation

3. insufficient Financial support

4. Political interference (local establishment)

Method for data collection

Secondary Data was collected for the structured questionnaire format from the Sagar region and their 10 sub-district. Primary data was collected for the qualitative responses in the questionnaire through interactions with the rural women during the visits to the health facilities.[6] The reference point for assessment of issues and status was all Community Health Center for all selected facilities.

Table 1. Education level of rural women

Options	Banda	Gadakota	Devori	Jaisinagar	Kesli	Khurai	Malthone	Rahatgarh	Shahgarh	Surkhi	Total	%
Illiterate	13	10	7	8	8	7	11	12	9	7	92	35.24
Primary	12	3	16	7	7	18	2	6	11	8	90	34.48
Secondary	5	9	6	6	6	5	1	4	5	8	55	21.07
Higher Secondary	0	2	1	5	1	0	4	0	1	0	14	5.36
Graduate	0	1	0	4	2	0	2	0	0	1	10	3.83
Total	30 (11.49)	25 (9.58)	30 (11.49)	30 (11.49)	20 (9.20)	30 (11.49)	20 (7.66)	22 (9.96)	26 (8.43)	24 (9.20)	261 (100)	100%

The table no.1 shows the education level of rural women in which 35.24 rural women are illiterate, 34.48 rural women have primary education, and 21.07 of rural women have secondary education level and 5.36 rural women have higher secondary education and 3.83 percentage of rural women are graduate.

Table 2. Occupation of rural women husband

Options	Banda	Gadakota	Devori	Jaisinagar	Kesli	Khurai	Malthone	Rahatgarh	Shahgarh	Surkhi	Total Res.	%
Agriculture	17	12	20	18	12	14	17	8	10	12	140	53.84
Govt. Employee	0	0	0	0	1	0	0	0	0	0	1	0.38
No Employment	3	2	2	4	4	0	1	8	2	10	36	13.84
Farm Worker	0	0	0	2	1	5	0	0	0	1	9	3.46
Private	10	11	5	6	3	5	2	8	10	0	60	23.07
Driver	0	0	0	0	3	0	0	0	0	0	2	0.76
Business	0	0	3	0	0	2	0	2	0	1	8	3.07
Others	0	0	0	0	0	4	0	0	0	0	4	1.53
Total	**30 (11.49)**	**25 (9.58)**	**30 (11.49)**	**30 (11.49)**	**24 (9.20)**	**30 (11.49)**	**20 (7.66)**	**26 (9.96)**	**22 (8.43)**	**24 (9.20)**	**261**	**100%**

According to table no.2 described that if women are married than their husband occupation 140 (53.84%) worked in agriculture, 1(0.38%) worked in Govt. Employee, 36 (13.84%) has no worked. 9 (3.46%) worked in Farm Worker, 60 (23.07) worked in Private, 2 (0.76%) were worked Driver, 8 (1.53%) are worked in Business, 4 (1.53%) others(according to season wise work.)

Table 3. Awareness about health literacy

Option	Banda	Gadakota	Devori	Jaisinagar	Kesli	Khurai	Malthone	Rahatgarh	Shahgarh	Surakhi	Total	%
Yes	20	8	17	18	8	17	12	10	18	13	141	54.02
No	10	17	13	12	16	13	8	12	8	11	120	45.97
Total	**30 (11.49)**	**25 (9.58)**	**30 (11.49)**	**30 (11.49)**	**24 (9.20)**	**30 (11.49)**	**20 (7.66)**	**22 (9.96)**	**26 (8.43)**	**24 (9.20)**	**261**	**100%**

The table and fig.3 shows that the awareness of health literacy among rural women was low. It was found that 54.02 of women were aware of health literacy, whereas 45.97 of women were unaware of health literacy.

Table 4. receiving health information by rural women

Option	Banda	Gadakota	Devori	Jaisinagar	Kesli	Khurai	Malthone	Rahatgarh	Shahgarh	Surakhi	Total Res.	%
In CHC	30	18	28	30	18	19	16	17	23	20	219	36.5
Sub-Center	0	5	6	8	8	5	6	4	8	7	57	9.5
At home	0	0	0	2	0	0	0	0	9	5	16	2.66
In ASHA	12	13	29	28	22	19	20	20	25	26	214	35.66
At PHP			7	10	5	3	3	5	8	3	44	7.33
District hospital	2	2	9	5	6	6	7	3	5	5	50	8.33
Any other please specify	0	0	0	0	0	0	0	0	0	0	0	0
Total	**44 (7.33)**	**38 (6.33)**	**79 (13.17)**	**83 (13.83)**	**59 (9.83)**	**52 (8.67)**	**52 (8.67)**	**49 (8.17)**	**78 (13)**	**66 (66)**	**600 (100)**	**100%**

The above table 4 shows that the receiving health information by rural women. It was found that the highest 36.5 percentage of rural women received from CHC, followed by 35.66 from AASHA, followed by 8.33 district hospital, Sub- health center 9.5 rural women has received health information from CHC.

Table 5. Awareness about contraception

Option	Banda	Gadakota	Devori	Jaisinagar	Kesli	Khurai	Malthone	Rahatgarh	Shahgarh	Surkhi	Total	%
Yes	16	21	28	26	18	24	8	18	19	11	189	72.41
No	14	4	2	4	6	6	12	4	7	13	72	27.58
Total	**30**	**25**	**30**	**30**	**24**	**30**	**20**	**22**	**26**	**24**	**261**	**100%**

The table no.5 shows that awareness about contraception among rural women. It was found that the percentage of awareness about contraception was 72.41 in total rural women of all CHC. Whereas 27.58 of rural women was not aware about contraception.

Table 6. Reason for not use contraception by rural women

Options	Banda	Gadakota	Devori	Jaisinagar	Kesli	Khurai	Malthone	Rahatgarh	Shahgarh	Surkhi	Total	%
Lack of information	10	6	9	15	8	14	8	12	9	10	101	38.69
Not agree Husband's	6	13	10	8	9	9	6	8	8	6	83	31.80
Side effect	14	6	11	7	7	7	6	2	9	8	77	29.50
Total	30 (11.49)	25 (9.58)	30 (11.49)	30 (9.20)	24 (11.49)	30 (11.49)	20 (7.66)	22 (9.96)	26 (8.43)	24 (9.20)	261	100%

The table no.6 shows that the reason for not using concentration by rural women. It was found the highest 38.69 percentage of rural women was not use contraception because of lake of information, ans 31.80 percentage of rural women's husband not agree husband, side effect is 29.50.

Finding of the study

1. To develop the health facilities for women and children. Investing in programmes for mothers which

increase access to maternal-child health care will pay direct the economic dividends to the nation by growing their capability as producers.

2. For women farmers, improved productivity is necessary. Productivity can be enhanced through access to land, credit, appropriate technology, production inputs, addition services and markets.
3. Employment establishment beyond agriculture is very essential for the representation of rural women. Programmes
4. For investing in agro-industries, cottage industries and other non-agricultural .
5. To develop health exhibition and health orientation programme should be encouraged.
6. This can be expert by improving communications such as water, roads and electricity, and access to labour saving equipment to reduce the burden of improved work, in particular on housework.
7. Proper facilities for blood storage is lacking at Community health center, which needs instant attention.Substitute sources of electricity and voltage stabilization must be gauranteed with instant achieve to ensure continuous supply of blood for deliveries of women.

Conclusions

Health literacy plays an significant role in reproductive knowledge and may impact behaviors and outcomes. While further research is necessary, healthcare providers should exploit health literacy best practices now to encourage high-quality care for rural women.

Periods, Perceptions and Practice- A Study of Menstrual Awareness among Adolescent Girls in a Tribal District of Odisha, India

Pallavi Mishra

Assistant Professor in Zoology, Department of Zoology, Govt. Autonomous College, Plulbani-762001, Odisha, India

Abstract

Menstruation is a normal biological phenomenon. Still it is associated with misperceptions, malpractices and challenges especially among female adolescents of low socioeconomic settings. The present study was conducted to investigate the knowledge about menstruation, determinants of menstrual hygiene management and the consequences of menstruation on college absenteeism in a tribal dominated backward district of Odisha, India. A college based cross-sectional questionnaire-based study was undertaken among randomly selected 740 female students who were attending 12th grade and undergraduate courses. About 64 % of girls had inappropriate knowledge about menstruation and MHM. Only 38 % girls used disposable sanitary napkins during menstruation. Almost 59 % of the respondents reported remaining absent from college during periods. High educational status of mother was found to be strong predictor of appropriate knowledge about menstruation among the adolescents. Economic constraint was found to be the major factor for not using disposable sanitary napkins which in turn is one of the major causes of college absenteeism. Girls also reported inability to change menstrual absorbents in college due to absence of proper disposal system.

Key Words: *Menstruation, Knowledge, Absenteeism, Hygiene, Adolescent.*

Introduction

The period of adolescence for a girl is a crucial period of reproductive development where physical and psychological preparation starts for motherhood. Adolescent girls enter puberty unwary, frightened and anxious about menstruation with limited information making it a taboo subject to raise. Inadequate education about puberty, poor menstrual health management (MHM) practice, insufficient water, sanitation and hygiene (WASH) facilities in educational institutes, cause school and college going girls to experience discomfort and humiliation during menstruation especially in low- and middle-income countries. [1] Although, the importance of puberty education is universally recognised, still the question of who should educate the young girls is debatable. Many countries resolve this issue by introducing appropriate reproductive health education in the school curricula, to familiarise young adolescents with puberty changes. India's National Health Mission programme has involved the female community health worker for this purpose with variable results. [2]

Menstruation can cause significant hindrance in the way of girls' access to health, education and future prospects if they are not equipped with good MHM. Estimates of the prevalence of methods of MHM like use of menstrual absorbents (cloth, toilet tissue, rags, leaves etc.), washing and drying practices, hygiene of genital parts, storing of absorbents and disposal of used absorbents vary greatly across countries. [3-4] Unhealthy menstrual practices are found to be particularly acute in rural areas and amongst women and girls of lower socio-economic groups. Improper MHM may result in urinary and reproductive tracts infections which are attributed to reuse of unhygienic sanitary absorbents. [5] World Bank statistics indicated that students remain absent in classes from one to four days every month during their menstrual cycle. [6] Several studies documented that girls face difficulty in managing menstruation in educational institutes due to lack of sanitary facilities and proper waste disposal system. Moreover, students had difficulty in attending class and performing in exams

due to menstrual related problems like blood leakage or staining as they did not use proper menstrual absorbents. This affects their academic performance.

There are scarce studies on perception on menstruation and practice of menstrual hygiene among tribal students in India. This study is therefore conducted with the aim of assessing the prevailing knowledge about menstruation and MHM and investigating the consequences of menstruation on college absenteeism among adolescent girls in this tribal dominated backward district of Odisha, India.

Materials and Method

Study design and setting

A college based cross-sectional study involving quantitative method was undertaken among randomly selected adolescent female students who were attending 12th grade and undergraduate courses during the time of data collection. This study was conducted in two undergraduate colleges in district Kandhamal, Odisha, India, during the period of August 2017 to February 2018. A total 740 students from two colleges were selected by doing systematic sampling.

Data collection procedure

After approval from the institutional ethical review committee, principal investigator and other team members of the project explained the nature and purpose of the study to all randomly selected students and written informed consent was taken from them. A structured pre-tested, close-ended questionnaire was developed and data was collected through face to face interviews. The questionnaire was divided into four sections comprising of variables on socio-demographic characteristics, knowledge about menstruation and MHM, practice of menstrual hygiene and reasons for college absenteeism during menstruation.

Data quality management and analysis

The data collected was compiled and imported to SPSS 19.0 (Statistical Package for Social Sciences). Descriptive statistics was used to determine mean and standard deviation for continuous variables like age while frequency and percentage for qualitative variables (caste, college, class year, place of residence). Multiple regressions were used to examine the effect of two or more independent variables on a single dependent variable to test the statistical significance at 95% confidence level. P-value of < 0.05 was considered as significant.

Results

Socio-demographic characteristics of participants

Seven hundred forty female students participated in the study. The mean age of the study participants was found to be 19 ± 1.2. About 339 (45.8 %) participants were below 18 years of age. Most of them resided in rural areas (n=397, 53.6%). About 43 % (n=319) belonged to reserved category (SC and ST). Mothers of most girls had below high school education (n=412, 62.5%) and were unemployed (n=564, 76 %). About a quarter of the girls (n=190) were from low socioeconomic settings (family income < Rs 10, 000).

Knowledge about menstruation and MHM

Only 36 % (n=268) respondents had appropriate knowledge; about menstruation and MHM. According to multivariate analysis students studying in final year (AOR (95 % C.I) 1.9 (1.6-2.3)) with monthly family income > Rs 10,000 [AOR (95 % C.I) 1.7 (1.2-2.5)] and whose mother had attended high school [AOR (95 % C.I) 3.7 (2.1-5.9)] had better knowledge than their counterparts (Table 1).

Practice of menstrual hygiene

Most of the respondents used homemade cloth (n=457, 62 %) and economic constraints 213 (75 %) seemed to be the main reason (Figure 1). Only 67 % (498) respondents disposed used absorbents whereas 242 (33 %) washed and reused them (Figure 2). Only 165 (22 %) students changed adsorbents at school.

Absenteeism during menstruation

As many as 439 (59 %) reported absence from college during menstruation. The major reason for college absenteeism was heavy bleeding and fear of staining their clothes (76 %) (Figure 3). Almost half the respondents felt uncomfortable being in school during menstruation because inability to change menstrual absorbent due to dirty toilets and lack of disposal facilities. Multivariate analysis showed that students who didn't use of disposable sanitary pads were associated with increase in absenteeism and vice versa [AOR (95%) 2.1 (1.8-3.2)] (Table 2).

Discussion

There is lack of awareness among the socially underdeveloped communities about the various measures needed for protection of health and dignity of young adolescent girls during menstruation.

In this study, we observed that most of the adolescent girls started menarche unaware of its biological cause. Majority of the girls had different misperceptions towards menstruation and faced different psychological trauma due to lack of any prior knowledge and unpreparedness during periods. These negative reactions like shame, irritation, tension, fear and guilt were also found in other studies. [7] Learning about menstrual cycle is important for adolescents for the purpose of avoiding unexpected menstrual bleeding and knowing about fertile periods and contraception. This lack of knowledge may be related to absence of reproductive education in schools and fewer parents to child communication about menstruation and MHM. These finding are closely related to other studies**.** **[8]** Ideally, school teachers or health workers should be the first source of information so that right knowledge about menstruation can be imparted to the young adolescents. We found mother to be the major source of information and higher educational status of adolescent's mothers to be an important predictor of knowledge about menstruation and MHM (Table 1, Figure 4). [9] The explanation for this can be attributed to the fact that educated women possess better knowledge and perception towards MHM and have access to various healthcare services information. The present study revealed that final years undergraduate students had better knowledge than those studying in first year and 12th grade. This suggests that increase in educational status of students clears the various doubts and misconceptions related to menstruation and makes them more aware.

Different types of menstrual absorbent materials were used which is dependent on the diversity of socio-economic settings of the girls. About 38% of the girls used cloth during menstruation instead of sanitary pads which was comparable to a study from Ethiopia. [10] Despite the discomfort being felt due to use of cloth, it still remains the preferred means for them, due to its easy availability, low cost and reusability which is in agreement with other studies. [11] Majority of the girls did not wash their genital area with soap or antiseptics, unaware of the importance of maintaining cleanliness in the genital area during menstruation as reported elsewhere. [12] Out of 740 respondents, only 29 % girls changed their menstrual absorbent more than twice and 71 % only once a day similar to another study. [13] A few girls reported itchiness, burning, and rashes in their genital areas which may be due to improper cleaning and drying (lack of exposure to sunlight) of the menstrual soak-up cloth similar to study from Nagpur. [14] Most of the girls avoided bathing during their periods due to lack of separate enclosed bathing space at their homes, scarcity of water or lack of privacy. The lack of toilets at home is of great concern with regard to safety, privacy and dignity, as reported repeatedly by women in India. [15] Only a quarter of the girls changed their menstrual absorbents at college, comparable to findings from other studies. [16] The major reason accounted was absence of proper disposal system at college. The girls who reported changing pads had to bring the soiled absorbent back home or throw it in open spaces. We observed that the urban girls disposed the used absorbents in routine household waste by wrapping them in sheets of papers and polythene related to findings from other studies. [3] However, in rural areas a range of options used for disposing of menstrual materials includes burning, burying, throwing in the waste bin, pit latrine or flushing. Inadequate disposal methods at times cause problems like clogging of toilet and polluting the local streams in villages. [17] Disposal of commercial pads is a matter of concern because of their high content of non-biodegradable components. [18]

In present study menstruation-related college absenteeism rate of 42% observed here was also consistent with previous reports. [19] Menstruating girls from socially deprived backgrounds especially residing in rural areas are more likely to miss college as they use cloths instead of sanitary pads. Even if girls manage to attend college during menstruation, the fear of staining their clothes or being humiliated for foul smell of menstrual absorbent reduces their concentration and makes them hesitant to participate in class activities. This concern has been raised in other studies. [10] Further due to absence of a proper waste disposal system, most girls end up carrying the used material back home or throwing them in open. This reveals the need for clean toilets combined with the establishment of proper waste disposal systems in educational institutes.

Conclusion

The results from the present study suggests negligence of adolescent girl's reproductive health

needs in these tribal areas. Lack of sanitized menstrual absorbents and sanitary facilities in educational institutes seriously jeopardizes academic performance in adolescent girls. In order to improve gender equality in educational institutes of these backward poor districts, emphasis should be given to adolescent girl's menstrual needs by providing them free or subsidized sanitary napkins. Further installation of incinerators in colleges can not only solve the pad disposal problem but also reduce environmental pollution due to throwing or burning of disposable sanitary pads. Hence, government should give special attention towards making educational institutes a comfortable place for girls.

Abstract

Background & Aim: Lateral Epicondylitis (LE) also known as Tennis Elbow is a lesion due to chronic overuse injury of wrist extensors which causes damage to the wrist extensor tendons at their origin i.e. lateral epicondyle of the humerus. Thus, the aim of this case report is to report about the efficacy of virtual reality through EMG biofeedback and myofascial release technique in the case of lateral epicondylitis.

Methodology: This study reports the efficacy virtual reality through EMG biofeedback and myofascial release technique along with pulsed ultrasound therapy in 37 year old male non-diabetic patient diagnosed with chronic lateral epicondylitis. The main intervention in this case involved virtual reality through EMG biofeedback and myofascial release technique (MFR) along with pulsed ultrasound therapy for 4 weeks. The treatment goal was to reduce inflammation, pain and restore wrist extensor muscle strength to avoid recurrence. The treatment outcome for pain was measured by 11 point Numerical Pain Rating scale, hand grip strength by hand dynamometer & functional score by Patient Rated Tennis Elbow Evaluation. All the outcome measures were taken and analysed at baseline and after end of treatment.

Conclusion: Combination of virtual reality through EMG biofeedback and myofascial release technique along with pulsed ultrasound therapy had promising result in rehabilitation of lateral epicondylitis and thus allowing return to work and play as quickly as possible.

Keywords - *Lateral Epicondylitis, Surface EMG, Biofeedback, MFR, Pulsed Ultrasound.*

Introduction

In non-traumatic elbow disorders, lateral elbow pain is the commonest medical consultation and most frequent diagnosis is lateral epicondylitis which is also known as tennis elbow.[1]

In 1873 Runge first described lateral epicondylitis as chronic degenerative disorder affecting the common wrist extensor tendon origin at the lateral epicondyle of the humerus leading to pain over the lateral epicondyle of the humerus and decreased grip strength[2]. The most common muscle getting affected in lateral epicondylitis is extensor carpi radialis brevis but in some cases other wrist extensor muscles like extensor carpi radialis longus, extensor digitorum, extensor carpi ulnaris and muscles like supinator can also be involved.[3]

Lateral epicondylitis is caused / aggravated by doing repeated wrist extension movement like due heavy labour work, playing tennis or typing. In addition to this factors like smoking and obesity are also identified as significant risk factors. Thus, lateral epicondylitis which occurs because of symptomatic degenerative process of extensor tendons of the wrist, many authors claim it tendinosis rather than tendinitis because of lack of inflammatory cells[4].

With the repetitive activities there is increase in shear force at tendon-bone junction causing extensor

Corresponding Author:
Parth Trivedi
E-mail: drparthtrivedi@live.in

muscles enthesis ultimately reducing the strength of the tendon. [5]

It is assumed that lateral epicondylitis affects around 1% to 3% of the population in middle aged individuals with ratio being similar in male and females each year. In United States every year around 1 million people have new onset of lateral epicondylitis[4] and this ultimately causes heavy socioeconomic burden because of lost workdays for several weeks[4].

In current medical practice there are various treatment options available for the treatment of lateral epicondylitis but with less evidence. The treatment options comprises of both conservative and surgical methods.

In physical therapy there are number of therapeutic modalities and technique available but none of them have proven significant and long lasting effect on lateral epicondylitis. Majority of the treatment will include progressive resisted exercises, ultrasound therapy, low level LASER therapy, soft tissue release technquie, manual mobilisation[6].

Soft tissue release technique like myofascial release technique basic principal is to release the fascial restriction by applying low load long duration stretch to myofascial system which thereby decreases the pain and imporves the function.By reducing the facial tightness, pressure over the strutures below fascial like nerves, blood vessels is releived and thus pain and functional performance is improved[7].

Nowadays, Virtual rehab is an emerging trend in physical therapy which is used in different populations. It is the rehab which is done using computerized stimulation in two dimension or three dimension which is in real time and interactive. Thus, this aids rehabilitation of the individual by giving feedback to the individual based on individual's condition.

Till this date there is no evidence regarding the combine use of myofascial release technique and virtual realtity biofeedback in the rehabilitation of lateral epicondylitis[8].

Thus, the main aim of this paper is to find the efficacy of Myofascial Release Technique with Virtual Reality Biofeedback in Lateral Epicondylitis in lateral epicondylitis.

This paper gives insight to the case report of one patient diagnosed with lateral epicondylitis with detailed examination, pathology and treatment given with its improvement.

Case Report

A 37- year old male patient, right hand dominant working in central armed police force with main work of doing clerical work which involved computer work and recreational tennis player predominately had chief complaints of pain over right epicondyle that had lasted for over 4 weeks. The patient complaint of increase in pain gradually after patient played tennis before 4 weeks and later hand grip strength was also affected. For few days patient ignored the pain and applied local ayurvedic ointments but that didn't reduce the pain. Patient than consulted an orthopaedic surgeon at Gandhinagar, Gujarat where patient was prescribed with aceclofenac (analgesic) and paracetamol (anti-inflammatory) medications and local topical analgesic spray for two weeks. After two weeks of allopathic treatment the patient was referred for physiotherapy.

At physiotherapy department detail assessment of the patient was undertaken in SOAP format (Subjective, Objective, Assessment and Planning) which included demographic details of the patient and history and examination of the patient.

The patient had no other systemic illness or never had undergone any major surgery in past. The patient was the only earning member in his family which comprised of his wife and two children. Patient was in this occupation since last 12 years.

On examination of tenderness; patient had grade 3 tenderness over right lateral epicondyle region. No ecchymosis was there but localized swelling was present when compared with opposite side. The active and passive range of motion assessment of right shoulder, elbow and wrist joint were full in all movements of the concerned joint apart from right wrist extension which was reduced by 4 degrees. The end feel examination of the right elbow was also normal but right wrist extension had empty end feel as patient felt pain in terminal range of wrist extension.

The patient was also tested for resisted isometric testing of right wrist extensors which was weak and painful. At last special test cozen's test was performed to confirm the diagnosis, which was positive. Thus, the

patient was diagnosed with right lateral epicondylitis affecting the right extensor carpi radialis brevis muscle.

The patient than was explained about the treatment procedure which included surface emg biofeedback through virtual reality and myofascial release technique including pulsed ultrasound therapy as mentioned. The treatment protocol was designed for 4 weeks with 3 sessions per week.

The patient agreed for the treatment and then the outcome measures of the patient were collected at the baseline. All the outcome measures were collected at the baseline and at the end of treatment i.e. 4th week.

The patient was assessed with the outcome measures mainly being pain, hand grip strength, functional performance and surface electromyography at baseline. Pain which was characterized as dull ache rated 6 out of 10 on 11 point numerical pain rating scale in which zero being no pain and 10 being the worst pain ever. The hand grip strength was measured by Jamar Hand Dynamometer which was 28lb. on average of 3 trials. The functional score of the patient was taken through Patient rated tennis elbow evaluation which was 64 out 100 in which higher score indicates more pain and more functional disability. The patient was also assessed with amplitude in surface EMG which was 120 µV.

Figure 1: Surface EMG biofeedback Virtual Game

Figure 1 shows the bunny game which was used as virtual reality through surface emg biofeedback. The game was into two segment which was comprised of rest and work phase.

Treatment Given:

1. Pulsed Ultrasound Therapy[7]: **Site:** Tenoperiosteal junction of the extensor carpi radialis brevis, At 1:4 Pulse Ratio, **Frequency:** 1MHz, **Intensity:** 1.5 W/cm2, **Duration:** 5 minutes.

2. Myofascial Release Technique[7]: Patient position was supine lying with affected side shoulder rotate internally, elbow flexion to around 15° and pronation, palm resting flat on table.

Procedure 1: This procedure involved treatment through common extensor tendon to extensor retinaculum of wrist which began through humerus, just proximal to lateral epicondyle. Fingertips were used to engage the periosteum from inferior of common extensor tendon and this was carried forward till extensor retinaculum of the wrist (5min, 2 repetitions). Then, the patient slowly flexed and extended the elbow within range of 5° to 10° during this procedure.

Procedure 2: This procedure involved treatment through periosteum of ulna, using the knuckles of hand (5min, 2 repetitions). Then the patient performed alternating ulnar and radial deviation of wrist.

Procedure 3: This treatment involved spreading of the radius from ulna, head of ulna with finger pads of one hand and dorsal tubercle of radius with the pads of other were treated after proper contact. The therapist engaged through to the periosteum and put a line of tension in a lateral and distal direction. It was carried for just a few centimeters with a firm intent to spread the bones (5min, 2 repetitions).

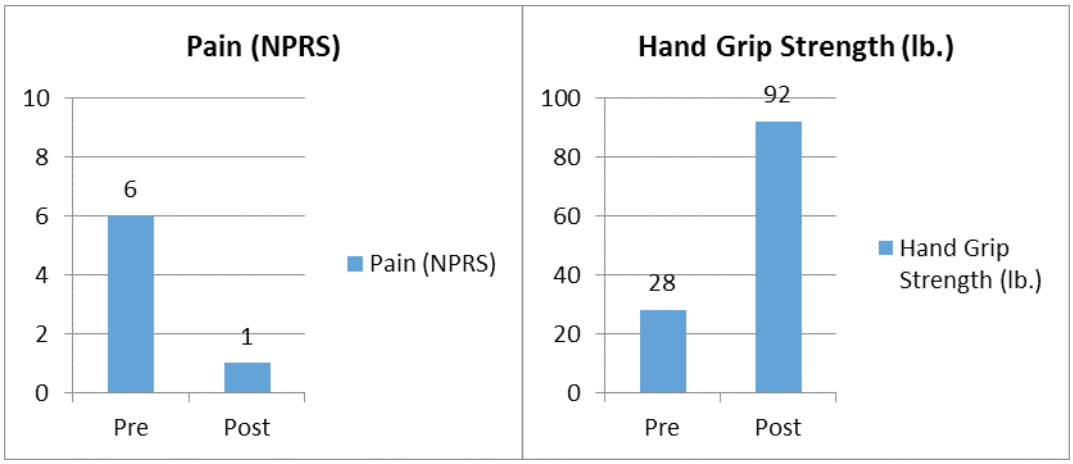
3. Surface EMG– Virtual Reality Biofeedback[8]: Patient Lying Supine.

Patient's motor unit action potential of wrist extensors was measured through surface EMG amplitude analysis. Than upper limit and lower limit was than identified and set. The Patient was than given virtual biofeedback in form of bunny game in which on appropriate contraction of wrist muscles as per the set upper and lower limit of the motor unit action potential causes bunny to move ahead and collect carrot.

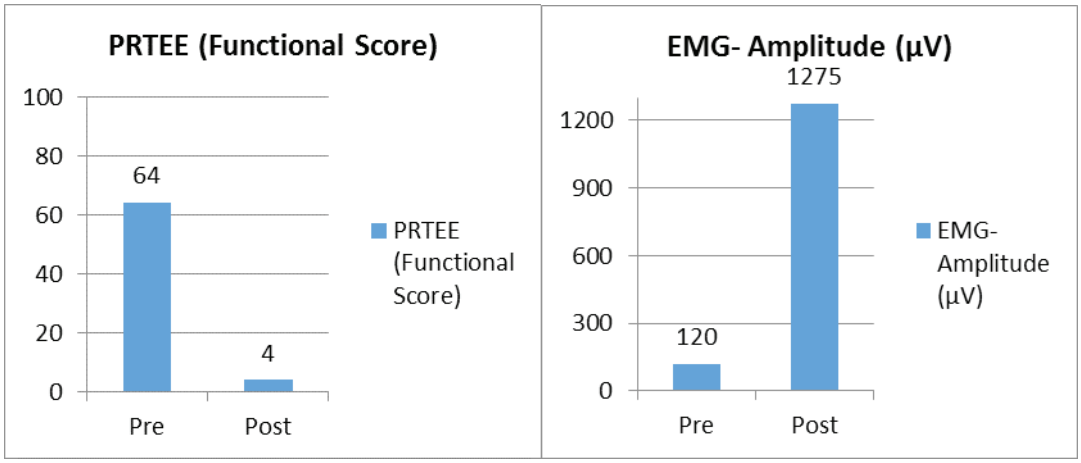
After the first treatment session patient reported to feel 40 percent better. All the outcome measures; pain (11point NPRS)[9], Hand Grip Strength (Hand Dynamometer)[7], Functional Score (PRTEE)[7] and Surface EMG amplitude[10] were taken at the end of treatment i.e. 4th week. Comparison of the same is mentioned in table 1 and outcome parameter wise comparison in shown as graphical representations in graph 1 & 2 respectively.

Table 1: Comparison of Pre and Post Outcome Measures

Outcome	**Pre**	**Post**
Pain	6	1
Hand Grip Strength (lb.)	28	92
PRTEE	64	4
EMG- Amplitude (µV)	120	1275



Graph 1: Pre & Post Comparison of Pain and Hand Grip Strength



Graph 2: Pre & Post Comparison of PRTEE and EMG

Patient was also recommended to purchase a light, non-vibrational professional racquet with moderate string tension and was also taught proper stroke techniques to avoid anuy recurrences after treatment session.

Discussion

Any rehabilitation protocol in orthopaedic injuries which is designed has the main aim to reduce pain and increase muscle function. Looking into this our main aim to present this case report was to find out an effective rehabilitation protocol which not only has its effect on reducing pain but also improves muscle function and thereby reducing the chances of recurrence.

In lateral epicondylitis extensor carpi radialis brevis muscle is the most injured muscle increased wrist movement which cause increase in tension leading to repetitive stress on the extensor carpi radialis brevis muscle. This ultimately results into pain over lateral epicondyle of the humerus which is the origin of common extensor of the wrist.[7] It is postulated that repetitive muscle contraction leads to angiofibroblastic degneration because of continous micro trauma resulting into failure of natural healing process.[3,5]

Thus understanding the biomechanics of the wrist and elbow is at most important as the tension and stress which is produced because of the repetitive injuries needs to be addressed.[3]

In lateral epicondylitis previous studies have reported that over 90% of cases responded well to conservative treatments but one of the meta analysis done by Labelle etal in 1992 concluded that there is no sufficeint evidence of any single treatment in lateral epicondylitis.[7.]

The same phenomenon is supported by Bisset et al which states that there are no long term benefits of physical therapy intervention in lateral epicondylitis.[7]

As this study focused on improving the pain and function of the pateint with lateral epicondylitis, MFR was given to the patient with the aim to release the fascia and thereby aligining the collagen fibres which imporves the tensile strength of the muscle and thereby reducing the pain, improving grip strength and functional performance as the fascia returns to the normal length. The reduction in pain due to MFR is mainly because of stimulation of afferent pathways and excitation of afferent A delta fibres which leads to segmental pain supression and activation of descending pain inhibiting pathway.[7]

Addition of virtual reality assisted surface emg biofeedback had an additive advantage as the accuracy of muscle strengthening was based on motor unit action potential graph. This not only helped the therapist in increasing the resistance of the strengthening program but also actively involved the patient as it had game component in it. Virtual reality through the phenomenon of task oriented training and repetition intensity helps in regaining the strength of the muscle and thereby reduces chances of reccurence. [8]

Ultrasound has proven effects on reducing the inflammation and improving the tissue healing; this would indeed improve muscle strength and power.[7]

As mentioned in table 1, at the end of 4 weeks of treatment there was significant improvement in all the outcome parameters. Even the amplitude analysis was in favour of the treatment.

Conclusion

We conclude that there are positive and promising result of using surface EMG biofeedback in terms of virtual reality in combination of myofascial release technique in lateral epicondylitis.

Throug this case report we recommend that the same protocol should be studied under larger group of people.

Conflict of Interest: We declare there was no conflict of interest in the entire journey of this case report.

Funding Source: All the required assistance regarding the treatment of the patient was given by C.M. Patel College of Physiotherapy, Gandhinagar, Gujarat.

Ethical Cleareance: Prior to the treatment of the patient; due ethical clearance was taken from the institutional ethical committee of C.M. Patel College of Physiotherapy, Gandhinagar, Gujarat.

Awareness of Causes, Consequences and Preventive Measures of Thyroid Disorder among Women in Punjab

Pooja Kansra[1], Vedica Awasthi[2]

[1]Associate Professor and Corresponding Author, Mittal School of Business, Lovely Professional University, India,
[2]Research Scholar, Mittal School of Business, Lovely Professional University, India

Abstract

Background and Objective: Thyroid is very common disease now-a-days and women are more risk prone than men. Therefore, main objective of the present study is to examine the awareness of thyroid disorders among the women of Jalandhar, Punjab.

Method: Primary data was collected from 200 women of Jalandhar with the help of a well-structured questionnaire.

Result: The result of the study demonstrated that age and family history were the important factors which influence thyroid disorder among women. The study clearly depicted that majority of the respondents were not aware of the symptoms and preventive measures of Thyroid. Thyroid leads to a rise in goiter, stress and depression which requires prevention at the early stage.

Conclusion: The significant determinants of awareness of Thyroid were age, education, family history and its incidence. The study suggested that one should take prevention measures after observing the symptoms like sudden weight gain, excessive hair fall, voice change and sore throat.

Key words: *Thyroid Disorder, Hypothyroidism, Hyperthyroidism, Awareness, Incidence.*

Introduction

Thyroid hormone disorder (THD) is a major health problem and related to a large range of diseases (Sijapati et al., 2019)[1]. Thyroid hormones are significant to the growth and development of a number of body tissues, and anthropometric factors are affected by thyroid disorders, such as hypothyroidism and thyrotoxicosis. An enlarged risk of thyroid cancer is among women with higher body mass index (BMI) or who had sudden weight gain (Bosetti et al., 2002)[2]. The body mass index of females were directly associated with thyroid cancer risk but not in case of men. Furthermore, in one of those studies found that height was directly associated with thyroid cancer risk in men (Maso et al., 2000)[3]. According to Bagcchi (2014)[4] prevalence of hypothyroidism is 11 percent in India as compared to 2 percent in UK and 4-6 percent in USA. It is expected that approximately every third person in India will suffer from thyroid disorders viz. weight gain and hormonal changes (Economic Times, 2017)[5].

Thyroid dysfunction, especially hypothyroidism, is more common in women (Alterio et al., 2007; Jung et al., 2018)[6,7]. Women who did not sense stress disorder signs were more expected to be elevated somatotype than women who sensed it (Jung et al., 2018)[7]. Skin is one of the organ which helps in observing a large number of the clinical symptoms. Hyperthyroidism symptoms which can be seen on skin includes warm,

Lovely Professional University, India
Email: pkansra@gmail.com

moist skin, palmo-plantar hyperhidrosis, facial flushing, skin pigmentation, pretibial myxedema, onycholysis, plummers nail etc. According to Ross et al. (2016, p.1343)[8], "*described evidence based clinical guidelines for the management of thyrotoxicosis that would be useful to generalist and subspecialty physicians and others providing care for patients with this condition*". Hypothyroidism symptoms of skin include dry coarse skin, hair loss, pruritus, hypohydrosis, yellow skin, brittle nails, loss of cuticle, vertical striations (Sijapati et al., 2019)[1]. Hypothyroidism if remains untreated or inadequately treated in pregnant women can compromise fetal neurocognitive development (Bagcchi, 2014)[4].

Thyroid disorder has well-characterized deadly effects and can lead to severe on the cardiovascular system (Nyirenda, 2005; Jung et al., 2018)[9,7]. Iodine deficiency is one of the risk factor for goiter, thyroid nodularity and hyperthyroidism. Iodine-induced hyperthyroidism takes place more often in state of long-term iodine deficiency (Volzke et al., 2003; Zimmermann and Boelaert, 2015)[10,11]. Significant differences were found between both regions with a slight difference in iodine excretion (Knudsen et al., 2000)[12]. Usually, radioiodine has been used for the treatment of various forms of thyrotoxicosis like Graves' disease, toxic nodular goiter and solitary toxic nodule for so many years. Over the time it is confirmed as a safe, effective and relatively reasonably priced therapy and significant differences in several aspects of clinical practice relating to the use of radioiodine treatment for benign thyroid disorders in the UK (Vaidya et al., 2008)[13].

Thyroid has relation with diseases like depression and diabetes too. The relation between thyroid hormones and depression was brought up in the late 1960s in a clinical group (Ittermann et al., 2015)[14]. Thyroid diseases and diabetes mellitus are the two most common endocrine disorders came across in clinical practice. Diabetes and thyroid disorders have mutual influence on each other and relations between both conditions have long been reported (Hage et al., 2011)[15]. It is observed that if a person had goiter in past has more risk of thyroid cancer (Bosetti et al., 2002)[2]. According to Likhtarov et al., (2006)[16] the thyroid cancer frequency rate increased statistically significant with increasing screening rate. Cancer is the most common disease of the endocrine system and the eighth most common cancer among women (Ward et al., 2010)[17]. Thyroid generally remained undetected and untreated among the Indian masses impaired the performance and economic productivity in the country. Considering various consequences of Thyroid disorder, it is required to study the awareness of causes, consequences and preventive measures of Thyroid disorders among the women in Jalandhar.

The study was organized into five sections. Section I introduces the various risk factors of Thyroid. The research methodology was extensively discussed in Section II of the present study. Section III, analyzed the empirical findings of the study. Section IV, concludes the whole discussion along with policy implications.

Methodology

Study design

The present study is descriptive, cross-sectional study in nature and conducted in the North Indian state of Punjab, where responses were collected with the help of a structured questionnaire. The data was collected from April 2018 to August 2018.

Material and Method

In the study an attempt was made to examine the awareness of the preventive measures and risk factors of Thyroid. For the collection of data a structured questionnaire was drafted. A sample of 200 women was obtained from an urban city of Punjab, Jalandhar using convenience sampling approach. The analysis of the data was made with the descriptive statistics and Logit regression. The dependent variable was defined as "Aware of Thyroid" and measured as 1=aware of thyroid and 0 otherwise. However, independent variable consists of socio-economic variables.

Empirical Analysis

Table 1 demonstrated that respondents were mainly of 18 to 25 years of age which was followed by age group of 25 to 35 years and below 18 years. Half of the respondents were post graduated and others were graduated, only few had done diploma. Majority of the respondents fell under the income group of ₹1 lakh to ₹2 which was followed by the income group of ₹2 lakh to ₹3 lakh category and then by up to ₹1 lakh category. Majority of the respondents were single, only 12 percent were married.

Table: 1: Demographic Characteristics of the Respondents

Characteristics (N=200)	**N (%)**
Age	
Below 18 years	14 (7)
18- 25 years	114(57)
25-35 years	72 (36)

Table 2 exhibited the awareness of respondents regarding the symptoms and risk factors of thyroid. It was observed that out of 200 respondents, 22 percent were aware of weight gain, only 3 percent of them were aware of irregular menstrual cycle; 52 percent were aware of hair fall; 61 percent were aware of sore throat, joint pain and voice change and 69 percent were aware of infertility; 77 percent were aware of puffy skin or dry skin and 79 percent were aware of goiter as various symptoms of thyroid. It was observed that respondents were aware for risk factors as: only 4 percent were aware for gender and pregnancy; 15 percent were aware for stress and 51 percent were aware for family history.

Table: 2: Awareness of Symptoms and Risk Factors of Thyroid

Awareness Regarding Symptoms		
Symptoms	Percent	
	Yes	No
Constipation/Diarrhea	12	88
Depression	11	89
Goiter (increased size of the thyroid)	79	21
Hair fall	52	48
Infertility	69	31
Irregular menstrual cycles	3	97
Skin problems	9	91
Sore throat, neck pain, joint pain	61	39
Thick puffy skin /or dry skin	77	23
Voice change	61	39
Weight gain	22	78
Awareness Regarding Risk Factors		
Variables	Percent	
	Yes	No
A diet low in iodine	25	75
Age	63	37
Family History	51	49
Gender	4	96
Not eating enough or eating certain vegetables	35	67
Obesity	48	52
Pregnancy	4	96
Smoking	15	85
Some foods that are high in goitrogens broccoli, cabbage, Brussels sprouts, cauliflower, radishes and turnips	69	31
Stress	35	65

Table 4, identified the various factors which influence the awareness of the women towards thyroid among the women with Logit regression. A significant association was observed between the age and awareness of thyroid among women. The regression coefficient clearly indicates that an inverse relationship was observed between the age and awareness. Thus, it can be concluded that younger respondents were more aware of thyroid. However, education of the respondent was directly related to the awareness. This clearly predicts that probability of awareness of thyroid increases with increase in education. The respondents with family history were more aware of thyroid as compared to others. It was observed that incidence of thyroid also significantly impacts its awareness.

Table 5 demonstrates the division of respondents based on healthcare utilization and access to a health facility. Majority of respondents used healthcare facilities for the treatment, whereas 30 percent respondents never visited any of the facility. Out of the total 90 respondents, 58 percent individuals utilized allopathic treatment facility which was followed by homeopathic and ayurvedic treatment facility. People prefer private hospitals/clinics (63 percent) more than government ones (37 percent). 'No long queue' was the major determinant for which 38 percent respondents visited the private health facility. Also, the availability of specialized treatment and clean healthcare ambience were the prerequisites which intended individuals to choose the type of health facility. Free or low-cost treatment was the least opted reason for the choice of treatment facility amongst the individuals of Punjab.

Table 5: Prevalence of Thyroid among Sampled Respondents

Utilization Pattern	**N= 128(%)**
Utilized health care services	
Yes	90 (70)
No	38 (30)

Type of health facility visited (N=90)	
Government Hospital	33 (37)
Private Hospital	22 (63)
Why this treatment? (N=90)	
Free or low cost treatment	4 (4)
Doctor was familiar	12 (13)
No long queues	34 (38)
Availability of specialized doctor/treatment	17 (19)
Cleanliness	23 (26)

Source: Author's Calculation

Conclusion

The above discussion clearly demonstrated that the sampled women had a low awareness towards the risk factors and prevention strategies of Thyroid. Awareness of Thyroid is the pre-requisite for its prevention. Thereby, awareness of the symptoms and its prevention strategies should be spread through mass camps in the country. Awareness of the symptoms and risk factors of thyroid among the common masses will help in the early diagnosis and prevention of the serious complications of thyroid. There is a need of policy intervention across multiple sectors, from high-level policy changes to individual-level behavioral changes. Continued surveillance of thyroid is necessary to monitor and evaluate its implications and to plan the appropriate strategies.

Abstract

The health concern of the alcoholic beverages has remained a key issue to be addressed to the consumers. The aim of the present study was to assess the antioxidant activity and cytotoxicity of the selected 22 bottled commercial alcoholic brands widely consumed in the Maharashtra state of India. The result of the present study shows that the brands of wines followed by whiskies and rums were more effective as free radical scavenging agents, containing considerable amount of polyphenols. Overall, the vodaka brands were observed to be more cytotoxic as compared to other brands. With few exceptions, there exists a positive correlation in the amount of polyphenols and free radical scavenging activity, while the former was negatively correlated with cytotoxicity.

***Key words**: Antioxidant; Alcoholic Beverages; Cytotoxicity; Polyphenol*

Introduction

Drinking of alcoholic beverages (ABs) is a global habit of majority of human beings. The trend of alcohol drinking is increasing all over the world considering its role as a stress or pain killer. The health concern of the ABs has remained a key issue to be addressed to the consumers in the present situation of 'stress rich satisfaction poor' socioeconomic scenario. During the process of production of ABs, manufacturers add variety of additives in the form of preservatives, flavors, coloring agents etc. which ultimately accounts for the final quality of the finished brands. Several studies have shown the benefits as well as adverse effects of the consumption of alcoholic beverages in daily life. The adverse effects of ABs are usually attributed with the type of brand, consumption frequency, amount of dose and the overall physiological status of the consumer; however the health benefits of many ABs are linked with the presence of therapeutically important substances such as flavonoids, phenolic compounds, amino acids etc. and the aforesaid factors. Series of scientific evidences showed that the people who are moderate drinkers of alcoholic beverages have substantially reduced the risk of many degenerative human ailments like coronary heart disease, cancer [1] etc. It has been also described that the flavonoids and other polyphenolic compounds derived from the source material are implicated in free radicals scavenging mechanism[2].

In the present study, 22 different commercial bottled alcoholic brands belonging to wine, whiskey, rum, gin, vodaka, local brand which are commonly consumed in Maharashtra state in particular and other states of India in general, were evaluated for their free radical scavenging activity and cytotoxicity against normal Chang liver cell line.

Antioxidant activities:

DPPH radical assay:

DPPH (1, 1-diphenyl-2-picryl hydrazine) radical scavenging assay was performed as per the earlier reported method[3]. The reaction cocktail was prepared by mixing individual sample of ABs with equal volume of DPPH radical (10^{-4} M in absolute ethanol) solution. After 20 min reaction time, the absorbance was recorded at 517 nm using UV-Visible spectrophotometer.

OH Radical scavenging activity

Hydroxyl radical (OH) scavenging activity was measured as per previously published protocol[4]. The reaction mixture contained 60 µl of 1mM, $Fecl_3$, 90 µl of 1mM 1, 10-phenanthroline, 2.4 ml of 0.2 M phosphate buffer (pH 7.8), 150 µl of 0.17 M H_2O_2 and 1.5 ml of individual brand. The reaction mixture was kept at room temperature for 5 minutes incubation and absorbance was recorded at 560 nm using UV-VIS spectrophotometer.

Superoxide anion scavenging activity

Superoxide anion radical (SOR) scavenging activity of the selected ABs was measured by generating them in a non enzymatic phenanzinemethosulfate- nicotinamide adenine dinucleotide (PMS-NADH) system though the reduction of nitro-bluetetrazolium (NBT)[5]. SORs were generated from the reaction mixture containing 3ml of tris-HCl buffer (100 mM, pH 7.4), 0.75 ml of NBT (300 mM), 0.75 ml of NADH and 0.3 ml of selected ABs.

Reducing Power activity

The reducing power (RP) of the selected brands was determined as per the previously described method[6]. The reaction cocktail contained 0.75 ml of individual alcoholic sample, 0.75 ml of phosphate buffer (0.2 N, pH 6.6) and 0.75 ml of potassium hexacyanoferrate ($K_3Fe(CN)_6$) (1% w/v). The mixture was incubated at 50^0 C in water bath for 20 min. The reaction was terminated by adding 0.75 ml of trichloroacetic acid (10%) and centrifuged for 10 minutes at 800 rpm. The supernatant (1.5 ml) of the individual reaction mixture was collected in different clean tubes and was mixed with 1.5 ml of distilled water followed by addition of 0.1ml of ferric chloride (0.1% w/v) and kept for 10 min. The absorbance of reaction mixture was measured at 700 nm.

Estimation of polyphenols:

The estimation of polyphenolic content from the selected ABs was determined by earlier reported method[7]. The phenolic compound undergoes reaction with an oxidizing agent phosphomolybdate present in the Folin-Ciocalteau reagent, the resultant reaction product is a blue coloured complex having maximum extinction at 660 nm. The amount of phenolics was calculated by using a standard curve using serial dilutions of catechol (500 µg/ml). The total amount of polyphenol was estimated as µg/ml of samples.

Evaluation of Cytotoxicity

The MTT cytotoxicity assay was performed as per the reported method[8]. Normal human Chang liver cell line was purchased from NCCS (National Center for Cell Science), Pune (MS). The cells were harvested and inoculated in 96 well (4×10^4 cells/well) microtiter plates. The cells were washed with phosphate buffered saline (PBS) and the cultured cells were then inoculated with and without the selected ABs. After 72 h incubation, the medium was aspirated followed by addition of 150 µL of MTT (3-(4, 5 dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide) solution (5 mg mL^{-1} In PBS, pH 7.2) to each well and the plates were incubated for 4 h at 37° C. After incubation, 800 µL of DMSO was added to the wells followed by gentle shaking to solubalize the formazan dye for 15 min. Absorbance was read at 540 nm and the cytotoxicity (%) was calculated.

The DPPH, OH and SOR radical scavenging activity, RP potential and cytoxicity (%) was calculated using the following formula and the results were compared with the respective reference compounds.

$$\text{Activity (\%)} = 1 - \frac{T}{C} \times 100$$

T= Absorbance of the test sample & C= Absorbance of the control sample

Results and Discussion

The results shows the efficacy of the selected brands of wines such as Madira (99.24%), Sumara (98.92%), Figuria (98.59%) and brands of rums like Mc Dowell (98.54%), Old Monk (98.54%) followed by whisky brands like Royal Challenge (96.47%), Signature (95.78%) and Royal Stag (95.56%) as excellent DPPH radical scavenging agents. The brandy, Honey Bee (99.24%) was also observed to possess excellent DPPH radical scavenging activity. While the remaining brands showed good DPPH radical scavenging activity in the range of 74.02 to 94.26 % as compared to ascorbic acid (95.31 %). DPPH radical is a stable free radical and it has been widely used to evaluate the free radical scavenging ability of different dietary antioxidants. The principle of the assay is that the antioxidant reacts with DPPH radical and converts into corresponding hydrazines. The fall in extinction is correlated with the potential of antioxidant to scavenge free radicals. Greater the DPPH reducing ability higher is the antioxidant potential[9].

Among the selected ABs, again the wine brands like Figuria (78.9%) and Samara (98.92%) followed by rums like Mc Dowell (77.3%) and Bacardi (73.6%) demonstrated significant OH radical scavenging activity, all other brands showed the activity in a range of 20.8-72.9 % as compared to reference compound α-Tocopherol (76.79 %). OH radicals are generated through Fenton reaction. These radicals are the most reactive radicals in the biological systems. The hyper reactivity of OH radicals paralyses variety of cellular functions by indiscriminate reactions with biologically important molecules like proteins, enzymes, nucleic acids etc. and excess production of OH radicals induces several degenerative diseases in humans [10].

The profile of the SOR scavenging activity indicates the effectiveness of wines like Madira (70.2%), Samara (69.5%) and Figuria (67.8%) as significant SOR scavenging agents. The other selected AB samples showed considerable SOR scavenging activity in the range of (48.71-65.5%) as compared to ascorbic acid (53.3 %). SORs are capable of damaging cellular membranes (through peroxidation reactions), protein and other macromolecules[11]. The cellular damage caused by SORs has been implicated in aging process and in initiation of numerous age related diseases such as cancer, heart disease, Parkinson's disease etc [12].

Once again the wine brands such as Figuria (88.6 %), Samara (79.7%) and Madira (78.26%) followed by rum, Mc Dowell (77.9%) have demonstrated good reducing ability. Remaining AB samples also showed considerable reducing activity in a range of 48.71-65.5%. In a general pharmacological notion compounds possessing reducing ability are considered good candidates for developing them as antioxidant agents. Higher reducing capability indicates greater antioxidant activity[13].

The maximum amount of polyphenols content was estimated in the wine brands like Figuria and Madira (2000 µg/ml), Samara (1596 µg/ml) followed by the rums such as Mc Dowell (1718 µg/ml) and Old Monk (1031 µg/ml). Other brands of the selected ABs were found to contain <370 µg/ml of polyphenols. ABs like wine has been reported to contain complex mixture of phenolic compounds possessing therapeutically important activities and free radical scavenging capabilities. The diverse biological activities of polyphenols are described to be health ameliorative and involved in preventing many degenerative diseases of humans [14]. It is this reputation of the polyphenols (especially in the wines) that minimizes the risk of heart disease and intake of wines in limited proportions acts as cardio protective agent[15]. Nevertheless many physicians recommend the intake of cardio protective wines to minimize the risk of cardio failure. In general it can be stated that the amount of polyphenol contents is positively correlated with antioxidant activity. To a greater extent this also holds true in case of the results of the present studies.

MTT colorimetric cell viability assay is one of the widely used methods to test the cytotoxicity of the different samples. Cell's survival is checked on the basis of the mitochondrial enzyme's ability to reduce the soluble yellow tetrazolium salt (MTT) to an insoluble formazan dye[16]. The selected ABs were evaluated for cytotoxicity against normal Chang liver cells.

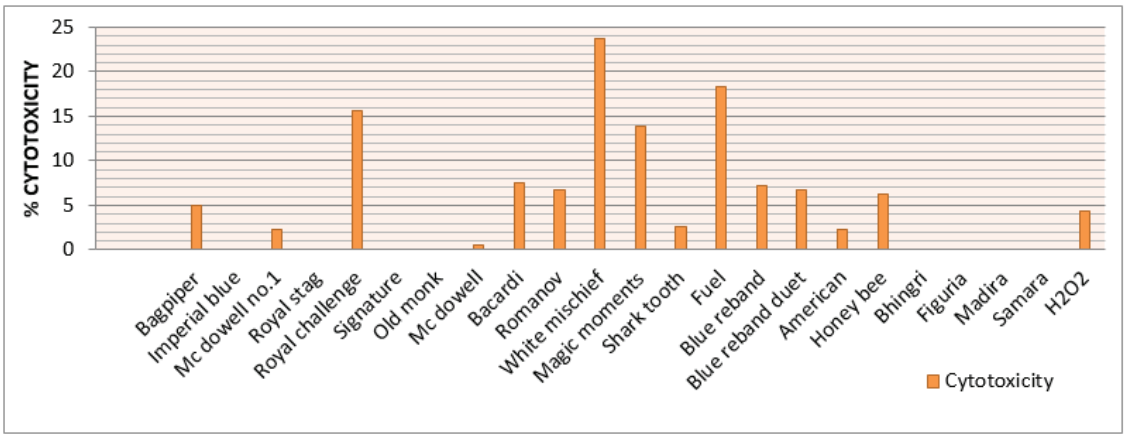

Figure 1. Profile of cytotoxicity (%) of the selected alcoholic beverages against human Chang liver cell line. The assay was performed using micro culture MTT method. The results are compared with hydrogen peroxide (20 mM). The results summarized are mean values of two parallel experiments.

The result summarized in Figure 1, indicates that all the vodaka brands (6.7-25.9 %) and Gins (6.7-18.4 %) have shown moderate cytotoxicity against Chang liver cells. Interestingly, wine brands were observed to be nontoxic towards Chang liver cells. No significant cytotoxicity was observed with whiskeys, rums and brandy. In general the cytotoxic effects of the ABs are linked with alcohol percentage and the types of additives used in the finished samples. Many times in *in vitro* cytotoxicity methods, it is difficult to ascertain the correct levels of toxicity of ABs due to volatilization of many toxic agents along with alcohol. One more important aspect of polyphenols especially flavonoids present in the ABs is linked with antitoxic, hepatoprotective, and cytoprotective effects. Moreover in several countries, plant flavonoids are widely used in the treatment of liver diseases and diseases associated with increased vascular permeability and capillary fragility[17]. The nontoxic nature of wines selected in the present study might be due to presence of the cytoprotective flavonoids derived from the source material.

It is concluded from the present study that the selected wines can be considered as effective antioxidant and free radical scavenging agents with no toxicity. The results of the present study may serve people a cursory ready reference for the health concerns of the selected ABs widely consumed in the Maharashtra state in particular and many other states of India in general. The results may also influence the manufacturers in reorienting their production strategies.

Evaluation of Difference in Bacterial Contamination of Toothbrushes between Patients With Gingivitis And Patients with Healthy Gingiva-A Pilot Study

Madhumathi.D[1], Sri Sakthi[2]

[1]Intern, [2]Reader, Department of Public Health Dentistry, Saveetha Dental College and Hospitals, Chennai, Tamil Nadu, India

Abstract

Aim: To Evaluate the difference in bacterial contamination of toothbrushes between patients with gingivitis and patients with healthy gingiva.

Objective: 1.To determine the bacterial contamination in terms of CFU/ml after brushing for a period of two weeks in patients with healthy gingiva.

2. To determine the bacterial contamination in terms of CFU/ml after brushing for a period of two weeks in patients with gingivitis.

3. To compare the difference in bacterial contamination in terms of CFU/ml between patients with healthy gingival and patients with gingivitis.

Background: The most commonly used method to maintain oral hygiene is toothbrush. Its main goal is to remove plaque, debris and stains which are responsible for gingivitis, periodontitis , tooth decay and halitosis. While removing, toothbrush becomes contaminated with blood, saliva, bacteria and soft debris. The toothbrush itself can act as a foci of infection and retard the disease prognosis and treatment outcomes.

***Keywords**: Toothbrush, Decontamination, bacterial colonization, brushing, gingivitis, healthy gingiva.*

Introduction

The human oral cavity is invaded by a more number of bacteria flora than any other anatomic area in the body .It has been found that more than 700 species of bacteria out of which 400 species were found in the periodontal pocket adjacent to teeth(1).Maintaining good health is very important for a good quality of life. The impact of oral health on general health has been proved time and again by many studies.(2,3,4,5,6) The mouth serves as a "window" to the rest of the body, providing signals of general health disorders. Bacteria from the mouth can cause infection in other parts of the body when the immune system has been compromised by disease or medical treatments (e.g., infective endocarditis). Systemic conditions and their treatment are also known to impact on oral health (e.g., reduced saliva flow, altered balance of oral microorganisms).Periodontal disease has an impact on cardiovascular system, this statement was proved by many stuides. In 2006, Holmlund et al., periodontal disease and number of remaining teeth related to a past history of heart attack and high blood pressure or hypertension .Other study showed that both periodontal disease and overall tooth loss from any cause are closely related to cardiovascular disease. Alman et al (2011) have shown a signicant positive association between loss of bone supporting teeth due to periodontal disease and CVD(25-28).Periodontal disease is often considered the 'sixth complication' of diabetes(29).

Oral Prophylaxis is a premise for oral health and daily plaque and debris removal is considered important

for oral health. Improper maintenance of oral hygiene leads to the accumulation of plaque around the tooth which is a primary cause for gingivitis and periodontitis. Thus, removal of plaque plays a main key role in maintaining oral hygiene.

Tooth brushing is the most commonly used, easiest and effective method of oral hygiene practice performed around the world.(7) Toothbrush plays an important role in maintaining personal oral hygiene and it is effective tool for removing the plaque. Not only the proper selection but also care should be taken in maintaining the toothbrush which is essential for good oral hygiene because the toothbrush also gets contaminated by bacteria. Toothbrushes must have the following requirements to remove the plaque; stiff bristles which is enough to remove plaque without causing trauma to the teeth and gums and small head with soft bristles. Organisms are not only associated with oral cavity but also seen in tooth brush which includes Streptococcus mutans, Staphylococcus aureus, Pseudomonas, Lactobacillus, Klebsiella, Candida species(1).

Toothbrushes also has a significant role in disease transmission and increase the risk of infection since they can serve as a reservoir for microorganisms in healthy, oral-diseased and in immunocompromised people. Contamination is the state of retention and survival of infectious organisms that occur on animate or inanimate objects.(8) Contaminated toothbrushes may play a role in both systemic and localized diseases. This toothbrush contamination is associated with transmission of severe health problems which includes cardiovascular diseases, respiratory disorders, gastrointestinal diseases,arthritis, bacteremia ,renal problems and stroke.(7,8)

Toothbrushes can become contaminated from the oral cavity, environment, hands, aerosol contamination, and storage containers and the bacteria which attach to the toothbrush gets accumulated and survive on toothbrushes will helps in transmitting the diseases. In 1920 Cobb reported that toothbrush is the cause of repeated infections in the oral cavity (9). Contaminated tooth brush acts as an environment for microbial transport, retention and growth. Toothbrush heads between the bristle tufts is a favourable medium for the growth of microorganisms. This can be the cause of reinfection of a person with pathogenic bacteria (autoinoculation) or it can acts as a significant risk of dissemination of infection for certain patients such as immunosuppressed, cardiopathic ,organ transplant recipients(11).

So, the contamination of toothbrush can be prevented by immersing it in disinfectant solutions like 0.1% Chlorhexidine gluconate and 1% Sodium hypochlorite and replacing in a regular time period. So far many studies have evaluated the contamination risk of tooth brushes, within the bias of literature search, it was inferred that, none of the studies has focussed on the difference in contamination between a patient with gingivitis against health gingiva. This difference is studied and found to be true significance, it could help in patient education and help in better treatment outcomes. Hence this study was done to investigate and compare the bacterial load on toothbrushes used by patients with healthy gingiva and gingivitis.

Materials and Method

Study design: A non randomized clinical trial.

Study setting: Approximately 1000 patients are visiting saveetha dental college daily.

Among them, 90% of the patients are diagnosed with poor oral hygiene and they were given a demo of modified bass brushing method followed by health education to improve their oral health.

Study Population:18 to 45 years who visited the OP of saveetha dental college were selected based on the study criteria.

Eligibility Criteria:

Ø **Inclusion Criteria**:

· Patients with age group between 18-45 years ,

· Group-A(gingivitis)-Based on gingival index by Loe and Silness.

· Group-B(Healthy gingiva)- gingiva which is firm in consistency, with pink colour and scalloped margins were included in this study.

Ø **Exclusion Criteria:** Patients with a history of systemic disease(Myocardial infarction, ischaemic heart disease, COPD, Bronchial asthma, Hyperthyroidism, Hypothyroidism, Hypercholestrolemia, hypertension, diabetes mellitus, renal disorders, blood disorders, Parkinsons disease, cushing syndrome), patients who had periodontitis and who are not willing to participate were excluded from this study.

Informed consent:

· Prior to start the study written informed consent was obtained from all the participants.

· Institution ethical committe approval was also obtained prior to the study.

Sample size: Based on the study by Taji.et.al, the sample size of this present study was

10%.

Sampling: A non probability type of sampling was used. Selective /judgemental. Patients

visiting the OP was choosen based on the inclusion and exclusion criteria until

the sample size was achieved in each group.

Armamentarium:

The following equipments/materials were used for the study:

· Steriled mouth mirror

· Surgical gloves

· Steriled containers

· Normal saline

· Cuvettes

· Micropipette

· Petri dish

· Nutrient agar

· Spirit lamp

· Metal loop

· Incubator

Method

All the gingivitis patients were selected based on gingival index given by Loe H and Silness P (1963).For assessing the severity of gingivitis, and its location by examining qualitative changes of gingival tissues. The severity of gingivitis is scored on the selected index teeth(16,36,12,32,24,44) .Tissues surrounding each tooth divided into 4 gingival scoring units which are Disto-facial papilla, Facial margin, Mesio-facial papilla and Lingual gingival margin.

Grading of the gingivitis:

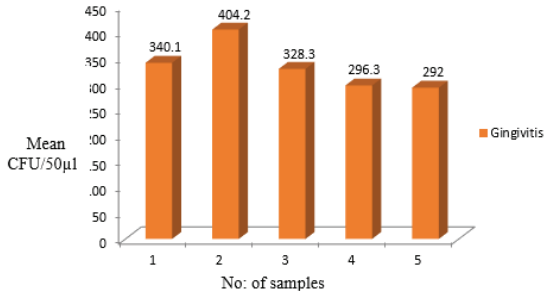
Score-0,gingival status is normal gingiva and the criteria is natural coral pink gingiva**;Score-1,gingival status is mild inflammation and the criteria is** slight changes in colour, slight edema. No bleeding on probing;Score-2 ,gingival status is moderate inflammation and the criteria is Redness, edema ,glazing and it bleeds on probing and score-3,gingival status is severe inflammation and the criteria is marked redness and edema/ ulceration/ tendency to bleed spontaneously.

All the examinees who met the criteria were informed about the study. Both were each given a new toothbrush with same brand of fluoridated tooth paste. Each subjects were given a demo of modified bass brushing method and they were requested to follow twice daily for a period of 2 weeks, since it is effecting in cleaning proximal and gingival sulcus. At the end of 2 weeks, brushes were collected in a sterile bag and processed.

Each toothbrush was then transferred into the container containing 10ml of steriled normal saline and mixed vigorously for 1 minute. After mixing,50µL of saline was transferred into the cuvette which is incubated at 37^0C for 1hr by placing in the incubator.

50µL of saline was then spread onto the plates of nutrient agar for the growth of an aerobic bacteria. Each sample was processed 3 times and incubated to minimise the manual and laboratory errors.The nutrient medium was incubated aerobically for 24hrs at 37^0C.Then total bacterial count was done. The results are tabulated which are as follows,

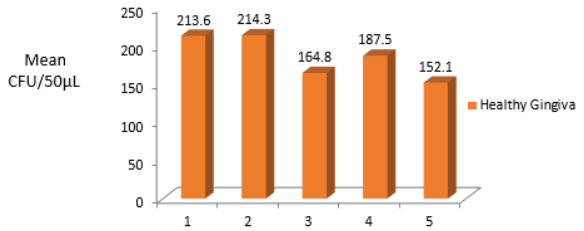
Result



Graph-1 shows the mean of bacterial colony counts of 5 samples in gingivitis patients.

Graph-1,depicts the mean of bacterial colony count in terms of CFU/50µL of all the 5 samples in gingivitis patients.Sample-1 has a mean of 340.1 cfu/50µL,sample-2 has a mean of 404.2 cfu/50µL, sample-3 has a mean of 328.3 cfu/50µL,sample-4 has a mean of 296.3cfu/50µL and sample-5 has a mean of 292cfu/50µL.

Figure-1 depicts the bacteria in agar plate of gingivitis patients.



Graph-2 shows the mean of bacterial colony counts of 5 samples in patients with healthy gingiva.

Graph-2,depicts the mean of bacterial colony count in terms of CFU/50µL of all the 5 samples in patients with healthy gingiva. Sample-1 has a mean of 213,6 cfu /50µL,sample-2 has a mean of 214,3cfu/50µL, sample-3 has a mean of 164.8 cfu/50µL,sample-4 has a mean of 187.5 cfu/50µL and sample-5 has a mean of 152.1 cfu/50µL.

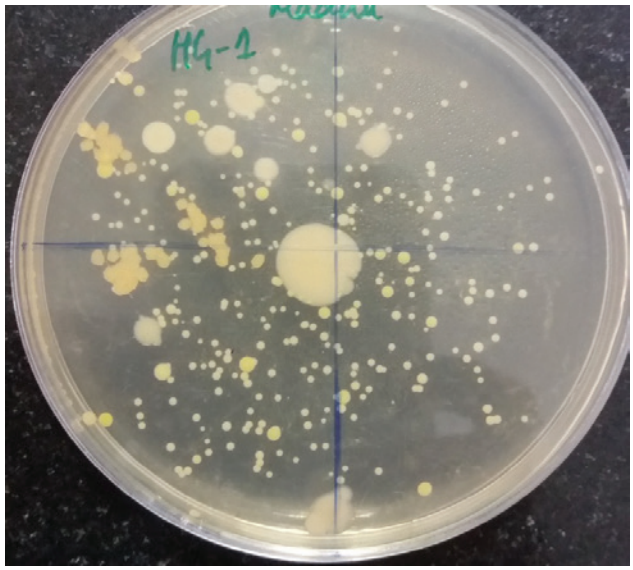


Figure-2 depicts the bacteria in agar plate of patients with healthy gingiva.

Discussion

The result of this study showed that the bacterial contamination was more in toothbrush used by gingivitis patients than the patients with healthy gingiva and the predominant microorganisms isolated were S. aureus, and S.mutans.

In the present study, microbial contamination was seen in all the 10 toothbrushes (100%) and this finding was consistent with some previous studies found microbes on all of the tested toothbrushes[12-15].But in one of the previous studies, microbial contamination was seen in 7 out of 10 toothbrushes (70%)[16].Bunetel et al. found that toothbrushes used by patients with existing oral disease quickly became contaminated [18].Several of the studies found that toothbrushes were contaminated before use[17-20]. Caudry et al. found that toothbrushes are heavily contaminated with normal use[8].

In the present study, Predominant microorganisms isolated were S. aureus, and S. mutans and this finding was consistent with most similar studies[12,13,14].In other

study, Microbial growth was detected on almost all of the brushes tested in this study (>90%), with development of streptococci observed on the vast majority of the brushes, which shows that toothbrushes are an excellent means of transport for bacteria. Nearly half of the brushes showed growth of mutans streptococci, members of the oral microflora, that are currently considered to be major cariogenic agents [24]. Other study reported that toothbrushes are heavily infected with escheriachia coli followed by klebsiella pneumonia , streptococcus pyogenes, staphylococcus auerus [31].Glass found that toothbrushes from both healthy patients and patients with oral disease contained potentially pathogenic bacteria and viruses such as Staphylococcus aureus, E. coli, Pseudomonas, and herpes simplex virus[17].Svanberg M. found that toothbrushes could be heavily infected with microorganisims especially mutans streptococci[30].

In the present study, the mean of bacterial colony count in gingivitis patients ranges from 10^2 to 10^5 Colony forming units /50µL and in patients with healthy gingiva the mean ranges from10^1 to 10^3 colony forming units/50µL. In one of the previous studies, the total microbial load per tooth- brush was found to be $10^4$to 10^6colony forming units[15].

The American Dental Association recommends a routine change of toothbrushes every 3 months [7]. According to the reports of Denny and glass[23,24] healthy patients replace their toothbrush every two weeks. Patients who are sick should change their toothbrushes at the beginning of an illness, when they first feel better, and when they are completely well. Chemotherapy or immune-suppressed patients should change their toothbrushes every three days, and persons submitted to major surgery should change their toothbrushes every day. So, the replacement of toothbrush in regular time periods is very essential to prevent the continuation of reinfection of oral diseases.

Conclusion

1.The result of this study showed that the bacterial contamination was more in toothbrush used by gingivitis patients than the patients with healthy gingiva and the predominant microorganisms isolated were S. aureus, and S.mutans.

2.Toothbrushes have an important role in transferring microorganisms which increases the risk of infection. So, the dentist should be more responsible in order to aware the patients for the issue of choosing, keeping and maintaining the hygiene of the toothbrushes, as well as their replacement in regular period of time.

Limitations of the study:

- A first limitation was the time constraint .
- A second limitation was the small sample size**.**

Direction of the future research: It is the follow up of this present study, assessment of progression and prognosis of a disease by using decontaminant solutions.

Prevalence of Cumulative Trauma Disorder of Wrist Joint in Auto Mechanical Workers

Mandar Kulkarni[1], Trupti Yadav[2]

[1]Final year, Faculty of Physiotherapy, [2]Assistant Professor, Department of Musculoskeletal Sciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be university, Karad, Maharashtra, India

Abstract

Purpose – To study prevalence of cumulative trauma disorder of wrist joint in Auto mechanical workers**. Method :** In this study 60 subjects were taken. Auto mechanical workers working more than 5 year were included in study to know incidence of CTD or wrist in Auto mechanical workers 4 special test were taken Majority group age was from 30-55 years of age. **Result :** In conducted study 4 special test were taken of subjects. In sharper's test was negative among all subjects in carpal compression test 3 (5%) subjects were positive. In phatent's test 11(18.33%) subjects were positive. In finkstein test 6 (10%) subjects very positive. Amount of CTD in Auto mechanical workers is 23.33%**. Conclusion:** The mean age of study subject was 36 years. Pains were preeminently & significantly observed among higher age group as compared to vesser age groups. Prevalence of CTD in AMW in present study in 23.33

Keywords: *cumulative trauma disorder, wrist, pain, flexibility*

Introduction

Anatomy

The wrist is complex joint that connects the radius and ulna to the carpal bones. The wrist joint allows for the manipulation of objects in space and provide us with the dexterity required for fine motor skills. The wrist joint is the junction of the distal end of the radius and ulna and the adjecent carpal bones. In this joint bones are smaller, there is less cartilage and ligaments are thinner which increases risk of injury. The eight carpal bones can be divided into two rows of four bones. The proximal row consist of scaphoid, lunate, triquetral, pisiform bone. The distal row consist of trapezium, trapezoid, capitates and hamate bone. There is direct connection between carpal bones and ulna, there is cartilaginous disc that acts to allow increase congruence between ulna and carpals. The disc is known as Triangular Fibrocartilage Complex (TFCC).[1]

Biomechanics

The wrist joint is a complex linkage between forearm and hand which is capable of impressive motion yet retaining a remarkable degree of stability. Carpal stability is derived from intra and intercarpal ligament in addition to closely approximated wrist flexor and extensor. Motion occurring at the campus is predominantly biplane radial ulnar deviation and palmar flexion and extension. The centre of motion for these planes of movement is located within the proximal and palmar pole of capitate. When painful condition arise at the wrist, a loss of wrist motion usually follows. Occasionally a loss of wrist extensor is noted with finger flexor activity. Wrist motion is essential for most activities of daily living, the preservation of wrist motion is for some individual essential for the performance of specific occupational or recreational activities.[2]

Cumulative Trauma Disorder (CTD)

Cumulative Trauma Disorder are caused due to excessive wear and tear on tendons, muscles and sensitive nerve tissue caused by continuous overuse on extended period of time. Repetition of small movements, poor posture, forceful grasping can all contribute to CTD. CTD may be present with pain, tenderness and loss of joint mobility or loss of co-ordination.[3]

Triangular Fibrocartilage Complex (TFCC)

TFCC is an area between radius and ulna, the two bones that make forearm. TFCC is made of several ligaments and tendons, as well as cartilage. It helps wrist move and stabilize forearm forearm bones when we grasp something with our hand. In TFCC injury main symptoms of TFCC tear is pain along the ulnar side of wrist , though might also feel pain throughout entire wrist. Other symptoms of TFCC tear include:

1) Clicking sound when we move our wrist

2) Swelling

3) Weakness

4) Tenderness

Cause of TFCC tear are caused by injury e.g- falling or landing on outstretched hand may damage cartilage, tendons or ligaments in TFCC.[4]

Carpal tunnel syndrome

Carpal tunnel syndrome is common condition that causes pain, numbness and tingling sensation in hand and arm. The condition occurs when median nerve is squeezed as it travels through the wrist. Symptoms of CTS are numbness, tingling and burning sensation and pain.[4]

De Quervain's Tenosynovitis

De Quervain's Tenosynovitis is painful condition affecting the tendons on radial side of wrist pain occurs when there is grasping action or while making fist. There may be pain near thumb base , swelling may be present in thumb. Difficulty in moving wrist while doing grasping or pinching. It may be also caused due to overuse of wrist.[4]

Extensor Carpi-ulnaris Tendinitis

Extensor Carpiulnaris Tendinitis is a injury of wrist in which the tendon of extensor Carpiulnaris muscle becomes irritated and inflamed. The most common symptom of extensor Carpiulnaris Tendinitis is pain on ulnar side of wrist pain increases when person grabs some object or flexion and extension of wrist may also trigger pain. Other symptoms are swelling, stiffness and decreased ROM.[4]

Materials and Method

Material

It was an observational study comprised over a period of 24 weeks. consecutive method was used for calculating sample size. As per sample size calculation, 60 was the actual sample size, 60 subjects were included using random sampling method for data collection. We had selected only those subjects who spend more than 5 years of working . Subjects with any recent trauma history, recent fractures, any pain due to pathology in wrist, decreased range of motion due to stiffness, soft tissue injury of wrist were excluded from the study.

Methodology

After receiving clearance from the institutional human research ethical committee of Krishna institute of medical sciences 'deemed to be' university for this study, Informed written consent was taken from all the subjects. Sixty subjects fulfilling the inclusion criteria i.e subjects who are working more than 5 years as aoutomechanical worker. After taking consent and necessary demographic data including name, age, sex, weight, height, working hours per day . All the subjects were assessed using tests: such as phalen's test, finklestein's test, carpal compression test were performed.

Inclusion Criteria:

- Individual who is automechanical workers working more than 5 year

Exclusion Criteria

- Any recent wrist trauma
- Individual whose occupation do not required repetitive wrist movement

Outcome Measures

- Visual analogue scale

Limitations

1. Subject selection was limited to active workers.
2. Those away from the job with CTDs at the time of evaluation (potentially more severe cases) would not have been available for study.

Results

Demographic Characteristics

In the present study, we assessed the age distribution of the study subjects. We observed that the majority of the study subjects belonged to the age group of 31-40 years (60%), followed by less than 30 years and 4150 years (20% each)

Presenting Symptoms

In the present study, we assessed the study subjects according to their presenting symptoms. We observed that 26.66% cases had pain and 23.33% cases presented with limitation in movements.

Sharpey's Test

In the present study, we conducted Sharpey's tests among the study participants. None of the study subjects showed positive results. (Table 3)

Table 1: Distribution of study participants according to their signs

Sharpey's test	Number of subjects	Percentage
POSITIVE	0	0
NEGATIVE	60	100%
TOTAL	60	100%

Carpal Compression Test

In the present study, we conducted Carpal compression testamong the study participants. 5% of the study subjects showed positive results. (Table 2)

Table 2: Distribution of study participants according to their signs

Carpal compression test	Number of subjects	Percentage
POSITIVE	3	5%
NEGATIVE	57	95%
TOTAL	60	100%

Phalen's Test

In the present study, we conducted Phalen's test among the study participants. 18.33% of the study subjects showed positive results. (Table 2)

Table 3: Distribution of study participants according to their signs

Phalen's test	Number of subjects	Percentage
POSITIVE	11	18.33%
NEGATIVE	49	81.66%
TOTAL	60	100%

Finkelstein Test

In the present study, we conducted Finkelstein testamong the study participants. 10% of the study subjects showed positive results. (Table 3)

Table 4: Distribution of study participants according to their signs

Finkelstein test	Number of subjects	Percentage
POSITIVE	6	10%
NEGATIVE	54	90%
TOTAL	60	100%

Cumulative Trauma Disorder

In the present study, we assessed the prevalence of cumulative Trauma Disorder of wrist joint. We observed that out of 60 study subjects, 14 subjects showed positive tests which suggests cumulative Trauma Disorder of wrist joint (23.33%). (Table 4)

Table 5: Distribution of study participants according to prevalence of cumulative Trauma Disorder of wrist joint

CTD	Number of subjects	Percentage
Present	14	23.33%
Absent	46	76.66%
TOTAL	60	100%

Comparison Between Age Distribution and Clinical Presentation

In the present study we assessed the association between demographic characteristics and clinical presentation of study subjects. We observed that pain and limitation of movements of wrist joint were prominently and significantly observed among higher age groups as compared to lesser age groups (Chi-square value: 10.62, p-value: 0.0069 for pain and Chi-square value: 8.61, p-value: 0.0134 for limitation of movements)

Comparison Between Age Distribution and Carpal Compression Test

In the present study, we studied the association between age distribution and positive demonstration of carpal compression test. We observed that the observation were not statistically significant, when analysed among various age groups (Chi-square value: 0.93, p-value: 0.62**).**

Comparison Between Age Distribution and Phalen's Test

In the present study, we studied the association between age distribution and positive demonstration of Phalen's test. We observed that the observations were found to be statistically significant, when analysed among various age groups. As the age increases, the prevalence of CTD inceases (Positive Phalen's test) (Chi-square value: 10.09, p-value: 0.0064**).**

Comparison Between Age Distribution and Finkelstein's Test

In the present study, we studied the association between age distribution and positive demonstration of Finkelstein's test. We observed that the observations were not statistically significant, when analysed among various age groups (Chi-square value: 3.82, p-value: 0.147**).**

Conclusion

The mean age of the study subjects was 36.7 years. The pain and limitation of movements of wrist joint were prominently and significantly observed among higher age groups as compared to lesser age groups The prevalence of cumulative Trauma Disorder of wrist joint in the present study was 23.33%, the percentage of carpal tunnel syndrome was ranged from 21.42% of all CTDs (positive Carpal compression tests) to 78.57% of all CTDs (positive Phalen's sign), and the percentage of various tendon disorders (de Quervain's disease) was 42.85% of all CTDs.

A Study to Assess the Knowledge on Cancer among Geriatric Patients at SRM General Hospital, Kattankulathur in Kancheepuram District, Tamil Nadu, India

Manju[1], T.Suseelal[2], C.Kanniammal[3]

[1]B.Sc Nursing, [2]Associate professor, SRM College of Nursing, [3]Dean, SRM College of Nursing, SRM Institute of Science and Technology, Kattankulathur, Chengalpattu Dist, Chennai, Tamil Nadu, India

Abstract

Cancer is a dread full disease in India and all over the world. Nowadays after age of 75 many people are living longer. Therefore special attention must be taken to the treatment of older cancer patients. Hence it is necessary assess the knowledge on cancer among the geriatric patients to develop awareness on cancer.

Objectives

1. To assess the knowledge on cancer among Geriatric patients at SRM General Hospital, Kattankulathur.
2. To associate the knowledge on cancer among Geriatric patients with their demographic variables.

Methodology: Non experimental descriptive research design was adopted to assess the knowledge regarding cancer among Geriatric patients. Totally 100 samples who fulfilled the inclusion criteria were selected by convenient sampling technique. Self structured objective type questionnaire was used to assess the knowledge on cancer among Geriatric patients in SRM General Hospital at kattankulathur.

Major Findings: The result of the study revealed 23(23%) patients have poor level of knowledge; 70 (70%) patients have moderate level of knowledge; 7 (7%) patients have high level of knowledge regarding cancer.

Conclusion: The study conclude that there is a need for health education among Geriatric patients to understand and treat cancer earlier, hence morbidity and mortality may be prevented and their quality of life may be improved.

Key words: *Knowledge, cancer, geriatric patients, Health education, Morbidity.*

Introduction

Cancer is one of the non communicable disease and it ends with poor survival among all age group. Only little research data is available in radiation and chemotherapy treatment. Globally incidence of cancer and mortality is increasing vomiting, loss of hair, oliguria, dehydration are experienced by patients after chemotherapy.

Also, very few research results are reported on cancer and risk factors of cancer and its knowledge on care. Hence, this research topic intended to assess the knowledge of geriatric people on cancer. So that health education can be planned to create awareness to seek early treatment.

According to WHO statistics worldwide 60% people die with chronic disease like cancer. WHO estimate that 8.8 million people are died in 2015 with cancer. According to one of the study done in Shandong province among elderly the prevalence of chronic disease was 81.8% and their daily health care expense

Corresponding Author :
Dr. T. Suseelal
Associate Professor**,** SRM College of Nursing,SRM Institute of Science and Technology, Kattankulathur, Chengalpattu Dist – 603203, Chennai, Tamil Nadu, India

was 28.8%.

In 2017, it is estimated that 13%, 6 cases per 100,000 per year affected by cancer, In UK 356,860 people are approximately affected. One of the states 1,688,780 new cases are diagnosed and 600,920 cases died with cancer in US. In Tamil Nadu 2 million people were affected and In Chennai 2012-2016 annual cancer predicted is 6100[3].Among Chinese old people aged over 60 years are affected with all type of cancers.[4]

In china cancer is the leading cause of death. In UK cancer is the first cause of death[5]. Approaching and assessing the knowledge on cancer and doing screening is a difficult process. Early detection, treatment and improving health among elderly people is an important role of health professionals.[6-8]

Thus the study intended to assess the knowledge on cancer and identify the risk factors to prevent and treat cancer earlier.

Method

Study setting: The study was conducted among geriatric patients those who are admitted and came to medical out-patient department in SRM general hospital, Kattankulathur.

Ethical consideration:

This study was conducted after the opinion of experts in nursing, statistician and SRM Ethical Committee approval during the month of January 2019.

Sample selections:

The Patients those who are admitted and those who are came to medical op in SRM general hospital kattankulathur. The sample size consisted of 100 patients who were selected by convenient sampling technique.

Data Collection Tool

Demographic variables which includes age, gender, marital status, education, occupation, place of living, health insurance status, duration of illness, family history of chronic diseases, if yes, types of chronic illness and visual acuity.

Face to face interview questionnaire which consist of 36 items was used to assess the knowledge on cancer among geriatric patients. It has questions on domains like causes, signs and symptoms, diagnosis, diet pattern, treatment, exercise, complications and health education Each correct answer carries score (1). Wrong answer carries score (0). Total score was 36. TheReliability of the tool was established by split half method. The coefficient correlation r = 0.996 which is greater than r=0.05 which was very high. Hence, the tool was considered reliable and feasible for proceeding with the main study.

Statistical Analysis

The data was tabulated in excel sheet and analysis was done with descriptive and inferencial statistics. The significant statistical p value was < 0.05.

Results

The demographic variables revealed among 100 participants majority of them were between 50-60 years (51%), both male and female were (50%), married were (58%), people with informal education were (64%), majority of them were unemployed (73%), urban population were (54%), majority of them had no insurance (67%), people with chronic disease were (63%), most of them with diabetes mellitus (41%), participants with myopia were (43%).

Table 1: Assessment of the level of knowledge on cancer among geriatric patients at SRM general hospital N= 100

S. No.	Level of Knowledge on Cancer	No. of Patients	Percentage
1	Poor Level Knowledge	23	23%
2	Moderate Level Knowledge	70	70%
3	High Level Knowledge	7	7%

The above table reveals that among 100 geriatric patients, 23 (23%) have poor level knowledge on cancer; 70 (70%) have moderate level knowledge on cancer; 7 (7%) have high level knowledge on cancer.

Regarding the association between knowledge of cancer among geriatric patients and with their demographic variables "Gender" is significant with ($p<0.05$). Other variables such as age, marital status, education, occupation, place of living, health insurance status, duration of illness, family history of chronic diseases, type of chronic disease, visual acuity are not having association with demographic variables.

Discussion

Cancer is thought to be the 2nd killing disease all over the world. Many people are not aware of the seriousness of this disease. Unfortunately many of the cancer in the affected organ are hidden for 4-5 years. Inspite of all vigorous treatment people lose their loved ones after spending lot of money for various treatment modalities in the hospital. It is hereditary disease in some families. Though the cause of cancer is unknown the food habits and job status and other environment pollution like smoking, radiation are causing abnormal cell growth in any part of the body. Some type of cancer like carcinoma of bronchi can not be diagnosed unless a biopsy is done. This may lead to mortality within short time if it is not identified earlier.[9,]

The warning signs of cancer must be taught to everyone to identify this disease earlier so that proper treatment can be given in the initial stage. Nowadays many new medications are found to care this disease. But if in fourth stage the treatment will not benefit. Hence it is the duty of all medical people and health care providers to support, educate and treat the people with any cancer to have quality and long life.

This result is consistent with the study done by Frida S. et al ., (2012) conducted a project in rural region of Tanzania on knowledge ,attitude and accessibility related to cervical cancer screening. Around 22.6% of the participants were enrolled in the study. The result revealed women's education level, knowledge on cervical cancer and prevention, husband permission for undergoing screening procedure, women's awareness on distance of cervical cancer services were associated with screening uptake and the study was found significant[10].

Also the study recommended to do further research on the knowledge and practice of cancer patients. The Present study helped to teach the participants and it cleared the patients doubts.

Conclusion

Thepresent study assessed the level of knowledge on cancer and association between knowledge on cancer among geriatric patients and with their demographic variables.The study concludes that there is a need for health education among geriatric patients to identify cancer earlier. So that death rate due to cancer can be reduced among all population.

Analysis of Factors Causing Extraction of Endodontically Treated Teeth-A Retroprospective Study

Mohammed Ahad[1], Pradeep S[2]

[1]Under Graduate Student, [2]Senior lecturer, Department of Conservative and Endodontics, Saveetha Dental College, Saveetha University, Chennai

Abstract

Aim: To study and analyze the various reasons for extraction of endodontically treated teeth.

Material and Method: 150 Endodontically treated teeth were reviewed, and the following reasons were recorded: patient's age, gender, type of tooth; presence and type of coronal restoration; motive of consultation; reasons for extraction.

Results: Pain was the primary reason for consultation .Mandibular first molar was the most common tooth involved followed by maxillary first molars. coronal failure where the main reason for extraction of endodontically treated teeth, this was due to neglegance in replacing permanent restoration where only 16% of the cases had either full veneer crown or post and core, followed by periodontal disease, vertical root fracture and non restorable caries.

Conclusion: A good coronal restoration is required for a successful long term outcomes.

Key words: *Endodontically treated teeth, Extraction, Pain, Molars, Coronal failure.*

Introduction

Root canal treatment is a "non-surgical" approach used to treat two particular endodontic diseases substances:"extirpated" vital, however irreversibly Inflamed pulp, where the objective is to keep up existing periapical health and therefore prevent Periapical disease; or the non-vital or dying, infected pulp related with apical periodontitis[1] . Success rate for endodontically treated tooth in around 40-96% which depends on differences in experimental design, patient selection, criteria for evaluation, clinical procedure, and length of postoperative observation[2-7] .This variation in suc-cess rate is to a limited extent because of the absence of a reasonable definition of the success and failure of endodontic treatment[3,6,7] . Albeit a few investigations have utilized tooth maintenance and the non appearance of clinical signs and indications to define success[3,6] ,most examinations have assessed to review radiograph to decide endodontic success. Since endodontic treatment is performed for the most part to avoid tooth extraction, it is imperative to assess the fate of endodontically treated teeth[8] . The survival or functionality of the endodontically treated tooth is currently the emerging aspect of endodontic treatment outcome, rather than healing[9].

Dental caries is of prime enthusiasm for the endodontist, as caries is thought to be a genuine risk to the long term result of endodontic treatment and also to the life span of root-filled teeth[10,11] . For instance, a current report observed nonrestorable caries injuries to be the primary explanation behind extraction of such teeth[12,13] . Despite the ob-vious significance of the issue, few examinations have been meant to investigate factors that impact the etiology and progression of caries in the root-filled tooth[14,15] . Dental caries is the fundamental cause of irreversible pulpi-tis and consequent root

canal treatment. Therefore , it may be suspected that endodontically treated teeth frequently are found in people with high caries hazard. Besides, there are signs in the literature that the loss of pulp vitality, depriving the dentin of a Several defence mechanism, will increase the suscep-tibility to caries. Additionally, the loss of an intrapulpal pain-signalling syestem will make it feasible for a caries lesion to be left undetected for a long period of time[16] . The microbial and non-microbial causes for essential root canal treatment failure have been completely looked into by Nair[17] Histo-pathological examinations recommended that Mostly likely the reason for treatment failure was intra-radicular microbes dwelling in accessory canals or alongside by the root-filling[18-20] . In a few examples, failure has been caused by: extra radicular actinomycosis[21-25] ; cystic apical periodontitis, foreign body response to cholesterol gems[26] , expelled dentine chips[24], expelled calcium hydroxide, expelled sealer, expelled amalgam[27], expelled gutta-percha filling material[27] or expelled cellulose segments from paper points, cotton wools, or pulses[28] . Several studies reveals failures can be because of not as much as ideal endodontic treatment however insufficient or unsuccessful restorative treatment is the significant issue. Almost 50% of all failures were because of fracture of the natural coronal tooth structure and seemed to involve either uncrowned teeth or crowned teeth without complete anchorage. They were considered unrestorable because of the degree of lost tooth structure. Teeth with crowns demonstrated longer clinical life than non-crowned teeth[29] . Vertical root fracture (VRFs) in endodontically treated teeth are a disappointing phenomenon for both the patient and dental specialist[30] . Diagnosis is frequently difficult because the signs, symptoms, and radiological features imitate true endodontic failure or periodontal infection, an issue that has been talked previously in the case reports[31-33.] Several etiologies for VRFs have been already recommended, mostly it is iatrogenic in origin . Two noteworthy causes are excessive pressure during lateral condensation of gutta-percha[31-33] and root canal reinforcement of these teeth at a later stage[31-35 .]

The aims of the present retrospective study, involving Indian adults, were to analyse the various factors that's leads to extraction of endodontically treated teeth such as Vertical root Fracture nonrestorable caries or cusp fracture, endodontic failure, periodontal disease, orthodontic or prosthetic reasons, and trauma and whether there were any associations between these reasons and tooth location, and the postendodontic permanent coronal restorations.

Materials and methods

Data were collected during a 2 month period between November - December 2018, from the oral surgery department, saveetha dental college , Tamil Nadu, chennai. A total of 150 cases was gathered and teeth that were extracted before the completion of root canal treatment was been excluded. Patients name age sex and any oral habits were obtained from record management system. The chief complaint for visiting the dentist after root canal treatment were noted (pain, mobility, trauma, other reasons).The tooth involved, the reason for extraction (caries, periodontal disease, endodontic failure, prosthetic, vertical root fractures, , orthodontic, esthetic, or other reasons to be specified)and whether the tooth is coronally restored with crown, post-core or with no permanent restoration was obtained and confirmed from pre-extraction periapical radiographs.

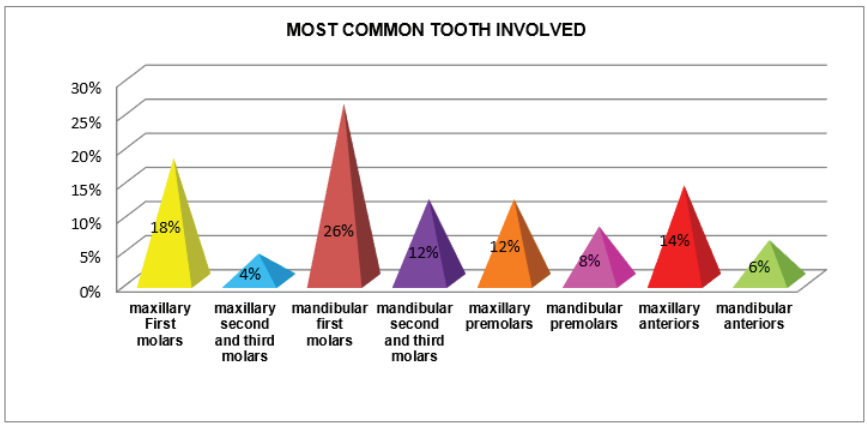

Figure 1

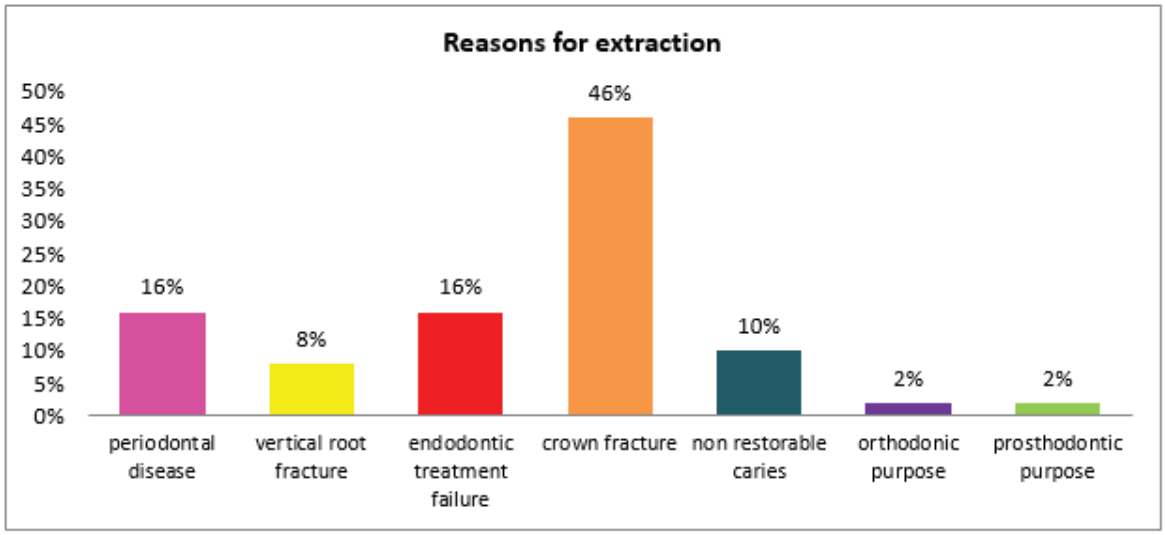

Figure 2

Results

Of the 150 cases taken for the study, 62% were male and 38% were female. The mean age was 37.7%±14.25%. 48% had underwent rct 1-2 years ago, whereas 18% of them had done rct more than 5 years ago. These root canal treatment done were mostly unintentionally (94%) while the rest were done for prosthodontics purpose as a full mouth rehabilitation cases. Dental pain was the main reason for visiting the dentist which accounts for 74% followed by dental mobility (10%), trauma (10%), and other reason for consultation were crown fracture were mentioned (4%). Molars were the most common tooth involved during emergency consultation. First mandibular molars (26%) were more common followed by maxillary first molar (18%), mandibular second and third molars (12%), maxillary incisors and canines(14%), maxillary first and second premolars (12%), mandibular first and second premolars(8%), mandibular incisors and canines(6%), maxillary second and third molars (4%).

Only 16% were previously coronally restored out of which 12% were restored with post and core and 4% were restored with crowns. 84% were not permanently restored and during time of extraction were with temporary coronal restoration and few were without coronal restoration at all. The reason on which the decision to extract the root canal treated tooth were based are presented in figure 2. Crown fracture(46%) was the most common reason for extraction due to neglegance in restoring the teeth with permanent restoration, followed by periodontal disease (16%), endodontic treatment failure (16%), vertical root fracture (10%), non restorable caries (8%), prosthodontics and orthodontic purpose each 2%.

Discussion

In this study, pain was the most common (74%) reason for consultation, similar to study done by toure et al (68.9%). Mandibular Molar's were the most common extracted teeth (46%), followed by maxillary molar (18%) which almost similar to study done by toure et al[8] , The predominance of mandibular molar was also noted by zadik et al[12] , in which around 44.6% were molars in the sample. 6% of mandibular incisor and canines were extracted in our study but zadik et al[12] , didn't had any case which involved mandibular anteriors, while toure et al represented 3.2%[8] .

In the present study, 84% of the extracted teeth never had a fully restored cuspal crown coverage, which was similarly seen in zadik et al (85%) and toure et al (94%), hence coronal fracture were the most primary reason for extraction of endodontically treated teeth(46%) in this study, where the other studies had more of nonrestorable caries and periodontal condition as reasons for extraction

Toure et al[8] reported periodontal reason as the main primary cause (40.3%) for extraction similarly seen in study done by Chen et al[36] and Vire[37] , who noted that 26.8% and 32%, respectively, whereas our study revealed only 16% and fuss et al had least cases of extraction caused due to periodontal diesease (5.5%)

Zadik et al[12] stated most common reason which relates to nonrestorable caries were the primary causes of extraction, whereas our study showed only 8% of extracted teeth caused due to non restorable caries which is slightly higher done study done by toure et al who had 5.2% of non restorable caries.

Prevalence of vertical fractures was found in sjogren study[2] which had 31% VRF in teeth after endodontic treatment. This contrasts with the results obtained in the present study, which revealed only 10% of extraction caused due to vertical root fracture similar to those of. Zadik et al 8.8%[12], toure et al[8] and Vire[37] with 13%

Fuss et al reported that endodontic treatment failure as the primary cause for extraction (63%) whereas only 16% reasons were found in our study similar to toure et al 19.3%[8] and zadik et al 12.1%[12]. Vire[37] revealed 59.4% were prosthetic failures which were due primarily to crown fracture.

Conclusion

The fate of endodontically treated teeth without a crown were the primary cause for teeth extraction followed by endodont treatment failure and periodontal disease. This study had limitation of lesser number of cases taken into account within a span of two months and no age limit hence a detailed study is necessary to obtained the results for the longevity of endodontically treated teeth.

Assessment of Nuclear Changes between Hans and Arecanut Chewing Patient in a Subset of Population

Mohammed Ahad[1], Gheena S[2], Remmiya Mary Varghese[2],

[1]UnderGraduate Student, [2]Senior lecturer, Saveetha Dental College, Saveetha University, 162, Poonamallee High Road, Velappanchavadi, Chennai

Abstract

Aim: To study nuclear changes occurring in patients with Arecanut and Hans chewing habits

Background: Adverse oral habits lead to premalignant lesions. Tobacco chewing, smoking and alcohol intake have been attributed to as major risk factors.Different forms of tobacco usage are prevalent in India and many of them are specific to certain areas. Hans is mixture of tobacco products usually kept in between the cheek and gum or upper lip teeth and chewing. Arecanut has been recently linked to oral submucosal fibrosis.Exfoliative cytology, which is a quick and simple procedure, is an important alternative to biopsy in certain situations. In exfoliative cytology, cells shed from body surfaces, such as the inside of the mouth, are collected and examined.

Materials and Method: Cytological smear was taken among 30 patients using exfoliative cytology method. Tobacco users were grouped into two groups Hans and arecanut chewing habits.

Results: The result of the study shows increase in frequency of micronuclei among arecanut users when compared with Hans users and controls

Conclusion: The study reveals early identification of premalignant lesion in patient using arecanut and Hans products when compared to normal individual.

Keywords: *Arecanut, Hans, Premalignant Lesion, Oral submucous fibrosis, Exfoliative cytology.*

Introduction

Oral disease is right now the 6th most basic danger on the world[1] . In India it is the most widely recognised danger among men and one of the five most common malignancies among women[2] . Annually around 274000 people in the world are affected by oral cancer[3] . It represents 5% of every single threatening tumour and 60% of these lesions are very much progressed at the beginning of diagnosis. Analysing and treating these lesions can avoid tumour growth[4] . Smokeless tobacco products (STP) are utilised without burning and this eliminates the risk of direct exposure of toxic substances to the lung and different tissues of the user and of the general population around the world. But, the utilization of STP may result in health hazard, local or systemic as per the substance of different lethal items, including nicotine and tobacco-particular nitrosamines[5] . There is a geographic variety in the rate of tumour of the head and neck among various nations of the world and among various region inside a nation. This demonstrates ecological components may assume an essential part in the pathogenesis of tumour of the head and neck. Tobacco smoking and alcohol intake have been credited to as significant hazard elements. In Asia, biting tobacco causes a high frequency of oral malignancies and in the US there have been reports of oral snuff as hazard in oral cancer[6] . Squamous cell carcinoma (SCC) comprises 90% of all oral malignancies,among oral cancers[7-8] . Numerous oral SCC arises from premalignant states of the oral cavity[9-10] . A wide exhibit of conditions have been embroiled in the improvement of oral cancer, including leukoplakia, discoid lupus erythematosus, erythroplakia, oral lichen planus, palatial lesions, oral submucous fibrosis and innate disorders, for example, dyskeratosis congenital and epidermolysis bullosa[11] . The early discovery of cancer is of basic significance

since survival rates extraordinarily enhances when the oral lesions is recognized at an early stage[12] . Exfoliative cytology, which is a straightforward, noninvasive procedure, could build the odds of prior recognition of premalignant and malignant lesions[13] . It depends on the checking of exfoliated cells or cells chip off the mucosa whether through common or counterfeit means which shows cytomorphological and nucleomorphological variation[14] . This can be achieved through Hematoxylin and eosin (H&E) stains which have been used for at least a century and are still essential for recognizing various tissue and morphologic changes that form the basis of analysing cancer diagnosis[15] . The present study aimed to detect nuclear changes in mucosa between HANS and Arecanut chewing users to that of normal control.

Materials and Method

The study material includes oral smear obtained from tobacco users which includes Hans, Arecanut and healthy individuals.A total of 30 patients, 10 patients with Hans chewing habit, 10 patients with Arecanut chewing habit and 10 patients with normal mucosa which excludes non-smokers and non-alcoholic were selected from the outpatients who attended the Saveetha Dental College and Hospital, Chennai, Tamilnadu from October 2016 to December 2016. Informed consent was obtained from all patients to obtain a cytological smear. Using a moistened wooden spatula dipped with saline, cells were scrapped from the mucosal layer and smeared on a clean glass slide.The slides were immediately fixed with propan-2-ol kept in a couplin jar. The slides were then stained with routine hematoxylin and eosin staining procedure and studied under light microscope.

Results

All patients were aged between 25-60 years. Only male patients were screened for the purpose of the study. The study among 30 individuals revealed that there is a significant increase in frequency of micronuclei among arecanut users when compared with Hans users and controls ($p<0.05$) ,whereas other genotoxic changes such as condensed chromatin , karryorhexis, karryolysis, binucleation, pyknoyic were statistically not significant ($p>0.05$).

Table 1: Genotoxic changes among tobacco users

Genotoxic changes	ARECANUT	HANS	P VALUE
Micronuclei	2.142857143	0.769230769	0.001996
Condensed chromatin	0.142857143	0	0.177959
Karryorhexis	0.571428571	0.538461538	0.471903
Karryolysis	2.571428571	3.692307692	0.276737
Binucleation	0.428571429	0.230769231	0.210177
Pyknotic	2.142857143	1.769230769	0.329392

Discussion

Tobacco use (either by smoking or chewing) has harmful effects on buccal mucosa. The major toxic components of tobacco are nicotine, tar and polycyclic hydrocarbons. Long-term use [of betel-arecanut preparations] has been associated with pre-cancerous oral lesions, oral submucosal fibrosis(OSMF),and squamous cell carcinoma. AN (areca catechu—an endosperm (nut/fruit) from tropical tree Areca catechu Linnaeus) is the fourth regularly utilized psychoactive substance chewed as a guide to absorption and as stimulant, either utilized alone or included with various tobacco or non tobacco substances to make different combination. AN is a piece of betel quid normally devoured in Asian countries[16] , "betel nut" is a wrong phrasing commonly utilized for AN. In this study we have assessed the nuclear changes in smokeless tobacco products such as Arecanut and

Hans. Areca nut is known to create mutagenic and genotoxic impacts on tissues of body which may prompt different neoplastic and preneoplastic lesions[17-18] . Commission on tumor (COC) has first considered carcinogenesis of AN in 1993-1994[19] . The objective cells of AN are oral fibroblast/myofibroblasts and keratinocytes[20.] HANS" chewing tobacco is the finest Indian tobacco with the mixtures of aromatics, spices and flavours. It is appreciated all over India for its strong taste. It's taste is enjoyed by sucking rawly placed between teeth and lips. Oral exfoliative cytology has been used extensively for screening cellular alterations, such as karyolysis, karyorrhexis, micronucleus formation, pyknosis, binucleation, broken egg nucleus, anucleation, and so on[21.] Carcinogenic and mutagenic compounds, including tobacco-particular nitrosamines[22] , are responsible for induction of Micro nuclei. These compounds are produced from nicotine by bacterial or enzymatic action. A similar formation occurs in the mouth induced by saliva[23] . Presence of tobacco specific nitrosamines (TSNAs) in SLT attributes to increase risk of cancer[24] . In India, Tobacoo processing is performed by farmers and little organizations with little control over fermentation and curing, which causes increase in production of TSNAs. The assessment of micronuclei in exfoliated cells is a promising tool for the study of epithelial carcinogens and can be used to detect mitotic interference or chromosome breakage, thought to be relevant to carcinogenesis[24] . Since 1937 micronuclei have been used as an indicator of genotoxic exposure due to its association with chromosomal aberrations, based on the radiation studies conducted by Brenneke and Mather[25] . Pyknotic cells are characterised by a small shrunken nucleus which contains a high density of nuclear material that is consistently but intensely stained. They may represent as an alternative mechanism of nuclear breaking down that is distinct from the procedure leading to the condensed chromatin and karyorrhectic cell death stage. Karyorrhectic cells are cells with nuclear disintegration involving the loss of integrity of the nucleus[25] . They have nucleus that are portrayed by more extensive nuclear chromatin collection in respect to condensed chromatin cells. They have densely speckled nuclear pattern demonstrative of nuclear fragmentation prompting the inevitable deterioration of the nucleus[25] . Karyolytic cells: Cells in which the nucleus is completely depleted of DNA and is apparent as a ghost like image[26] . Cells with condensed chromatin demonstrates a generally striated nuclear pattern in which the aggregated chromatin is intensely stained. In these cells it is clear that the chromatin is aggregating in some regions of the nucleus whilst being lost in the other areas. At the point when chromatin aggregation is extensive the nucleus may appear to be fragmenting[26].

Our study was based on assessing the nuclear changes between two different tobacco chewing products, arecanut consuming had increase in micronuclei count when compared to hans tobacoo. Other studies done were based on comparison between smokers and tobacco chewers. Sarto et al., analyzed the genotoxic changes induced by tobacco on 25 individuals ,they observed a significantly higher frequency of micronuclei[27] . Patel PB et al., conducted a study to analyze tobacco related genotoxic effects into tobacco chewers monitoring chromosome aberrations (CA) and micronuceli From their study, they concluded that MN is a better surrogate biomarker to predict genotoxicity than CA for tobacco exposure and DNA damage index in tobacco chewers[28] . Pradeep et al., done a comparative study of genotoxicity in different tobacco related habits using micronucleus assay in exfoliated buccal epithelial cells, they concluded that tobacco in any form is genotoxic especially smokers are of higher risk[29]

Conclusion

This study concludes the importance of early recognition of cellular alteration for identification of pre-malignant changes in the patient with tobacco chewing. Exfoliative cytology cannot be taken as final diagnosis, biopsy is utmost important in detecting the premalignant lesions. This study was based on limited population hence a large scale study group is required to evaluate the nuclear changes by arecanut and Hans chewing tobacco.

Antibacterial Activity of *Acacia Catechu* Seed Against Urinary Tract Pathogens

Mohammed Ahad, Remmiya Mary Varghese[2]

[1]UnderGraduate BDS, [2]Senior lecturer, Saveetha Dental College, Saveetha university, 162, Poonamallee High Road, Velappanchavadi, Chennai

Abstract

Aim: The aim of the study is to investigate the antibacterial efficacy of the *Acacia catechu seed* extract against selected Urinary tract pathogens

Background :*Acacia catechu* is known as Cutch tree.This plant has following medicinal properties: Astringent, Bactericidal, Refrigerant, Stimulant, Masticator, Expectorant. Acacia catechu seeds are flat, dark brown and measure 5-8 mm in diameter. The seeds are edible and the extract is useful in the treatment of many medical conditions in the Ayurveda.

Reason: Urinary tract infections are most common infection caused in woman, hence this study can determine the antibacterial effectiveness among the pathogens causing urinary tract infections.

***Key words**: Acacia catechu, Medicinal, Urinary tract infection, Antibacterial.*

Introduction

The acknowledgment of traditional medicine as an elective type of health insurance and the in-efficiency and other ill-effects of accessible anti-microbials has driven researchers to investigate the capability of therapeutic plants which are a rich wellspring of antimicrobial agents and effective medication[1]. The development of bacterial resistance from by and by accessible antibiotics has required the search for new antibacterial agents[2]. The gram positive bacterium, for example, Staphylococcus aureus is predominantly in charge of post operative wound contaminations, endo-carditis, toxic shock syndrome, osteomyelitis and sustenance harming[3]. Bacillus subtilis are rod shaped aerobic microorganisms and are accounted for to have some pathogenic part[4] . The gram negative bacterium, for example, Escherichia coli is available in human Intestine and bring down lower urinary tract contamination, coleocystis or septicemia[5] . Pseudomonas predominantly causes urinary tract contamination, wound or burn infection, chronic otitis media, septicemia and so forth in people[6] . Work has been done which go for knowing the diverse antimicrobial and phyto-chemical constituents of medicinal plants and utilizing them for the treatment of microbial contaminations as conceivable adjust locals to chemically manufactured medications to which numerous irresistible microorganisms have turned out to be resistant[7]

Acacia catechu is a moderate size deciduous, thorny tree common to Southern Asia and widely distributed in India.It is commonly known as “khair” and its various parts have been used since ancient times in Ayurvedic medicine[8,24,26] .In Ayurveda, is used in the treatment of cough, dysentery, throat infections, chronic ulcers and wounds[9,25] . Catechu is also reported for its anti-inflammatory,antimicrobial immunomodulatory, antipyretic, antidiarrhoeal and hypoglycemic[10-13] properties. Urinary tract infections occur when bacteria enter the urinary tract through the urethra and begin to multiply in the bladder[14.] The bark of this plant is strong antioxidant, anti-inflammatory, anti-bacterial, astringent and antifungal in nature. The extract of this plant is used

to treat diarrhoea and sore throats, also useful in high blood pressure, bronchial asthma, cough, leucorrhoea, dysentery, colitis, gastric problems, and leprosy. It is used as mouthwash for sore throat, gingivitis, mouth, gum, dental and oral infections. The heartwood is used to yield concentrated aqueous extract i.e. cutch which is cooling, astringent and digestive. It is useful in boils, cough, ulcers and eruptions of the skin. Decoction of the bark is given internally in case of leprosy. Acacia spp. produces gum exudates, traditionally called gum Arabic or gum Acacia, which are widely used in the food industry such as adhesives, stabilizers, emul- sifiers, and in chronic renal failure[15-16] . Main chemical constituents of Acacia catechu are catechin, (-) epicatechin, lupeol, procyanidin AC, kaempferol, epigallocatechin, acid, quercetin, poriferasterol glucosides, poriferasterol acyglucosides, lupenone, epicatechin gallate, epigallocatechin gallete rocatechin, phloroglucin, protocatechuic, dihydrokaemferol, taxifolin, (+)-afzelchin gum and mineral[17-23] . The chief phytoconstituents of the heartwood are catechin and epicatechin.

Urinary tract infections (UTIs) are the most common conditions requiring medical treatment with 6-10% of all young females demonstrating bacteriuria[27-28] . The incidence of UTI's increases with age and 25-50% of females aged 80 or more have bacteriuria[29] . Urinary tract infection are a continuous issue overall which are caused by microbial invasion to different tissues of the urinary tract. Urine is normally sterile, that is, free of microscopic organisms, infections, and parasites[30] . A urinary tract disease is a condition in which at least one sections or more of the urinary framework (the kidneys, ureters, bladder, and urethra) become contaminated. UTIs are a standout amongst the most widely recognized bacterial contaminations in all general population , with an expected general rate of 18 for every 1000 person per year. It is the most regular bacterial disease recorded in older people[31] . Moreover, UTIs are a noteworthy reason for clinic affirmations and are related with significant morbidity and mortality and additionally a high financial burden[32] . The financial burden of using the emergency department for the treatment of UTIs is evaluated to be $2 billion US dollars every year [33] . UTIs can show in a wide clinical range from bacteriuria with restricted clinical indications to sepsis[34] . The primary essential hazard factors for the advancement of UTI include: age, presence of catheter, diminished mental status, chronic comorbidities, neurogenic bladder, urinary incontinence, diabetes, male prostatic hypertrophy, being female, gynecological disorders etc. Secondary hazard factors incorporate other contamination, dehydration, immobility, colonization with resistant organism, and poor individual cleanliness. Older adults, particularly ladies, are at increased risk of secondary disease after the advancement of a urinary tract contamination[32] . UTIs are classified into three groups, depending on the factors that trigger the infections such as complicated and uncomplicated, depending on whether the infection is occurring they are classified as Primary or recurrent, based on signs and symptoms they are classified as asymptomatic and symptomatic[34]. Most of the urinary tract infections are caused by gram-negative bacteria like Escherichia coli, Klebsiella sp., Pseudomonas aeruginosa. The treatment mainly involves use of antibiotics but the pathogenic bacteria are becoming increasingly resistant to antibiotics[35-36] . Diarrhoea is a syndrome that can be caused by different bacterial, viral and parasitic pathogens. Accurate understanding of the cause of diarrhoea in a given setting is an onerous task that requires systematic monitoring of the various pathogens. The availability of a well equipped clinical microbiology laboratory is a prerequisite to undertake such studies. Clinical studies conducted at the National Institute of Cholera and Enteric Diseases (NICED), which includes hospital and community, based surveillance for diarrhoea was focused on common enteric pathogens using conventional assay[37-39] . The present study aimed at antibacterial potential of Acacia catechu seeds.

Materials and Method

Plant Material:

Acacia seed is obtained from Green chem Herbal extract and formulations, Bengaluru .

Antibacterial activity:

Microorganisms tested

1. S. a – *Staphylococcus aureus* MTCC3381
2. E. c – *Escherichia coli* MTCC739
3. K. p – *Klebsiella pneumonia* MTCC432
4. P. a – *Pseudomonas aeruginosa* MTCC424

Minimum Inhibitory Concentration (MIC)

The minimum inhibitory concentration (MIC), which is considered as the least concentration of the

sample which inhibits the visible growth of a microbe was determined by the broth dilution method.

Preparation of inocula

Organisms were subcultured on nutrient agar, followed by incubation for 24h at 37°C. Inocula were prepared by transferring several colonies of microorganisms to sterile nutrient broth. The suspensions were mixed for 15sec and incubated for 24h at 37 °C. Required volume of suspension culture was diluted to match the turbidity of 0.5 McFarland standard (1.5x108 CFU/mL).

Preparation of sample

Samples were prepared in dimethylsulphoxide (DMSO) at the concentration of 2 mg/ml.

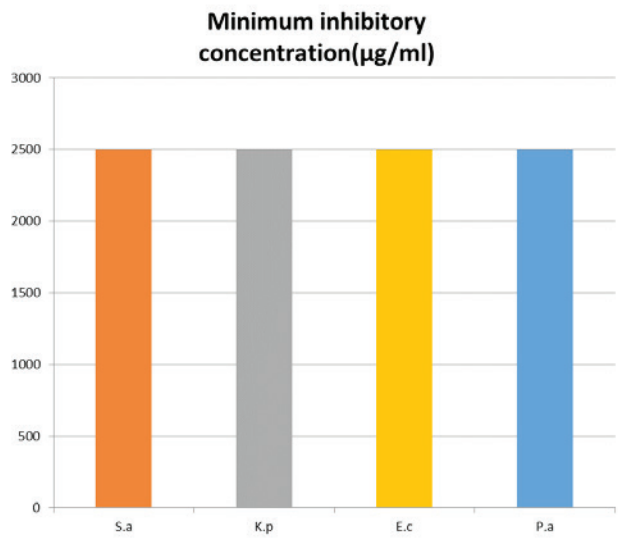
Broth dilution assay

A series of 15 tubes were filled with 0.5 ml sterilized nutrient broth. Sequentially, test tubes 2□14 received an additional 0.5 ml of the Sample serially diluted to create a concentration sequence from 5000 □ 1.2.µg. The first tube served as the control. All the tubes received 0.5ml of inoculum. The tubes were vortexed well and incubated for 24h at 37°C. The resulting turbidity was observed, and after 24 h MIC was determined to be where growth was no longer visible by assessment of turbidity by optical density readings at 600nm.

Result and Discussion

Acacia catechu seed was tested against *Staphylococcus aureus, Escherichia coli, Pseudomonas aeruginosa, Klebsiella pneumoniae which are* the major pathogen that commonly causes urinary tract infection. Microbroth dilution was performed Which revealed no growth from the concentration at 2500mg/ml. The values recorded are means of three independent analysis ± Standard Deviation (n=3). Different research have been led on antimicrobial action of A.catechu extract, and exhibited good to excellent action contingent upon the organism included. An aqueous extract of A.catechu displays direct movement against a numerous drug resistant Salmonella typhi which was conducted by rani et al[40] Patel et al demonstrated that an aqueous extract of A.catechu resin from heartwood displayed excellent action against Bacillus subtilis, while a petroleum ether extract gave amazing activity against Pseudomonas aeruginosa, and a chloroform remove was dynamic against Staphylo-coccus aureus. No recognizable proof of dynamic constituents was led[41] .

Joshi et al conducted a study based on An ethyl acetic acid derivation concentrate of heartwood which displayed antimicrobial action against B. subtilis, S. aureus, Klebsiella pneumonia, and Shigella species[42] . A methanol extract of A.catechu was appeared to have antimicrobial activities against B. subtilis, S. aureus, Sal.typhi, Escherichia coli, P.aeruginosa, and Candida albicans studied by Negi and Dave in 2010[43] . Voravuthikunchai et al states that Aqueous and ethanol concentrates of A. catechu showed direct action against hospital isolates of methicillin-resistant S. aureus[44] . Lakshmi et al have additionally exhibited that ethanol concentrates of A. catechu exhibit inhibitory movement against different organisms[45] .



Conclusion

The study reveals that *Acacia catechu* could be useful in the management of Urinary tract infection. Rotavirus and cholera vaccines are now available as prescription product in India for the first time after a hiatus of 30 years. Not much progress has, however, been made with a Shigella vaccine. It would be interesting to see how these vaccines would ameliorate the burden of enteric infections in settings of diarrhoea in endemic areas all over India[46] .

Effectiveness of Music Therapy and Visual Imagery Techniques on Preoperative Anxiety among Children Undergoing Surgeries in Selected Hospitals of Rajasthan-Pilot Study

Mohanasundari SK[1], Padmaja A[2], Kirtikumar Rathord[3], Sunil Kothari[4]

[1]Scholar in INC, College of Nursing, AIIMS Jodhpur, Rajasthan, [2]Vice-Principal/Professor, College of Nursing, SVIMS, Tirupati.AP., [3]Associate Professor, Dept of Pediatric surgery, AIIMS Jodhpur, [4]HOD of pediatric surgery Department. Dr SNMC Jodhpur

Abstract

Introduction: Increasing attention is nowadays being paid to a variety of non-pharmacological interventions for decreasing preoperative anxiety such as music therapy, music medicine interventions, and visual imagery technique and so on. Method: 3 arm RCT was conducted to assess the effectiveness of music therapy and visual imagery techniques on preoperative anxiety with total 36 children aged between 4 to 12 years. Group A received Music therapy and group B received Visual imagery technique for 15 to 30 minutes duration minimum 3 times a day. Group C (control group) received conventional intervention. Result: The mean and SD score of pre and post-test in experimental group A, B and C was 7 ±3.43 & 1.67 ±2.06, 15.33 ±4.86 & 8.83 ±4.78, and 19.67 ±14.88 & 19.08 ±12.12 respectively. The effect size of group A was 1.88 & Group B was 1.34. Conclusion: If music therapy or visual imagery technique given especially just before giving anesthesia, the child will experience very less anxiety.

***Key words**: Music therapy, visual imagery technique, conventional interventions, preoperative anxiety and children undergoing surgeries.*

Introduction

Background:

Each year, > 2 million children undergo surgical procedures. The perioperative phase can be stressful for the children, their parents, and the nurses who care for them. Children may experience anxiety and fear about surgery, pain, separation from parents, unfamiliar surroundings, the unknown, unpleasant sensory stimulation, and loss of autonomy and control.[1] In the immediate preoperative period, which corresponds to 24 hours before surgery, discomfort is imminent for the children and their family, regardless of the type of surgery, outpatient or hospital approach and cultural context in which the child is inserted.[2,3] In addition, the susceptibility of the child, lack of understanding about the surgical procedure, unknown hospital environment, fear of physical injury, separation from their parents and feelings of sadness and punishment related to the fact that surgery is a scheduled procedure may contribute to such discomfort.[4,5]

Several evidence indicate age and temperament of the child, behavioral problems during health care previous surgery and hospitalizations level of parental education and maternal anxiety as factors associated with preoperative anxiety in children.[6-10]

Anxieties in children arise due to their altered interpretation of healthcare surroundings. Anxiety manifestations are variable as children transition through different stages of physical, emotional, and psychological development. Parental separation and

Mob.: 9396805831

induction of anesthesia have been implicated as the most stressful periods for children to endure during their surgical experience.[11]

Anxiety is a common feeling among children in the preoperative period. As acute stress source, anxiety induces functional changes in the central nervous system, increases the deleterious effects on the child's body when associated with other perioperative stressors[12] produces negative behaviors and high pain intensity scores in the postoperative period.[13.] In addition, anxiety causes sleep disruption, nausea, fatigue, and inadequate responses to anesthesia and analgesia leading to higher costs for the health services and family.[14]

Increased anxiety, disturbances in eating and sleeping, as well as increased pain and analgesic use; continue to be psychological problems during postoperative period also. Parents also anxious and their concern about the competency of staff, possible complications, and how to support their child, unfamiliarity of surroundings, role expectations, added to parental stress and anxiety that can transmit to their children.[1]

The literature revealed the effects of preoperative pediatric anxiety as contributory to the manifestation of numerous postoperative psychological behavioral changes such as feeding and sleeping problems, bedwetting, withdrawal and apathy, and these symptoms exist up to 2 weeks after surgery. [15]

Certain interventions like music may provide a viable alternative to sedatives and anti-anxiety drugs for reducing preoperative anxiety.[16]

Visualization & imagery (sometimes referred to as guided imagery) techniques offer yet another avenue for anxiety reduction.[17]

Nurses must have an understanding of the impact of surgery on children & families to help ease the stress of this difficult time.[18] Present study focused on effect of two complementary therapies such as music therapy & visual imagery technique with conventional interventions in management of preoperative anxiety in children.

Method

The effectiveness of music therapy & visual imagery technique versus conventional interventions on preoperative anxiety among 36 children aged between 4- 12 years undergoing surgery in UMAID hospital was assessed in 3 arm Randomized controlled trial research design. The Children undergoing elective/planned surgery were included & children with emergency surgery, mentally retarded, hearing impairment, undergoing ear surgeries & participating in any other clinical trial were not included in the study. The samples were randomly distributed into 3 groups (12 in each) through computer-generated randomization allocation sequence.

Tool has 4 sessions[(19,20)] section-1 was demographic variables (e.g. accompanying parent, age of the child, gender of the child, habitat, religion, socio economic status, duration of preoperative period, previous hospitalization & previous experience with anesthesia/ Surgery. The level of parental anxiety was assessed through numerical visual anxiety scale (NVAS) Session-2 was physiological variables (e.g. pain, respiration & pulse rate). Preoperative pain of the child was assessed through numerical visual pain scale (NVPS). Session -3 was standard rating scale -Hamilton Anxiety rating scale. The scale contains 14 items. A total score range of 0-56 is given with each item scored on a scale of 0 (not present) to 4 (severe). Session 4 was semi structured check list of conventional intervention (e.g. The use of toys, playing games, watching videos, cartoons, psychological support, story telling, play therapy, preadmission tour ward & others interventions). The setting reliability of the tool was tested found to be r=0.76.

Ethical permission was obtained from institutional ethical committee of Dr SNMC Jodhpur. The informed consent was obtained from the children above 7 years & from the guardian of children below 7 years.

On 1st preparative day children were screened for anxiety with Hamilton Anxiety rating scale (HAM-A). Recorded demographic data, level of pain & vital signs. For group-A from the day of admission until administering preoperative medication, prerecorded instrumental music was played 3 times a day on average, through head phone for the period of 15 to 30 minutes. Group B received prerecorded guided visual imagery audio through headphone for the period of 15 to 30 minutes from the day of admission until receiving preoperative sedative medications. The child received other conventional interventions throughout the preoperative period. The children in all 3 group received two or more conventional intervention as a part of supportive measures which helped to reduce

preoperative anxiety of the children , they are Parental presence, the use of toys, playing games, videos, drawing cartoons, psychological support, storytelling & listening, playing actively/passively. After the intervention children from all 3 groups were reassessed for level of anxiety through HAM-A, reassessed for pain & vital signs, & all the samples were questioned & assessed for the conventional interventions received until receiving preoperative sedative medications. The data was compiled & analyzed with help of SPSS-16.

Results

It was inferred from the table-1 that 50% children who exposed to music therapy with convention intervention showed improvement in anxiety reduction from mild to no anxiety. There was no one in music therapy group experience neither moderate nor severe anxiety at pre & post-test. The children who exposed to visual imagery technique showed improvement up to 42.4% & anxiety was reduced to moderate to mild & no one had sever anxiety in pre & posttest. Children who received conventional intervention alone suffered from mild to severe level of anxiety in post -test (41.7% mild, 16.7% moderate, 25% severe & 16.7% very sever anxiety), were in pretest it was 58.3% with mild anxiety & 41.7% children had severe to very severe anxiety.

It was inferred from the table-2 that the samples in experimental group A (music therapy) experienced 76.1 % of reduction in anxiety level, were as samples in experimental group-B (visual imagery technique the anxiety reduction rate was 42.4%, & in control group C the reduction rate was 2.89% only. The effect size was calculated by Cohen's D & it was 1.88 among children exposed to music therapy & it was 1.34 among children exposed to visual imagery technique. So it was interpreted that the music therapy was very effective in reducing preoperative anxiety level of the children when comparing to visual imagery technique. And both the interventions were effective when comparing to conventional intervention alone. As the effect size in control group was only 0.04.

From Table 3 it was interpreted that there was significant difference exist between pre & posttest anxiety level within & between the experimental group A, experimental group B & control group C at $p<0.05$ level as tested by one way ANOVA.

It was inferred from the table-4 that experimental group A posttest mean was significantly different from the experimental groups B & control Group C. Group B posttest mean was significantly different from group A but not with group C. Were as group C post-test mean was not significantly different from Group A & group B. So it was interpreted that the Music therapy (Group A) was more effective in reducing preoperative anxiety level when comparing to VIT or conventional intervention. The pretest mean was significantly different between group A& B but not with group C.

Table-1: Frequency and percentage distribution of samples in pre and posttest. N=36

Score	**Interpretation**	**Frequency (%)**

Discussion

The mean - pre & post test score of experimental group A was 7 ±3.43 and 1.67 ±2.06 and mean difference was -5.33 and the effect size was 1.88. The mean pre and post -test score of experimental group B was 15.33 ±4.86 and 8.83 ±4.78 and mean difference was -6.5 and the effect size was 1.34. The post-test mean difference in experimental groups B was 18% more when comparing with experimental group A. The mean pre and post -test score of control group was 19.67 ±14.88and 19.08 ±12.12.

Around 50% Children exposed to music therapy experienced no preoperative anxiety at posttest. The present study shows that the samples in experimental group A (music therapy) experienced 76.1 % of reduction in anxiety level, were as samples in experimental group-B (visual imagery technique) the anxiety reduction rate was 42.4%, and in control group C the reduction rate was 2.89% only when comparing to pretest anxiety level. The find of one way ANOVA interpreted that there was significant difference exist between 3 groups & post hoc test interprets that the Music therapy (Group A) was more effective in reducing preoperative anxiety level of the children when comparing to VIT or conventional intervention.

Similarly the findings of this study was supported by studies conducted by Goldbeck L (2012)[21] on multimodal music therapy for children with anxiety disorders, Lambert et al (1996)[22] on effect of hypnosis/ guided imagery on the postoperative course of pediatric surgical patients), Thomas MB (2003)[23] et al on effect of relaxation & guided imagery on autonomic nervous system & Hartling et al (2013)[25] on music to reduce pain & distress in the pediatric emergency department. This study finding was contrast to the study finding of Kain ZN et.al (2004)[24] who assessed interactive music therapy is an effective treatment for pre-induction anxiety.

Conclusion

It was concluded that music & visual imagery technique both are effective in reducing preoperative anxiety level of the children when comparing to children who received conventional intervention alone. Music therapy was even more effective when comparing with visual imagery technique. If music therapy given especially just before giving anesthesia, the child will experience very less anxiety or no anxiety & that could reduce the post-operative stay & improve outcome status of the child. Music therapy & visual imagery technique can become part of preoperative intervention.

Conflict of Interest: No actual or potential conflict of interest

CBCT use to Evaluate Vital Mandibular Inter-Foramin Anatomical Structures

Needhika Chibber[1], Satvinder Singh[2], Supinder Sudan[3], Megha Anand[3]

[1]Registrar (OMR), [2]Associate Professor, HOD (OMR), Indira Gandhi Government Dental College, Jammu, [3]House Surgeon (OMR), Indira Gandhi Government Dental College, Jammu

Abstract

Background: The aim of the study was to evaluate the vital anatomical structures in the mandibular inter-foramin region and to investigate the presence of sexual dimorphism with respect to the left and right sides region using CBCT.

Materials & Method: A total of 60 CBCT scans (30 male & 30 female) were analysed for the MF position & shape, presence and measurement of AL & MIC (both in mm), patterns of emergence of mandibular canal, symmetry of MF & AL. All the scans were taken by CS 9300 (Care stream Health India Private Limited) CBCT machine adjusted at 80 kVp, 15mA, Voxel size 0.3x0.3x0.3 and field of view (FOV) of 10x5 (mandible only). The acquired images were reconstructed into multiplane views (axial, panoramic and cross-sectional) for evaluation.

Results: Position 4 of MF (below the apex of second premolar) was most common on right side while position 3 (between first & second premolar) on left side, with 75% of symmetrical MF position. The prevalence of MIC was noted in 93.75% of the patients with mean length of 12.09±5.95 mm. The prevalence of AL was 53.13% with mean length of 1.07±1.42mm.

Conclusion: The present study recommends a CBCT evaluation of inter-foraminal anatomical structures before planning the placement of implants. However, no sexual dimorphism was found regarding these parameters.

Keywords: *Anterior mental loop, inferior alveolar nerve, mental foramen, mandibular incisive canal.*

Introduction

The mandibular incisive canal (MIC) is described as a continuation of the IAC anterior to the MF and contains one of the terminal branches of the IAN, the Incisive branch. The MF has been reported to vary in its position in different genders and ethnic groups having different craniofacial skeletal and dental occlusion.[1] Philips *et al* [2] reported that its average size was 4.6mm horizontally and 3.4mm vertically. The knowledge of the position of MF is important in clinical dentistry when administering local or regional anaesthesia, orthodontic tooth movement/surgery, performing periapical surgery and implant placement in the mental region of the mandible. The MF is occasionally misdiagnosed as a radiolucent lesion in the periapical area of the mandibular premolar region.[3] The MF also aids in interpreting anatomical landmark in oral and forensic pathology.[4]

The use of appropriate imaging techniques is therefore essential to enable the accurate identification and location of these vital structures. With the development of computed tomography (CT) three dimensional (3D) assessments of craniofacial structures become possible and widely available means for head and neck diagnosis and treatment planning. The excessive radiation exposure, increased cost and limited availability impede the routine use of this technology for dental applications.

Now cone beam CT (CBCT) offers a promising alternative approach since it provides sub-millimeter resolution images of high diagnostic quality with short time and reduced radiation dose up to 15 times lower than multi-slice CT scans (MSCT) and produce images that demonstrate on different planes and real size of anatomical structures.[5] In recent years, several studies have analysed the characteristics of anatomical landmarks in the mandibular anterior region in various populations around the world. Nevertheless, to date few studies have evaluated by CBCT in population from North-eastern India. With this background, the present study was conducted to evaluate the vital anatomical structures in the mandibular inter-foraminal region and to investigate the presence of sexual dimorphism and differences with respect to the left and right sides region using CBCT.

Materials & Method

The cross sectional study was conducted on randomly selected 60 CBCT scans taken as a part of the planning procedure/diagnostic workup for implant placements, orthognathic surgeries, bone harvesting from the chin and mandibular osteotomies in Indira Gandhi Government Dental College, Jammu. The study sample consisted of 30 males and 30 females between the age of 20 to 70 years. The CBCTs were performed in a private maxillofacial radiology clinic located in Jammu. All the scans were taken by the same technologist, following a standardized protocol for patient positioning and exposure parameter settings. The informed and written consent was taken for each patient. The institutional ethical committee clearance was obtained before the conduct of study.

The inclusion criteria consisted of; 1. Patients who are fully dentate in posterior regions of two sides including the second premolars and first, second molars without crowding or spacing, 2. Cone-beam CT scans displaying the entire mandibular bone of both sides, free of large pathologies and 3. Absence of pathology that could affect the position of MF, AL or MIC. The exclusion criteria considered was as; 1. CBCT of patients with history of maxillofacial trauma, fracture or supernumerary or impacted teeth in region of interest (ROI), 2. Syndromic patients, 3. Pregnant females, and 4. Presence of implants or metal artefacts in the Mandibular Inter-foraminal region.

Method: The diluted 0.2% chlorhexidine gluconate mouthwash was given to rinse the oral cavity. A detailed case history including the individuals demographic details (age, gender, Address etc), general and medical history followed by through clinical examination was carried out in a systematic manner. Then the hard tissue intra-oral examination was carried out for each patient for the number of teeth present, presence or absence of dental caries, calculus, gingival recession, periodontal pockets and the findings were entered in a specially designed performa. After the clinical examination, the CBCT scan of the selected patients was accomplished with a Cone-beam volumetric tomography Device CS 9300 (Care stream Health India Pvt. Ltd) adjusted at 80 kVp, 15mA, Voxel size 0.3x0.3x0.3. The CBCT images were taken with field of view of (FOV) of 10x5 (mandible only) & 17x13.5 (full mouth) and were used only if they cover the ROI and matched the inclusion criteria.

Mental Foramen (MF): The MF position was assessed relative to the adjacent mandibular teeth on the right and left sides as: Position 1: Between canine and first premolar; Position 2: Below the first premolar; Position 3: Between first and second premolars; Position 4**:** Below the second premolar; Position 5: Between second premolar and first molar; Position 6: Below the first molar. The position of MF was also recorded on the basis of gender and symmetry (MF on both sides with same anterio-posterior position relative to the teeth) or asymmetry (MF on both sides with different anterio-posterior position relative to the teeth). The shape of MF was recorded as: oval, round and irregular.

The **length AL** was measured between the anterior border of the AL and the anterior margin of the MF. The **MIC length** was determined by measuring the distance in millimetre between the most anterior border of the MF and the most mesial slice where the canal was definitely visible in cross-sectional images. In addition, the differences with respect to the left and right sides and the presence of sexual dimorphism was also investigated.

The data thus collected was tabulated and statistically analysed using SPSS 18.0 (Microsoft Corporation Inc., Chicago, IL, USA) statistical software.

Results

The overall mean age of the patients was found to be 42.64±16.22 years with males having slightly more age than females although the difference was insignificant.

In the present study, most common position noted for MF of right side related to teeth on CBCT was position 4 (in line with the apex of the second premolar) & position 3 (between the apices of the first and second premolars) for males while for females it was position 4 (Table 1).

The mean length of AL noted on the right side for both genders was 1.22±1.92 mm while on left side it was 0.92±1.14 mm. The overall mean length of AL for both sides was found to be 1.07±1.42 mm with statistically insignificant difference. (Table 2)

Present study showed the existence of MIC in 93.75% of the patients. The three patients had symmetrical absence of MIC and four showed absence of either side only. The mean length of MIC noted on right side for both genders was 12.90±6.11 mm while on left side it was 11.28±6.17 mm. The overall mean MIC length for both sides was found to be 12.09±5.95 mm. (Table 3) Moreover, no correlation was found between MF positions with emergence patterns of mental canal from MF for either side. ($p>0.05$)

Table 1: Association between gender and position of right and left mental foramen

Mental foramen Position	Right		Left	
	Male, n (%)	Female, n (%)	Male, n (%)	Female, n (%)
Position 1	0	0	0	0
Position 2	5 (16.67%)	1 (3.33%)	3 (10%)	0
Position 3	12 (40%)	12 (40%)	15 (50%)	16 (53.33%)
Position 4	10 (33.33%)	15 (50%)	10 (33.33%)	9 (30%)

Discussion

The CBCT provides multiplanar reconstructions and true –to size images at very low radiation dosage, which enables excellent resolutions and good contrast for the visualization of these dento-alveolar inter-foraminal structures compared to CT and conventional radiographic view.[4] The CT acquires image data using rows of detectors, while CBCT exposes the whole section of the patient over one detector.

In our series of 60 CBCTs scans, the most common position for the MF was between first and second premolars. The sexual dimorphism was not found ($p>0.05$) regarding positions of MF in the studied population. The position was determined along the long axis of the teeth, considering the whole width of the teeth. Similar results were seen by Moiseiwtsch *et al*[1] in a North American Caucasian population and also by Fishel*et al*[6], Olasoji*et al*[7] in Northern Nigerian adults. In contrary, few previous similar studies performed in other populations such as Malays, Asian Indians, Kenyan, Africans and Moroccan found most common position for the MF in line with the second premolar. The difference in results could be due to genetics, which play an important role in determining the morphological characteristics of dental structures.

In our study, at least one AL of the mandibular canal was visualized in 53.13% of the patients. This is higher than the prevalence reported by Ngeow *et al*[8] who conducted the study using panoramic radiographic images. The relatively low prevalence rates reported in those studies may reflect the failure of panoramic radiography to detect the presence of the anterior loop, due to the limitations & disadvantages of radiography like two dimensionality, distortion, the presence of overlapping structures and calcification degree of the cortex which represents radiopaque in radiographic images.

In our study, mean value of the AL was 1.07±1.42 mm, coinciding with the values found by other authors also using CBCT. However, in a study performed in South-eastern Brazil was found a mean 2.41 mm length of AL in the analyzed CBCT scans. These differences may be at least partly due to the racial influence.

The present study showed 93.75% visibility of the MIC by CBCTs, with mean length of 12.09±5.95 mm. The same results were found in the study by Pires *et al*[9] documenting 83% & 93% existence of MIC on CBCTs and spiral CTs respectively. In contrast, most of the cadaver dissection studies, it is possible to find 100% of existence of the MIC/nerve. The reason could be that the MIC becomes smaller while progressing from distal to the anterior part of the mandible to midline, so sometimes MIC narrows as it approaches the midline, and its visibility might be hindered by limited spatial and contrast resolution and by the partial volume averaging effect in inherent in the CBCT images.

Conclusion

It can be concluded that there may be large variations in the anatomical landmarks in the mandibular inter-mental foraminal region, and therefore the concept of

"a safe region" during surgical procedures in the inter-foraminal region should be questioned and a detailed study of the region must be performed using multiplaner images of CBCT during preoperative surgical planning. Our study showed that oral radiologist obtains high rates of identification of AL and MIC when CBCT images are used. The large variations in the lengths of AL & MIC was obtained, so it is suggested that preoperative radiographic evaluation of both should be carried out case by case, using CBCT scans which could clearly show the 3D structures.

Comparison of Foot Posture in Runners (Sprinters) and Non-Runners in Indian Population- An Observational Study

Nikhil Aggarwal[1], Nidhi Ved[2]

[1]Assistant Professor Chandigarh University, Mohali, NH-95, Ludhiana Chandigarh state Highway, Punjab,
[2]Assistant Professor RK University, Rajkot, Bhavnagar Highway, Kasturba Dham, Rajkot Gujarat

Abstract

Introduction : The foot and ankle are located most distally in the lower limb and are responsible for allowing effective weight reception and generating torque required for propulsion during dynamic activities. Proper foot motion specifically subtalar pronation and supination are critical to achieving these functions. The normal foot transitions between pronation and supination to optimize adaptability versus stability as needed but foot mal alignments may negatively affect the lower leg to function optimally during weight bearing stance.

Aim : To compare the foot posture of Indian Runners and Non- Runners.

Objectives : (1) To determine the foot posture of runners in Indian Population. (2) To determine the foot posture of non-runners in Indian population. (3) To compare the foot posture of Indian runners and non-runners.

Method: 30 runners and 30 non-runners participated in the study. Footprint indices and Navicular drop was calculated. Foot print indices i.e. Arch angle, Chippaux- Smirak index, Staheli index, Arch length index, arch index, footprint index, truncated arch index were calculated using an ink pad and Navicular drop were calculated of the dominant feet.

Results: The normality of data was checked by using Shapiro-Wilk test which shows data was of parametric type. Comparison between the groups was done by unpaired t-test The arch index and truncated arch index were significantly higher in runners than non-runner and Staheli index was significantly higher in Non-runner than runners.

Conclusion: The result of this study shows that Runners have more pronated foot as compared to Non-runner.

Keywords*: Foot Posture, Runners, Navicular Drop, Footprint Indices.*

Introduction

When humans adopted a bipedal posture and gave up the use of the upper extremities for movement, body weight was transmitted from the vertebral column through the pelvis and lower extremities, especially the feet[1]. The foot became the contact point with the ground and evolved so that it could easily adapt to changes in both weight and the ground surface to absorb forces while walking or standing and to facilitate rotational movements[2 3]. For this purpose, its structure forms an arch on a bony skeleton strengthen by ligaments and muscles, unlike the feet of other primate's[4.5].

The foot and ankle are located most distally in the lower limb and are responsible for allowing effective weight reception and generating torque required for propulsion during dynamic activities[6]. Proper foot motion specifically subtalar pronation and supination are critical to achieving these functions. The normal foot transitions between pronation and supination to optimize adaptability versus stability as needed but

foot mal alignments may negatively affect the lower leg to function optimally during weight bearing stance. Considering that the foot is the most distal segment in the lower extremity chain and represents a relatively small base of support upon which the body maintains balance, it seems reasonable that even minor biomechanical alterations in the support surface may influence postural-control strategies[7].

Aims and Objectives

To determine the foot posture of runners (Sprinters) in Indian Population

· To determine the foot posture of non-runners (Non-sprinters) in Indian population.

· To compare the foot posture of Indian Runners and Non- Runners.

Hypothesis

H_0- There is no significant Difference in foot posture of runners (Sprinters) and non-runner in Indian population.

H_1- There is a significant Difference in foot posture of runners (Sprinters) and non-runner in Indian population

Operational Defination

SPRINTERS: Sprinters are the athletes who races up to and including the 400m. Subjects included were involved in the sprinting events and participated in competitions at inter collage level. The subjects are also participating in competitions till date.

Methodology

· Research Design: Comparative Study

· Sample Size: 60 Subjects

· Sample Source: New Delhi

· Inclusion Criteria:

o Asymptomatic Males and Females

o Runners and Non-runners

o Age Group 18 to 25 years

o Willing to participate in the study

· Exclusion Criteria:[89]

o Any history of Systemic disease, neurological disorder, cardiovascular disorder, malignancy, unhealed scars or wounds on lower extremity, vestibular problem foot surgery or Back problem for more than one year.

· Instrumentations:

o Instruments and Tool used:

§ Black marker

§ 3*5 index card

§ Measuring tape

§ Washable ink pad

§ Centimeter calibrated Graph Sheet

Procedure

Potential subjects of age group 18 to 25 years were apprised of the procedure and its potential risks and benefits and the evaluation was done. Subjects those who fulfill the study's inclusive and exclusive criteria and give their consent form were included in the study. Prior to testing, the subjects were familiarized with the testing procedure

Measuring the Navicular Drop:

The subject was placed in a sitting position with their feet flat on a firm surface and with the knees flexed to 90* and ankle in neutral position. After that the most prominent point of the Navicular tubercle while maintain subtalar neutral position was identified and marked with a pen. Subtalar neutral position was established when talar depressions are equal on medial and lateral side of the ankle.

While maintaining the subtalar neutral position, index card was placed in the inner aspect of the hind foot, with the card placed from the floor in a vertical position passing the Navicular bone. The level of the most prominent point of the Navicular tuberclue was marked on the card.

The subject was then asked to stand without changing the position of the feet and to distribute equal weight on the both feet. In the standing position, the most prominent point of the Navicular relative to the floor s again identified and marked on the card. Finally, the difference between the original heights of the Navicular

tuberclue in sitting position as assessed with a measuring tape.

Measuring the Footprint indices:

Seven footprint indices was calculated: the arch(Clarke) angle, Chippaux-Smirak index, Staheli index, Arch length index, Arch index, Footprint index and Truncated arch index using the ink pad. The subject was instructed to stand on a washable inkpad with totally covering the plantar aspect of the dominant foot. Then he/she was instructed to stand on a cm-calibrated graph sheet provided, so that it totally covers his/her dominant foot.

Arch (Clark) angle:

This is the angle between the line connecting the medial side-most points of the heel and metatarsal regions and the line connecting the lateral most point on the medial foot border to the medial most point of the metatarsal region[10.11.12]. Normal values for the Clarke's angle are considered in intervals from 42* to 54*. Higher value indicates High-arched foot and Lower values indicates flatfoot.

Chippaux Smirak index:

This is the ratio of the minimum width of the midfoot arch region to the maximum width of the forefoot[13]. The minimum CSI value, 0% indicated a high arch, 0.1+_ 29.9% indicated a normal arch, 30+_ 39.9% indicated an intermediary arch, 40+ 44.9% indicated a lowered arch and a percentage of 45% or above indicated a morphological flat arch foot.

Staheli index:

This is the ratio of minimum width of the midfoot arch region to the maximum width of the rearfoot[14].

Arch length index:

This is the ratio of the length of the line between the medial area-most points of the metatarsal and heel region to the border length of the arch outline between these points[15].

Arch index:

This is the ratio of the area of the middle third of the toeless footprint to overall toeless footprint area. A line is drawn between the center point of the second toe and the posterior most point on the heel. Two parallel lines perpendicular to this line are drawn to divide the toeless footprint area into equal thirds[13]. An arch index of less than 0.21 has been said to be indicative of a cavus foot, while the greater than 0.26 is indicative of planus foot whereas arch index between 0.21-0.26 corroborate normal arch height.

Footprint index:

This is the ratio of the non-contact area to the contact areas of the toeless footprint. The non-contact area is the area between the medial borderline axis formed by the medial most points of the metatarsal and the heel regions of the footprint and the medial border of the footprint outline. The contact area is the area of the toeless footprint[13].

Truncated arch index:

This is the ratio of the non-contact area (the arch area) to the truncated footprint area. The non-contact area is the area between the medial border line and the medial footprint outline. The truncated footprint area is bounded to the medial borderline axis of the footprint through the medial most points of the metatarsal and heel regions of the footprint[13].

Result

Statistical Analysis

Study design: Comparative study.

Statistical software: The statistical software named SPSS 20.00 was used for data analysis. Microsoft Excel and Word were used to generate graphs and tables.

Test: The normality of data was checked by using Shapiro-Wilk test which shows data was of parametric type. Comparison between with groups was done by unpaired t-test.

Level of significance (p value) was set to 0.05

For Dominant foot, Arch index, and Truncated arch index were significantly higher in runners (Sprinter) and Non- runner (Non-sprinter) ($p<0.05$). Whereas Staheli index was higher in

Non-runners (Non-Sprinters)

Discussion

This study was about the differences in foot posture of sprinters and non-runners. The study included 30 subjects in each group. In this study arch index and truncated arch index of right foot was found to be higher for sprinters whereas Staheli index was higher for non-sprinters. For left foot arch length index and truncated arch index was higher for sprinters whereas Staheli index was higher for non-sprinters.

These differences can be due to the difference in muscle function and force distribution between runners and non –runners. Powerful muscles strength in lower extremity was usually considered to be required for excellent performances in running and foot arch would

then be functionally changed for compensation. The primary extrinsic muscles, such as the posterior tibial, flexor halluces longus, flexor digitorum longus, and wabductor hallicus longus, and the intrinsic muscles of the foot are dynamic supporters of MLA and do not become active until walking.[4,16,17]

Certain muscles in the foot and ankle either depress or support the arch, and their insuffiency may result in changes in the sole. For example, posterior tibial tendon rupture and tenosynovitis results in flat foot[16]. The posterior tibia, peroneus brevis/longus, flexor hallicus longus muscles. Flexor didgitorum longus, and abductor halliucis longus muscls, for example, support the formation of the medial longitudinal arch; whereras the extensor hallicus longus and tibialis anterior muscles have a depressing effect on this arch[17].

Most of the movement in running depends on the lower extremity musces and of course on the foot. Consequentlty, prolonged activation of these muscles might cause lasting changes in the sole of the foot, which would be detected in the static footprint parameters. Although some of the parameters in the present study differed between the sprinters and non-runners, these parameters do not reflect the same processes, as the truncated arch index is directly proportional to the arch height whereas Staheli index are inversely proportional to the arch height. During specific movement in running pressure on the different areas of the sole and resistance to this pressure could have different effect[16].

The result of this study matches with the study done by Dr Cenk Murat Ozer et. al on professional football player and controlled group where they found higher value for Truncated arch index for right foot and arch length index and truncated arch index for left foot.

Urry and wearing[18] studied the arch index and identified statistically significant difference between some contact areas of the sole using ink footprints and electronic images obtained with pressure platforms.

Miyashita and associates have reported that integrated EMG activity of the tibialis anterior and gastrocnemius increases exponentially with increasing speed[19]. Ito.et.al reported that with increasing running speed, the EMG increased during swing but remained the same during support phase[20].

According to Schlee et al[21]., 2009 and Gerlach et al[22].,2005 loading rates have been reported to remain unchanged after a prolonged run above lactate threshold or decrease after a graded exercise test. Perhaps the MLA became less stiff after the run which decreased loading rate.

Conclusion

The result of this study shows that Runners (Sprinters) have more pronated foot as compared to Non- runner.

Clinical relevance

Knowledge of type of foot posture will help to provide an optimal environment for muscle strengthening and/ or tendon rehabilitation. After the analysis of the foot posture more focused exercise program can be design to focus on specific part of the foot i.e. rear foot, mid foot or hind foot which is majorly responsible for the alteration in foot posture.

Limitation

· There is no one variable present which can measure every component of foot posture.

· Blinding was not done in the study.

· Only one type of the runners was included in the study.

· Sample size was relatively small.

Further recommendations

· Equal number of male and female can be included in the study.

· All variables can also be measured by different methods and them the results can be correlated to make a universally accepted method.

· Different types of runners can also be included in the study.

Prevalence of Lumbar Spine Dysfunction in Sugar Industry Workers of Karad Taluka

Nikhil Jitendra Desale[1], Javid H. Sagar[2]

[1]Final Year, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad,
[2]Professor, Department of Cardiopulmonary Sciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad

Abstract

Background: From past few years, in most of the industrialized world there has been increase in number of individuals having problem in musculoskeletal system. The term spinal dysfunction refers to an abnormal increase or decrease in spinal movement (mobility). Sugar industry workers are directly involved in the production process that's why some existing studies shows that the sugar industry work is characterized by repetitive movement, heavy load movement, wrong or awkward posture, forceful activity which causes cumulative trauma to the spine due to increase variability in weights.

Repetitive bending movement causes backache, prolonged working hours causes feeling of fatigue, long hour movement of hand causes numbness of fingers and strenuous activities all these activities put workers at risk for work related musculoskeletal disorders. There was hardly any literature available on the prevalence of spinal dysfunction in sugar industry workers in rural Maharashtra. Hence this observational study is to find out prevalence of spinal dysfunction in sugar industry workers in karad taluka.

Methods: This is an observational study which included 100 subjects. Then they were screened and distributed according to their age, gender, BMI and were asked to fill the modified oswestry low back pain disability Questionnaire. Later the subjects were assessede using modified oswestry low back pain disability Questionnaire.

Result: In this study 100 sugar industry workers (68 males and 32 females) were taken for study. It was found that 59 sugar industry workers had a lumbar spine dysfunction. The age is from 30-above 50 years of workers were taken in this study, which was found to be more prevalent in male(63%) than in female(50%), although this difference was not statistically significant.

Conclusion: This study has provided the evidence to support the increase in lumbar spine dysfunction in sugar industry workers of karad taluka.

***Keywords**: Lumbar spine dysfunction, sugar industry workers, modified oswestry low back pain disability Questionnaire.*

Introduction

From past few years, in most of the industrialized world there has been increase in number of individuals having problem in musculoskeletal system.

Musculoskeletal disorders are defined as a group of disorder that affect the musculoskeletal system including the nerve, tendon, muscle supporting structure such as intervertebral disc.[1]

The term spinal dysfunction refers to an abnormal increase or decrease in spinal movement (mobility). The term may use to describe a spinal segment, a spinal region or the whole spine. Spinal dysfunction includes prolapsed discs, degeneration, sciatica, referred leg

pain.[7]

Sugar industry workers are directly involved in the production process that's why some existing studies shows that the sugar industry work is characterized by repetitive movement, heavy load movement, wrong or awkward posture, forceful activity which causes cumulative trauma to the spine due to increase variability in weights.[1,4]

Repetitive bending movement causes backache, prolonged working hours causes feeling of fatigue, long hour movement of hand causes numbness of fingers and strenuous activities all these activities put workers at risk for work related musculoskeletal disorders.[2-3]

Here are some examples of physical hazards which sugar industry workers are facing everyday includes lifting and carrying heavy weights, working with frequently flexed trunk, risk of slips and falls on slippery and uneven surfaces, risk of accident caused by any unpredictable activity.[4]

There was hardly any literature available on the prevalence of spinal dysfunction in sugar industry workers in rural Maharashtra.

Hence this observational study is to find out prevalence of spinal dysfunction in sugar industry workers in karad taluka.

Material and Method

An observational study of Analytical study design was used to investigate the prevalence of spinal dysfunction in sugar industry workers in karad taluka. An approval for the study was obtained from the Protocol committee and Institutional Ethical Committee of Krishna Institute of Medical Sciences Deemed To Be University and written consent was obtained from each participant.

Participants

Participants were approached from karad taluka. It is an observational study which included 100 subjects. The subjects were screened and those fulfilling the inclusion and exclusion criteria were distributed according to their age, gender, BMI and were asked to fill the modified oswestry low back pain disability Questionnaire. Inclusion Criteria: 1.Sugar industry Workers, 2.both males and females, 3.sugar industry workers working for overtime/extra time. Exclusion Criteria: 1.Intervertebral disc prolapsed, 2.Recent spinal surgeries, 3.Patient undergone laminectomy, 4.Any secondary complications. Later the subjects were assessed using modified oswestry low back pain disability Questionnaire.

Assessment procedure

Before the assessment, demographic data of all participants were recorded. Then the participants were screened and those fulfilling the inclusion and exclusion criteria were distributed according to their age, gender, BMI and were asked to fill the modified oswestry low back pain disability Questionnaire. Modified oswestry low back pain disability Questionnaire was used to assess the participants.

Statistical Analyses

Statistical analysis was done manually and by using the statistics software INSTAT so as to verify the results derived. The statistical analysis of parametric data was done by using chi square test.

Results

Table no.1. Gender Wise distribution

Gender	No of patient present with low back pain	No. of patient	Percentage
Male	43	68	63%
Female	16	32	50%
total	59	100	59%

Table no.2. Age Wise Distribution

Age(years)	No. of patient present with low back pain	Total No. of patient	Percentage
30-39	29	50	58%
40-49	22	39	56%
50 or more than 50	9	11	81%
total	51	100	51%

Table no.3. Physical parameters for sugar industry workers

PARAMETERS	MEAN	SD	P-VALUE	T-VALUE
AGE	40.630	7.205	<0.0001	56.391

MODIFIED OSWESTRY LOW BACK PAIN DISABILITY INDEX	24.580	7.289	<0.0001	33.720

Ns: Considered as non significant

Discussion

The industrial work of heavy lifting and carrying those heavy weights from one place to other increases the mechanical work load on the workers body is the one of the main cause of having the low back pain in industrial workers.

Working with carrying heavy weights repeatedly causes the musculoskeletal pain in the worker's body and in that pain low back pain is the most common and most severe musculoskeletal pain workers experienced at the workplace. This low back pain is causes due to the lumbar spine dysfunction.

Sugar industry workers has to lift heavy weights of sugarcane on their shoulder and back that causes the musculoskeletal pain and most common is low back pain due to the repeated bending activity with the heavy stress on the back. This occurs in with workers who have poor ergonomic knowledge about handling the heavy load on their shoulders and back. The pain is very severe sometimes that is affecting the day to day life of the workers.

In this study 100 sugar industry workers (68 males and 32 females) were taken for study. It was found that 59 sugar industry workers had a lumbar spine dysfunction. The age is from 30-above 50 years of workers were taken in this study, which was found to be more prevalent in male(63%) than in female(50%), although this difference was not statistically significant.

This study was conducted in KIMS, where subjects were selected as per the criteria and underwent a study where they had to answer the questions of Oswestry low back pain questionnaire. Subjects were informed about the study and prior consent was taken.

The results of this study showed are based on statistical analysis that there was significant increase in low back pain in sugar industry workers of karad taluka.

CONCLUSION

The present study based on statistical analysis showed that there was significant increase in low back pain in sugar industry workers thus providing evidence

to support the increase in lumbar spine dysfunction in sugar industry workers of the karad taluka.

Acknowledgement

I would like to thank respected Dean Dr. G. Varadharajulu, Dean, Faculty of Physiotherapy, KIMSDU for his inspiration, motivation, valuable guidance and suggestions throughout this project. I wish to express my sincere thanks to Dr. S. V. Kakade, Department of Biostatistics, KIMSDU for helping to carry out statistical analysis. I would also like to express my sincere thanks to Dr. JAVID H SAGAR, Professor, department of cardiopulmonary sciences, Faculty of Physiotherapy, KIMSDU. I express my sincere thanks to the volunteers who participated in my project for their kind cooperation in my project work.

System Level Barriers in Early Initiation of Breastfeeding- Finding from a Cross-sectional Survey in Khagaria District of State Bihar, India

Nishtha Kathuria[1], Priya Krishnan[2], Rajesh Kumar Sinha[3], Theophilus Lakiang[4], Javvad Suri[5], Sunil Mehra[6]

[1]Assistant Director- Maternal, Child Health and Nutrition, [2]Senior Program Manager, [3]Deputy Director- Research and Health Economics, [4]Regional Manager- Research, [5]Deputy Director- Maternal and Child Health, [6]Executive Director, MAMTA Health Institute for Mother and Child, New Delhi, India

Abstract

Purpose: Despite 55% children aged 0-6 months being exclusively breastfed in India, 0.26 million children die each year from diarrhoea and pneumonia that can be prevented through early initiation of and exclusive breastfeeding (EIBF). A study was conducted to assess the factors associated with EIBF in 20 villages from the District Khagaria (State Bihar).

Method: The cross-sectional study was carried out from Jan-March 2017 with a sample of 288 married women who had delivered in last 1 year. Bivariate and multivariate logistic regression analyses were performed to identify associated factors of EIBF.

Results: Analyses show that institutional delivery (aOR: 2.69; CI 1.22 to 5.93; $p<0.05$) and delivery with normal mode (aOR: 4.61; CI 1.74 to 12.18; $p<0.01$) were significant contributors of EIBF. Additionally, likelihoods of EIBF were lower when the delivery was performed in a private institution (OR 0.28, CI 0.14 to 0.59; $p<0.001$) and by a doctor (OR 0.33, CI 0.18 to 0.60; $p<0.001$). Besides, higher birth order (OR 2.00, CI 0.98 to 4.10; $p<0.05$) was also found to be significantly associated with EIBF.

Conclusion: System level efforts are needed to promote EIBF, along with improved training and reinforcement in doctors for breastfeeding. Reduction in caesarean section rates can positively contribute to EIBF.

Key words: *Breastfeeding, Public Health, Determinants, Caesarean, Nurses*

Introdution

Early initiation of breastfeeding (EIBF) within the first hour of delivery is recommended by the World Health Organization (WHO) to reduce newborn deaths [1,2]. EIBF means neonates are introduced to colostrum which confers numerous benefits including active and passive immunity against a wide range of pathogenic diseases [1,2]. It also reduces postpartum bleeding in mothers, as well as protects against the leading causes of neonatal mortality such as respiratory tract infections (pneumonia, in particular), diarrhoea, and neonatal sepsis [2,3,4]. EIBF is responsible for enhancing bonding, improving the chances of breastfeeding success, additionally contributes to longer breastfeeding duration [5]. Despite the numerous benefits, EIBF rate is poor in many countries including India [7,8]. Although India reports 55% exclusive breastfeeding rate in children below the age of six months, there is a high population of under-six months children who die each year [8], that could have been reduced through EIBF, exclusive breastfeeding till 6 months and continued breastfeeding [7].

India has witnessed a considerable decline in maternal and new-born mortality indicators with increase

Corresponding Author:
Dr. Rajesh Kumar Sinha
Deputy Director- Research and Health Economics
Email: rajeshks@mamtahimc.org

in institutional deliveries. The rate of institutional deliveries increased by 52.9 percentage points between 1998-99 (NFHS-2) and 2015-16 (NFHS-4) however, the rates of EIBF and exclusive breastfeeding showed dismal improvements of just 8.1 and 25.7 percentage points respectively [8, 9].

Presently as per the National survey, the EIBF is 41.6% in the country with as low as 25.2% in Uttar Pradesh [8]. Additionally, with increase in institutional deliveries there has been a rise in caesarean sections as well. Prospective cohort studies in India have shown that infants born by caesarean section were almost four times less likely to initiate breast feeding within one hour of birth than infants born by vaginal delivery [11].

This study was conducted to assess facilitators and inhibitors of EIBF in rural Khagaria district of Bihar, India.

Method

Study Design and participation: A population-based, cross-sectional study was undertaken between Jan and March 2017. We assumed a 0.25 prevalence of EIBF (p) with a degree of precision (d) of 0.05 at 95% confidence interval (CI). The sample size was calculated by the following equation: $([Z^2 \times p \times q]/[d^2])$. The sample size estimated was 288. Two-stage sampling design was adopted in the study. From the study block, 20 villages (primary sample unit) were selected randomly. The secondary sample unit was at the household level. List of eligible population was obtained from the health service providers. After that, 288 eligible samples were randomly selected from the list.

Data Collection: Data was collected through interviews, using pretested structured questionnaire, after obtaining informed consent from mothers. Interviewers recruited for data collection were trained before actual data collection work. 10% questionnaires were randomly chosen for quality checks by Supervisors. Breastfeeding information for the latest child was included in the study.

Data analysis: Data was analysed using SPSS-20 software (IBM Corporation). Descriptive analysis was performed to determine the prevalence of EIBF and to present the background characteristics of the subjects. Chi square tests ($\chi 2$) were performed to evaluate the association of the independent and socio-demographic variables with the EIBF. Multivariate logistic regression analysis was performed to examine the association of exploratory variables with dependent variable (EIBF) after adjusting for socio-demographic variables. A p-value <0.05 was considered statistically significant.

Results

Mean age of the respondents was 22.5 (± 2.16) years. 78% of respondents were from the Scheduled Caste/ Scheduled Tribe or Other Backward Classes. 66% were below the poverty line (BPL). 33% of respondents were less than 21 years of age. 84% of respondents had institutional delivery. 83% of these deliveries took place in public hospitals. 76% of the deliveries were conducted by Skilled Birth Attendant (SBA) or local/ indigenous Traditional Birth Attendant (TBA). 83% of deliveries were through the normal vaginal route. 66% of the mothers had received information about breast feeding during their antenatal care visits. 75% of mothers initiated breast feeding within one hour while 25% had initiated late.

The social determinants of EIBF

Bivariate Analysis

Type of institution for delivery, mode of delivery, service provider during delivery and birth order were significantly associated ($p<0.05$) with EIBF. EIBF was not significantly associated with poverty status, type of family, breast feeding information received during antenatal care, age of the respondent, level of mother's education and place of delivery. Respondent who had vaginal birth (normal delivery) (OR 5.57, CI 2.66 to 11.63; $p<0.001$) was more likely to initiate early breast feeding compared to those who had caesarean delivery. Respondent whose delivery was performed by a doctor (OR 0.33, CI 0.18 to 0.60; $p<0.001$) and who delivered in a private institution (OR 0.28, CI 0.14 to 0.59; $p<0.001$) had less likelihoods of initiating early breast feeding compared to those whose delivery was performed by a SBA/TBA and those who delivered in a public institution, respectively. Respondent with three or more children was (OR 2.00, CI 0.98 to 4.10; $p<0.05$) more likely to initiate early breastfeeding compared to those with less than three children.

Multivariate Analysis

EIBF rate was significantly associated with place of delivery and mode of delivery. In the bivariate analysis, place of delivery was not associated with EIBF but it was found to be significantly associated in the multivariate

analysis. Respondent who had undergone institutional delivery was (aOR: 2.69; CI 1.22 to 5.93; p<0.05) more likely to initiate early breastfeeding compared to those who had delivered at home. Mode of delivery was found significantly associated with EIBF in the bivariate analysis, was also found significantly associated in the multivariate analysis. Respondent who had normal delivery was (aOR: 4.61; CI 1.74 to 12.18; p<0.01) more likely to initiate early breastfeeding compared to those with caesarean delivery.

In the bivariate analysis, doctors performing the delivery was found to be a significant barrier to EIBF, though no significant association was found in the multivariate analysis. Similarly, birth order was found significantly associated with EIBF in the bivariate analysis but not in the multivariate analysis. Association of types of institution for delivery (public/private) was separately assessed only in the bivariate analysis and not in the multivariate analysis.

Table 1: Early Initiation (within 1 hour after birth) and correlating factors (EIBF: Early initiation of BF), LIBF (Late Initiation of Breast Feeding)

Variables		Initiation of Breast feeding			Chi Square	Odds Ratio	CI	p value
		EIBF (n=) (%)	LIBF (n=) (%)	Total				
Age	Less than 20	72 (80)	18 (20)	90	1.86	1.52	0.83 to 2.81	0.17

Discussion

In the present study 75% of mothers initiated breastfeeding within 1 hour. Bivariate and multivariate analyses show that the important factors contributing to the EIBF were the place of delivery, mode of delivery and service provider attending the delivery. The EIBF rates in private hospitals were significantly lower than public hospitals. The reasons attributed to this could be poor knowledge and uptake of government programs and high caesarean section rates in private hospitals. In India, caesarean section rates are disproportionately higher than public health facilities [20].

Similar results were obtained in other studies wherein caesarean section was found to be a significant barrier in EIBF [13, 14]. In India, with increase in institutional deliveries, caesarean section rates are increasing at an alarming rate [8] and needs to be factored in for EIBF promotion [19]. The interventions for removing this impediment can be directed at the service delivery level. One study showed that Quality Improvement (QI) approach was able to accomplish sustained improvement in EIBF rates in caesarean deliveries from 0 to 93% [10]. In another trial in Karnataka, deployment of a trained lactation manager resulted in no significant difference in EIBF rates in normal and caesarean births [20]. Recently, a joint statement has been released by Federation of Obstetrics & Gynaecological Societies of India (FOGSI) and Indian Academy of Paediatrics (IAP) which calls for greater engagement with private sector, policy to support immediate skin-to-skin contact, raising awareness on pre and post-surgery lactation support, educating mothers and families, presence of birth companion and mother support groups [21].

The likelihood of EIBF was lower when a doctor was the birth attendant. One study reported that, mothers with a midwife birth attendant were six times more likely to exclusively breastfeed the baby at least for six months compared to those who had an obstetrician birth attendant [22]. The reasons for lesser rates with physicians

or obstetricians could be high number of cases a doctor attends in resource limited settings, limiting their time to support breastfeeding. An alternative model with a nursing led model of maternity care may be considered to address this. WHO estimates 85% of pregancies do not require specialized interventions; a professionally trained nurse or a midwive can handle bulk of the workload and address barriers to breastfeeding. Furthermore, studies have shown that nurses directly impact breastfeeding success through emotional, informational and tangible support [22].

Lastly, higher birth order contributed significantly to EIBF. There is evidence to support that mothers are likely to choose the same feeding method for each of their children, independent of the number of children they have. Breastfeeding promotion must take into consideration previous infant feeding experiences, if any [23].

Limitation of the study

As this was a cross-sectional study, it cannot provide cause and effect relationship between EIBF and risk factors taken for the analysis. Secondly, as the study was self-report in nature, it is susceptible to biases such as responder bias, recall bias, interviewer bias and social desirability bias. Also, the study was conducted only in 20 villages therefore, the findings cannot be generalised for the entire districts.

Conclusion

The study findings show that system level interventions like efforts to reduce caesarean section rates, systemic support to doctors, greater engagement with private hospitals, introduction of lactation manager at hospitals, de-medicalization of child birth through nurses and midwives, could lead to improved breastfeeding outcomes.

Ethics: The study was part of one of the nutrition promotion projects. Informed consent was taken from all study participants.

Abstract

The time children spend, by watching television is increasing as everybody around them are busy. It is not just their favorite cartoons or movies that they watch but also many very different advertisements, which come in between these programs. Food advertisements are commercials or advertisements of food, both healthy and unhealthy. As the children watch these advertisements which are being presented in a very appealing manner, an inner urge is being created in children to try these food items and they start demanding these for their consumption. The study concentrates on preschoolers (3 -6 years) who are just stepping out to the society. Their initial years are very interesting for the study as they observe everything very keenly. Food preferences of children changes vastly in these initial years. The study gets to know the impact of food advertisement in children.

Keywords: *Food advertisements, food preferences, preschoolers.*

Introduction

Children are exposed to a huge amount of food advertising through various media, especially television. There is substantial evidence that this advertising influence children's food preferences and consumption and is likely to contribute to overweight and obesity. Current regulations are ineffective for reducing children's exposure to unhealthy food advertising.

The endorsements of food products by cartoon characters and offers and gifts are used to attract children's attention and persuade them to requestor buy an advertised product. Evidences prove that young children lack the ability to discriminate between healthy and unhealthy food.

Behavioural outcomes such as purchase requests have been shown to be modified by attractive advertisements. Parents are concerned about the advertising of food products at times when children watch television, and in particular, of unhealthy food. The particular aspects which concerned them are that such advertising is usually for unhealthy foods and that it creates a desire, expectation and / or demand for these foods.

In this study we are analysing the impact of food advertisement on pre-schoolers in Kochi city. Pre-schoolers are absolutely fresh and they are just stepping to the world around so their preferences and choices change over time, so these few years at preschool is brought under study. Behavioural outcomes such as purchase requests, have been shown to be modified by food advertisements.

Statement of the Problem

Future of a nation belongs to the young blood, today's children are tomorrow's youth. It is very important that the health of children is been taken utmost care. Children's food preferences and choices should be administered carefully. Food advertising plays a significant role in the mind of children about their food preferences. The study aims at understanding the impact of food advertising on the food preferences of pre-schoolers in Kochi city.

Objectives

The objectives of the study are designed as follows:

i. To study the factors that attract children towards advertisements.

ii. To study the food advertising influence on the various age categories of preschoolers.

iii. To estimate the time spend by children watching television and its influences on food choices.

Research Methodology

Exploratory study has been used for this topic. The study is based in a survey of the respondents (mothers of preschoolers). For that 200 samples were distributed, of which 120 were completely filled and returned, purposive sampling is the technique used. The data are collected through primary and secondary sources. Structured questionnaire has been used for collecting primary data, data was collected from parents of preschoolers at various school events like sports day and annual day of different pre-schools in Kochi. The data collected are analysed using Statistical Package for Social Sciences (SPSS).The various tests used were Chi square, Correlation and one way AVOVA. Secondary data was collected from various journals, articles and information from websites.

Hypothesis

H1: Food advertisements have a positive relationship with Children's Food preferences.

H2: The time spend on television and food advertisement based demands are positively related.

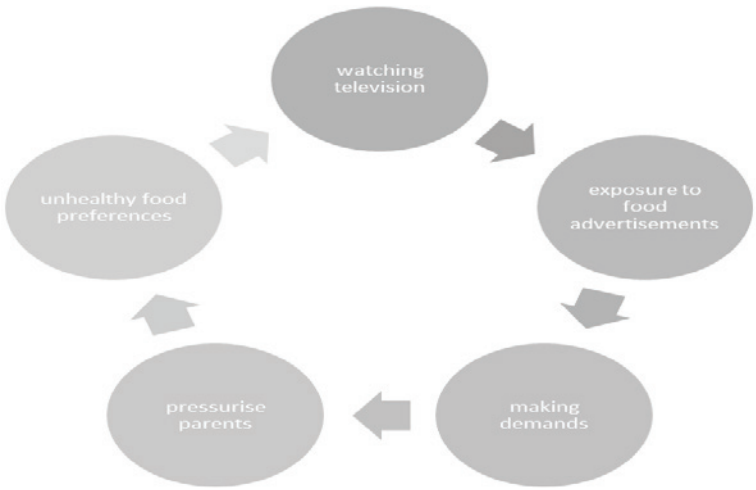
H3: There is a significant relationship between the age of pre-schoolers and the influence of food advertisement

LITERATURE REVIEW

Food preferences of children are not formed in a day, as an infant and in the initial years as a toddler a child eats normally what his mother feeds him or her. Once he starts distinguishing between tastes the child starts showing likes and dislikes for certain food items, even then parents can take the upper hand in deciding what the child should eat. But when the child starts to communicate, your tiny tots comes out with 'demands'. Normally these demands are for products which parents are least interested to feed the child.

Now the question is how children get to know about these products. When the child is inside home, the best thing to keep them sit in a place for some time is to switch on the television with their favourite cartoon programmes. The fact is that they don't only watch these cartoons in television but there are very many 'food advertisements' in television, which are very appealing to the kids.

Once, twice, thrice or more time they watch these advertisements an urge is grown these little minds to just try them, and then they start communicating about their demands, normally this starts in the pre-schooling age, where they see the outside world at large in the absence of their parents. The demand might be met sometimes or might be denied, depending on the parents. In the long run, these demands turn out to be a habit and result to unhealthy eating habits



Considerable scientific evidence establishes a link between unhealthy food advertising and children's food choices, purchases and consumption

The exposure that young mind goes through as a result of food advertising is a subject matter of study, their preferences and choice of what they eat are greatly influenced by the media advertisements at large.(1)

Children have been constituted as a very important consumer group, new day marketers are ready to pay more to this group recognising them as a primary market, an influencing market and a future market. The study underlines the fact that advertising influences children purchase request and family dynamics. (3)

Food advertisements in television has always been criticised as they play a major role in promoting unhealthy dietary practices among children. The study concluded that food advertisement environment should be changed in such a way that nutritious foods are promoted and unhealthy (junk) foods should be unrepresented and thus healthy eating habits can be reinforced. (8)
